<sup>a</sup>This option is dynamic, but only the server should set this information. You should not set the value of this variable manually.

<sup>b</sup>This option is dynamic, but only the server should set this information. You should not set the value of this variable manually.

For additional system variable information, see these sections:

- [Section 6.1.6, “Using System Variables”](#), discusses the syntax for setting and displaying system variable values.
- [Section 6.1.6.2, “Dynamic System Variables”](#), lists the variables that can be set at runtime.
- Information on tuning system variables can be found in [Section 6.1.1, “Configuring the Server”](#).
- [Section 15.14, “InnoDB Startup Options and System Variables”](#), lists InnoDB system variables.
- [NDB Cluster System Variables](#), lists system variables which are specific to MySQL Cluster.
- For information on server system variables specific to replication, see [Section 18.1.6, “Replication and Binary Logging Options and Variables”](#).

**Note**

Some of the following variable descriptions refer to “enabling” or “disabling” a variable. These variables can be enabled with the `SET` statement by setting them to `ON` or `1`, or disabled by setting them to `OFF` or `0`. Boolean variables can be set at startup to the values `ON`, `TRUE`, `OFF`, and `FALSE` (not case sensitive), as well as `1` and `0`. See [Section 5.2.5, “Program Option Modifiers”](#).

Some system variables control the size of buffers or caches. For a given buffer, the server might need to allocate internal data structures. These structures typically are allocated from the total memory allocated to the buffer, and the amount of space required might be platform dependent. This means that when you assign a value to a system variable that controls a buffer size, the amount of space actually available might differ from the value assigned. In some cases, the amount might be less than the value assigned. It is also possible that the server will adjust a value upward. For example, if you assign a value of 0 to a variable for which the minimal value is 1024, the server will set the value to 1024.

Values for buffer sizes, lengths, and stack sizes are given in bytes unless otherwise specified.

Some system variables take file name values. Unless otherwise specified, the default file location is the data directory if the value is a relative path name. To specify the location explicitly, use an absolute path name. Suppose that the data directory is `/var/mysql/data`. If a file-valued variable is given as a relative path name, it will be located under `/var/mysql/data`. If the value is an absolute path name, its location is as given by the path name.

- `authentication_windows_log_level`

|                            |   |         |
|----------------------------|---|---------|
| <b>Introduced</b>          | 5.7.9   |         |
| <b>Command-Line Format</b> | <code>--authentication_windows_log_level</code> |         |
| <b>Permitted Values</b>    | <b>Type</b>                                     | integer |
|                            | <b>Default</b>                                  | 0       |
|                            | <b>Min Value</b>                                | 0       |
|                            | <b>Max Value</b>                                | 4       |

This variable is available only if the `authentication_windows` Windows authentication plugin is enabled and debugging code is enabled. See [Section 7.5.1.6, “The Windows Native Authentication Plugin”](#).

This variable sets the logging level for the Windows authentication plugin. The following table shows the permitted values.

| Value | Description                                |
|-------|--|
| 0     | No logging                                 |
| 1     | Log only error messages                    |
| 2     | Log level 1 messages and warning messages  |
| 3     | Log level 2 messages and information notes |
| 4     | Log level 3 messages and debug messages    |

This variable was added in MySQL 5.7.9.

- `authentication_windows_use_principal_name`

|                   |       |

| <b>Introduced</b> | 5.7.9 |
|-------------------|-------|

|                            |  |         |
|----------------------------|--|---------|
| <b>Command-Line Format</b> | <code>--authentication_windows_use_principal_name</code> |         |
| <b>Permitted Values</b>    | <b>Type</b>  | boolean |
|                            | <b>Default</b>   | ON      |

This variable is available only if the `authentication_windows` Windows authentication plugin is enabled. See [Section 7.5.1.6, “The Windows Native Authentication Plugin”](#).

A client that authenticates using the `InitSecurityContext()` function should provide a string identifying the service to which it connects (`targetName`). MySQL uses the principal name (UPN) of the account under which the server is running. The UPN has the form `user_id@computer_name` and need not be registered anywhere to be used. This UPN is sent by the server at the beginning of authentication handshake.

This variable controls whether the server sends the UPN in the initial challenge. By default, the variable is enabled. For security reasons, it can be disabled to avoid sending the server's account name to a client in clear text. If the variable is disabled, the server always sends a `0x00` byte in the first challenge, the client does not specify `targetName`, and as a result, NTLM authentication is used.

If the server fails to obtain its UPN (which will happen primarily in environments that do not support Kerberos authentication), the UPN is not sent by the server and NTLM authentication is used.

This variable was added in MySQL 5.7.9.

- `autocommit`

|                            |                               |                         |
|----------------------------|-------------------------------|-------------------------|
| <b>Command-Line Format</b> | <code>--autocommit[=#]</code> |                         |
| <b>System Variable</b>     | <b>Name</b>                   | <code>autocommit</code> |
|                            | <b>Variable Scope</b>         | Global, Session         |
|                            | <b>Dynamic Variable</b>       | Yes                     |
| <b>Permitted Values</b>    | <b>Type</b>                   | boolean                 |
|                            | <b>Default</b>                | ON                      |

The autocommit mode. If set to 1, all changes to a table take effect immediately. If set to 0, you must use `COMMIT` to accept a transaction or `ROLLBACK` to cancel it. If `autocommit` is 0 and you change it to 1, MySQL performs an automatic `COMMIT` of any open transaction. Another way to begin a transaction is to use a `START TRANSACTION` or `BEGIN` statement. See [Section 14.3.1, “START TRANSACTION, COMMIT, and ROLLBACK Syntax”](#).

By default, client connections begin with `autocommit` set to 1. To cause clients to begin with a default of 0, set the global `autocommit` value by starting the server with the `--autocommit=0` option. To set the variable using an option file, include these lines:

```
[mysqld]
autocommit=0
```

- `automatic_sp_privileges`

|                        |                         |                                      |
|------------------------|-------------------------|--------------------------------------|
| <b>System Variable</b> | <b>Name</b>             | <code>automatic_sp_privileges</code> |
|                        | <b>Variable Scope</b>   | Global                               |
|                        | <b>Dynamic Variable</b> | Yes                                  |
|                        |                         | 691                                  |

|                         |                |         |
|-------------------------|----------------|---------|
| <b>Permitted Values</b> | <b>Type</b>    | boolean |
|                         | <b>Default</b> | TRUE    |

When this variable has a value of 1 (the default), the server automatically grants the [EXECUTE](#) and [ALTER ROUTINE](#) privileges to the creator of a stored routine, if the user cannot already execute and alter or drop the routine. (The [ALTER ROUTINE](#) privilege is required to drop the routine.) The server also automatically drops those privileges from the creator when the routine is dropped. If [automatic\\_sp\\_privileges](#) is 0, the server does not automatically add or drop these privileges.

The creator of a routine is the account used to execute the [CREATE](#) statement for it. This might not be the same as the account named as the [DEFINER](#) in the routine definition.

See also [Section 22.2.2, “Stored Routines and MySQL Privileges”](#).

- [auto\\_generate\\_certs](#)

|                            |   |                                     |
|----------------------------|---|-------------------------------------|
| <b>Introduced</b>          | 5.7.5   |                                     |
| <b>Command-Line Format</b> | <code>--auto_generate_certs[={OFF ON}]</code> |                                     |
| <b>System Variable</b>     | <b>Name</b>                                   | <a href="#">auto_generate_certs</a> |
|                            | <b>Variable Scope</b>                         | Global                              |
|                            | <b>Dynamic Variable</b>                       | No                                  |
| <b>Permitted Values</b>    | <b>Type</b>                                   | boolean                             |
|                            | <b>Default</b>                                | ON                                  |

This variable is available if the server was compiled using OpenSSL (see [Section 7.4.1, “OpenSSL Versus yaSSL”](#)). It controls whether the server autogenerates SSL key and certificate files in the data directory, if they do not already exist.

At startup, the server automatically generates server-side and client-side SSL certificate and key files in the data directory if the [auto\\_generate\\_certs](#) system variable is enabled, no SSL options other than `--ssl` are specified, and the server-side SSL files are missing from the data directory. These files enable secure client connections using SSL; see [Section 7.4.4, “Configuring MySQL to Use Secure Connections”](#).

For more information about SSL file autogeneration, including file names and characteristics, see [Section 7.4.6.1, “Creating SSL and RSA Certificates and Keys using MySQL”](#)

The [sha256\\_password\\_auto\\_generate\\_rsa\\_keys](#) system variable is related but controls autogeneration of RSA key-pair files needed for secure password exchange using RSA over unencrypted connections.

- [avoid\\_temporal\\_upgrade](#)

|                            |  |  |
|----------------------------|--|--|
| <b>Introduced</b>          | 5.7.6  |  |
| <b>Deprecated</b>          | 5.7.6  |  |
| <b>Command-Line Format</b> | <code>--avoid_temporal_upgrade={OFF ON}</code> |  |
| <b>System Variable</b>     | <b>Name</b>                                    | <a href="#">avoid_temporal_upgrade</a> |
|                            | <b>Variable Scope</b>                          | Global                                 |
|                            | <b>Dynamic Variable</b>                        | Yes                                    |
| <b>Permitted Values</b>    | <b>Type</b>                                    | boolean                                |

|  |                |     |
|--|----------------|-----|
|  | <b>Default</b> | OFF |
|--|----------------|-----|

This variable controls whether `ALTER TABLE` implicitly upgrades temporal columns found to be in pre-5.6.4 format (`TIME`, `DATETIME`, and `TIMESTAMP` columns without support for fractional seconds precision). Upgrading such columns requires a table rebuild, which prevents any use of fast alterations that might otherwise apply to the operation to be performed.

This variable is disabled by default. Enabling it causes `ALTER TABLE` not to rebuild temporal columns and thereby be able to take advantage of possible fast alterations.

This variable is deprecated and will be removed in a future MySQL release.

- `back_log`

|                         |                         |                       |
|-------------------------|-------------------------|-----------------------|
| <b>System Variable</b>  | <b>Name</b>             | <code>back_log</code> |
|                         | <b>Variable Scope</b>   | Global                |
|                         | <b>Dynamic Variable</b> | No                    |
| <b>Permitted Values</b> | <b>Type</b>             | integer               |
|                         | <b>Default</b>          | -1 (autosized)        |
|                         | <b>Min Value</b>        | 1                     |
|                         | <b>Max Value</b>        | 65535                 |

The number of outstanding connection requests MySQL can have. This comes into play when the main MySQL thread gets very many connection requests in a very short time. It then takes some time (although very little) for the main thread to check the connection and start a new thread. The `back_log` value indicates how many requests can be stacked during this short time before MySQL momentarily stops answering new requests. You need to increase this only if you expect a large number of connections in a short period of time.

In other words, this value is the size of the listen queue for incoming TCP/IP connections. Your operating system has its own limit on the size of this queue. The manual page for the Unix `listen()` system call should have more details. Check your OS documentation for the maximum value for this variable. `back_log` cannot be set higher than your operating system limit.

The default value is based on the following formula, capped to a limit of 900:

```
50 + (max_connections / 5)
```

- `basedir`

|                            |                                 |                      |
|----------------------------|---------------------------------|----------------------|
| <b>Command-Line Format</b> | <code>--basedir=dir_name</code> |                      |
| <b>System Variable</b>     | <b>Name</b>                     | <code>basedir</code> |
|                            | <b>Variable Scope</b>           | Global               |
|                            | <b>Dynamic Variable</b>         | No                   |
| <b>Permitted Values</b>    | <b>Type</b>                     | directory name       |

The MySQL installation base directory. This variable can be set with the `--basedir` option. Relative path names for other variables usually are resolved relative to the base directory.

- `big_tables`

|                            |                           |                         |
|----------------------------|---------------------------|-------------------------|
| <b>Command-Line Format</b> | <code>--big-tables</code> |                         |
| <b>System Variable</b>     | <b>Name</b>               | <code>big_tables</code> |
|                            | <b>Variable Scope</b>     | Global, Session         |
|                            | <b>Dynamic Variable</b>   | Yes                     |
| <b>Permitted Values</b>    | <b>Type</b>               | boolean                 |
|                            | <b>Default</b>            | <code>OFF</code>        |

If set to 1, all temporary tables are stored on disk rather than in memory. This is a little slower, but the error `The table tbl_name is full` does not occur for `SELECT` operations that require a large temporary table. The default value for a new connection is 0 (use in-memory temporary tables). Normally, you should never need to set this variable, because in-memory tables are automatically converted to disk-based tables as required.

- `bind_address`

|                            |                                  |                           |
|----------------------------|----------------------------------|---------------------------|
| <b>Command-Line Format</b> | <code>--bind-address=addr</code> |                           |
| <b>System Variable</b>     | <b>Name</b>                      | <code>bind_address</code> |
|                            | <b>Variable Scope</b>            | Global                    |
|                            | <b>Dynamic Variable</b>          | No                        |
| <b>Permitted Values</b>    | <b>Type</b>                      | string                    |
|                            | <b>Default</b>                   | <code>*</code>            |

The value of the `--bind-address` option.

This variable has no effect for the embedded server (`libmysqld`) and as of MySQL 5.7.2 is no longer visible within the embedded server.

- `block_encryption_mode`

|                            |  |                                    |
|----------------------------|--|------------------------------------|
| <b>Introduced</b>          | 5.7.4                                  |                                    |
| <b>Command-Line Format</b> | <code>--block_encryption_mode=#</code> |                                    |
| <b>System Variable</b>     | <b>Name</b>                            | <code>block_encryption_mode</code> |
|                            | <b>Variable Scope</b>                  | Global, Session                    |
|                            | <b>Dynamic Variable</b>                | Yes                                |
| <b>Permitted Values</b>    | <b>Type</b>                            | string                             |
|                            | <b>Default</b>                         | <code>aes-128-ecb</code>           |

This variable controls the block encryption mode for block-based algorithms such as AES. It affects encryption for `AES_ENCRYPT()` and `AES_DECRYPT()`.

`block_encryption_mode` takes a value in `aes-keylen-mode` format, where *keylen* is the key length in bits and *mode* is the encryption mode. The value is not case sensitive. Permitted *keylen* values are 128, 192, and 256. Permitted encryption modes depend on whether MySQL was compiled using OpenSSL or yaSSL:

- For OpenSSL, permitted *mode* values are: [ECB](#), [CBC](#), [CFB1](#), [CFB8](#), [CFB128](#), [OFB](#)
- For yaSSL, permitted *mode* values are: [ECB](#), [CBC](#)

For example, this statement causes the AES encryption functions to use a key length of 256 bits and the CBC mode:

```
SET block_encryption_mode = 'aes-256-cbc';
```

An error occurs for attempts to set [block\\_encryption\\_mode](#) to a value containing an unsupported key length or a mode that the SSL library does not support.

- [bulk\\_insert\\_buffer\\_size](#)

|  |  |   |
|--|--|---|
| <b>Command-Line Format</b>                 | <code>--bulk_insert_buffer_size=#</code> |   |
| <b>System Variable</b>                     | <b>Name</b>                              | <a href="#">bulk_insert_buffer_size</a> |
|  | <b>Variable Scope</b>                    | Global, Session                         |
|  | <b>Dynamic Variable</b>                  | Yes                                     |
| <b>Permitted Values</b> (32-bit platforms) | <b>Type</b>                              | integer                                 |
|  | <b>Default</b>                           | <a href="#">8388608</a>                 |
|  | <b>Min Value</b>                         | 0                                       |
|  | <b>Max Value</b>                         | <a href="#">4294967295</a>              |
| <b>Permitted Values</b> (64-bit platforms) | <b>Type</b>                              | integer                                 |
|  | <b>Default</b>                           | <a href="#">8388608</a>                 |
|  | <b>Min Value</b>                         | 0                                       |
|  | <b>Max Value</b>                         | <a href="#">18446744073709551615</a>    |

MyISAM uses a special tree-like cache to make bulk inserts faster for [INSERT ... SELECT](#), [INSERT ... VALUES \(...\), \(...\), ...](#), and [LOAD DATA INFILE](#) when adding data to nonempty tables. This variable limits the size of the cache tree in bytes per thread. Setting it to 0 disables this optimization. The default value is 8MB.

- [character\\_set\\_client](#)

|                         |                         |                                      |
|-------------------------|-------------------------|--------------------------------------|
| <b>System Variable</b>  | <b>Name</b>             | <a href="#">character_set_client</a> |
|                         | <b>Variable Scope</b>   | Global, Session                      |
|                         | <b>Dynamic Variable</b> | Yes                                  |
| <b>Permitted Values</b> | <b>Type</b>             | string                               |

The character set for statements that arrive from the client. The session value of this variable is set using the character set requested by the client when the client connects to the server. (Many clients support a `--default-character-set` option to enable this character set to be specified explicitly. See also [Section 11.1.4, “Connection Character Sets and Collations”](#).) The global value of

the variable is used to set the session value in cases when the client-requested value is unknown or not available, or the server is configured to ignore client requests:

- The client is from a version of MySQL older than MySQL 4.1, and thus does not request a character set.
- The client requests a character set not known to the server. For example, a Japanese-enabled client requests `sjis` when connecting to a server not configured with `sjis` support.
- `mysqld` was started with the `--skip-character-set-client-handshake` option, which causes it to ignore client character set configuration. This reproduces MySQL 4.0 behavior and is useful should you wish to upgrade the server without upgrading all the clients.

`ucs2`, `utf16`, `utf16le`, and `utf32` cannot be used as a client character set, which means that they also do not work for `SET NAMES` or `SET CHARACTER SET`.

- `character_set_connection`

|                         |                         |                                       |
|-------------------------|-------------------------|---------------------------------------|
| <b>System Variable</b>  | <b>Name</b>             | <code>character_set_connection</code> |
|                         | <b>Variable Scope</b>   | Global, Session                       |
|                         | <b>Dynamic Variable</b> | Yes                                   |
| <b>Permitted Values</b> | <b>Type</b>             | string                                |

The character set used for literals that do not have a character set introducer and for number-to-string conversion. For information about introducers, see [Section 11.1.3.8, “Character Set Introducers”](#).

- `character_set_database`

|                         |  |                                     |
|-------------------------|--|-------------------------------------|
| <b>System Variable</b>  | <b>Name</b>  | <code>character_set_database</code> |
|                         | <b>Variable Scope</b>  | Global, Session                     |
|                         | <b>Dynamic Variable</b>  | Yes                                 |
| <b>Footnote</b>         | This option is dynamic, but only the server should set this information. You should not set the value of this variable manually. |                                     |
| <b>Permitted Values</b> | <b>Type</b>  | string                              |

The character set used by the default database. The server sets this variable whenever the default database changes. If there is no default database, the variable has the same value as `character_set_server`.

The global `character_set_database` and `collation_database` system variables are deprecated as of MySQL 5.7.6 and will be removed in a future version of MySQL.

Assigning a value to the session `character_set_database` and `collation_database` system variables is deprecated as of MySQL 5.7.6 and assignments produce a warning. The session variables will become read only in a future version of MySQL and assignments will produce an error. It will remain possible to access the session variables to determine the database character set and collation for the default database.

- `character_set_filesystem`

|                            |  |
|----------------------------|--|
| <b>Command-Line Format</b> | <code>--character-set-filesystem=name</code> |
|----------------------------|--|

|                         |                         |                                       |
|-------------------------|-------------------------|---------------------------------------|
| <b>System Variable</b>  | <b>Name</b>             | <code>character_set_filesystem</code> |
|                         | <b>Variable Scope</b>   | Global, Session                       |
|                         | <b>Dynamic Variable</b> | Yes                                   |
| <b>Permitted Values</b> | <b>Type</b>             | string                                |
|                         | <b>Default</b>          | <code>binary</code>                   |

The file system character set. This variable is used to interpret string literals that refer to file names, such as in the `LOAD DATA INFILE` and `SELECT ... INTO OUTFILE` statements and the `LOAD_FILE()` function. Such file names are converted from `character_set_client` to `character_set_filesystem` before the file opening attempt occurs. The default value is `binary`, which means that no conversion occurs. For systems on which multibyte file names are permitted, a different value may be more appropriate. For example, if the system represents file names using UTF-8, set `character_set_filesystem` to `'utf8'`.

- `character_set_results`

|                         |                         |                                    |
|-------------------------|-------------------------|------------------------------------|
| <b>System Variable</b>  | <b>Name</b>             | <code>character_set_results</code> |
|                         | <b>Variable Scope</b>   | Global, Session                    |
|                         | <b>Dynamic Variable</b> | Yes                                |
| <b>Permitted Values</b> | <b>Type</b>             | string                             |

The character set used for returning query results such as result sets or error messages to the client.

- `character_set_server`

|                            |                                     |                                   |
|----------------------------|-------------------------------------|-----------------------------------|
| <b>Command-Line Format</b> | <code>--character-set-server</code> |                                   |
| <b>System Variable</b>     | <b>Name</b>                         | <code>character_set_server</code> |
|                            | <b>Variable Scope</b>               | Global, Session                   |
|                            | <b>Dynamic Variable</b>             | Yes                               |
| <b>Permitted Values</b>    | <b>Type</b>                         | string                            |
|                            | <b>Default</b>                      | <code>latin1</code>               |

The server's default character set.

- `character_set_system`

|                         |                         |                                   |
|-------------------------|-------------------------|-----------------------------------|
| <b>System Variable</b>  | <b>Name</b>             | <code>character_set_system</code> |
|                         | <b>Variable Scope</b>   | Global                            |
|                         | <b>Dynamic Variable</b> | No                                |
| <b>Permitted Values</b> | <b>Type</b>             | string                            |
|                         | <b>Default</b>          | <code>utf8</code>                 |

The character set used by the server for storing identifiers. The value is always `utf8`.

- `character_sets_dir`

|                            |  |                                 |
|----------------------------|--|---------------------------------|
| <b>Command-Line Format</b> | <code>--character-sets-dir=dir_name</code> |                                 |
| <b>System Variable</b>     | <b>Name</b>                                | <code>character_sets_dir</code> |
|                            | <b>Variable Scope</b>                      | Global                          |
|                            | <b>Dynamic Variable</b>                    | No                              |
| <b>Permitted Values</b>    | <b>Type</b>                                | directory name                  |

The directory where character sets are installed.

- `check_proxy_users`

|                            |  |                                |
|----------------------------|--|--------------------------------|
| <b>Introduced</b>          | 5.7.7  |                                |
| <b>Command-Line Format</b> | <code>--check_proxy_users=[={OFF ON}]</code> |                                |
| <b>System Variable</b>     | <b>Name</b>                                  | <code>check_proxy_users</code> |
|                            | <b>Variable Scope</b>                        | Global                         |
|                            | <b>Dynamic Variable</b>                      | Yes                            |
| <b>Permitted Values</b>    | <b>Type</b>                                  | boolean                        |
|                            | <b>Default</b>                               | <code>OFF</code>               |

This variable controls whether the server performs proxy user mapping for authentication plugins that request it. With `check_proxy_users` enabled, it may also be necessary to enable plugin-specific system variables to take advantage of server proxy user mapping support:

- For the `mysql_native_password` plugin, enable `mysql_native_password_proxy_users`.
- For the `sha256_password` plugin, enable `sha256_password_proxy_users`.

For information about user proxying, see [Section 7.3.9, “Proxy Users”](#).

This variable was added in MySQL 5.7.7. Before 5.7.7, proxy user mapping is available only for plugins that implement it for themselves.

- `collation_connection`

|                         |                         |                                   |
|-------------------------|-------------------------|-----------------------------------|
| <b>System Variable</b>  | <b>Name</b>             | <code>collation_connection</code> |
|                         | <b>Variable Scope</b>   | Global, Session                   |
|                         | <b>Dynamic Variable</b> | Yes                               |
| <b>Permitted Values</b> | <b>Type</b>             | string                            |

The collation of the connection character set.

- `collation_database`

|                        |                       |                                 |
|------------------------|-----------------------|---------------------------------|
| <b>System Variable</b> | <b>Name</b>           | <code>collation_database</code> |
|                        | <b>Variable Scope</b> | Global, Session                 |

|                         |  |        |
|-------------------------|--|--------|
|                         | <b>Dynamic Variable</b>  | Yes    |
| <b>Footnote</b>         | This option is dynamic, but only the server should set this information. You should not set the value of this variable manually. |        |
| <b>Permitted Values</b> | <b>Type</b>  | string |

The collation used by the default database. The server sets this variable whenever the default database changes. If there is no default database, the variable has the same value as `collation_server`.

The global `character_set_database` and `collation_database` system variables are deprecated as of MySQL 5.7.6 and will be removed in a future version of MySQL.

Assigning a value to the session `character_set_database` and `collation_database` system variables is deprecated as of MySQL 5.7.6 and assignments produce a warning. The session variables will become read only in a future version of MySQL and assignments will produce an error. It will remain possible to access the session variables to determine the database character set and collation for the default database.

- `collation_server`

|                            |                                 |                                |
|----------------------------|---------------------------------|--------------------------------|
| <b>Command-Line Format</b> | <code>--collation-server</code> |                                |
| <b>System Variable</b>     | <b>Name</b>                     | <code>collation_server</code>  |
|                            | <b>Variable Scope</b>           | Global, Session                |
|                            | <b>Dynamic Variable</b>         | Yes                            |
| <b>Permitted Values</b>    | <b>Type</b>                     | string                         |
|                            | <b>Default</b>                  | <code>latin1_swedish_ci</code> |

The server's default collation.

- `completion_type`

|                            |                                  |                              |
|----------------------------|----------------------------------|------------------------------|
| <b>Command-Line Format</b> | <code>--completion_type=#</code> |                              |
| <b>System Variable</b>     | <b>Name</b>                      | <code>completion_type</code> |
|                            | <b>Variable Scope</b>            | Global, Session              |
|                            | <b>Dynamic Variable</b>          | Yes                          |
| <b>Permitted Values</b>    | <b>Type</b>                      | enumeration                  |
|                            | <b>Default</b>                   | <code>NO_CHAIN</code>        |
|                            | <b>Valid Values</b>              | <code>NO_CHAIN</code>        |
|                            |                                  | <code>CHAIN</code>           |
|                            |                                  | <code>RELEASE</code>         |
|                            |                                  | 0                            |
|                            |                                  | 1                            |
|                            |                                  | 2                            |

The transaction completion type. This variable can take the values shown in the following table. The variable can be assigned using either the name values or corresponding integer values.

| Value                        | Description  |
|------------------------------|--|
| <code>NO_CHAIN</code> (or 0) | <code>COMMIT</code> and <code>ROLLBACK</code> are unaffected. This is the default value.   |
| <code>CHAIN</code> (or 1)    | <code>COMMIT</code> and <code>ROLLBACK</code> are equivalent to <code>COMMIT AND CHAIN</code> and <code>ROLLBACK AND CHAIN</code> , respectively. (A new transaction starts immediately with the same isolation level as the just-terminated transaction.) |
| <code>RELEASE</code> (or 2)  | <code>COMMIT</code> and <code>ROLLBACK</code> are equivalent to <code>COMMIT RELEASE</code> and <code>ROLLBACK RELEASE</code> , respectively. (The server disconnects after terminating the transaction.)  |

`completion_type` affects transactions that begin with `START TRANSACTION` or `BEGIN` and end with `COMMIT` or `ROLLBACK`. It does not apply to implicit commits resulting from execution of the statements listed in [Section 14.3.3, “Statements That Cause an Implicit Commit”](#). It also does not apply for `XA COMMIT`, `XA ROLLBACK`, or when `autocommit=1`.

- `concurrent_insert`

|                            |                                      |                                |
|----------------------------|--------------------------------------|--------------------------------|
| <b>Command-Line Format</b> | <code>--concurrent_insert[=#]</code> |                                |
| <b>System Variable</b>     | <b>Name</b>                          | <code>concurrent_insert</code> |
|                            | <b>Variable Scope</b>                | Global                         |
|                            | <b>Dynamic Variable</b>              | Yes                            |
| <b>Permitted Values</b>    | <b>Type</b>                          | enumeration                    |
|                            | <b>Default</b>                       | <code>AUTO</code>              |
|                            | <b>Valid Values</b>                  | <code>NEVER</code>             |
|                            |                                      | <code>AUTO</code>              |
|                            |                                      | <code>ALWAYS</code>            |
|                            |                                      | 0                              |
|                            |                                      | 1                              |
|                            |                                      | 2                              |

If `AUTO` (the default), MySQL permits `INSERT` and `SELECT` statements to run concurrently for `MyISAM` tables that have no free blocks in the middle of the data file. If you start `mysqld` with `--skip-new`, this variable is set to `NEVER`.

This variable can take the values shown in the following table. The variable can be assigned using either the name values or corresponding integer values.

| Value                      | Description   |
|----------------------------|---|
| <code>NEVER</code> (or 0)  | Disables concurrent inserts   |
| <code>AUTO</code> (or 1)   | (Default) Enables concurrent insert for <code>MyISAM</code> tables that do not have holes   |
| <code>ALWAYS</code> (or 2) | Enables concurrent inserts for all <code>MyISAM</code> tables, even those that have holes. For a table with a hole, new rows are inserted at the end of the table if it is in use by another thread. Otherwise, MySQL acquires a normal write lock and inserts the row into the hole. |

See also [Section 9.11.3, “Concurrent Inserts”](#).

- `connect_timeout`

|                            |                                  |                              |
|----------------------------|----------------------------------|------------------------------|
| <b>Command-Line Format</b> | <code>--connect_timeout=#</code> |                              |
| <b>System Variable</b>     | <b>Name</b>                      | <code>connect_timeout</code> |
|                            | <b>Variable Scope</b>            | Global                       |
|                            | <b>Dynamic Variable</b>          | Yes                          |
| <b>Permitted Values</b>    | <b>Type</b>                      | integer                      |
|                            | <b>Default</b>                   | 10                           |
|                            | <b>Min Value</b>                 | 2                            |
|                            | <b>Max Value</b>                 | 31536000                     |

The number of seconds that the `mysqld` server waits for a connect packet before responding with `Bad handshake`. The default value is 10 seconds.

Increasing the `connect_timeout` value might help if clients frequently encounter errors of the form `Lost connection to MySQL server at 'XXX', system error: errno`.

- `core_file`

|                         |                         |                        |
|-------------------------|-------------------------|------------------------|
| <b>System Variable</b>  | <b>Name</b>             | <code>core_file</code> |
|                         | <b>Variable Scope</b>   | Global                 |
|                         | <b>Dynamic Variable</b> | No                     |
| <b>Permitted Values</b> | <b>Type</b>             | boolean                |
|                         | <b>Default</b>          | OFF                    |

Whether to write a core file if the server crashes. This variable is set by the `--core-file` option.

- `datadir`

|                            |                                 |                      |
|----------------------------|---------------------------------|----------------------|
| <b>Command-Line Format</b> | <code>--datadir=dir_name</code> |                      |
| <b>System Variable</b>     | <b>Name</b>                     | <code>datadir</code> |
|                            | <b>Variable Scope</b>           | Global               |
|                            | <b>Dynamic Variable</b>         | No                   |
| <b>Permitted Values</b>    | <b>Type</b>                     | directory name       |

The MySQL data directory. This variable can be set with the `--datadir` option.

- `date_format`

This variable is unused. It is deprecated and will be removed in a future MySQL release.

- `datetime_format`

This variable is unused. It is deprecated and will be removed in a future MySQL release.

- `debug`

|                                   |                                      |  |
|-----------------------------------|--------------------------------------|--|
| <b>Command-Line Format</b>        | <code>--debug[=debug_options]</code> |  |
| <b>System Variable</b>            | <b>Name</b>                          | <code>debug</code>                     |
|                                   | <b>Variable Scope</b>                | Global, Session                        |
|                                   | <b>Dynamic Variable</b>              | Yes                                    |
| <b>Permitted Values (Unix)</b>    | <b>Type</b>                          | string                                 |
|                                   | <b>Default</b>                       | <code>d:t:i:o,/tmp/mysqld.trace</code> |
| <b>Permitted Values (Windows)</b> | <b>Type</b>                          | string                                 |
|                                   | <b>Default</b>                       | <code>d:t:i:0,\mysqld.trace</code>     |

This variable indicates the current debugging settings. It is available only for servers built with debugging support. The initial value comes from the value of instances of the `--debug` option given at server startup. The global and session values may be set at runtime; the `SUPER` privilege is required, even for the session value.

Assigning a value that begins with `+` or `-` cause the value to added to or subtracted from the current value:

```
mysql> SET debug = 'T';
mysql> SELECT @@debug;
+-----+
| @@debug |
+-----+
| T       |
+-----+

mysql> SET debug = '+P';
mysql> SELECT @@debug;
+-----+
| @@debug |
+-----+
| P:T     |
+-----+

mysql> SET debug = '-P';
mysql> SELECT @@debug;
+-----+
| @@debug |
+-----+
| T       |
+-----+
```

For more information, see [Section 27.5.3, “The DBUG Package”](#).

- `debug_sync`

|                         |                         |                         |
|-------------------------|-------------------------|-------------------------|
| <b>System Variable</b>  | <b>Name</b>             | <code>debug_sync</code> |
|                         | <b>Variable Scope</b>   | Session                 |
|                         | <b>Dynamic Variable</b> | Yes                     |
| <b>Permitted Values</b> | <b>Type</b>             | string                  |

This variable is the user interface to the Debug Sync facility. Use of Debug Sync requires that MySQL be configured with the `-DENABLE_DEBUG_SYNC=1` CMake option (see [Section 2.9.4](#),

“MySQL Source-Configuration Options”). If Debug Sync is not compiled in, this system variable is not available.

The global variable value is read only and indicates whether the facility is enabled. By default, Debug Sync is disabled and the value of `debug_sync` is `OFF`. If the server is started with `--debug-sync-timeout=N`, where `N` is a timeout value greater than 0, Debug Sync is enabled and the value of `debug_sync` is `ON - current signal` followed by the signal name. Also, `N` becomes the default timeout for individual synchronization points.

The session value can be read by any user and will have the same value as the global variable. The session value can be set by users that have the `SUPER` privilege to control synchronization points.

For a description of the Debug Sync facility and how to use synchronization points, see [MySQL Internals: Test Synchronization](#).

- `default_authentication_plugin`

|                            |  |  |
|----------------------------|--|--|
| <b>Introduced</b>          | 5.7.2  |  |
| <b>Command-Line Format</b> | <code>--default-authentication-plugin=plugin_name</code> |  |
| <b>System Variable</b>     | <b>Name</b>  | <code>default_authentication_plugin</code>                         |
|                            | <b>Variable Scope</b>                                    | Global   |
|                            | <b>Dynamic Variable</b>                                  | No   |
| <b>Permitted Values</b>    | <b>Type</b>  | enumeration  |
|                            | <b>Default</b>   | <code>mysql_native_password</code>                                 |
|                            | <b>Valid Values</b>                                      | <code>mysql_native_password</code><br><code>sha256_password</code> |

The default authentication plugin. Permitted values are `mysql_native_password` (use MySQL native passwords; this is the default) and `sha256_password` (use SHA-256 passwords). For more information about these plugins, see [Section 7.5.1.1, “The Native Authentication Plugin”](#), and [Section 7.5.1.4, “The SHA-256 Authentication Plugin”](#).

#### Note

If you use this variable to change the default authentication plugin to a value other than `mysql_native_password`, clients older than MySQL 5.5.6 will no longer be able to connect because they will not understand the resulting change to the authentication protocol.

The value of `default_authentication_plugin` affects these aspects of server operation:

- It determines which authentication plugin the server assigns to new accounts created by `CREATE USER` and `GRANT` statements that do not name a plugin explicitly with an `IDENTIFIED WITH` clause.
- It sets the `old_passwords` system variable at startup to the value that is consistent with the password hashing method required by the default plugin. The `old_passwords` value affects hashing of passwords specified in the `IDENTIFIED BY` clause of `CREATE USER` and `GRANT`, and passwords specified as the argument to the `PASSWORD()` function.
- For an account created with either of the following statements, the server associates the account with the default authentication plugin and assigns the account the given password, hashed according to the value of `old_passwords`.

```
CREATE USER ... IDENTIFIED BY 'cleartext password';
GRANT ... IDENTIFIED BY 'cleartext password';
```

- For an account created with either of the following statements, the statement fails if the password hash is not encrypted using the hash format required by the default authentication plugin. Otherwise, the server associates the account with the default authentication plugin and assigns the account the given password hash.

```
CREATE USER ... IDENTIFIED BY PASSWORD 'encrypted password';
GRANT ... IDENTIFIED BY PASSWORD 'encrypted password';
```

This variable was added in MySQL 5.7.2. Earlier in MySQL 5.7, use the `--default-authentication-plugin` command-line option instead, which is used the same way at server startup, but cannot be accessed at runtime.

- `default_password_lifetime`

|  |  |  |
|--|--|--|
| <b>Introduced</b>                      | 5.7.4                                      |  |
| <b>Command-Line Format</b>             | <code>--default_password_lifetime=#</code> |  |
| <b>System Variable</b>                 | <b>Name</b>                                | <code>default_password_lifetime</code> |
|  | <b>Variable Scope</b>                      | Global                                 |
|  | <b>Dynamic Variable</b>                    | Yes                                    |
| <b>Permitted Values (&lt;= 5.7.10)</b> | <b>Type</b>                                | integer                                |
|  | <b>Default</b>                             | 360                                    |
|  | <b>Min Value</b>                           | 0                                      |
|  | <b>Max Value</b>                           | 65535                                  |
| <b>Permitted Values (&gt;= 5.7.11)</b> | <b>Type</b>                                | integer                                |
|  | <b>Default</b>                             | 0                                      |
|  | <b>Min Value</b>                           | 0                                      |
|  | <b>Max Value</b>                           | 65535                                  |

This variable defines the global automatic password expiration policy. It applies to accounts that use MySQL built-in authentication methods (accounts that use an authentication plugin of `mysql_native_password`, `mysql_old_password`, or `sha256_password`).

The default `default_password_lifetime` value is 0, which disables automatic password expiration. If the value of `default_password_lifetime` is a positive integer *N*, it indicates the permitted password lifetime; passwords must be changed every *N* days.

The global password expiration policy can be overridden as desired for individual accounts using the `ALTER USER` statement. See [Section 7.3.6, “Password Expiration Policy”](#).

#### Note

From MySQL 5.7.4 to 5.7.10, the default `default_password_lifetime` value is 360 (passwords must be changed approximately once per year). For those versions, be aware that, if you make no changes to the `default_password_lifetime` variable or to individual user accounts, all user passwords will expire after 360 days, and all user accounts will start

running in restricted mode when this happens. Clients (which are effectively users) connecting to the server will then get an error indicating that the password must be changed: `ERROR 1820 (HY000): You must reset your password using ALTER USER statement before executing this statement.`

However, this is easy to miss for clients that automatically connect to the server, such as connections made from scripts. To avoid having such clients suddenly stop working due to a password expiring, make sure to change the password expiration settings for those clients, like this:

```
ALTER USER 'script'@'localhost' PASSWORD EXPIRE NEVER
```

Alternatively, set the `default_password_lifetime` variable to 0, thus disabling automatic password expiration for all users.

- `default_storage_engine`

|                            |  |                                     |
|----------------------------|--|-------------------------------------|
| <b>Command-Line Format</b> | <code>--default-storage-engine=name</code> |                                     |
| <b>System Variable</b>     | <b>Name</b>                                | <code>default_storage_engine</code> |
|                            | <b>Variable Scope</b>                      | Global, Session                     |
|                            | <b>Dynamic Variable</b>                    | Yes                                 |
| <b>Permitted Values</b>    | <b>Type</b>                                | enumeration                         |
|                            | <b>Default</b>                             | InnoDB                              |

The default storage engine. This variable sets the storage engine for permanent tables only. To set the storage engine for `TEMPORARY` tables, set the `default_tmp_storage_engine` system variable.

To see which storage engines are available and enabled, use the `SHOW ENGINES` statement or query the `INFORMATION_SCHEMA.ENGINES` table.

`default_storage_engine` should be used in preference to `storage_engine`, which is deprecated and was removed in MySQL 5.7.5.

If you disable the default storage engine at server startup, you must set the default engine for both permanent and `TEMPORARY` tables to a different engine or the server will not start.

- `default_tmp_storage_engine`

|                            |  |   |
|----------------------------|--|---|
| <b>Command-Line Format</b> | <code>--default_tmp_storage_engine=name</code> |   |
| <b>System Variable</b>     | <b>Name</b>                                    | <code>default_tmp_storage_engine</code> |
|                            | <b>Variable Scope</b>                          | Global, Session                         |
|                            | <b>Dynamic Variable</b>                        | Yes                                     |
| <b>Permitted Values</b>    | <b>Type</b>                                    | enumeration                             |
|                            | <b>Default</b>                                 | InnoDB                                  |

The default storage engine for `TEMPORARY` tables (created with `CREATE TEMPORARY TABLE`). To set the storage engine for permanent tables, set the `default_storage_engine` system variable. Also see the discussion of that variable regarding possible values.

If you disable the default storage engine at server startup, you must set the default engine for both permanent and [TEMPORARY](#) tables to a different engine or the server will not start.

- [default\\_week\\_format](#)

|                            |                                      |                                     |
|----------------------------|--------------------------------------|-------------------------------------|
| <b>Command-Line Format</b> | <code>--default_week_format=#</code> |                                     |
| <b>System Variable</b>     | <b>Name</b>                          | <a href="#">default_week_format</a> |
|                            | <b>Variable Scope</b>                | Global, Session                     |
|                            | <b>Dynamic Variable</b>              | Yes                                 |
| <b>Permitted Values</b>    | <b>Type</b>                          | integer                             |
|                            | <b>Default</b>                       | 0                                   |
|                            | <b>Min Value</b>                     | 0                                   |
|                            | <b>Max Value</b>                     | 7                                   |

The default mode value to use for the [WEEK\(\)](#) function. See [Section 13.7, “Date and Time Functions”](#).

- [delay\\_key\\_write](#)

|                            |                                       |                                 |

|                            | <b>Dynamic Variable</b>               | Yes                             |
| <b>Permitted Values</b>    | <b>Type</b>                           | enumeration                     |
|                            | <b>Default</b>                        | ON                              |
|                            | <b>Valid Values</b>                   | ON                              |
|                            |                                       | OFF                             |
|                            |                                       | ALL                             |

This option applies only to [MyISAM](#) tables. It can have one of the following values to affect handling of the [DELAY\\_KEY\\_WRITE](#) table option that can be used in [CREATE TABLE](#) statements.

| Option | Description  |
|--------|--|
| OFF    | <a href="#">DELAY_KEY_WRITE</a> is ignored.  |
| ON     | MySQL honors any <a href="#">DELAY_KEY_WRITE</a> option specified in <a href="#">CREATE TABLE</a> statements. This is the default value. |
| ALL    | All new opened tables are treated as if they were created with the <a href="#">DELAY_KEY_WRITE</a> option enabled.                       |

If [DELAY\\_KEY\\_WRITE](#) is enabled for a table, the key buffer is not flushed for the table on every index update, but only when the table is closed. This speeds up writes on keys a lot, but if you use this feature, you should add automatic checking of all [MyISAM](#) tables by starting the server with the `--myisam-recover-options` option (for example, `--myisam-recover-options=BACKUP,FORCE`). See [Section 6.1.4, “Server Command Options”](#), and [Section 16.2.1, “MyISAM Startup Options”](#).

**Warning**

If you enable external locking with `--external-locking`, there is no protection against index corruption for tables that use delayed key writes.

- `delayed_insert_limit`

|  |                                       |                                   |
|--|---------------------------------------|-----------------------------------|
| <b>Deprecated</b>                          | 5.6.7                                 |                                   |

| <b>System Variable</b>     | <b>Name</b>                             | <code>delayed_insert_timeout</code> |
|                            | <b>Variable Scope</b>                   | Global                              |
|                            | <b>Dynamic Variable</b>                 | Yes                                 |
| <b>Permitted Values</b>    | <b>Type</b>                             | integer                             |
|                            | <b>Default</b>                          | 300                                 |

This system variable is deprecated (because `DELAYED` inserts are not supported), and will be removed in a future release.

- `delayed_queue_size`

|                            |                                     |                                 |
|----------------------------|-------------------------------------|---------------------------------|
| <b>Deprecated</b>          | 5.6.7                               |                                 |
| <b>Command-Line Format</b> | <code>--delayed_queue_size=#</code> |                                 |
| <b>System Variable</b>     | <b>Name</b>                         | <code>delayed_queue_size</code> |

|  |                         |                      |
|--|-------------------------|----------------------|
|  | <b>Variable Scope</b>   | Global               |
|  | <b>Dynamic Variable</b> | Yes                  |
| <b>Permitted Values</b> (32-bit platforms) | <b>Type</b>             | integer              |
|  | <b>Default</b>          | 1000                 |
|  | <b>Min Value</b>        | 1                    |
|  | <b>Max Value</b>        | 4294967295           |
| <b>Permitted Values</b> (64-bit platforms) | <b>Type</b>             | integer              |
|  | <b>Default</b>          | 1000                 |
|  | <b>Min Value</b>        | 1                    |
|  | <b>Max Value</b>        | 18446744073709551615 |

This system variable is deprecated (because `DELAYED` inserts are not supported), and will be removed in a future release.

- `disabled_storage_engines`

|                            |  |                                       |
|----------------------------|--|---------------------------------------|
| <b>Introduced</b>          | 5.7.8  |                                       |
| <b>Command-Line Format</b> | <code>--disabled_storage_engines=engine[,engine]...</code> |                                       |
| <b>System Variable</b>     | <b>Name</b>  | <code>disabled_storage_engines</code> |
|                            | <b>Variable Scope</b>                                      | Global                                |
|                            | <b>Dynamic Variable</b>                                    | No                                    |
| <b>Permitted Values</b>    | <b>Type</b>  | string                                |
|                            | <b>Default</b>   | empty string                          |

This variable indicates which storage engines cannot be used to create tables or tablespaces. For example, to prevent new `MyISAM` or `FEDERATED` tables from being created, start the server with these lines in the server option file:

```
[mysqld]
disabled_storage_engines="MyISAM,FEDERATED"
```

By default, `disabled_storage_engines` is empty (no engines disabled), but it can be set to a comma-separated list of one or more engines (not case sensitive). Any engine named in the value cannot be used to create tables or tablespaces with `CREATE TABLE` or `CREATE TABLESPACE`, and cannot be used with `ALTER TABLE ... ENGINE` or `ALTER TABLESPACE ... ENGINE` to change the storage engine of existing tables or tablespaces. Attempts to do so result in an `ER_DISABLED_STORAGE_ENGINE` error.

`disabled_storage_engines` does not restrict other DDL statements for existing tables, such as `CREATE INDEX`, `TRUNCATE TABLE`, `ANALYZE TABLE`, `DROP TABLE`, or `DROP TABLESPACE`. This permits a smooth transition so that existing tables or tablespaces that use a disabled engine can be migrated to a permitted engine by means such as `ALTER TABLE ... ENGINE permitted_engine`.

It is permitted to set the `default_storage_engine` or `default_tmp_storage_engine` system variable to a storage engine that is disabled. This could cause applications to behave erratically or fail, although that might be a useful technique in a development environment for identifying applications that use disabled engines, so that they can be modified.

`disabled_storage_engines` is disabled and has no effect if the server is started with any of these options: `--bootstrap`, `--initialize`, `--initialize-insecure`, `--skip-grant-tables`.

- `disconnect_on_expired_password`

|                            |   |   |
|----------------------------|---|---|
| <b>Introduced</b>          | 5.7.1   |   |
| <b>Command-Line Format</b> | <code>--disconnect_on_expired_password[=#]</code> |   |
| <b>System Variable</b>     | <b>Name</b>                                       | <code>disconnect_on_expired_password</code> |
|                            | <b>Variable Scope</b>                             | Session                                     |
|                            | <b>Dynamic Variable</b>                           | No  |
| <b>Permitted Values</b>    | <b>Type</b>                                       | boolean                                     |
|                            | <b>Default</b>                                    | ON  |

This variable controls how the server handles clients with expired passwords:

- If the client indicates that it can handle expires passwords, the value of `disconnect_on_expired_password` is irrelevant. The server permits the client to connect but puts it in sandbox mode.
- If the client does not indicate that it can handle expires passwords, the server handles the client according to the value of `disconnect_on_expired_password`:
  - If `disconnect_on_expired_password` is enabled, the server disconnects the client.
  - If `disconnect_on_expired_password` is disabled, the server permits the client to connect but puts it in sandbox mode.

For more information about the interaction of client and server settings relating to expired-password handling, see [Section 7.3.7, “Password Expiration and Sandbox Mode”](#).

- `div_precision_increment`

|                            |  |                                      |
|----------------------------|--|--------------------------------------|
| <b>Command-Line Format</b> | <code>--div_precision_increment=#</code> |                                      |
| <b>System Variable</b>     | <b>Name</b>                              | <code>div_precision_increment</code> |
|                            | <b>Variable Scope</b>                    | Global, Session                      |
|                            | <b>Dynamic Variable</b>                  | Yes                                  |
| <b>Permitted Values</b>    | <b>Type</b>                              | integer                              |
|                            | <b>Default</b>                           | 4                                    |
|                            | <b>Min Value</b>                         | 0                                    |
|                            | <b>Max Value</b>                         | 30                                   |

This variable indicates the number of digits by which to increase the scale of the result of division operations performed with the `/` operator. The default value is 4. The minimum and maximum values are 0 and 30, respectively. The following example illustrates the effect of increasing the default value.

```
mysql> SELECT 1/7;
+-----+
| 1/7    |
+-----+
| 0.1429  |
+-----+
mysql> SET div_precision_increment = 12;
mysql> SELECT 1/7;
+-----+
| 1/7    |
+-----+
| 0.142857142857 |
+-----+
```

- `end_markers_in_json`

|                         |                         |                                  |
|-------------------------|-------------------------|----------------------------------|
| <b>System Variable</b>  | <b>Name</b>             | <code>end_markers_in_json</code> |
|                         | <b>Variable Scope</b>   | Global, Session                  |
|                         | <b>Dynamic Variable</b> | Yes                              |
| <b>Permitted Values</b> | <b>Type</b>             | boolean                          |
|                         | <b>Default</b>          | <code>OFF</code>                 |

Whether optimizer JSON output should add end markers.

- `eq_range_index_dive_limit`

|                                       |                         |  |
|---------------------------------------|-------------------------|--|
| <b>System Variable</b>                | <b>Name</b>             | <code>eq_range_index_dive_limit</code> |
|                                       | <b>Variable Scope</b>   | Global, Session                        |
|                                       | <b>Dynamic Variable</b> | Yes                                    |
| <b>Permitted Values (&lt;= 5.7.3)</b> | <b>Type</b>             | integer                                |
|                                       | <b>Default</b>          | <code>10</code>                        |
|                                       | <b>Min Value</b>        | <code>0</code>                         |
|                                       | <b>Max Value</b>        | <code>4294967295</code>                |
| <b>Permitted Values (&gt;= 5.7.4)</b> | <b>Type</b>             | integer                                |
|                                       | <b>Default</b>          | <code>200</code>                       |
|                                       | <b>Min Value</b>        | <code>0</code>                         |
|                                       | <b>Max Value</b>        | <code>4294967295</code>                |

This variable indicates the number of equality ranges in an equality comparison condition when the optimizer should switch from using index dives to index statistics in estimating the number of qualifying rows. It applies to evaluation of expressions that have either of these equivalent forms, where the optimizer uses a nonunique index to look up `col_name` values:

```
col_name IN(val1, ..., valN)
col_name = val1 OR ... OR col_name = valN
```

In both cases, the expression contains *N* equality ranges. The optimizer can make row estimates using index dives or index statistics. If `eq_range_index_dive_limit` is greater than 0, the optimizer uses existing index statistics instead of index dives if there are `eq_range_index_dive_limit` or more equality ranges. Thus, to permit use of index dives for up to *N* equality ranges, set `eq_range_index_dive_limit` to *N* + 1. To disable use of index statistics and always use index dives regardless of *N*, set `eq_range_index_dive_limit` to 0.

For more information, see [Equality Range Optimization of Many-Valued Comparisons](#).

To update table index statistics for best estimates, use `ANALYZE TABLE`.

- `error_count`

The number of errors that resulted from the last statement that generated messages. This variable is read only. See [Section 14.7.5.17, “SHOW ERRORS Syntax”](#).

- `event_scheduler`

|                            |  |                              |
|----------------------------|--|------------------------------|
| <b>Command-Line Format</b> | <code>--event-scheduler[=value]</code> |                              |
| <b>System Variable</b>     | <b>Name</b>                            | <code>event_scheduler</code> |
|                            | <b>Variable Scope</b>                  | Global                       |
|                            | <b>Dynamic Variable</b>                | Yes                          |
| <b>Permitted Values</b>    | <b>Type</b>                            | enumeration                  |
|                            | <b>Default</b>                         | <code>OFF</code>             |
|                            | <b>Valid Values</b>                    | <code>ON</code>              |
|                            |  | <code>OFF</code>             |
|                            |  | <code>DISABLED</code>        |

This variable indicates the status of the Event Scheduler; possible values are `ON`, `OFF`, and `DISABLED`, with the default being `OFF`. This variable and its effects on the Event Scheduler's operation are discussed in greater detail in the [Overview section of the Events chapter](#).

- `expire_logs_days`

|                            |                                   |                               |
|----------------------------|-----------------------------------|-------------------------------|
| <b>Command-Line Format</b> | <code>--expire_logs_days=#</code> |                               |
| <b>System Variable</b>     | <b>Name</b>                       | <code>expire_logs_days</code> |
|                            | <b>Variable Scope</b>             | Global                        |
|                            | <b>Dynamic Variable</b>           | Yes                           |
| <b>Permitted Values</b>    | <b>Type</b>                       | integer                       |
|                            | <b>Default</b>                    | 0                             |
|                            | <b>Min Value</b>                  | 0                             |
|                            | <b>Max Value</b>                  | 99                            |

The number of days for automatic binary log file removal. The default is 0, which means “no automatic removal.” Possible removals happen at startup and when the binary log is flushed. Log flushing occurs as indicated in [Section 6.4, “MySQL Server Logs”](#).

To remove binary log files manually, use the `PURGE BINARY LOGS` statement. See [Section 14.4.1.1, “PURGE BINARY LOGS Syntax”](#).

- `explicit_defaults_for_timestamp`

|                            |  |  |
|----------------------------|--|--|
| <b>Deprecated</b>          | 5.6.6  |  |
| <b>Command-Line Format</b> | <code>--explicit_defaults_for_timestamp=#</code> |  |
| <b>System Variable</b>     | <b>Name</b>                                      | <code>explicit_defaults_for_timestamp</code> |
|                            | <b>Variable Scope</b>                            | Global, Session                              |
|                            | <b>Dynamic Variable</b>                          | No   |
| <b>Permitted Values</b>    | <b>Type</b>                                      | boolean                                      |
|                            | <b>Default</b>                                   | <code>FALSE</code>                           |

In MySQL, the `TIMESTAMP` data type differs in nonstandard ways from other data types:

- `TIMESTAMP` columns not explicitly declared with the `NULL` attribute are assigned the `NOT NULL` attribute. (Columns of other data types, if not explicitly declared as `NOT NULL`, permit `NULL` values.) Setting such a column to `NULL` sets it to the current timestamp.
- The first `TIMESTAMP` column in a table, if not declared with the `NULL` attribute or an explicit `DEFAULT` or `ON UPDATE` clause, is automatically assigned the `DEFAULT CURRENT_TIMESTAMP` and `ON UPDATE CURRENT_TIMESTAMP` attributes.
- `TIMESTAMP` columns following the first one, if not declared with the `NULL` attribute or an explicit `DEFAULT` clause, are automatically assigned `DEFAULT '0000-00-00 00:00:00'` (the “zero” timestamp). For inserted rows that specify no explicit value for such a column, the column is assigned `'0000-00-00 00:00:00'` and no warning occurs.

Those nonstandard behaviors remain the default for `TIMESTAMP` but as of MySQL 5.6.6 are deprecated and this warning appears at startup:

```
[Warning] TIMESTAMP with implicit DEFAULT value is deprecated.
Please use --explicit_defaults_for_timestamp server option (see
documentation for more details).
```

As indicated by the warning, to turn off the nonstandard behaviors, enable the `explicit_defaults_for_timestamp` system variable at server startup. With this variable enabled, the server handles `TIMESTAMP` as follows instead:

- `TIMESTAMP` columns not explicitly declared as `NOT NULL` permit `NULL` values. Setting such a column to `NULL` sets it to `NULL`, not the current timestamp.
- No `TIMESTAMP` column is assigned the `DEFAULT CURRENT_TIMESTAMP` or `ON UPDATE CURRENT_TIMESTAMP` attributes automatically. Those attributes must be explicitly specified.
- `TIMESTAMP` columns declared as `NOT NULL` and without an explicit `DEFAULT` clause are treated as having no default value. For inserted rows that specify no explicit value for such a column, the result depends on the SQL mode. If strict SQL mode is enabled, an error occurs. If strict SQL mode is not enabled, the column is assigned the implicit default of `'0000-00-00`

00:00:00' and a warning occurs. This is similar to how MySQL treats other temporal types such as `DATETIME`.

#### Note

`explicit_defaults_for_timestamp` is itself deprecated because its only purpose is to permit control over now-deprecated `TIMESTAMP` behaviors that will be removed in a future MySQL release. When that removal occurs, `explicit_defaults_for_timestamp` will have no purpose and will be removed as well.

- `external_user`

|                         |                         |                            |
|-------------------------|-------------------------|----------------------------|
| <b>System Variable</b>  | <b>Name</b>             | <code>external_user</code> |
|                         | <b>Variable Scope</b>   | Session                    |
|                         | <b>Dynamic Variable</b> | No                         |
| <b>Permitted Values</b> | <b>Type</b>             | string                     |

The external user name used during the authentication process, as set by the plugin used to authenticate the client. With native (built-in) MySQL authentication, or if the plugin does not set the value, this variable is `NULL`. See [Section 7.3.9, “Proxy Users”](#).

- `flush`

|                            |                         |                    |
|----------------------------|-------------------------|--------------------|
| <b>Command-Line Format</b> | <code>--flush</code>    |                    |
| <b>System Variable</b>     | <b>Name</b>             | <code>flush</code> |
|                            | <b>Variable Scope</b>   | Global             |
|                            | <b>Dynamic Variable</b> | Yes                |
| <b>Permitted Values</b>    | <b>Type</b>             | boolean            |
|                            | <b>Default</b>          | <code>OFF</code>   |

If `ON`, the server flushes (synchronizes) all changes to disk after each SQL statement. Normally, MySQL does a write of all changes to disk only after each SQL statement and lets the operating system handle the synchronizing to disk. See [Section B.5.3.3, “What to Do If MySQL Keeps Crashing”](#). This variable is set to `ON` if you start `mysqld` with the `--flush` option.

- `flush_time`

|                            |                             |                         |
|----------------------------|-----------------------------|-------------------------|
| <b>Command-Line Format</b> | <code>--flush_time=#</code> |                         |
| <b>System Variable</b>     | <b>Name</b>                 | <code>flush_time</code> |
|                            | <b>Variable Scope</b>       | Global                  |
|                            | <b>Dynamic Variable</b>     | Yes                     |
| <b>Permitted Values</b>    | <b>Type</b>                 | integer                 |
|                            | <b>Default</b>              | 0                       |
|                            | <b>Min Value</b>            | 0                       |

|                                      |                  |         |
|--------------------------------------|------------------|---------|
| <b>Permitted Values</b><br>(Windows) | <b>Type</b>      | integer |
|                                      | <b>Default</b>   | 0       |
|                                      | <b>Min Value</b> | 0       |

If this is set to a nonzero value, all tables are closed every `flush_time` seconds to free up resources and synchronize unflushed data to disk. This option is best used only on systems with minimal resources.

- `foreign_key_checks`

If set to 1 (the default), foreign key constraints for `InnoDB` tables are checked. If set to 0, foreign key constraints are ignored, with a couple of exceptions. When re-creating a table that was dropped, an error is returned if the table definition does not conform to the foreign key constraints referencing the table. Likewise, an `ALTER TABLE` operation returns an error if a foreign key definition is incorrectly formed. For more information, see [Section 14.1.18.5, “Using FOREIGN KEY Constraints”](#).

Setting this variable has the same effect on `NDB` tables as it does for `InnoDB` tables. Typically you leave this setting enabled during normal operation, to enforce [referential integrity](#). Disabling foreign key checking can be useful for reloading `InnoDB` tables in an order different from that required by their parent/child relationships. See [Section 15.8.7, “InnoDB and FOREIGN KEY Constraints”](#).

Setting `foreign_key_checks` to 0 also affects data definition statements: `DROP SCHEMA` drops a schema even if it contains tables that have foreign keys that are referred to by tables outside the schema, and `DROP TABLE` drops tables that have foreign keys that are referred to by other tables.

#### Note

Setting `foreign_key_checks` to 1 does not trigger a scan of the existing table data. Therefore, rows added to the table while `foreign_key_checks=0` will not be verified for consistency.

As of MySQL 5.7.5, dropping an index required by a foreign key constraint is not permitted, even with `foreign_key_checks=0`. The foreign key constraint must be removed before dropping the index (Bug #70260).

- `ft_boolean_syntax`

|                            |                                       |  |
|----------------------------|---------------------------------------|--|
| <b>Command-Line Format</b> | <code>--ft_boolean_syntax=name</code> |  |
| <b>System Variable</b>     | <b>Name</b>                           | <code>ft_boolean_syntax</code>               |
|                            | <b>Variable Scope</b>                 | Global                                       |
|                            | <b>Dynamic Variable</b>               | Yes  |
| <b>Permitted Values</b>    | <b>Type</b>                           | string                                       |
|                            | <b>Default</b>                        | <code>+ -&gt;&lt; ( ) ~* : " "&amp;  </code> |

The list of operators supported by boolean full-text searches performed using `IN BOOLEAN MODE`. See [Section 13.9.2, “Boolean Full-Text Searches”](#).

The default variable value is `' + ->< ( ) ~* : " "& | '`. The rules for changing the value are as follows:

- Operator function is determined by position within the string.
- The replacement value must be 14 characters.
- Each character must be an ASCII nonalphanumeric character.

- Either the first or second character must be a space.
- No duplicates are permitted except the phrase quoting operators in positions 11 and 12. These two characters are not required to be the same, but they are the only two that may be.
- Positions 10, 13, and 14 (which by default are set to `:`, `&`, and `|`) are reserved for future extensions.
- `ft_max_word_len`

|                            |                                  |                              |
|----------------------------|----------------------------------|------------------------------|
| <b>Command-Line Format</b> | <code>--ft_max_word_len=#</code> |                              |
| <b>System Variable</b>     | <b>Name</b>                      | <code>ft_max_word_len</code> |
|                            | <b>Variable Scope</b>            | Global                       |
|                            | <b>Dynamic Variable</b>          | No                           |
| <b>Permitted Values</b>    | <b>Type</b>                      | integer                      |
|                            | <b>Min Value</b>                 | 10                           |

The maximum length of the word to be included in a `MyISAM FULLTEXT` index.

#### Note

`FULLTEXT` indexes on `MyISAM` tables must be rebuilt after changing this variable. Use `REPAIR TABLE tbl_name QUICK`.

- `ft_min_word_len`

|                            |                                  |                              |
|----------------------------|----------------------------------|------------------------------|
| <b>Command-Line Format</b> | <code>--ft_min_word_len=#</code> |                              |
| <b>System Variable</b>     | <b>Name</b>                      | <code>ft_min_word_len</code> |
|                            | <b>Variable Scope</b>            | Global                       |
|                            | <b>Dynamic Variable</b>          | No                           |
| <b>Permitted Values</b>    | <b>Type</b>                      | integer                      |
|                            | <b>Default</b>                   | 4                            |
|                            | <b>Min Value</b>                 | 1                            |

The minimum length of the word to be included in a `MyISAM FULLTEXT` index.

#### Note

`FULLTEXT` indexes on `MyISAM` tables must be rebuilt after changing this variable. Use `REPAIR TABLE tbl_name QUICK`.

- `ft_query_expansion_limit`

|                            |   |                                       |
|----------------------------|---|---------------------------------------|
| <b>Command-Line Format</b> | <code>--ft_query_expansion_limit=#</code> |                                       |
| <b>System Variable</b>     | <b>Name</b>                               | <code>ft_query_expansion_limit</code> |
|                            | <b>Variable Scope</b>                     | Global                                |

|                         |                         |         |
|-------------------------|-------------------------|---------|
|                         | <b>Dynamic Variable</b> | No      |
| <b>Permitted Values</b> | <b>Type</b>             | integer |
|                         | <b>Default</b>          | 20      |
|                         | <b>Min Value</b>        | 0       |
|                         | <b>Max Value</b>        | 1000    |

The number of top matches to use for full-text searches performed using `WITH QUERY EXPANSION`.

- `ft_stopword_file`

|                            |   |                               |
|----------------------------|---|-------------------------------|
| <b>Command-Line Format</b> | <code>--ft_stopword_file=file_name</code> |                               |
| <b>System Variable</b>     | <b>Name</b>                               | <code>ft_stopword_file</code> |
|                            | <b>Variable Scope</b>                     | Global                        |
|                            | <b>Dynamic Variable</b>                   | No                            |
| <b>Permitted Values</b>    | <b>Type</b>                               | file name                     |

The file from which to read the list of stopwords for full-text searches on `MyISAM` tables. The server looks for the file in the data directory unless an absolute path name is given to specify a different directory. All the words from the file are used; comments are *not* honored. By default, a built-in list of stopwords is used (as defined in the `storage/myisam/ft_static.c` file). Setting this variable to the empty string ( `' '` ) disables stopwords filtering. See also [Section 13.9.4, “Full-Text Stopwords”](#).

#### Note

`FULLTEXT` indexes on `MyISAM` tables must be rebuilt after changing this variable or the contents of the stopwords file. Use `REPAIR TABLE tbl_name QUICK`.

- `general_log`

|                            |                            |                          |
|----------------------------|----------------------------|--------------------------|
| <b>Command-Line Format</b> | <code>--general-log</code> |                          |
| <b>System Variable</b>     | <b>Name</b>                | <code>general_log</code> |
|                            | <b>Variable Scope</b>      | Global                   |
|                            | <b>Dynamic Variable</b>    | Yes                      |
| <b>Permitted Values</b>    | <b>Type</b>                | boolean                  |
|                            | <b>Default</b>             | <code>OFF</code>         |

Whether the general query log is enabled. The value can be 0 (or `OFF`) to disable the log or 1 (or `ON`) to enable the log. The default value depends on whether the `--general_log` option is given. The destination for log output is controlled by the `log_output` system variable; if that value is `NONE`, no log entries are written even if the log is enabled.

- `general_log_file`

|                            |   |                               |
|----------------------------|---|-------------------------------|
| <b>Command-Line Format</b> | <code>--general-log-file=file_name</code> |                               |
| <b>System Variable</b>     | <b>Name</b>                               | <code>general_log_file</code> |

|                         |                         |                            |
|-------------------------|-------------------------|----------------------------|
|                         | <b>Variable Scope</b>   | Global                     |
|                         | <b>Dynamic Variable</b> | Yes                        |
| <b>Permitted Values</b> | <b>Type</b>             | file name                  |
|                         | <b>Default</b>          | <code>host_name.log</code> |

The name of the general query log file. The default value is `host_name.log`, but the initial value can be changed with the `--general_log_file` option.

- `group_concat_max_len`

|  |                                       |                                   |
|--|---------------------------------------|-----------------------------------|
| <b>Command-Line Format</b>                 | <code>--group_concat_max_len=#</code> |                                   |
| <b>System Variable</b>                     | <b>Name</b>                           | <code>group_concat_max_len</code> |
|  | <b>Variable Scope</b>                 | Global, Session                   |
|  | <b>Dynamic Variable</b>               | Yes                               |
| <b>Permitted Values</b> (32-bit platforms) | <b>Type</b>                           | integer                           |
|  | <b>Default</b>                        | <code>1024</code>                 |
|  | <b>Min Value</b>                      | <code>4</code>                    |
|  | <b>Max Value</b>                      | <code>4294967295</code>           |
| <b>Permitted Values</b> (64-bit platforms) | <b>Type</b>                           | integer                           |
|  | <b>Default</b>                        | <code>1024</code>                 |
|  | <b>Min Value</b>                      | <code>4</code>                    |
|  | <b>Max Value</b>                      | <code>18446744073709551615</code> |

The maximum permitted result length in bytes for the `GROUP_CONCAT()` function. The default is 1024.

- `have_compress`

`YES` if the `zlib` compression library is available to the server, `NO` if not. If not, the `COMPRESS()` and `UNCOMPRESS()` functions cannot be used.

- `have_crypt`

`YES` if the `crypt()` system call is available to the server, `NO` if not. If not, the `ENCRYPT()` function cannot be used.

- `have_dynamic_loading`

`YES` if `mysqld` supports dynamic loading of plugins, `NO` if not. If the value is `NO`, you cannot use options such as `--plugin-load` to load plugins at server startup, or the `INSTALL PLUGIN` statement to load plugins at runtime.

- `have_geometry`

`YES` if the server supports spatial data types, `NO` if not.

- `have_openssl`

This variable is an alias for [have\\_ssl](#).

- [have\\_profiling](#)

**YES** if statement profiling capability is present, **NO** if not. If present, the [profiling](#) system variable controls whether this capability is enabled or disabled. See [Section 14.7.5.31, “SHOW PROFILES Syntax”](#).

This variable is deprecated and will be removed in a future MySQL release.

- [have\\_query\\_cache](#)

**YES** if `mysqld` supports the query cache, **NO** if not.

- [have\\_rtree\\_keys](#)

**YES** if `RTREE` indexes are available, **NO** if not. (These are used for spatial indexes in `MyISAM` tables.)

- [have\\_ssl](#)

**YES** if `mysqld` supports SSL connections, **NO** if not. **DISABLED** indicates that the server was compiled with SSL support, but was not started with the appropriate `--ssl-xxx` options. For more information, see [Section 7.4.2, “Building MySQL with Support for Secure Connections”](#).

- [have\\_statement\\_timeout](#)

|                         |                         |  |
|-------------------------|-------------------------|--|
| <b>Introduced</b>       | 5.7.4                   |  |
| <b>System Variable</b>  | <b>Name</b>             | <a href="#">have_statement_timeout</a> |
|                         | <b>Variable Scope</b>   | Global                                 |
|                         | <b>Dynamic Variable</b> | No                                     |
| <b>Permitted Values</b> | <b>Type</b>             | boolean                                |

Whether the statement execution timeout feature is available (see [Statement Execution Time Optimizer Hints](#)). The value can be **NO** if the background thread used by this feature could not be initialized.

- [have\\_symlink](#)

**YES** if symbolic link support is enabled, **NO** if not. This is required on Unix for support of the `DATA DIRECTORY` and `INDEX DIRECTORY` table options. If the server is started with the `--skip-symbolic-links` option, the value is **DISABLED**.

This variable has no meaning on Windows.

- [host\\_cache\\_size](#)

|                         |                         |                                 |
|-------------------------|-------------------------|---------------------------------|
| <b>System Variable</b>  | <b>Name</b>             | <a href="#">host_cache_size</a> |
|                         | <b>Variable Scope</b>   | Global                          |
|                         | <b>Dynamic Variable</b> | Yes                             |
| <b>Permitted Values</b> | <b>Type</b>             | integer                         |
|                         | <b>Default</b>          | -1 (autosized)                  |
|                         | <b>Min Value</b>        | 0                               |

|  |                  |       |
|--|------------------|-------|
|  | <b>Max Value</b> | 65536 |
|--|------------------|-------|

The size of the internal host cache (see [Section 9.12.5.2, “DNS Lookup Optimization and the Host Cache”](#)). Setting the size to 0 disables the host cache. Changing the cache size at runtime implicitly causes a `FLUSH HOSTS` operation to clear the host cache and truncate the `host_cache` table.

The default value is 128, plus 1 for a value of `max_connections` up to 500, plus 1 for every increment of 20 over 500 in the `max_connections` value, capped to a limit of 2000.

Use of `--skip-host-cache` is similar to setting the `host_cache_size` system variable to 0, but `host_cache_size` is more flexible because it can also be used to resize, enable, or disable the host cache at runtime, not just at server startup.

If you start the server with `--skip-host-cache`, that does not prevent changes to the value of `host_cache_size`, but such changes have no effect and the cache is not re-enabled even if `host_cache_size` is set larger than 0.

- `hostname`

|                         |                         |                       |
|-------------------------|-------------------------|-----------------------|
| <b>System Variable</b>  | <b>Name</b>             | <code>hostname</code> |
|                         | <b>Variable Scope</b>   | Global                |
|                         | <b>Dynamic Variable</b> | No                    |
| <b>Permitted Values</b> | <b>Type</b>             | string                |

The server sets this variable to the server host name at startup.

- `identity`

This variable is a synonym for the `last_insert_id` variable. It exists for compatibility with other database systems. You can read its value with `SELECT @@identity`, and set it using `SET identity`.

- `ignore_db_dirs`

|                         |                         |                             |
|-------------------------|-------------------------|-----------------------------|
| <b>System Variable</b>  | <b>Name</b>             | <code>ignore_db_dirs</code> |
|                         | <b>Variable Scope</b>   | Global                      |
|                         | <b>Dynamic Variable</b> | No                          |
| <b>Permitted Values</b> | <b>Type</b>             | string                      |

A comma-separated list of names that are not considered as database directories in the data directory. The value is set from any instances of `--ignore-db-dir` given at server startup.

As of MySQL 5.7.11, `--ignore-db-dir` can be used at data directory initialization time with `mysqld --initialize` to specify directories that the server should ignore for purposes of assessing whether an existing data directory is considered empty. See [Section 2.10.1.1, “Initializing the Data Directory Manually Using mysqld”](#).

- `init_connect`

|                            |                                  |                           |
|----------------------------|----------------------------------|---------------------------|
| <b>Command-Line Format</b> | <code>--init-connect=name</code> |                           |
| <b>System Variable</b>     | <b>Name</b>                      | <code>init_connect</code> |

|                         |                         |        |
|-------------------------|-------------------------|--------|
|                         | <b>Variable Scope</b>   | Global |
|                         | <b>Dynamic Variable</b> | Yes    |
| <b>Permitted Values</b> | <b>Type</b>             | string |

A string to be executed by the server for each client that connects. The string consists of one or more SQL statements, separated by semicolon characters. For example, each client session begins by default with autocommit mode enabled. For older servers (before MySQL 5.5.8), there is no global `autocommit` system variable to specify that autocommit should be disabled by default, but as a workaround `init_connect` can be used to achieve the same effect:

```
SET GLOBAL init_connect='SET autocommit=0';
```

The `init_connect` variable can also be set on the command line or in an option file. To set the variable as just shown using an option file, include these lines:

```
[mysqld]
init_connect='SET autocommit=0'
```

The content of `init_connect` is not executed for users that have the `SUPER` privilege. This is done so that an erroneous value for `init_connect` does not prevent all clients from connecting. For example, the value might contain a statement that has a syntax error, thus causing client connections to fail. Not executing `init_connect` for users that have the `SUPER` privilege enables them to open a connection and fix the `init_connect` value.

The server discards any result sets produced by statements in the value of `init_connect`.

- `init_file`

|                            |                                    |                        |
|----------------------------|------------------------------------|------------------------|
| <b>Command-Line Format</b> | <code>--init-file=file_name</code> |                        |
| <b>System Variable</b>     | <b>Name</b>                        | <code>init_file</code> |
|                            | <b>Variable Scope</b>              | Global                 |
|                            | <b>Dynamic Variable</b>            | No                     |
| <b>Permitted Values</b>    | <b>Type</b>                        | file name              |

The name of the file specified with the `--init-file` option when you start the server. This should be a file containing SQL statements that you want the server to execute when it starts. Each statement must be on a single line and should not include comments. For more information, see the description of `--init-file`.

- `innodb_xxx`

InnoDB system variables are listed in [Section 15.14, “InnoDB Startup Options and System Variables”](#). These variables control many aspects of storage, memory use, and I/O patterns for InnoDB tables, and are especially important now that InnoDB is the default storage engine.

- `insert_id`

The value to be used by the following `INSERT` or `ALTER TABLE` statement when inserting an `AUTO_INCREMENT` value. This is mainly used with the binary log.

- `interactive_timeout`

|                            |                                      |                                  |
|----------------------------|--------------------------------------|----------------------------------|
| <b>Command-Line Format</b> | <code>--interactive_timeout=#</code> |                                  |
| <b>System Variable</b>     | <b>Name</b>                          | <code>interactive_timeout</code> |
|                            | <b>Variable Scope</b>                | Global, Session                  |
|                            | <b>Dynamic Variable</b>              | Yes                              |
| <b>Permitted Values</b>    | <b>Type</b>                          | integer                          |
|                            | <b>Default</b>                       | 28800                            |
|                            | <b>Min Value</b>                     | 1                                |

The number of seconds the server waits for activity on an interactive connection before closing it. An interactive client is defined as a client that uses the `CLIENT_INTERACTIVE` option to `mysql_real_connect()`. See also `wait_timeout`.

- `internal_tmp_disk_storage_engine`

|                                       |   |   |
|---------------------------------------|---|---|
| <b>Introduced</b>                     | 5.7.5   |   |
| <b>Command-Line Format</b>            | <code>--internal_tmp_disk_storage_engine=#</code> |   |
| <b>System Variable</b>                | <b>Name</b>                                       | <code>internal_tmp_disk_storage_engine</code> |
|                                       | <b>Variable Scope</b>                             | Global  |
|                                       | <b>Dynamic Variable</b>                           | Yes   |
| <b>Permitted Values (5.7.5)</b>       | <b>Type</b>                                       | enumeration                                   |
|                                       | <b>Default</b>                                    | <code>MYISAM</code>                           |
|                                       | <b>Valid Values</b>                               | <code>MYISAM</code>                           |
|                                       |   | <code>INNODB</code>                           |
| <b>Permitted Values (&gt;= 5.7.6)</b> | <b>Type</b>                                       | enumeration                                   |
|                                       | <b>Default</b>                                    | <code>INNODB</code>                           |
|                                       | <b>Valid Values</b>                               | <code>MYISAM</code>                           |
|                                       |   | <code>INNODB</code>                           |

The storage engine for on-disk internal temporary tables (see [Section 9.4.4, “Internal Temporary Table Use in MySQL”](#)). Permitted values are `MYISAM` and `INNODB`.

This variable was added in MySQL 5.7.5 with a default of `MYISAM`. In MySQL 5.7.6, the default value was changed to `INNODB`. With this change, the `optimizer` uses the `InnoDB` storage engine by default for on-disk internal temporary tables.

Under `internal_tmp_disk_storage_engine=INNODB`, queries that generate temporary tables that exceed `InnoDB row or column limits` will return `Row size too large` or `Too many columns` errors. The workaround is to set `internal_tmp_disk_storage_engine` to `MYISAM`.

- `join_buffer_size`

|                            |                                   |                               |
|----------------------------|-----------------------------------|-------------------------------|
| <b>Command-Line Format</b> | <code>--join_buffer_size=#</code> |                               |
| <b>System Variable</b>     | <b>Name</b>                       | <code>join_buffer_size</code> |
|                            | <b>Variable Scope</b>             | Global, Session               |

|   |                         |                      |
|---|-------------------------|----------------------|
|   | <b>Dynamic Variable</b> | Yes                  |
| <b>Permitted Values</b><br>(Windows)              | <b>Type</b>             | integer              |
|   | <b>Default</b>          | 262144               |
|   | <b>Min Value</b>        | 128                  |
|   | <b>Max Value</b>        | 4294967295           |
| <b>Permitted Values</b> (Other, 32-bit platforms) | <b>Type</b>             | integer              |
|   | <b>Default</b>          | 262144               |
|   | <b>Min Value</b>        | 128                  |
|   | <b>Max Value</b>        | 4294967295           |

|   | <b>Default</b>          | 262144               |
|   | <b>Min Value</b>        | 128                  |
|   | <b>Max Value</b>        | 18446744073709547520 |

The minimum size of the buffer that is used for plain index scans, range index scans, and joins that do not use indexes and thus perform full table scans. Normally, the best way to get fast joins is to add indexes. Increase the value of `join_buffer_size` to get a faster full join when adding indexes is not possible. One join buffer is allocated for each full join between two tables. For a complex join between several tables for which indexes are not used, multiple join buffers might be necessary.

Unless Batched Key Access (BKA) is used, there is no gain from setting the buffer larger than required to hold each matching row, and all joins allocate at least the minimum size, so use caution in setting this variable to a large value globally. It is better to keep the global setting small and change to a larger setting only in sessions that are doing large joins. Memory allocation time can cause substantial performance drops if the global size is larger than needed by most queries that use it.

When BKA is used, the value of `join_buffer_size` defines how large the batch of keys is in each request to the storage engine. The larger the buffer, the more sequential access will be to the right hand table of a join operation, which can significantly improve performance.

The default is 256KB. The maximum permissible setting for `join_buffer_size` is 4GB-1. Larger values are permitted for 64-bit platforms (except 64-bit Windows, for which large values are truncated to 4GB-1 with a warning).

For additional information about join buffering, see [Section 9.2.1.10, “Nested-Loop Join Algorithms”](#). For information about Batched Key Access, see [Section 9.2.1.14, “Block Nested-Loop and Batched Key Access Joins”](#).

- `keep_files_on_create`

|                            |                                       |                                   |
|----------------------------|---------------------------------------|-----------------------------------|
| <b>Command-Line Format</b> | <code>--keep_files_on_create=#</code> |                                   |
| <b>System Variable</b>     | <b>Name</b>                           | <code>keep_files_on_create</code> |
|                            | <b>Variable Scope</b>                 | Global, Session                   |

|                         |                         |         |
|-------------------------|-------------------------|---------|
|                         | <b>Dynamic Variable</b> | Yes     |
| <b>Permitted Values</b> | <b>Type</b>             | boolean |
|                         | <b>Default</b>          | OFF     |

If a `MyISAM` table is created with no `DATA DIRECTORY` option, the `.MYD` file is created in the database directory. By default, if `MyISAM` finds an existing `.MYD` file in this case, it overwrites it. The same applies to `.MYI` files for tables created with no `INDEX DIRECTORY` option. To suppress this behavior, set the `keep_files_on_create` variable to `ON` (1), in which case `MyISAM` will not overwrite existing files and returns an error instead. The default value is `OFF` (0).

If a `MyISAM` table is created with a `DATA DIRECTORY` or `INDEX DIRECTORY` option and an existing `.MYD` or `.MYI` file is found, `MyISAM` always returns an error. It will not overwrite a file in the specified directory.

- `key_buffer_size`

|  |                                  |                                   |

| <b>Permitted Values</b> (32-bit platforms) | <b>Type</b>                      | integer                           |
|  | <b>Default</b>                   | 8388608                           |
|  | <b>Min Value</b>                 | 8                                 |
|  | <b>Max Value</b>                 | 4294967295                        |
| <b>Permitted Values</b> (64-bit platforms) | <b>Type</b>                      | integer                           |
|  | <b>Default</b>                   | 8388608                           |
|  | <b>Min Value</b>                 | 8                                 |
|  | <b>Max Value</b>                 | <code>OS_PER_PROCESS_LIMIT</code> |

Index blocks for `MyISAM` tables are buffered and are shared by all threads. `key_buffer_size` is the size of the buffer used for index blocks. The key buffer is also known as the key cache.

The maximum permissible setting for `key_buffer_size` is 4GB-1 on 32-bit platforms. Larger values are permitted for 64-bit platforms. The effective maximum size might be less, depending on your available physical RAM and per-process RAM limits imposed by your operating system or hardware platform. The value of this variable indicates the amount of memory requested. Internally, the server allocates as much memory as possible up to this amount, but the actual allocation might be less.

You can increase the value to get better index handling for all reads and multiple writes; on a system whose primary function is to run MySQL using the `MyISAM` storage engine, 25% of the machine's total memory is an acceptable value for this variable. However, you should be aware that, if you make the value too large (for example, more than 50% of the machine's total memory), your system might start to page and become extremely slow. This is because MySQL relies on the operating system to perform file system caching for data reads, so you must leave some room for the file

system cache. You should also consider the memory requirements of any other storage engines that you may be using in addition to [MyISAM](#).

For even more speed when writing many rows at the same time, use [LOCK TABLES](#). See [Section 9.2.2.1, “Speed of INSERT Statements”](#).

You can check the performance of the key buffer by issuing a [SHOW STATUS](#) statement and examining the [Key\\_read\\_requests](#), [Key\\_reads](#), [Key\\_write\\_requests](#), and [Key\\_writes](#) status variables. (See [Section 14.7.5, “SHOW Syntax”](#).) The [Key\\_reads/Key\\_read\\_requests](#) ratio should normally be less than 0.01. The [Key\\_writes/Key\\_write\\_requests](#) ratio is usually near 1 if you are using mostly updates and deletes, but might be much smaller if you tend to do updates that affect many rows at the same time or if you are using the [DELAY\\_KEY\\_WRITE](#) table option.

The fraction of the key buffer in use can be determined using [key\\_buffer\\_size](#) in conjunction with the [Key\\_blocks\\_unused](#) status variable and the buffer block size, which is available from the [key\\_cache\\_block\\_size](#) system variable:

```
1 - ((Key_blocks_unused * key_cache_block_size) / key_buffer_size)
```

This value is an approximation because some space in the key buffer is allocated internally for administrative structures. Factors that influence the amount of overhead for these structures include block size and pointer size. As block size increases, the percentage of the key buffer lost to overhead tends to decrease. Larger blocks results in a smaller number of read operations (because more keys are obtained per read), but conversely an increase in reads of keys that are not examined (if not all keys in a block are relevant to a query).

It is possible to create multiple [MyISAM](#) key caches. The size limit of 4GB applies to each cache individually, not as a group. See [Section 9.10.2, “The MyISAM Key Cache”](#).

- [key\\_cache\\_age\\_threshold](#)

|  |  |   |
|--|--|---|
| <b>Command-Line Format</b>                 | <code>--key_cache_age_threshold=#</code> |   |
| <b>System Variable</b>                     | <b>Name</b>                              | <a href="#">key_cache_age_threshold</a> |
|  | <b>Variable Scope</b>                    | Global                                  |
|  | <b>Dynamic Variable</b>                  | Yes                                     |
| <b>Permitted Values</b> (32-bit platforms) | <b>Type</b>                              | integer                                 |
|  | <b>Default</b>                           | 300                                     |
|  | <b>Min Value</b>                         | 100                                     |
|  | <b>Max Value</b>                         | 4294967295                              |
| <b>Permitted Values</b> (64-bit platforms) | <b>Type</b>                              | integer                                 |
|  | <b>Default</b>                           | 300                                     |
|  | <b>Min Value</b>                         | 100                                     |
|  | <b>Max Value</b>                         | 18446744073709551615                    |

This value controls the demotion of buffers from the hot sublist of a key cache to the warm sublist. Lower values cause demotion to happen more quickly. The minimum value is 100. The default value is 300. See [Section 9.10.2, “The MyISAM Key Cache”](#).

- `key_cache_block_size`

|                            |                                       |                                   |
|----------------------------|---------------------------------------|-----------------------------------|
| <b>Command-Line Format</b> | <code>--key_cache_block_size=#</code> |                                   |
| <b>System Variable</b>     | <b>Name</b>                           | <code>key_cache_block_size</code> |
|                            | <b>Variable Scope</b>                 | Global                            |
|                            | <b>Dynamic Variable</b>               | Yes                               |
| <b>Permitted Values</b>    | <b>Type</b>                           | integer                           |
|                            | <b>Default</b>                        | 1024                              |
|                            | <b>Min Value</b>                      | 512                               |
|                            | <b>Max Value</b>                      | 16384                             |

The size in bytes of blocks in the key cache. The default value is 1024. See [Section 9.10.2, “The MyISAM Key Cache”](#).

- `key_cache_division_limit`

|                            |   |                                       |
|----------------------------|---|---------------------------------------|
| <b>Command-Line Format</b> | <code>--key_cache_division_limit=#</code> |                                       |
| <b>System Variable</b>     | <b>Name</b>                               | <code>key_cache_division_limit</code> |
|                            | <b>Variable Scope</b>                     | Global                                |
|                            | <b>Dynamic Variable</b>                   | Yes                                   |
| <b>Permitted Values</b>    | <b>Type</b>                               | integer                               |
|                            | <b>Default</b>                            | 100                                   |
|                            | <b>Min Value</b>                          | 1                                     |
|                            | <b>Max Value</b>                          | 100                                   |

The division point between the hot and warm sublists of the key cache buffer list. The value is the percentage of the buffer list to use for the warm sublist. Permissible values range from 1 to 100. The default value is 100. See [Section 9.10.2, “The MyISAM Key Cache”](#).

- `large_files_support`

|                        |                         |                                  |
|------------------------|-------------------------|----------------------------------|
| <b>System Variable</b> | <b>Name</b>             | <code>large_files_support</code> |
|                        | <b>Variable Scope</b>   | Global                           |
|                        | <b>Dynamic Variable</b> | No                               |

Whether `mysqld` was compiled with options for large file support.

- `large_pages`

|                            |                            |                          |
|----------------------------|----------------------------|--------------------------|
| <b>Command-Line Format</b> | <code>--large-pages</code> |                          |
| <b>System Variable</b>     | <b>Name</b>                | <code>large_pages</code> |

|                                 |                         |                    |
|---------------------------------|-------------------------|--------------------|
|                                 | <b>Variable Scope</b>   | Global             |
|                                 | <b>Dynamic Variable</b> | No                 |
| <b>Platform Specific</b>        | Linux                   |                    |
| <b>Permitted Values (Linux)</b> | <b>Type</b>             | boolean            |
|                                 | <b>Default</b>          | <code>FALSE</code> |

Whether large page support is enabled (via the `--large-pages` option). See [Section 9.12.4.2, “Enabling Large Page Support”](#).

- `large_page_size`

|                                 |                         |                              |
|---------------------------------|-------------------------|------------------------------|
| <b>System Variable</b>          | <b>Name</b>             | <code>large_page_size</code> |
|                                 | <b>Variable Scope</b>   | Global                       |
|                                 | <b>Dynamic Variable</b> | No                           |
| <b>Permitted Values (Linux)</b> | <b>Type</b>             | integer                      |
|                                 | <b>Default</b>          | <code>0</code>               |

If large page support is enabled, this shows the size of memory pages. Large memory pages are supported only on Linux; on other platforms, the value of this variable is always 0. See [Section 9.12.4.2, “Enabling Large Page Support”](#).

- `last_insert_id`

The value to be returned from `LAST_INSERT_ID()`. This is stored in the binary log when you use `LAST_INSERT_ID()` in a statement that updates a table. Setting this variable does not update the value returned by the `mysql_insert_id()` C API function.

- `lc_messages`

|                            |                                 |                          |
|----------------------------|---------------------------------|--------------------------|
| <b>Command-Line Format</b> | <code>--lc-messages=name</code> |                          |
| <b>System Variable</b>     | <b>Name</b>                     | <code>lc_messages</code> |
|                            | <b>Variable Scope</b>           | Global, Session          |
|                            | <b>Dynamic Variable</b>         | Yes                      |
| <b>Permitted Values</b>    | <b>Type</b>                     | string                   |
|                            | <b>Default</b>                  | <code>en_US</code>       |

The locale to use for error messages. The default is `en_US`. The server converts the argument to a language name and combines it with the value of `lc_messages_dir` to produce the location for the error message file. See [Section 11.2, “Setting the Error Message Language”](#).

- `lc_messages_dir`

|                            |   |                              |
|----------------------------|---|------------------------------|
| <b>Command-Line Format</b> | <code>--lc-messages-dir=dir_name</code> |                              |
| <b>System Variable</b>     | <b>Name</b>                             | <code>lc_messages_dir</code> |
|                            | <b>Variable Scope</b>                   | Global                       |

|                         |                         |                |
|-------------------------|-------------------------|----------------|
|                         | <b>Dynamic Variable</b> | No             |
| <b>Permitted Values</b> | <b>Type</b>             | directory name |

The directory where error messages are located. The server uses the value together with the value of `lc_messages` to produce the location for the error message file. See [Section 11.2, “Setting the Error Message Language”](#).

- `lc_time_names`

|                         |                         |                            |
|-------------------------|-------------------------|----------------------------|
| <b>System Variable</b>  | <b>Name</b>             | <code>lc_time_names</code> |
|                         | <b>Variable Scope</b>   | Global, Session            |
|                         | <b>Dynamic Variable</b> | Yes                        |
| <b>Permitted Values</b> | <b>Type</b>             | string                     |

This variable specifies the locale that controls the language used to display day and month names and abbreviations. This variable affects the output from the `DATE_FORMAT()`, `DAYNAME()` and `MONTHNAME()` functions. Locale names are POSIX-style values such as `'ja_JP'` or `'pt_BR'`. The default value is `'en_US'` regardless of your system's locale setting. For further information, see [Section 11.7, “MySQL Server Locale Support”](#).

- `license`

|                         |                         |                      |
|-------------------------|-------------------------|----------------------|
| <b>System Variable</b>  | <b>Name</b>             | <code>license</code> |
|                         | <b>Variable Scope</b>   | Global               |
|                         | <b>Dynamic Variable</b> | No                   |
| <b>Permitted Values</b> | <b>Type</b>             | string               |
|                         | <b>Default</b>          | <code>GPL</code>     |

The type of license the server has.

- `local_infile`

|                         |                         |                           |
|-------------------------|-------------------------|---------------------------|
| <b>System Variable</b>  | <b>Name</b>             | <code>local_infile</code> |
|                         | <b>Variable Scope</b>   | Global                    |
|                         | <b>Dynamic Variable</b> | Yes                       |
| <b>Permitted Values</b> | <b>Type</b>             | boolean                   |
|                         | <b>Default</b>          | <code>true</code>         |

Whether `LOCAL` is supported for `LOAD DATA INFILE` statements. If this variable is disabled, clients cannot use `LOCAL` in `LOAD DATA` statements. While the default for this variable is `true`, whether `LOAD DATA INFILE LOCAL` is actually permitted depends on how MySQL was compiled, as well as a number of settings on both the server and the client; see [Section 7.1.6, “Security Issues with LOAD DATA LOCAL”](#), for details.

- `lock_wait_timeout`

|                            |                                    |
|----------------------------|------------------------------------|
| <b>Command-Line Format</b> | <code>--lock_wait_timeout=#</code> |
|----------------------------|------------------------------------|

|                         |                         |                                |
|-------------------------|-------------------------|--------------------------------|
| <b>System Variable</b>  | <b>Name</b>             | <code>lock_wait_timeout</code> |
|                         | <b>Variable Scope</b>   | Global, Session                |
|                         | <b>Dynamic Variable</b> | Yes                            |
| <b>Permitted Values</b> | <b>Type</b>             | integer                        |
|                         | <b>Default</b>          | <code>31536000</code>          |
|                         | <b>Min Value</b>        | <code>1</code>                 |
|                         | <b>Max Value</b>        | <code>31536000</code>          |

This variable specifies the timeout in seconds for attempts to acquire metadata locks. The permissible values range from 1 to 31536000 (1 year). The default is 31536000.

This timeout applies to all statements that use metadata locks. These include DML and DDL operations on tables, views, stored procedures, and stored functions, as well as `LOCK TABLES`, `FLUSH TABLES WITH READ LOCK`, and `HANDLER` statements.

This timeout does not apply to implicit accesses to system tables in the `mysql` database, such as grant tables modified by `GRANT` or `REVOKE` statements or table logging statements. The timeout does apply to system tables accessed directly, such as with `SELECT` or `UPDATE`.

The timeout value applies separately for each metadata lock attempt. A given statement can require more than one lock, so it is possible for the statement to block for longer than the `lock_wait_timeout` value before reporting a timeout error. When lock timeout occurs, `ER_LOCK_WAIT_TIMEOUT` is reported.

`lock_wait_timeout` does not apply to delayed inserts, which always execute with a timeout of 1 year. This is done to avoid unnecessary timeouts because a session that issues a delayed insert receives no notification of delayed insert timeouts.

- `locked_in_memory`

|                        |                         |                               |
|------------------------|-------------------------|-------------------------------|
| <b>System Variable</b> | <b>Name</b>             | <code>locked_in_memory</code> |
|                        | <b>Variable Scope</b>   | Global                        |
|                        | <b>Dynamic Variable</b> | No                            |

Whether `mysqld` was locked in memory with `--memlock`.

- `log_backward_compatible_user_definitions`

|                            |  |   |
|----------------------------|--|---|
| <b>Introduced</b>          | 5.7.6  |   |
| <b>Removed</b>             | 5.7.9  |   |
| <b>Command-Line Format</b> | <code>--log_backward_compatible_user_definitions[={OFF ON}]</code> |   |
| <b>System Variable</b>     | <b>Name</b>  | <code>log_backward_compatible_user_definitions</code> |
|                            | <b>Variable Scope</b>  | Global  |
|                            | <b>Dynamic Variable</b>  | Yes   |
| <b>Permitted Values</b>    | <b>Type</b>  | boolean   |

|  |                |     |
|--|----------------|-----|
|  | <b>Default</b> | OFF |
|--|----------------|-----|

Whether to log the *user\_specification* part of `CREATE USER`, `ALTER USER`, and `GRANT` statements in backward-compatible (pre-5.7.6) fashion:

- By default, this variable is disabled. The server writes user specifications as `user IDENTIFIED WITH auth_plugin AS 'hash_string'`.
- When enabled, the server writes user specifications as `user IDENTIFIED BY PASSWORD 'hash_string'`. Enabling this variable ensures better compatibility for cross-version replication.

This variable was removed in MySQL 5.7.9 and replaced by `log_built_in_as_identified_by_password`.

- `log_bin_trust_function_creators`

|                            |  |  |
|----------------------------|--|--|
| <b>Command-Line Format</b> | <code>--log-bin-trust-function-creators</code> |  |
| <b>System Variable</b>     | <b>Name</b>                                    | <code>log_bin_trust_function_creators</code> |
|                            | <b>Variable Scope</b>                          | Global                                       |
|                            | <b>Dynamic Variable</b>                        | Yes  |
| <b>Permitted Values</b>    | <b>Type</b>                                    | boolean                                      |
|                            | <b>Default</b>                                 | FALSE  |

This variable applies when binary logging is enabled. It controls whether stored function creators can be trusted not to create stored functions that will cause unsafe events to be written to the binary log. If set to 0 (the default), users are not permitted to create or alter stored functions unless they have the `SUPER` privilege in addition to the `CREATE ROUTINE` or `ALTER ROUTINE` privilege. A setting of 0 also enforces the restriction that a function must be declared with the `DETERMINISTIC` characteristic, or with the `READS SQL DATA` or `NO SQL` characteristic. If the variable is set to 1, MySQL does not enforce these restrictions on stored function creation. This variable also applies to trigger creation. See [Section 22.7, “Binary Logging of Stored Programs”](#).

- `log_built_in_as_identified_by_password`

|                            |  |   |
|----------------------------|--|---|
| <b>Introduced</b>          | 5.7.9  |   |
| <b>Command-Line Format</b> | <code>--log_built_in_as_identified_by_password[={OFF ON}]</code> |   |
| <b>System Variable</b>     | <b>Name</b>  | <code>log_built_in_as_identified_by_password</code> |
|                            | <b>Variable Scope</b>  | Global  |
|                            | <b>Dynamic Variable</b>  | Yes   |
| <b>Permitted Values</b>    | <b>Type</b>  | boolean   |
|                            | <b>Default</b>   | OFF   |

This variable affects binary logging of user-management statements. If enabled, binary logging for `CREATE USER` statements involving built-in authentication plugins rewrites the statements to include an `IDENTIFIED BY PASSWORD` clause, and `SET PASSWORD` statements are logged as `SET PASSWORD` statements, rather than being rewritten to `ALTER USER` statements.

This variable was added in MySQL 5.7.9. It replaces the `log_backward_compatible_user_definitions` variable.

- `log_error`

|                            |                                      |                        |
|----------------------------|--------------------------------------|------------------------|
| <b>Command-Line Format</b> | <code>--log-error[=file_name]</code> |                        |
| <b>System Variable</b>     | <b>Name</b>                          | <code>log_error</code> |
|                            | <b>Variable Scope</b>                | Global                 |
|                            | <b>Dynamic Variable</b>              | No                     |
| <b>Permitted Values</b>    | <b>Type</b>                          | file name              |

The location of the error log, or `stderr` if the server is writing error message to the standard error output. See [Section 6.4.2, “The Error Log”](#).

- `log_error_verbosity`

|                            |                                      |                                  |
|----------------------------|--------------------------------------|----------------------------------|
| <b>Introduced</b>          | 5.7.2                                |                                  |
| <b>Command-Line Format</b> | <code>--log_error_verbosity=#</code> |                                  |
| <b>System Variable</b>     | <b>Name</b>                          | <code>log_error_verbosity</code> |
|                            | <b>Variable Scope</b>                | Global                           |
|                            | <b>Dynamic Variable</b>              | Yes                              |
| <b>Permitted Values</b>    | <b>Type</b>                          | integer                          |
|                            | <b>Default</b>                       | 3                                |
|                            | <b>Min Value</b>                     | 1                                |
|                            | <b>Max Value</b>                     | 3                                |

This variable controls verbosity of the server in writing error, warning, and note messages to the error log. The following table shows the permitted values. The default is 3.

| Verbosity Value | Message Types Logged        |
|-----------------|-----------------------------|
| 1               | Errors only                 |
| 2               | Errors and warnings         |
| 3               | Errors, warnings, and notes |

`log_error_verbosity` was added in MySQL 5.7.2. It is preferred over, and should be used instead of, the older `log_warnings` system variable. See the description of `log_warnings` for information about how that variable relates to `log_error_verbosity`. In particular, assigning a value to `log_warnings` assigns a value to `log_error_verbosity` and vice versa.

- `log_output`

|                            |                                |                         |
|----------------------------|--------------------------------|-------------------------|
| <b>Command-Line Format</b> | <code>--log-output=name</code> |                         |
| <b>System Variable</b>     | <b>Name</b>                    | <code>log_output</code> |
|                            | <b>Variable Scope</b>          | Global                  |
|                            | <b>Dynamic Variable</b>        | Yes                     |
| <b>Permitted Values</b>    | <b>Type</b>                    | set                     |

|  |                     |       |
|--|---------------------|-------|
|  | <b>Default</b>      | FILE  |
|  | <b>Valid Values</b> | TABLE |
|  |                     | FILE  |
|  |                     | NONE  |

The destination for general query log and slow query log output. The value can be a comma-separated list of one or more of the words `TABLE` (log to tables), `FILE` (log to files), or `NONE` (do not log to tables or files). The default value is `FILE`. `NONE`, if present, takes precedence over any other specifiers. If the value is `NONE` log entries are not written even if the logs are enabled. If the logs are not enabled, no logging occurs even if the value of `log_output` is not `NONE`. For more information, see [Section 6.4.1, “Selecting General Query and Slow Query Log Output Destinations”](#).

- `log_queries_not_using_indexes`

|                            |  |  |
|----------------------------|--|--|
| <b>Command-Line Format</b> | <code>--log-queries-not-using-indexes</code> |  |
| <b>System Variable</b>     | <b>Name</b>                                  | <code>log_queries_not_using_indexes</code> |
|                            | <b>Variable Scope</b>                        | Global                                     |
|                            | <b>Dynamic Variable</b>                      | Yes  |
| <b>Permitted Values</b>    | <b>Type</b>                                  | boolean                                    |
|                            | <b>Default</b>                               | OFF  |

Whether queries that do not use indexes are logged to the slow query log. See [Section 6.4.5, “The Slow Query Log”](#).

- `log_syslog`

|                                   |                                   |                         |
|-----------------------------------|-----------------------------------|-------------------------|
| <b>Introduced</b>                 | 5.7.5                             |                         |
| <b>Command-Line Format</b>        | <code>--log_syslog[={0 1}]</code> |                         |
| <b>System Variable</b>            | <b>Name</b>                       | <code>log_syslog</code> |
|                                   | <b>Variable Scope</b>             | Global                  |
|                                   | <b>Dynamic Variable</b>           | Yes                     |
| <b>Permitted Values (Unix)</b>    | <b>Type</b>                       | boolean                 |
|                                   | <b>Default</b>                    | OFF                     |
| <b>Permitted Values (Windows)</b> | <b>Type</b>                       | boolean                 |
|                                   | <b>Default</b>                    | ON                      |

Whether to write error log output to `syslog` (on Unix and Unix-like systems) or Event Log (on Windows). The default value is platform specific:

- On Unix and Unix-like systems, `syslog` output is disabled by default.
- On Windows, Event Log output is enabled by default, which is consistent with older MySQL versions.

Regardless of the default, `log_syslog` can be set explicitly to control output on any supported platform.

`syslog` output control is orthogonal to sending error output to a file or (on Windows) to the console. Error output can be directed to the latter destination in addition to or instead of `syslog` as desired. See [Section 6.4.2, “The Error Log”](#).

- `log_syslog_facility`

|                            |  |                                  |
|----------------------------|--|----------------------------------|
| <b>Introduced</b>          | 5.7.5                                    |                                  |
| <b>Command-Line Format</b> | <code>--log_syslog_facility=value</code> |                                  |
| <b>System Variable</b>     | <b>Name</b>                              | <code>log_syslog_facility</code> |
|                            | <b>Variable Scope</b>                    | Global                           |
|                            | <b>Dynamic Variable</b>                  | Yes                              |
| <b>Permitted Values</b>    | <b>Type</b>                              | string                           |
|                            | <b>Default</b>                           | <code>daemon</code>              |

The facility for error log output written to `syslog` (what type of program is sending the message). This variable has no effect unless the `log_syslog` system variable is enabled. See [Section 6.4.2, “The Error Log”](#).

The permitted values can vary per operating system; consult your system `syslog` documentation.

This variable does not exist on Windows.

- `log_syslog_include_pid`

|                            |   |                                     |
|----------------------------|---|-------------------------------------|
| <b>Introduced</b>          | 5.7.5   |                                     |
| <b>Command-Line Format</b> | <code>--log_syslog_include_pid[={0 1}]</code> |                                     |
| <b>System Variable</b>     | <b>Name</b>                                   | <code>log_syslog_include_pid</code> |
|                            | <b>Variable Scope</b>                         | Global                              |
|                            | <b>Dynamic Variable</b>                       | Yes                                 |
| <b>Permitted Values</b>    | <b>Type</b>                                   | boolean                             |
|                            | <b>Default</b>                                | <code>ON</code>                     |

Whether to include the server process ID in each line of error log output written to `syslog`. This variable has no effect unless the `log_syslog` system variable is enabled. See [Section 6.4.2, “The Error Log”](#).

This variable does not exist on Windows.

- `log_syslog_tag`

|                            |                                     |                             |
|----------------------------|-------------------------------------|-----------------------------|
| <b>Introduced</b>          | 5.7.5                               |                             |
| <b>Command-Line Format</b> | <code>--log_syslog_tag=value</code> |                             |
| <b>System Variable</b>     | <b>Name</b>                         | <code>log_syslog_tag</code> |
|                            | <b>Variable Scope</b>               | Global                      |
|                            | <b>Dynamic Variable</b>             | Yes                         |
| <b>Permitted Values</b>    | <b>Type</b>                         | string                      |

|  |                |                           |
|--|----------------|---------------------------|
|  | <b>Default</b> | <code>empty string</code> |
|--|----------------|---------------------------|

The tag to be added to the server identifier in error log output written to `syslog`. This variable has no effect unless the `log_syslog` system variable is enabled. See [Section 6.4.2, “The Error Log”](#).

By default, the server identifier is `mysqld` with no tag. If a tag of `tag_val` is specified, it is appended to the server identifier with a leading hyphen, resulting in an identifier of `mysqld-tag_val`.

On Windows, to use a tag that does not already exist, the server must be run from an account with Administrator privileges, to permit creation of a registry entry for the tag. Elevated privileges are not required if the tag already exists.

- `log_timestamps`

|                            |                                 |                             |
|----------------------------|---------------------------------|-----------------------------|
| <b>Introduced</b>          | 5.7.2                           |                             |
| <b>Command-Line Format</b> | <code>--log_timestamps=#</code> |                             |
| <b>System Variable</b>     | <b>Name</b>                     | <code>log_timestamps</code> |
|                            | <b>Variable Scope</b>           | Global                      |
|                            | <b>Dynamic Variable</b>         | Yes                         |
| <b>Permitted Values</b>    | <b>Type</b>                     | enumeration                 |
|                            | <b>Default</b>                  | UTC                         |
|                            | <b>Valid Values</b>             | UTC<br>SYSTEM               |

This variable controls the timestamp time zone of error log messages, and of general query log and slow query log messages written to files. It does not affect the time zone of general query log and slow query log messages written to tables (`mysql.general_log`, `mysql.slow_log`). Rows retrieved from those tables can be converted from the local system time zone to any desired time zone with `CONVERT_TZ()` or by setting the session `time_zone` system variable.

Permitted `log_timestamps` values are `UTC` (the default) and `SYSTEM` (local system time zone).

Timestamps are written using ISO 8601 / RFC 3339 format: `YYYY-MM-DDThh:mm:ss.uuuuuu` plus a tail value of `Z` signifying Zulu time (UTC) or `±hh:mm` (an offset from UTC).

This variable was added in MySQL 5.7.2. Before 5.7.2, timestamps in log messages were written using the local system time zone by default, not `UTC`. If you want the previous log message time zone default, set `log_timestamps=SYSTEM`.

- `log_throttle_queries_not_using_indexes`

|                         |                         |   |
|-------------------------|-------------------------|---|
| <b>System Variable</b>  | <b>Name</b>             | <code>log_throttle_queries_not_using_indexes</code> |
|                         | <b>Variable Scope</b>   | Global  |
|                         | <b>Dynamic Variable</b> | Yes   |
| <b>Permitted Values</b> | <b>Type</b>             | integer   |
|                         | <b>Default</b>          | 0   |

If `log_queries_not_using_indexes` is enabled, the `log_throttle_queries_not_using_indexes` variable limits the number of such queries per

minute that can be written to the slow query log. A value of 0 (the default) means “no limit”. For more information, see [Section 6.4.5, “The Slow Query Log”](#).

- [log\\_slow\\_admin\\_statements](#)

|                         |                         |   |
|-------------------------|-------------------------|---|
| <b>Introduced</b>       | 5.7.1                   |   |
| <b>System Variable</b>  | <b>Name</b>             | <a href="#">log_slow_admin_statements</a> |
|                         | <b>Variable Scope</b>   | Global                                    |
|                         | <b>Dynamic Variable</b> | Yes                                       |
| <b>Permitted Values</b> | <b>Type</b>             | boolean                                   |
|                         | <b>Default</b>          | <a href="#">OFF</a>                       |

Include slow administrative statements in the statements written to the slow query log. Administrative statements include [ALTER TABLE](#), [ANALYZE TABLE](#), [CHECK TABLE](#), [CREATE INDEX](#), [DROP INDEX](#), [OPTIMIZE TABLE](#), and [REPAIR TABLE](#).

- [log\\_warnings](#)

|  |                                    |                                      |
|--|------------------------------------|--------------------------------------|
| <b>Deprecated</b>                                    | 5.7.2                              |                                      |
| <b>Command-Line Format</b>                           | <a href="#">--log-warnings[=#]</a> |                                      |
| <b>System Variable</b>                               | <b>Name</b>                        | <a href="#">log_warnings</a>         |

|--|------------------|----------------------|
|  | <b>Max Value</b> | 18446744073709551615 |
|--|------------------|----------------------|

Whether to produce additional warning messages to the error log. This variable is enabled by default (the default is 1 before MySQL 5.7.2, 2 as of 5.7.2). To disable it, set it to 0. The server logs messages about statements that are unsafe for statement-based logging if the value is greater than 0. Aborted connections and access-denied errors for new connection attempts are logged if the value is greater than 1. See [Section B.5.2.11, “Communication Errors and Aborted Connections”](#).

Enabling this option by setting it greater than 0 is recommended, if you use replication, to get more information about what is happening, such as messages about network failures and reconnections. If the value is greater than 1, aborted connections are written to the error log, and access-denied errors for new connection attempts are written.

If a slave server is started with `log_warnings` enabled, the slave prints messages to the error log to provide information about its status, such as the binary log and relay log coordinates where it starts its job, when it is switching to another relay log, when it reconnects after a disconnect, and so forth.

As of MySQL 5.7.2, information items previously governed by `log_warnings` are governed by `log_error_verbosity`, which is preferred over, and should be used instead of, the older `log_warnings` system variable. (The `log_warnings` system variable and `--log-warnings` command-line option are deprecated and will be removed in a future MySQL release.)

Assigning a value to `log_warnings` assigns a value to `log_error_verbosity` and vice versa. The variables are related as follows:

- Suppression of all `log_warnings` items, achieved with `log_warnings=0`, is achieved with `log_error_verbosity=1` (errors only).
- Items printed for `log_warnings=1` or higher count as warnings and are printed for `log_error_verbosity=2` or higher.
- Items printed for `log_warnings=2` count as notes and are printed for `log_error_verbosity=3`.

As of MySQL 5.7.2, the default log level is controlled by `log_error_verbosity`, which has a default of 3. In addition, the default for `log_warnings` changes from 1 to 2, which corresponds to `log_error_verbosity=3`. To achieve a logging level similar to the previous default, set `log_error_verbosity=2`.

In MySQL 5.7.2 and higher, use of `log_warnings` is still permitted but maps onto use of `log_error_verbosity` as follows:

- Setting `log_warnings=0` is equivalent to `log_error_verbosity=1` (errors only).
- Setting `log_warnings=1` is equivalent to `log_error_verbosity=2` (errors, warnings).
- Setting `log_warnings=2` (or higher) is equivalent to `log_error_verbosity=3` (errors, warnings, notes), and the server sets `log_warnings` to 2 if a larger value is specified.
- `long_query_time`

|                            |                                  |                              |
|----------------------------|----------------------------------|------------------------------|
| <b>Command-Line Format</b> | <code>--long_query_time=#</code> |                              |
| <b>System Variable</b>     | <b>Name</b>                      | <code>long_query_time</code> |
|                            | <b>Variable Scope</b>            | Global, Session              |

|                         |                         |         |
|-------------------------|-------------------------|---------|
|                         | <b>Dynamic Variable</b> | Yes     |
| <b>Permitted Values</b> | <b>Type</b>             | numeric |
|                         | <b>Default</b>          | 10      |
|                         | <b>Min Value</b>        | 0       |

If a query takes longer than this many seconds, the server increments the `Slow_queries` status variable. If the slow query log is enabled, the query is logged to the slow query log file. This value is measured in real time, not CPU time, so a query that is under the threshold on a lightly loaded system might be above the threshold on a heavily loaded one. The minimum and default values of `long_query_time` are 0 and 10, respectively. The value can be specified to a resolution of microseconds. For logging to a file, times are written including the microseconds part. For logging to tables, only integer times are written; the microseconds part is ignored. See [Section 6.4.5, “The Slow Query Log”](#).

- `low_priority_updates`

|                            |                                     |                                   |
|----------------------------|-------------------------------------|-----------------------------------|
| <b>Command-Line Format</b> | <code>--low-priority-updates</code> |                                   |
| <b>System Variable</b>     | <b>Name</b>                         | <code>low_priority_updates</code> |
|                            | <b>Variable Scope</b>               | Global, Session                   |
|                            | <b>Dynamic Variable</b>             | Yes                               |
| <b>Permitted Values</b>    | <b>Type</b>                         | boolean                           |
|                            | <b>Default</b>                      | <code>FALSE</code>                |

If set to 1, all `INSERT`, `UPDATE`, `DELETE`, and `LOCK TABLE WRITE` statements wait until there is no pending `SELECT` or `LOCK TABLE READ` on the affected table. This affects only storage engines that use only table-level locking (such as `MyISAM`, `MEMORY`, and `MERGE`).

- `lower_case_file_system`

|                         |                         |                                     |
|-------------------------|-------------------------|-------------------------------------|
| <b>System Variable</b>  | <b>Name</b>             | <code>lower_case_file_system</code> |
|                         | <b>Variable Scope</b>   | Global                              |
|                         | <b>Dynamic Variable</b> | No                                  |
| <b>Permitted Values</b> | <b>Type</b>             | boolean                             |

This variable describes the case sensitivity of file names on the file system where the data directory is located. `OFF` means file names are case sensitive, `ON` means they are not case sensitive. This variable is read only because it reflects a file system attribute and setting it would have no effect on the file system.

- `lower_case_table_names`

|                            |   |                                     |
|----------------------------|---|-------------------------------------|
| <b>Command-Line Format</b> | <code>--lower_case_table_names[=#]</code> |                                     |
| <b>System Variable</b>     | <b>Name</b>                               | <code>lower_case_table_names</code> |
|                            | <b>Variable Scope</b>                     | Global                              |
|                            | <b>Dynamic Variable</b>                   | No                                  |

|                         |                  |         |
|-------------------------|------------------|---------|
| <b>Permitted Values</b> | <b>Type</b>      | integer |
|                         | <b>Default</b>   | 0       |
|                         | <b>Min Value</b> | 0       |
|                         | <b>Max Value</b> | 2       |

If set to 0, table names are stored as specified and comparisons are case sensitive. If set to 1, table names are stored in lowercase on disk and comparisons are not case sensitive. If set to 2, table names are stored as given but compared in lowercase. This option also applies to database names and table aliases. For additional information, see [Section 10.2.2, “Identifier Case Sensitivity”](#).

On Windows the default value is 1. On OS X, the default value is 2.

You should *not* set `lower_case_table_names` to 0 if you are running MySQL on a system where the data directory resides on a case-insensitive file system (such as on Windows or OS X). It is an unsupported combination that could result in a hang condition when running an `INSERT INTO ... SELECT ... FROM tbl_name` operation with the wrong `tbl_name` letter case. With `MyISAM`, accessing table names using different letter cases could cause index corruption.

As of MySQL 5.7.9, an error message is printed and the server exits if you attempt to start the server with `--lower_case_table_names=0` on a case-insensitive file system.

If you are using `InnoDB` tables, you should set this variable to 1 on all platforms to force names to be converted to lowercase.

The setting of this variable in MySQL 5.7 affects the behavior of replication filtering options with regard to case sensitivity. (Bug #51639) See [Section 18.2.5, “How Servers Evaluate Replication Filtering Rules”](#), for more information.

- `max_allowed_packet`

|                            |                                     |                                 |
|----------------------------|-------------------------------------|---------------------------------|
| <b>Command-Line Format</b> | <code>--max_allowed_packet=#</code> |                                 |
| <b>System Variable</b>     | <b>Name</b>                         | <code>max_allowed_packet</code> |
|                            | <b>Variable Scope</b>               | Global, Session                 |
|                            | <b>Dynamic Variable</b>             | Yes                             |
| <b>Permitted Values</b>    | <b>Type</b>                         | integer                         |
|                            | <b>Default</b>                      | 4194304                         |
|                            | <b>Min Value</b>                    | 1024                            |
|                            | <b>Max Value</b>                    | 1073741824                      |

The maximum size of one packet or any generated/intermediate string, or any parameter sent by the `mysql_stmt_send_long_data()` C API function. The default is 4MB.

The packet message buffer is initialized to `net_buffer_length` bytes, but can grow up to `max_allowed_packet` bytes when needed. This value by default is small, to catch large (possibly incorrect) packets.

You must increase this value if you are using large `BLOB` columns or long strings. It should be as big as the largest `BLOB` you want to use. The protocol limit for `max_allowed_packet` is 1GB. The value should be a multiple of 1024; nonmultiples are rounded down to the nearest multiple.

When you change the message buffer size by changing the value of the `max_allowed_packet` variable, you should also change the buffer size on the client side if your client program permits it. The default `max_allowed_packet` value built in to the client library is 1GB, but individual client programs might override this. For example, `mysql` and `mysqldump` have defaults of 16MB and 24MB, respectively. They also enable you to change the client-side value by setting `max_allowed_packet` on the command line or in an option file.

The session value of this variable is read only. The client can receive up to as many bytes as the session value. However, the server will not send to the client more bytes than the current global `max_allowed_packet` value. (The global value could be less than the session value if the global value is changed after the client connects.)

- `max_connect_errors`

|  |                                     |                                 |
|--|-------------------------------------|---------------------------------|
| <b>Command-Line Format</b>                 | <code>--max_connect_errors=#</code> |                                 |
| <b>System Variable</b>                     | <b>Name</b>                         | <code>max_connect_errors</code> |
|  | <b>Variable Scope</b>               | Global                          |
|  | <b>Dynamic Variable</b>             | Yes                             |
| <b>Permitted Values</b> (32-bit platforms) | <b>Type</b>                         | integer                         |
|  | <b>Default</b>                      | 100                             |
|  | <b>Min Value</b>                    | 1                               |
|  | <b>Max Value</b>                    | 4294967295                      |
| <b>Permitted Values</b> (64-bit platforms) | <b>Type</b>                         | integer                         |
|  | <b>Default</b>                      | 100                             |
|  | <b>Min Value</b>                    | 1                               |
|  | <b>Max Value</b>                    | 18446744073709551615            |

If more than this many successive connection requests from a host are interrupted without a successful connection, the server blocks that host from further connections. You can unblock blocked hosts by flushing the host cache. To do so, issue a `FLUSH HOSTS` statement or execute a `mysqladmin flush-hosts` command. If a connection is established successfully within fewer than `max_connect_errors` attempts after a previous connection was interrupted, the error count for the host is cleared to zero. However, once a host is blocked, flushing the host cache is the only way to unblock it. The default is 100.

- `max_connections`

|                            |                                  |                              |
|----------------------------|----------------------------------|------------------------------|
| <b>Command-Line Format</b> | <code>--max_connections=#</code> |                              |
| <b>System Variable</b>     | <b>Name</b>                      | <code>max_connections</code> |
|                            | <b>Variable Scope</b>            | Global                       |
|                            | <b>Dynamic Variable</b>          | Yes                          |
| <b>Permitted Values</b>    | <b>Type</b>                      | integer                      |
|                            | <b>Default</b>                   | 151                          |

|                  |        |
|------------------|--------|
| <b>Min Value</b> | 1      |
| <b>Max Value</b> | 100000 |

The maximum permitted number of simultaneous client connections. By default, this is 151. See [Section B.5.2.7, “Too many connections”](#), for more information.

Increasing this value increases the number of file descriptors that `mysqld` requires. If the required number of descriptors are not available, the server reduces the value of `max_connections`. See [Section 9.4.3.1, “How MySQL Opens and Closes Tables”](#), for comments on file descriptor limits.

Connections refused because the `max_connections` limit is reached increment the `Connection_errors_max_connections` status variable.

- `max_delayed_threads`

|                     |                                      |                                  |
|---------------------|--------------------------------------|----------------------------------|
| Deprecated          | 5.6.7                                |                                  |
| Command-Line Format | <code>--max_delayed_threads=#</code> |                                  |
| System Variable     | Name                                 | <code>max_delayed_threads</code> |
|                     | Variable Scope                       | Global, Session                  |
|                     | Dynamic Variable                     | Yes                              |
| Permitted Values    | Type                                 | integer                          |
|                     | Default                              | <code>20</code>                  |
|                     | Min Value                            | <code>0</code>                   |
|                     | Max Value                            | <code>16384</code>               |

This system variable is deprecated (because `DELAYED` inserts are not supported), and will be removed in a future release.

- `max_digest_length`

|                     |                                    |                                |
|---------------------|------------------------------------|--------------------------------|
| Introduced          | 5.7.6                              |                                |
| Command-Line Format | <code>--max_digest_length=#</code> |                                |
| System Variable     | Name                               | <code>max_digest_length</code> |
|                     | Variable Scope                     | Global                         |
|                     | Dynamic Variable                   | No                             |
| Permitted Values    | Type                               | integer                        |
|                     | Default                            | <code>1024</code>              |
|                     | Min Value                          | 0                              |
|                     | Max Value                          | <code>1048576</code>           |

The maximum number of bytes available for computing statement digests (see [Section 24.8, “Performance Schema Statement Digests”](#)). Once this amount of space is used during digest

computation for a statement, no further tokens from the parsed statement are collected or figure into the digest value. Statements that differ only after that many bytes of parsed statement tokens produce the same digest and are aggregated for digest statistics.

Decreasing the `max_digest_length` value reduces memory use but causes the digest value of more statements to become indistinguishable if they differ only at the end. Increasing the value permits longer statements to be distinguished but increases memory use, particularly for workloads that involve large numbers of simultaneous sessions (`max_digest_length` bytes are allocated per session).

This variable was added in MySQL 5.7.6. Until 5.7.8, this variable applies to Performance Schema and to other server functions that use digests, such as query rewrite plugins. As of 5.7.8, it no longer applies to Performance Schema; instead, use `performance_schema_max_digest_length`.

- `max_error_count`

|                            |                                  |                              |
|----------------------------|----------------------------------|------------------------------|
| <b>Command-Line Format</b> | <code>--max_error_count=#</code> |                              |
| <b>System Variable</b>     | <b>Name</b>                      | <code>max_error_count</code> |
|                            | <b>Variable Scope</b>            | Global, Session              |
|                            | <b>Dynamic Variable</b>          | Yes                          |
| <b>Permitted Values</b>    | <b>Type</b>                      | integer                      |
|                            | <b>Default</b>                   | 64                           |
|                            | <b>Min Value</b>                 | 0                            |
|                            | <b>Max Value</b>                 | 65535                        |

The maximum number of error, warning, and note messages to be stored for display by the `SHOW ERRORS` and `SHOW WARNINGS` statements. This is the same as the number of condition areas in the diagnostics area, and thus the number of conditions that can be inspected by `GET DIAGNOSTICS`.

- `max_execution_time`

|                            |                                     |                                 |
|----------------------------|-------------------------------------|---------------------------------|
| <b>Introduced</b>          | 5.7.8                               |                                 |
| <b>Command-Line Format</b> | <code>--max_execution_time=#</code> |                                 |
| <b>System Variable</b>     | <b>Name</b>                         | <code>max_execution_time</code> |
|                            | <b>Variable Scope</b>               | Global, Session                 |
|                            | <b>Dynamic Variable</b>             | Yes                             |
| <b>Permitted Values</b>    | <b>Type</b>                         | integer                         |
|                            | <b>Default</b>                      | 0                               |

The execution timeout for `SELECT` statements, in milliseconds. If the value is 0, timeouts are not enabled.

`max_execution_time` applies as follows:

- The global `max_execution_time` value provides the default for the session value for new connections. The session value applies to `SELECT` executions executed within the session that include no `MAX_EXECUTION_TIME(N)` optimizer hint or for which `N` is 0.

- `max_execution_time` applies to read-only `SELECT` statements. Statements that are not read only are those that invoke a stored function that modifies data as a side effect.
- `max_execution_time` is ignored for `SELECT` statements in stored programs.

This variable was added in MySQL 5.7.8. Previously, it was named `max_statement_time`.

- `max_heap_table_size`

|  |                                      |                                  |
|--|--------------------------------------|----------------------------------|
| <b>Command-Line Format</b>                 | <code>--max_heap_table_size=#</code> |                                  |
| <b>System Variable</b>                     | <b>Name</b>                          | <code>max_heap_table_size</code> |
|  | <b>Variable Scope</b>                | Global, Session                  |
|  | <b>Dynamic Variable</b>              | Yes                              |
| <b>Permitted Values</b> (32-bit platforms) | <b>Type</b>                          | integer                          |
|  | <b>Default</b>                       | 16777216                         |
|  | <b>Min Value</b>                     | 16384                            |
|  | <b>Max Value</b>                     | 4294967295                       |
| <b>Permitted Values</b> (64-bit platforms) | <b>Type</b>                          | integer                          |
|  | <b>Default</b>                       | 16777216                         |
|  | <b>Min Value</b>                     | 16384                            |
|  | <b>Max Value</b>                     | 1844674407370954752              |

This variable sets the maximum size to which user-created `MEMORY` tables are permitted to grow. The value of the variable is used to calculate `MEMORY` table `MAX_ROWS` values. Setting this variable has no effect on any existing `MEMORY` table, unless the table is re-created with a statement such as `CREATE TABLE` or altered with `ALTER TABLE` or `TRUNCATE TABLE`. A server restart also sets the maximum size of existing `MEMORY` tables to the global `max_heap_table_size` value.

This variable is also used in conjunction with `tmp_table_size` to limit the size of internal in-memory tables. See [Section 9.4.4, “Internal Temporary Table Use in MySQL”](#).

`max_heap_table_size` is not replicated. See [Section 18.4.1.23, “Replication and MEMORY Tables”](#), and [Section 18.4.1.38, “Replication and Variables”](#), for more information.

- `max_insert_delayed_threads`

|                         |                         |   |
|-------------------------|-------------------------|---|
| <b>Deprecated</b>       | 5.6.7                   |   |
| <b>System Variable</b>  | <b>Name</b>             | <code>max_insert_delayed_threads</code> |
|                         | <b>Variable Scope</b>   | Global, Session                         |
|                         | <b>Dynamic Variable</b> | Yes                                     |
| <b>Permitted Values</b> | <b>Type</b>             | integer                                 |

This variable is a synonym for `max_delayed_threads`.

This system variable is deprecated (because `DELAYED` inserts are not supported), and will be removed in a future release.

- `max_join_size`

|                            |                                |                            |
|----------------------------|--------------------------------|----------------------------|
| <b>Command-Line Format</b> | <code>--max_join_size=#</code> |                            |
| <b>System Variable</b>     | <b>Name</b>                    | <code>max_join_size</code> |
|                            | <b>Variable Scope</b>          | Global, Session            |
|                            | <b>Dynamic Variable</b>        | Yes                        |
| <b>Permitted Values</b>    | <b>Type</b>                    | integer                    |
|                            | <b>Default</b>                 | 18446744073709551615       |
|                            | <b>Min Value</b>               | 1                          |
|                            | <b>Max Value</b>               | 18446744073709551615       |

Do not permit statements that probably need to examine more than `max_join_size` rows (for single-table statements) or row combinations (for multiple-table statements) or that are likely to do more than `max_join_size` disk seeks. By setting this value, you can catch statements where keys are not used properly and that would probably take a long time. Set it if your users tend to perform joins that lack a `WHERE` clause, that take a long time, or that return millions of rows.

Setting this variable to a value other than `DEFAULT` resets the value of `sql_big_selects` to 0. If you set the `sql_big_selects` value again, the `max_join_size` variable is ignored.

If a query result is in the query cache, no result size check is performed, because the result has previously been computed and it does not burden the server to send it to the client.

- `max_length_for_sort_data`

|                            |   |                                       |
|----------------------------|---|---------------------------------------|
| <b>Command-Line Format</b> | <code>--max_length_for_sort_data=#</code> |                                       |
| <b>System Variable</b>     | <b>Name</b>                               | <code>max_length_for_sort_data</code> |
|                            | <b>Variable Scope</b>                     | Global, Session                       |
|                            | <b>Dynamic Variable</b>                   | Yes                                   |
| <b>Permitted Values</b>    | <b>Type</b>                               | integer                               |
|                            | <b>Default</b>                            | 1024                                  |
|                            | <b>Min Value</b>                          | 4                                     |
|                            | <b>Max Value</b>                          | 8388608                               |

The cutoff on the size of index values that determines which `filesort` algorithm to use. See [Section 9.2.1.15, “ORDER BY Optimization”](#).

- `max_points_in_geometry`

|                            |   |
|----------------------------|---|
| <b>Introduced</b>          | 5.7.8   |
| <b>Command-Line Format</b> | <code>--max_points_in_geometry=integer</code> |

|                         |                         |                                     |
|-------------------------|-------------------------|-------------------------------------|
| <b>System Variable</b>  | <b>Name</b>             | <code>max_points_in_geometry</code> |
|                         | <b>Variable Scope</b>   | Global                              |
|                         | <b>Dynamic Variable</b> | Yes                                 |
| <b>Permitted Values</b> | <b>Type</b>             | integer                             |
|                         | <b>Default</b>          | <code>65536</code>                  |
|                         | <b>Min Value</b>        | <code>3</code>                      |
|                         | <b>Max Value</b>        | <code>1048576</code>                |

The maximum value of the `points_per_circle` argument to the `ST_Buffer_Strategy()` function.

- `max_prepared_stmt_count`

|                            |  |                                      |
|----------------------------|--|--------------------------------------|
| <b>Command-Line Format</b> | <code>--max_prepared_stmt_count=#</code> |                                      |
| <b>System Variable</b>     | <b>Name</b>                              | <code>max_prepared_stmt_count</code> |
|                            | <b>Variable Scope</b>                    | Global                               |
|                            | <b>Dynamic Variable</b>                  | Yes                                  |
| <b>Permitted Values</b>    | <b>Type</b>                              | integer                              |
|                            | <b>Default</b>                           | <code>16382</code>                   |
|                            | <b>Min Value</b>                         | <code>0</code>                       |
|                            | <b>Max Value</b>                         | <code>1048576</code>                 |

This variable limits the total number of prepared statements in the server. It can be used in environments where there is the potential for denial-of-service attacks based on running the server out of memory by preparing huge numbers of statements. If the value is set lower than the current number of prepared statements, existing statements are not affected and can be used, but no new statements can be prepared until the current number drops below the limit. The default value is 16,382. The permissible range of values is from 0 to 1 million. Setting the value to 0 disables prepared statements.

- `max_relay_log_size`

|                            |                                     |                                 |
|----------------------------|-------------------------------------|---------------------------------|
| <b>Command-Line Format</b> | <code>--max_relay_log_size=#</code> |                                 |
| <b>System Variable</b>     | <b>Name</b>                         | <code>max_relay_log_size</code> |
|                            | <b>Variable Scope</b>               | Global                          |
|                            | <b>Dynamic Variable</b>             | Yes                             |
| <b>Permitted Values</b>    | <b>Type</b>                         | integer                         |
|                            | <b>Default</b>                      | <code>0</code>                  |
|                            | <b>Min Value</b>                    | <code>0</code>                  |

|  |                  |            |
|--|------------------|------------|
|  | <b>Max Value</b> | 1073741824 |
|--|------------------|------------|

If a write by a replication slave to its relay log causes the current log file size to exceed the value of this variable, the slave rotates the relay logs (closes the current file and opens the next one). If `max_relay_log_size` is 0, the server uses `max_binlog_size` for both the binary log and the relay log. If `max_relay_log_size` is greater than 0, it constrains the size of the relay log, which enables you to have different sizes for the two logs. You must set `max_relay_log_size` to between 4096 bytes and 1GB (inclusive), or to 0. The default value is 0. See [Section 18.2.2, “Replication Implementation Details”](#).

- `max_seeks_for_key`

|  |                                    |                                |
|--|------------------------------------|--------------------------------|
| <b>Command-Line Format</b>                 | <code>--max_seeks_for_key=#</code> |                                |
| <b>System Variable</b>                     | <b>Name</b>                        | <code>max_seeks_for_key</code> |
|  | <b>Variable Scope</b>              | Global, Session                |
|  | <b>Dynamic Variable</b>            | Yes                            |
| <b>Permitted Values</b> (32-bit platforms) | <b>Type</b>                        | integer                        |
|  | <b>Default</b>                     | 4294967295                     |
|  | <b>Min Value</b>                   | 1                              |
|  | <b>Max Value</b>                   | 4294967295                     |
| <b>Permitted Values</b> (64-bit platforms) | <b>Type</b>                        | integer                        |
|  | <b>Default</b>                     | 18446744073709551615           |
|  | <b>Min Value</b>                   | 1                              |
|  | <b>Max Value</b>                   | 18446744073709551615           |

Limit the assumed maximum number of seeks when looking up rows based on a key. The MySQL optimizer assumes that no more than this number of key seeks are required when searching for matching rows in a table by scanning an index, regardless of the actual cardinality of the index (see [Section 14.7.5.22, “SHOW INDEX Syntax”](#)). By setting this to a low value (say, 100), you can force MySQL to prefer indexes instead of table scans.

- `max_sort_length`

|                            |                                  |                              |
|----------------------------|----------------------------------|------------------------------|
| <b>Command-Line Format</b> | <code>--max_sort_length=#</code> |                              |
| <b>System Variable</b>     | <b>Name</b>                      | <code>max_sort_length</code> |
|                            | <b>Variable Scope</b>            | Global, Session              |
|                            | <b>Dynamic Variable</b>          | Yes                          |
| <b>Permitted Values</b>    | <b>Type</b>                      | integer                      |
|                            | <b>Default</b>                   | 1024                         |
|                            | <b>Min Value</b>                 | 4                            |

|  |                  |         |
|--|------------------|---------|
|  | <b>Max Value</b> | 8388608 |
|--|------------------|---------|

The number of bytes to use when sorting data values. The server uses only the first `max_sort_length` bytes of each value and ignores the rest. Consequently, values that differ only after the first `max_sort_length` bytes compare as equal for `GROUP BY`, `ORDER BY`, and `DISTINCT` operations.

Increasing the value of `max_sort_length` may require increasing the value of `sort_buffer_size` as well. For details, see [Section 9.2.1.15, “ORDER BY Optimization”](#)

- `max_sp_recursion_depth`

|                            |   |                                     |
|----------------------------|---|-------------------------------------|
| <b>Command-Line Format</b> | <code>--max_sp_recursion_depth[=#]</code> |                                     |
| <b>System Variable</b>     | <b>Name</b>                               | <code>max_sp_recursion_depth</code> |
|                            | <b>Variable Scope</b>                     | Global, Session                     |
|                            | <b>Dynamic Variable</b>                   | Yes                                 |
| <b>Permitted Values</b>    | <b>Type</b>                               | integer                             |
|                            | <b>Default</b>                            | 0                                   |
|                            | <b>Max Value</b>                          | 255                                 |

The number of times that any given stored procedure may be called recursively. The default value for this option is 0, which completely disables recursion in stored procedures. The maximum value is 255.

Stored procedure recursion increases the demand on thread stack space. If you increase the value of `max_sp_recursion_depth`, it may be necessary to increase thread stack size by increasing the value of `thread_stack` at server startup.

- `max_statement_time`

|                         |                         |                                 |
|-------------------------|-------------------------|---------------------------------|
| <b>Introduced</b>       | 5.7.4                   |                                 |
| <b>Removed</b>          | 5.7.8                   |                                 |
| <b>System Variable</b>  | <b>Name</b>             | <code>max_statement_time</code> |
|                         | <b>Variable Scope</b>   | Global, Session                 |
|                         | <b>Dynamic Variable</b> | Yes                             |
| <b>Permitted Values</b> | <b>Type</b>             | integer                         |
|                         | <b>Default</b>          | 0                               |

The execution timeout for `SELECT` statements, in milliseconds. If the value is 0, timeouts are not enabled.

`max_statement_time` applies as follows:

- The global `max_statement_time` value provides the default for the session value for new connections. The session value applies to `SELECT` statements executed within the session that include no `MAX_STATEMENT_TIME = N` option or for which `N` is 0.

- `max_statement_time` applies to read-only `SELECT` statements. Statements that are not read only are those that invoke a stored function that modifies data as a side effect.
- `max_statement_time` is ignored for `SELECT` statements in stored programs.

This variable was added in MySQL 5.7.4 and renamed to `max_execution_time` in MySQL 5.7.8.

- `max_tmp_tables`

This variable is unused. It is deprecated and will be removed in a future MySQL release.

- `max_user_connections`

|                            |                                       |                                   |
|----------------------------|---------------------------------------|-----------------------------------|
| <b>Command-Line Format</b> | <code>--max_user_connections=#</code> |                                   |
| <b>System Variable</b>     | <b>Name</b>                           | <code>max_user_connections</code> |
|                            | <b>Variable Scope</b>                 | Global, Session                   |
|                            | <b>Dynamic Variable</b>               | Yes                               |
| <b>Permitted Values</b>    | <b>Type</b>                           | integer                           |
|                            | <b>Default</b>                        | 0                                 |
|                            | <b>Min Value</b>                      | 0                                 |
|                            | <b>Max Value</b>                      | 4294967295                        |

The maximum number of simultaneous connections permitted to any given MySQL user account. A value of 0 (the default) means “no limit.”

This variable has a global value that can be set at server startup or runtime. It also has a read-only session value that indicates the effective simultaneous-connection limit that applies to the account associated with the current session. The session value is initialized as follows:

- If the user account has a nonzero `MAX_USER_CONNECTIONS` resource limit, the session `max_user_connections` value is set to that limit.
- Otherwise, the session `max_user_connections` value is set to the global value.

Account resource limits are specified using the `CREATE USER` or `ALTER USER` statement. See [Section 7.3.4, “Setting Account Resource Limits”](#).

- `max_write_lock_count`

|  |                                       |                                   |
|--|---------------------------------------|-----------------------------------|
| <b>Command-Line Format</b>                 | <code>--max_write_lock_count=#</code> |                                   |
| <b>System Variable</b>                     | <b>Name</b>                           | <code>max_write_lock_count</code> |

|  | <b>Max Value</b> | 18446744073709551615 |

After this many write locks, permit some pending read lock requests to be processed in between.

- `mecab_rc_file`

|                            |                              |                            |
|----------------------------|------------------------------|----------------------------|
| <b>Introduced</b>          | 5.7.6                        |                            |
| <b>Command-Line Format</b> | <code>--mecab_rc_file</code> |                            |
| <b>System Variable</b>     | <b>Name</b>                  | <code>mecab_rc_file</code> |
|                            | <b>Variable Scope</b>        | Global                     |
|                            | <b>Dynamic Variable</b>      | No                         |
| <b>Permitted Values</b>    | <b>Type</b>                  | directory name             |

The `mecab_rc_file` option is used when setting up the MeCab full-text parser.

The `mecab_rc_file` option defines the path to the `mecabrc` configuration file, which is the configuration file for MeCab. The option is read-only and can only be set at startup. The `mecabrc` configuration file is required to initialize MeCab.

For information about the MeCab full-text parser, see [Section 13.9.9, “MeCab Full-Text Parser Plugin”](#).

For information about options that can be specified in the MeCab `mecabrc` configuration file, refer to the [MeCab Documentation](#) on the [Google Developers](#) site.

- `metadata_locks_cache_size`

|                         |                         |  |
|-------------------------|-------------------------|--|
| <b>Deprecated</b>       | 5.7.4                   |  |
| <b>System Variable</b>  | <b>Name</b>             | <code>metadata_locks_cache_size</code> |
|                         | <b>Variable Scope</b>   | Global                                 |
|                         | <b>Dynamic Variable</b> | No                                     |
| <b>Permitted Values</b> | <b>Type</b>             | integer                                |
|                         | <b>Default</b>          | 1024                                   |
|                         | <b>Min Value</b>        | 1                                      |
|                         | <b>Max Value</b>        | 1048576                                |

The size of the metadata locks cache. The server uses this cache to avoid creation and destruction of synchronization objects. This is particularly helpful on systems where such operations are expensive, such as Windows XP.

In MySQL 5.7.4, metadata locking implementation changes make this variable unnecessary, so it is deprecated and will be removed in a future MySQL release.

- `metadata_locks_hash_instances`

|                         |                         |  |
|-------------------------|-------------------------|--|
| <b>Deprecated</b>       | 5.7.4                   |  |
| <b>System Variable</b>  | <b>Name</b>             | <code>metadata_locks_hash_instances</code> |
|                         | <b>Variable Scope</b>   | Global                                     |
|                         | <b>Dynamic Variable</b> | No   |
| <b>Permitted Values</b> | <b>Type</b>             | integer                                    |
|                         | <b>Default</b>          | 8  |
|                         | <b>Min Value</b>        | 1  |
|                         | <b>Max Value</b>        | 1024                                       |

The set of metadata locks can be partitioned into separate hashes to permit connections accessing different objects to use different locking hashes and reduce contention. The `metadata_locks_hash_instances` system variable specifies the number of hashes (default 8).

In MySQL 5.7.4, metadata locking implementation changes make this variable unnecessary, so it is deprecated and will be removed in a future MySQL release.

- `min_examined_row_limit`

|  |   |                                     |
|--|---|-------------------------------------|
| <b>Command-Line Format</b>                 | <code>--min-examined-row-limit=#</code> |                                     |
| <b>System Variable</b>                     | <b>Name</b>                             | <code>min_examined_row_limit</code> |
|  | <b>Variable Scope</b>                   | Global, Session                     |
|  | <b>Dynamic Variable</b>                 | Yes                                 |
| <b>Permitted Values</b> (32-bit platforms) | <b>Type</b>                             | integer                             |
|  | <b>Default</b>                          | 0                                   |
|  | <b>Min Value</b>                        | 0                                   |
|  | <b>Max Value</b>                        | 4294967295                          |
| <b>Permitted Values</b> (64-bit platforms) | <b>Type</b>                             | integer                             |
|  | <b>Default</b>                          | 0                                   |
|  | <b>Min Value</b>                        | 0                                   |
|  | <b>Max Value</b>                        | 18446744073709551615                |

Queries that examine fewer than this number of rows are not logged to the slow query log.

- `multi_range_count`

|                   |       |
|-------------------|-------|
| <b>Deprecated</b> | 5.6.7 |
|-------------------|-------|

|                            |                                    |                                |
|----------------------------|------------------------------------|--------------------------------|

| <b>System Variable</b>     | <b>Name</b>                        | <code>multi_range_count</code> |
|                            | <b>Variable Scope</b>              | Global, Session                |
|                            | <b>Dynamic Variable</b>            | Yes                            |
| <b>Permitted Values</b>    | <b>Type</b>                        | integer                        |
|                            | <b>Default</b>                     | 256                            |
|                            | <b>Min Value</b>                   | 1                              |
|                            | <b>Max Value</b>                   | 4294967295                     |

This variable has no effect. It is deprecated and will be removed in a future MySQL release.

- `myisam_data_pointer_size`

|                            |   |                                       |
|----------------------------|---|---------------------------------------|
| <b>Command-Line Format</b> | <code>--myisam_data_pointer_size=#</code> |                                       |
| <b>System Variable</b>     | <b>Name</b>                               | <code>myisam_data_pointer_size</code> |
|                            | <b>Variable Scope</b>                     | Global                                |
|                            | <b>Dynamic Variable</b>                   | Yes                                   |
| <b>Permitted Values</b>    | <b>Type</b>                               | integer                               |
|                            | <b>Default</b>                            | 6                                     |
|                            | <b>Min Value</b>                          | 2                                     |
|                            | <b>Max Value</b>                          | 7                                     |

The default pointer size in bytes, to be used by `CREATE TABLE` for `MyISAM` tables when no `MAX_ROWS` option is specified. This variable cannot be less than 2 or larger than 7. The default value is 6. See [Section B.5.2.12, “The table is full”](#).

- `myisam_max_sort_file_size`

|  |  |  |
|--|--|--|
| <b>Command-Line Format</b>                 | <code>--myisam_max_sort_file_size=#</code> |  |
| <b>System Variable</b>                     | <b>Name</b>                                | <code>myisam_max_sort_file_size</code> |
|  | <b>Variable Scope</b>                      | Global                                 |
|  | <b>Dynamic Variable</b>                    | Yes                                    |
| <b>Permitted Values (32-bit platforms)</b> | <b>Type</b>                                | integer                                |
|  | <b>Default</b>                             | 2147483648                             |
| <b>Permitted Values (64-bit platforms)</b> | <b>Type</b>                                | integer                                |
|  | <b>Default</b>                             | 9223372036854775807                    |

The maximum size of the temporary file that MySQL is permitted to use while re-creating a `MyISAM` index (during `REPAIR TABLE`, `ALTER TABLE`, or `LOAD DATA INFILE`). If the file size would be

larger than this value, the index is created using the key cache instead, which is slower. The value is given in bytes.

If [MyISAM](#) index files exceed this size and disk space is available, increasing the value may help performance. The space must be available in the file system containing the directory where the original index file is located.

- [myisam\\_mmap\\_size](#)

|  |                                   |                                      |
|--|-----------------------------------|--------------------------------------|
| <b>Command-Line Format</b>                 | <code>--myisam_mmap_size=#</code> |                                      |
| <b>System Variable</b>                     | <b>Name</b>                       | <a href="#">myisam_mmap_size</a>     |
|  | <b>Variable Scope</b>             | Global                               |
|  | <b>Dynamic Variable</b>           | No                                   |
| <b>Permitted Values</b> (32-bit platforms) | <b>Type</b>                       | integer                              |
|  | <b>Default</b>                    | <a href="#">4294967295</a>           |
|  | <b>Min Value</b>                  | <a href="#">7</a>                    |
|  | <b>Max Value</b>                  | <a href="#">4294967295</a>           |
| <b>Permitted Values</b> (64-bit platforms) | <b>Type</b>                       | integer                              |
|  | <b>Default</b>                    | <a href="#">18446744073709551615</a> |
|  | <b>Min Value</b>                  | <a href="#">7</a>                    |
|  | <b>Max Value</b>                  | <a href="#">18446744073709551615</a> |

The maximum amount of memory to use for memory mapping compressed [MyISAM](#) files. If many compressed [MyISAM](#) tables are used, the value can be decreased to reduce the likelihood of memory-swapping problems.

- [myisam\\_recover\\_options](#)

|                        |                         |  |

|   | <b>Default</b>                           | 8388608                              |

|  |                  |                      |
|--|------------------|----------------------|
|  | <b>Min Value</b> | 4096                 |
|  | <b>Max Value</b> | 18446744073709551615 |

The size of the buffer that is allocated when sorting [MyISAM](#) indexes during a [REPAIR TABLE](#) or when creating indexes with [CREATE INDEX](#) or [ALTER TABLE](#).

The maximum permissible setting for `myisam_sort_buffer_size` is 4GB-1. Larger values are permitted for 64-bit platforms.

- `myisam_stats_method`

|                            |   |                                  |
|----------------------------|---|----------------------------------|
| <b>Command-Line Format</b> | <code>--myisam_stats_method=name</code> |                                  |
| <b>System Variable</b>     | <b>Name</b>                             | <code>myisam_stats_method</code> |
|                            | <b>Variable Scope</b>                   | Global, Session                  |
|                            | <b>Dynamic Variable</b>                 | Yes                              |
| <b>Permitted Values</b>    | <b>Type</b>                             | enumeration                      |
|                            | <b>Default</b>                          | <code>nulls_unequal</code>       |
|                            | <b>Valid Values</b>                     | <code>nulls_equal</code>         |
|                            |   | <code>nulls_unequal</code>       |
|                            |   | <code>nulls_ignored</code>       |

How the server treats [NULL](#) values when collecting statistics about the distribution of index values for [MyISAM](#) tables. This variable has three possible values, `nulls_equal`, `nulls_unequal`, and `nulls_ignored`. For `nulls_equal`, all [NULL](#) index values are considered equal and form a single value group that has a size equal to the number of [NULL](#) values. For `nulls_unequal`, [NULL](#) values are considered unequal, and each [NULL](#) forms a distinct value group of size 1. For `nulls_ignored`, [NULL](#) values are ignored.

The method that is used for generating table statistics influences how the optimizer chooses indexes for query execution, as described in [Section 9.3.7, “InnoDB and MyISAM Index Statistics Collection”](#).

- `myisam_use_mmap`

|                            |                                |                              |
|----------------------------|--------------------------------|------------------------------|
| <b>Command-Line Format</b> | <code>--myisam_use_mmap</code> |                              |
| <b>System Variable</b>     | <b>Name</b>                    | <code>myisam_use_mmap</code> |
|                            | <b>Variable Scope</b>          | Global                       |
|                            | <b>Dynamic Variable</b>        | Yes                          |
| <b>Permitted Values</b>    | <b>Type</b>                    | boolean                      |
|                            | <b>Default</b>                 | <code>OFF</code>             |

Use memory mapping for reading and writing [MyISAM](#) tables.

- `mysql_native_password_proxy_users`

|                            |  |
|----------------------------|--|
| <b>Introduced</b>          | 5.7.7  |
| <b>Command-Line Format</b> | <code>--mysql_native_password_proxy_users=[={OFF ON}]</code> |

|                         |                         |   |
|-------------------------|-------------------------|---|
| <b>System Variable</b>  | <b>Name</b>             | <a href="#">mysql_native_password_proxy_users</a> |
|                         | <b>Variable Scope</b>   | Global  |
|                         | <b>Dynamic Variable</b> | Yes   |
| <b>Permitted Values</b> | <b>Type</b>             | boolean   |
|                         | <b>Default</b>          | <a href="#">OFF</a>                               |

This variable controls whether the [mysql\\_native\\_password](#) built-in authentication plugin supports proxy users. It has no effect unless the [check\\_proxy\\_users](#) system variable is enabled. For information about user proxying, see [Section 7.3.9, “Proxy Users”](#).

This variable was added in MySQL 5.7.7. Before 5.7.7, [mysql\\_native\\_password](#) does not support proxy users.

- [named\\_pipe](#)

|                                      |                         |                            |
|--------------------------------------|-------------------------|----------------------------|
| <b>System Variable</b>               | <b>Name</b>             | <a href="#">named_pipe</a> |
|                                      | <b>Variable Scope</b>   | Global                     |
|                                      | <b>Dynamic Variable</b> | No                         |
| <b>Platform Specific</b>             | Windows                 |                            |
| <b>Permitted Values</b><br>(Windows) | <b>Type</b>             | boolean                    |
|                                      | <b>Default</b>          | <a href="#">OFF</a>        |

(Windows only.) Indicates whether the server supports connections over named pipes.

- [net\\_buffer\\_length](#)

|                            |                                       |                                   |
|----------------------------|---------------------------------------|-----------------------------------|
| <b>Command-Line Format</b> | <a href="#">--net_buffer_length=#</a> |                                   |
| <b>System Variable</b>     | <b>Name</b>                           | <a href="#">net_buffer_length</a> |
|                            | <b>Variable Scope</b>                 | Global, Session                   |
|                            | <b>Dynamic Variable</b>               | Yes                               |
| <b>Permitted Values</b>    | <b>Type</b>                           | integer                           |
|                            | <b>Default</b>                        | <a href="#">16384</a>             |
|                            | <b>Min Value</b>                      | <a href="#">1024</a>              |
|                            | <b>Max Value</b>                      | <a href="#">1048576</a>           |

Each client thread is associated with a connection buffer and result buffer. Both begin with a size given by [net\\_buffer\\_length](#) but are dynamically enlarged up to [max\\_allowed\\_packet](#) bytes as needed. The result buffer shrinks to [net\\_buffer\\_length](#) after each SQL statement.

This variable should not normally be changed, but if you have very little memory, you can set it to the expected length of statements sent by clients. If statements exceed this length, the connection buffer is automatically enlarged. The maximum value to which [net\\_buffer\\_length](#) can be set is 1MB.

The session value of this variable is read only.

- `net_read_timeout`

|                            |                                   |                               |
|----------------------------|-----------------------------------|-------------------------------|
| <b>Command-Line Format</b> | <code>--net_read_timeout=#</code> |                               |
| <b>System Variable</b>     | <b>Name</b>                       | <code>net_read_timeout</code> |
|                            | <b>Variable Scope</b>             | Global, Session               |
|                            | <b>Dynamic Variable</b>           | Yes                           |
| <b>Permitted Values</b>    | <b>Type</b>                       | integer                       |
|                            | <b>Default</b>                    | 30                            |
|                            | <b>Min Value</b>                  | 1                             |

The number of seconds to wait for more data from a connection before aborting the read. When the server is reading from the client, `net_read_timeout` is the timeout value controlling when to abort. When the server is writing to the client, `net_write_timeout` is the timeout value controlling when to abort. See also `slave_net_timeout`.

- `net_retry_count`

|  |                                  |                              |
|--|----------------------------------|------------------------------|
| <b>Command-Line Format</b>                 | <code>--net_retry_count=#</code> |                              |
| <b>System Variable</b>                     | <b>Name</b>                      | <code>net_retry_count</code> |
|  | <b>Variable Scope</b>            | Global, Session              |
|  | <b>Dynamic Variable</b>          | Yes                          |
| <b>Permitted Values (32-bit platforms)</b> | <b>Type</b>                      | integer                      |
|  | <b>Default</b>                   | 10                           |
|  | <b>Min Value</b>                 | 1                            |
|  | <b>Max Value</b>                 | 4294967295                   |
| <b>Permitted Values (64-bit platforms)</b> | <b>Type</b>                      | integer                      |
|  | <b>Default</b>                   | 10                           |
|  | <b>Min Value</b>                 | 1                            |
|  | <b>Max Value</b>                 | 18446744073709551615         |

If a read or write on a communication port is interrupted, retry this many times before giving up. This value should be set quite high on FreeBSD because internal interrupts are sent to all threads.

- `net_write_timeout`

|                            |                                    |                                |
|----------------------------|------------------------------------|--------------------------------|
| <b>Command-Line Format</b> | <code>--net_write_timeout=#</code> |                                |
| <b>System Variable</b>     | <b>Name</b>                        | <code>net_write_timeout</code> |
|                            | <b>Variable Scope</b>              | Global, Session                |
|                            | <b>Dynamic Variable</b>            | Yes                            |

|                         |                  |         |
|-------------------------|------------------|---------|
| <b>Permitted Values</b> | <b>Type</b>      | integer |
|                         | <b>Default</b>   | 60      |
|                         | <b>Min Value</b> | 1       |

The number of seconds to wait for a block to be written to a connection before aborting the write. See also `net_read_timeout`.

- `new`

|                            |                         |                    |
|----------------------------|-------------------------|--------------------|
| <b>Command-Line Format</b> | <code>--new</code>      |                    |
| <b>System Variable</b>     | <b>Name</b>             | <code>new</code>   |
|                            | <b>Variable Scope</b>   | Global, Session    |
|                            | <b>Dynamic Variable</b> | Yes                |
| <b>Disabled by</b>         | <code>skip-new</code>   |                    |
| <b>Permitted Values</b>    | <b>Type</b>             | boolean            |
|                            | <b>Default</b>          | <code>FALSE</code> |

This variable was used in MySQL 4.0 to turn on some 4.1 behaviors, and is retained for backward compatibility. Its value is always `OFF`.

In MySQL Cluster, setting this variable to `ON` makes it possible to employ partitioning types other than `KEY` or `LINEAR KEY` with `NDB` tables. *This feature is experimental only, and not supported in production.* For additional information, see [User-defined partitioning and the NDB storage engine \(MySQL Cluster\)](#).

- `ngram_token_size`

|                            |                                 |                               |
|----------------------------|---------------------------------|-------------------------------|
| <b>Introduced</b>          | 5.7.6                           |                               |
| <b>Command-Line Format</b> | <code>--ngram_token_size</code> |                               |
| <b>System Variable</b>     | <b>Name</b>                     | <code>ngram_token_size</code> |
|                            | <b>Variable Scope</b>           | Global                        |
|                            | <b>Dynamic Variable</b>         | No                            |
| <b>Permitted Values</b>    | <b>Type</b>                     | integer                       |
|                            | <b>Default</b>                  | 2                             |
|                            | <b>Min Value</b>                | 1                             |
|                            | <b>Max Value</b>                | 10                            |

Defines the n-gram token size for the n-gram full-text parser. The `ngram_token_size` option is read-only and can only be modified at startup. The default value is 2 (bigram). The maximum value is 10.

For more information about how to configure this variable, see [Section 13.9.8, “ngram Full-Text Parser”](#).

- `offline_mode`

|                            |                                 |                           |
|----------------------------|---------------------------------|---------------------------|
| <b>Introduced</b>          | 5.7.5                           |                           |
| <b>Command-Line Format</b> | <code>--offline_mode=val</code> |                           |
| <b>System Variable</b>     | <b>Name</b>                     | <code>offline_mode</code> |
|                            | <b>Variable Scope</b>           | Global                    |
|                            | <b>Dynamic Variable</b>         | Yes                       |
| <b>Permitted Values</b>    | <b>Type</b>                     | boolean                   |
|                            | <b>Default</b>                  | <code>OFF</code>          |

Whether the server is in “offline mode”, which has these characteristics:

- Connected client users who do not have the `SUPER` privilege are disconnected on the next request, with an appropriate error. Disconnection includes terminating running statements and releasing locks. Such clients also cannot initiate new connections, and receive an appropriate error.
- Connected client users who have the `SUPER` privilege are not disconnected, and can initiate new connections to manage the server.
- Replication slave threads are permitted to keep applying data to the server.

Only users who have the `SUPER` privilege can control offline mode. To put a server in offline mode, change the value of the `offline_mode` system variable from `OFF` to `ON`. To resume normal operations, change `offline_mode` from `ON` to `OFF`. In offline mode, clients that are refused access receive an `ER_SERVER_OFFLINE_MODE` error.

- `old`

|                            |                         |                  |
|----------------------------|-------------------------|------------------|
| <b>Command-Line Format</b> | <code>--old</code>      |                  |
| <b>System Variable</b>     | <b>Name</b>             | <code>old</code> |
|                            | <b>Variable Scope</b>   | Global           |
|                            | <b>Dynamic Variable</b> | No               |

`old` is a compatibility variable. It is disabled by default, but can be enabled at startup to revert the server to behaviors present in older versions.

When `old` is enabled, it changes the default scope of index hints to that used prior to MySQL 5.1.17. That is, index hints with no `FOR` clause apply only to how indexes are used for row retrieval and not to resolution of `ORDER BY` or `GROUP BY` clauses. (See [Section 9.9.4, “Index Hints”](#).) Take care about enabling this in a replication setup. With statement-based binary logging, having different modes for the master and slaves might lead to replication errors.

- `old_alter_table`

|                            |                                |                              |
|----------------------------|--------------------------------|------------------------------|
| <b>Command-Line Format</b> | <code>--old-alter-table</code> |                              |
| <b>System Variable</b>     | <b>Name</b>                    | <code>old_alter_table</code> |
|                            | <b>Variable Scope</b>          | Global, Session              |
|                            | <b>Dynamic Variable</b>        | Yes                          |

|                         |                |         |
|-------------------------|----------------|---------|
| <b>Permitted Values</b> | <b>Type</b>    | boolean |
|                         | <b>Default</b> | OFF     |

When this variable is enabled, the server does not use the optimized method of processing an [ALTER TABLE](#) operation. It reverts to using a temporary table, copying over the data, and then renaming the temporary table to the original, as used by MySQL 5.0 and earlier. For more information on the operation of [ALTER TABLE](#), see [Section 14.1.8, “ALTER TABLE Syntax”](#).

- [old\\_passwords](#)

|                                       |                         |                               |
|---------------------------------------|-------------------------|-------------------------------|
| <b>Deprecated</b>                     | 5.7.6                   |                               |
| <b>System Variable</b>                | <b>Name</b>             | <a href="#">old_passwords</a> |
|                                       | <b>Variable Scope</b>   | Global, Session               |
|                                       | <b>Dynamic Variable</b> | Yes                           |
| <b>Permitted Values (&lt;= 5.7.4)</b> | <b>Type</b>             | enumeration                   |
|                                       | <b>Default</b>          | 0                             |
|                                       | <b>Valid Values</b>     | 0                             |
|                                       |                         | 1                             |
| <b>Permitted Values (&gt;= 5.7.5)</b> | <b>Valid Values</b>     | 2                             |
|                                       |                         |                               |
|                                       | <b>Type</b>             | enumeration                   |
|                                       | <b>Default</b>          | 0                             |
| <b>Permitted Values (&gt;= 5.7.5)</b> | <b>Valid Values</b>     | 0                             |
|                                       |                         | 1                             |
|                                       |                         | 2                             |

#### Note

This system variable is deprecated as of MySQL 5.7.6 and will be removed in a future MySQL release.

This variable controls the password hashing method used by the [PASSWORD\(\)](#) function. It also influences password hashing performed by [CREATE USER](#) and [GRANT](#) statements that specify a password using an [IDENTIFIED BY](#) clause.

The following table shows the permitted values of [old\\_passwords](#), the password hashing method for each value, and which authentication plugins use passwords hashed with each method.

| Value | Password Hashing Method  | Associated Authentication Plugin      |
|-------|--------------------------|---------------------------------------|
| 0     | MySQL 4.1 native hashing | <a href="#">mysql_native_password</a> |
| 1     | Pre-4.1 (“old”) hashing  | <a href="#">mysql_old_password</a>    |
| 2     | SHA-256 hashing          | <a href="#">sha256_password</a>       |

#### Note

Passwords that use the pre-4.1 hashing method are less secure than passwords that use the native password hashing method and should be avoided. Pre-4.1 passwords are deprecated and support for them is removed in MySQL 5.7.5. Consequently, [old\\_passwords=1](#), which causes [PASSWORD\(\)](#) to generate pre-4.1 password hashes, is not permitted as of 5.7.5. For account upgrade instructions, see [Section 7.5.1.3, “Migrating Away from Pre-4.1 Password Hashing and the mysql\\_old\\_password Plugin”](#).

If `old_passwords=1`, `PASSWORD(str)` returns the same value as `OLD_PASSWORD(str)`. The latter function is not affected by the value of `old_passwords`.

If you set `old_passwords=2`, follow the instructions for using the `sha256_password` plugin at [Section 7.5.1.4, “The SHA-256 Authentication Plugin”](#).

The server sets the global `old_passwords` value during startup to be consistent with the password hashing method required by the default authentication plugin. The default plugin is `mysql_native_password` unless the `default_authentication_plugin` system variable is set otherwise.

As of MySQL 5.7.1, when a client successfully connects to the server, the server sets the session `old_passwords` value appropriately for the account authentication method. For example, if the account uses the `sha256_password` authentication plugin, the server sets `old_passwords=2`.

For additional information about authentication plugins and hashing formats, see [Section 7.3.8, “Pluggable Authentication”](#), and [Section 7.1.2.4, “Password Hashing in MySQL”](#).

- `open_files_limit`

|                            |                                   |                                |
|----------------------------|-----------------------------------|--------------------------------|
| <b>Command-Line Format</b> | <code>--open-files-limit=#</code> |                                |
| <b>System Variable</b>     | <b>Name</b>                       | <code>open_files_limit</code>  |
|                            | <b>Variable Scope</b>             | Global                         |
|                            | <b>Dynamic Variable</b>           | No                             |
| <b>Permitted Values</b>    | <b>Type</b>                       | integer                        |
|                            | <b>Default</b>                    | 5000, with possible adjustment |
|                            | <b>Min Value</b>                  | 0                              |
|                            | <b>Max Value</b>                  | platform dependent             |

The number of files that the operating system permits `mysqld` to open. The value of this variable at runtime is the real value permitted by the system and might be different from the value you specify at server startup. The value is 0 on systems where MySQL cannot change the number of open files.

The effective `open_files_limit` value is based on the value specified at system startup (if any) and the values of `max_connections` and `table_open_cache`, using these formulas:

```

1) 10 + max_connections + (table_open_cache * 2)
2) max_connections * 5
3) open_files_limit value specified at startup, 5000 if none

```

The server attempts to obtain the number of file descriptors using the maximum of those three values. If that many descriptors cannot be obtained, the server attempts to obtain as many as the system will permit.

- `optimizer_prune_level`

|                            |  |                                    |
|----------------------------|--|------------------------------------|
| <b>Command-Line Format</b> | <code>--optimizer_prune_level[=#]</code> |                                    |
| <b>System Variable</b>     | <b>Name</b>                              | <code>optimizer_prune_level</code> |
|                            | <b>Variable Scope</b>                    | Global, Session                    |

|                         |                         |         |
|-------------------------|-------------------------|---------|
|                         | <b>Dynamic Variable</b> | Yes     |
| <b>Permitted Values</b> | <b>Type</b>             | boolean |
|                         | <b>Default</b>          | 1       |

Controls the heuristics applied during query optimization to prune less-promising partial plans from the optimizer search space. A value of 0 disables heuristics so that the optimizer performs an exhaustive search. A value of 1 causes the optimizer to prune plans based on the number of rows retrieved by intermediate plans.

- `optimizer_search_depth`

|                            |   |                                     |
|----------------------------|---|-------------------------------------|
| <b>Command-Line Format</b> | <code>--optimizer_search_depth[=#]</code> |                                     |
| <b>System Variable</b>     | <b>Name</b>                               | <code>optimizer_search_depth</code> |
|                            | <b>Variable Scope</b>                     | Global, Session                     |
|                            | <b>Dynamic Variable</b>                   | Yes                                 |
| <b>Permitted Values</b>    | <b>Type</b>                               | integer                             |
|                            | <b>Default</b>                            | 62                                  |
|                            | <b>Min Value</b>                          | 0                                   |
|                            | <b>Max Value</b>                          | 62                                  |

The maximum depth of search performed by the query optimizer. Values larger than the number of relations in a query result in better query plans, but take longer to generate an execution plan for a query. Values smaller than the number of relations in a query return an execution plan quicker, but the resulting plan may be far from being optimal. If set to 0, the system automatically picks a reasonable value.

- `optimizer_switch`

|                                       |                                       |   |
|---------------------------------------|---------------------------------------|---|
| <b>Command-Line Format</b>            | <code>--optimizer_switch=value</code> |   |
| <b>System Variable</b>                | <b>Name</b>                           | <code>optimizer_switch</code>                   |
|                                       | <b>Variable Scope</b>                 | Global, Session                                 |
|                                       | <b>Dynamic Variable</b>               | Yes   |
| <b>Permitted Values (&lt;= 5.7.4)</b> | <b>Type</b>                           | set   |
|                                       | <b>Valid Values</b>                   | <code>batched_key_access={on off}</code>        |
|                                       |                                       | <code>block_nested_loop={on off}</code>         |
|                                       |                                       | <code>engine_condition_pushdown={on off}</code> |
|                                       |                                       | <code>firstmatch={on off}</code>                |
|                                       |                                       | <code>index_condition_pushdown={on off}</code>  |
|                                       |                                       | <code>index_merge={on off}</code>               |
|                                       |                                       | <code>index_merge_intersection={on off}</code>  |
|                                       |                                       | <code>index_merge_sort_union={on off}</code>    |
|                                       |                                       | <code>index_merge_union={on off}</code>         |

|                                       |                     | subquery_materialization_cost_based={on off} |
|                                       |                     | use_index_extensions={on off}                |

The `optimizer_switch` system variable enables control over optimizer behavior. The value of this variable is a set of flags, each of which has a value of `on` or `off` to indicate whether the corresponding optimizer behavior is enabled or disabled. This variable has global and session values and can be changed at runtime. The global default can be set at server startup.

To see the current set of optimizer flags, select the variable value:

```
mysql> SELECT @@optimizer_switch\G
***** 1. row *****
@@optimizer_switch: index_merge=on,index_merge_union=on,
                    index_merge_sort_union=on,
                    index_merge_intersection=on,
                    engine_condition_pushdown=on,
                    index_condition_pushdown=on,
                    mrr=on,mrr_cost_based=on,
                    block_nested_loop=on,batched_key_access=off,
                    materialization=on,semijoin=on,loosescan=on,
                    firstmatch=on,duplicateweedout=on,
                    subquery_materialization_cost_based=on,
                    use_index_extensions=on,
                    condition_fanout_filter=on,derived_merge=on
```

For more information about the syntax of this variable and the optimizer behaviors that it controls, see [Section 9.9.2, “Controlling Switchable Optimizations”](#).

- `optimizer_trace`

|                        |             |                              |
|------------------------|-------------|------------------------------|
| <b>System Variable</b> | <b>Name</b> | <code>optimizer_trace</code> |
|------------------------|-------------|------------------------------|

|                         |                         |                 |
|-------------------------|-------------------------|-----------------|
|                         | <b>Variable Scope</b>   | Global, Session |
|                         | <b>Dynamic Variable</b> | Yes             |
| <b>Permitted Values</b> | <b>Type</b>             | string          |

This variable controls optimizer tracing. For details, see [MySQL Internals: Tracing the Optimizer](#).

- `optimizer_trace_features`

|                         |                         |                                       |
|-------------------------|-------------------------|---------------------------------------|
| <b>System Variable</b>  | <b>Name</b>             | <code>optimizer_trace_features</code> |
|                         | <b>Variable Scope</b>   | Global, Session                       |
|                         | <b>Dynamic Variable</b> | Yes                                   |
| <b>Permitted Values</b> | <b>Type</b>             | string                                |

This variable enables or disables selected optimizer tracing features. For details, see [MySQL Internals: Tracing the Optimizer](#).

- `optimizer_trace_limit`

|                         |                         |                                    |
|-------------------------|-------------------------|------------------------------------|
| <b>System Variable</b>  | <b>Name</b>             | <code>optimizer_trace_limit</code> |
|                         | <b>Variable Scope</b>   | Global, Session                    |
|                         | <b>Dynamic Variable</b> | Yes                                |
| <b>Permitted Values</b> | <b>Type</b>             | integer                            |
|                         | <b>Default</b>          | <code>1</code>                     |

The maximum number of optimizer traces to display. For details, see [MySQL Internals: Tracing the Optimizer](#).

- `optimizer_trace_max_mem_size`

|                         |                         |   |
|-------------------------|-------------------------|---|
| <b>System Variable</b>  | <b>Name</b>             | <code>optimizer_trace_max_mem_size</code> |
|                         | <b>Variable Scope</b>   | Global, Session                           |
|                         | <b>Dynamic Variable</b> | Yes                                       |
| <b>Permitted Values</b> | <b>Type</b>             | integer                                   |
|                         | <b>Default</b>          | <code>16384</code>                        |

The maximum cumulative size of stored optimizer traces. For details, see [MySQL Internals: Tracing the Optimizer](#).

- `optimizer_trace_offset`

|                        |                         |                                     |
|------------------------|-------------------------|-------------------------------------|
| <b>System Variable</b> | <b>Name</b>             | <code>optimizer_trace_offset</code> |
|                        | <b>Variable Scope</b>   | Global, Session                     |
|                        | <b>Dynamic Variable</b> | Yes                                 |

|                         |                |         |
|-------------------------|----------------|---------|
| <b>Permitted Values</b> | <b>Type</b>    | integer |
|                         | <b>Default</b> | -1      |

The offset of optimizer traces to display. For details, see [MySQL Internals: Tracing the Optimizer](#).

- [performance\\_schema\\_XXX](#)

Performance Schema system variables are listed in [Section 24.13, “Performance Schema System Variables”](#). These variables may be used to configure Performance Schema operation.

- [parser\\_max\\_mem\\_size](#)

|  |                                      |                                     |
|--|--------------------------------------|-------------------------------------|
| <b>Introduced</b>                          | 5.7.12                               |                                     |
| <b>Command-Line Format</b>                 | <code>--parser_max_mem_size=N</code> |                                     |
| <b>System Variable</b>                     | <b>Name</b>                          | <a href="#">parser_max_mem_size</a> |
|  | <b>Variable Scope</b>                | Global, Session                     |
|  | <b>Dynamic Variable</b>              | Yes                                 |

|----------------------------|------------------------------------|----------------------------|
| <b>Command-Line Format</b> | <code>--plugin_dir=dir_name</code> |                            |
| <b>System Variable</b>     | <b>Name</b>                        | <a href="#">plugin_dir</a> |

|                         |                         |                                 |
|-------------------------|-------------------------|---------------------------------|
|                         | <b>Variable Scope</b>   | Global                          |
|                         | <b>Dynamic Variable</b> | No                              |
| <b>Permitted Values</b> | <b>Type</b>             | directory name                  |
|                         | <b>Default</b>          | <code>BASEDIR/lib/plugin</code> |

The path name of the plugin directory.

If the plugin directory is writable by the server, it may be possible for a user to write executable code to a file in the directory using `SELECT ... INTO DUMPFILE`. This can be prevented by making `plugin_dir` read only to the server or by setting `--secure-file-priv` to a directory where `SELECT` writes can be made safely.

- `port`

|                            |                         |                    |
|----------------------------|-------------------------|--------------------|
| <b>Command-Line Format</b> | <code>--port=#</code>   |                    |
| <b>System Variable</b>     | <b>Name</b>             | <code>port</code>  |
|                            | <b>Variable Scope</b>   | Global             |
|                            | <b>Dynamic Variable</b> | No                 |
| <b>Permitted Values</b>    | <b>Type</b>             | integer            |
|                            | <b>Default</b>          | <code>3306</code>  |
|                            | <b>Min Value</b>        | <code>0</code>     |
|                            | <b>Max Value</b>        | <code>65535</code> |

The number of the port on which the server listens for TCP/IP connections. This variable can be set with the `--port` option.

- `preload_buffer_size`

|                            |                                      |                                  |
|----------------------------|--------------------------------------|----------------------------------|
| <b>Command-Line Format</b> | <code>--preload_buffer_size=#</code> |                                  |
| <b>System Variable</b>     | <b>Name</b>                          | <code>preload_buffer_size</code> |
|                            | <b>Variable Scope</b>                | Global, Session                  |
|                            | <b>Dynamic Variable</b>              | Yes                              |
| <b>Permitted Values</b>    | <b>Type</b>                          | integer                          |
|                            | <b>Default</b>                       | <code>32768</code>               |
|                            | <b>Min Value</b>                     | <code>1024</code>                |
|                            | <b>Max Value</b>                     | <code>1073741824</code>          |

The size of the buffer that is allocated when preloading indexes.

- `profiling`

If set to 0 or [OFF](#) (the default), statement profiling is disabled. If set to 1 or [ON](#), statement profiling is enabled and the [SHOW PROFILE](#) and [SHOW PROFILES](#) statements provide access to profiling information. See [Section 14.7.5.31, “SHOW PROFILES Syntax”](#).

This variable is deprecated and will be removed in a future MySQL release.

- [profiling\\_history\\_size](#)

The number of statements for which to maintain profiling information if [profiling](#) is enabled. The default value is 15. The maximum value is 100. Setting the value to 0 effectively disables profiling. See [Section 14.7.5.31, “SHOW PROFILES Syntax”](#).

This variable is deprecated and will be removed in a future MySQL release.

- [protocol\\_version](#)

|                         |                         |                                  |
|-------------------------|-------------------------|----------------------------------|
| <b>System Variable</b>  | <b>Name</b>             | <a href="#">protocol_version</a> |
|                         | <b>Variable Scope</b>   | Global                           |
|                         | <b>Dynamic Variable</b> | No                               |
| <b>Permitted Values</b> | <b>Type</b>             | integer                          |

The version of the client/server protocol used by the MySQL server.

- [proxy\\_user](#)

|                         |                         |                            |
|-------------------------|-------------------------|----------------------------|
| <b>System Variable</b>  | <b>Name</b>             | <a href="#">proxy_user</a> |
|                         | <b>Variable Scope</b>   | Session                    |
|                         | <b>Dynamic Variable</b> | No                         |
| <b>Permitted Values</b> | <b>Type</b>             | string                     |

If the current client is a proxy for another user, this variable is the proxy user account name. Otherwise, this variable is [NULL](#). See [Section 7.3.9, “Proxy Users”](#).

- [pseudo\\_slave\\_mode](#)

|                         |                         |                                   |
|-------------------------|-------------------------|-----------------------------------|
| <b>System Variable</b>  | <b>Name</b>             | <a href="#">pseudo_slave_mode</a> |
|                         | <b>Variable Scope</b>   | Session                           |
|                         | <b>Dynamic Variable</b> | Yes                               |
| <b>Permitted Values</b> | <b>Type</b>             | integer                           |

This variable is for internal server use.

- [pseudo\\_thread\\_id](#)

|                        |                         |                                  |
|------------------------|-------------------------|----------------------------------|
| <b>System Variable</b> | <b>Name</b>             | <a href="#">pseudo_thread_id</a> |
|                        | <b>Variable Scope</b>   | Session                          |
|                        | <b>Dynamic Variable</b> | Yes                              |

|                         |             |         |
|-------------------------|-------------|---------|
| <b>Permitted Values</b> | <b>Type</b> | integer |
|-------------------------|-------------|---------|

This variable is for internal server use.

- `query_alloc_block_size`

|  |   |                                     |
|--|---|-------------------------------------|
| <b>Command-Line Format</b>                           | <code>--query_alloc_block_size=#</code> |                                     |
| <b>System Variable</b>                               | <b>Name</b>                             | <code>query_alloc_block_size</code> |
|  | <b>Variable Scope</b>                   | Global, Session                     |
|  | <b>Dynamic Variable</b>                 | Yes                                 |
| <b>Permitted Values</b> (>= 5.7.9)                   | <b>Type</b>                             | integer                             |
|  | <b>Default</b>                          | 8192                                |
|  | <b>Min Value</b>                        | 1024                                |
|  | <b>Max Value</b>                        | 4294967295                          |
|  | <b>Block Size</b>                       | 1024                                |
| <b>Permitted Values</b> (32-bit platforms, <= 5.7.8) | <b>Type</b>                             | integer                             |
|  | <b>Default</b>                          | 8192                                |
|  | <b>Min Value</b>                        | 1024                                |
|  | <b>Max Value</b>                        | 4294967295                          |
|  | <b>Block Size</b>                       | 1024                                |
| <b>Permitted Values</b> (64-bit platforms, <= 5.7.8) | <b>Type</b>                             | integer                             |
|  | <b>Default</b>                          | 8192                                |
|  | <b>Min Value</b>                        | 1024                                |
|  | <b>Max Value</b>                        | 18446744073709551615                |
|  | <b>Block Size</b>                       | 1024                                |

The allocation size of memory blocks that are allocated for objects created during statement parsing and execution. If you have problems with memory fragmentation, it might help to increase this parameter.

- `query_cache_limit`

|                            |                                    |                                |
|----------------------------|------------------------------------|--------------------------------|
| <b>Command-Line Format</b> | <code>--query_cache_limit=#</code> |                                |
| <b>System Variable</b>     | <b>Name</b>                        | <code>query_cache_limit</code> |
|                            | <b>Variable Scope</b>              | Global                         |
|                            | <b>Dynamic Variable</b>            | Yes                            |

|  |                  |                      |
|--|------------------|----------------------|
| <b>Permitted Values</b> (32-bit platforms) | <b>Type</b>      | integer              |
|  | <b>Default</b>   | 1048576              |
|  | <b>Min Value</b> | 0                    |
|  | <b>Max Value</b> | 4294967295           |
| <b>Permitted Values</b> (64-bit platforms) | <b>Type</b>      | integer              |
|  | <b>Default</b>   | 1048576              |
|  | <b>Min Value</b> | 0                    |
|  | <b>Max Value</b> | 18446744073709551615 |

Do not cache results that are larger than this number of bytes. The default value is 1MB.

- [query\\_cache\\_min\\_res\\_unit](#)

|  |   |  |
|--|---|--|
| <b>Command-Line Format</b>                 | <code>--query_cache_min_res_unit=#</code> |  |
| <b>System Variable</b>                     | <b>Name</b>                               | <a href="#">query_cache_min_res_unit</a> |
|  | <b>Variable Scope</b>                     | Global                                   |
|  | <b>Dynamic Variable</b>                   | Yes                                      |
| <b>Permitted Values</b> (32-bit platforms) | <b>Type</b>                               | integer                                  |
|  | <b>Default</b>                            | 4096                                     |
|  | <b>Min Value</b>                          | 512                                      |
|  | <b>Max Value</b>                          | 4294967295                               |
| <b>Permitted Values</b> (64-bit platforms) | <b>Type</b>                               | integer                                  |
|  | <b>Default</b>                            | 4096                                     |
|  | <b>Min Value</b>                          | 512                                      |
|  | <b>Max Value</b>                          | 18446744073709551615                     |

The minimum size (in bytes) for blocks allocated by the query cache. The default value is 4096 (4KB). Tuning information for this variable is given in [Section 9.10.3.3, “Query Cache Configuration”](#).

- [query\\_cache\\_size](#)

|  |                                   |                                  |
|--|-----------------------------------|----------------------------------|
| <b>Command-Line Format</b>                 | <code>--query_cache_size=#</code> |                                  |
| <b>System Variable</b>                     | <b>Name</b>                       | <a href="#">query_cache_size</a> |
|  | <b>Variable Scope</b>             | Global                           |
|  | <b>Dynamic Variable</b>           | Yes                              |
| <b>Permitted Values</b> (32-bit platforms) | <b>Type</b>                       | integer                          |
|  | <b>Default</b>                    | 1048576                          |

|  |                  |                      |
|--|------------------|----------------------|
| <b>Permitted Values</b> (64-bit platforms) | <b>Min Value</b> | 0                    |
|  | <b>Max Value</b> | 4294967295           |
|  | <b>Type</b>      | integer              |
|  | <b>Default</b>   | 1048576              |
|  | <b>Min Value</b> | 0                    |
|  | <b>Max Value</b> | 18446744073709551615 |

The amount of memory allocated for caching query results. By default, the query cache is disabled. This is achieved using a default value of 1M, with a default for `query_cache_type` of 0. (To reduce overhead significantly if you set the size to 0, you should also start the server with `query_cache_type=0`.)

The permissible values are multiples of 1024; other values are rounded down to the nearest multiple. `query_cache_size` bytes of memory are allocated even if `query_cache_type` is set to 0. See [Section 9.10.3.3, “Query Cache Configuration”](#), for more information.

The query cache needs a minimum size of about 40KB to allocate its structures. (The exact size depends on system architecture.) If you set the value of `query_cache_size` too small, a warning will occur, as described in [Section 9.10.3.3, “Query Cache Configuration”](#).

- `query_cache_type`

|                            |                                   |                               |
|----------------------------|-----------------------------------|-------------------------------|
| <b>Command-Line Format</b> | <code>--query_cache_type=#</code> |                               |
| <b>System Variable</b>     | <b>Name</b>                       | <code>query_cache_type</code> |
|                            | <b>Variable Scope</b>             | Global, Session               |
|                            | <b>Dynamic Variable</b>           | Yes                           |
| <b>Permitted Values</b>    | <b>Type</b>                       | enumeration                   |
|                            | <b>Default</b>                    | 0                             |
|                            | <b>Valid Values</b>               | 0                             |
|                            |                                   | 1                             |
|                            |                                   | 2                             |

Set the query cache type. Setting the `GLOBAL` value sets the type for all clients that connect thereafter. Individual clients can set the `SESSION` value to affect their own use of the query cache. Possible values are shown in the following table.

| Option                   | Description   |
|--------------------------|---|
| 0 or <code>OFF</code>    | Do not cache results in or retrieve results from the query cache. Note that this does not deallocate the query cache buffer. To do that, you should set <code>query_cache_size</code> to 0. |
| 1 or <code>ON</code>     | Cache all cacheable query results except for those that begin with <code>SELECT SQL_NO_CACHE</code> .   |
| 2 or <code>DEMAND</code> | Cache results only for cacheable queries that begin with <code>SELECT SQL_CACHE</code> .  |

This variable defaults to `OFF`.

If the server is started with `query_cache_type` set to 0, it does not acquire the query cache mutex at all, which means that the query cache cannot be enabled at runtime and there is reduced overhead in query execution.

- `query_cache_wlock_invalidate`

|                            |   |   |
|----------------------------|---|---|
| <b>Command-Line Format</b> | <code>--query_cache_wlock_invalidate</code> |   |
| <b>System Variable</b>     | <b>Name</b>                                 | <code>query_cache_wlock_invalidate</code> |
|                            | <b>Variable Scope</b>                       | Global, Session                           |
|                            | <b>Dynamic Variable</b>                     | Yes                                       |
| <b>Permitted Values</b>    | <b>Type</b>                                 | boolean                                   |
|                            | <b>Default</b>                              | <code>FALSE</code>                        |

Normally, when one client acquires a `WRITE` lock on a `MyISAM` table, other clients are not blocked from issuing statements that read from the table if the query results are present in the query cache. Setting this variable to 1 causes acquisition of a `WRITE` lock for a table to invalidate any queries in the query cache that refer to the table. This forces other clients that attempt to access the table to wait while the lock is in effect.

- `query_prealloc_size`

|  |                                      |                                   |
|--|--------------------------------------|-----------------------------------|
| <b>Command-Line Format</b>                 | <code>--query_prealloc_size=#</code> |                                   |
| <b>System Variable</b>                     | <b>Name</b>                          | <code>query_prealloc_size</code>  |
|  | <b>Variable Scope</b>                | Global, Session                   |
|  | <b>Dynamic Variable</b>              | Yes                               |
| <b>Permitted Values (32-bit platforms)</b> | <b>Type</b>                          | integer                           |
|  | <b>Default</b>                       | <code>8192</code>                 |
|  | <b>Min Value</b>                     | <code>8192</code>                 |
|  | <b>Max Value</b>                     | <code>4294967295</code>           |
|  | <b>Block Size</b>                    | <code>1024</code>                 |
| <b>Permitted Values (64-bit platforms)</b> | <b>Type</b>                          | integer                           |
|  | <b>Default</b>                       | <code>8192</code>                 |
|  | <b>Min Value</b>                     | <code>8192</code>                 |
|  | <b>Max Value</b>                     | <code>18446744073709551615</code> |
|  | <b>Block Size</b>                    | <code>1024</code>                 |

The size of the persistent buffer used for statement parsing and execution. This buffer is not freed between statements. If you are running complex queries, a larger `query_prealloc_size` value might be helpful in improving performance, because it can reduce the need for the server to perform memory allocation during query execution operations.

- `rand_seed1`

The `rand_seed1` and `rand_seed2` variables exist as session variables only, and can be set but not read. The variables—but not their values—are shown in the output of `SHOW VARIABLES`.

The purpose of these variables is to support replication of the `RAND()` function. For statements that invoke `RAND()`, the master passes two values to the slave, where they are used to seed the random number generator. The slave uses these values to set the session variables `rand_seed1` and `rand_seed2` so that `RAND()` on the slave generates the same value as on the master.

- `rand_seed2`

See the description for `rand_seed1`.

- `range_alloc_block_size`

|   |   |                                     |
|---|---|-------------------------------------|
| <b>Command-Line Format</b>                                | <code>--range_alloc_block_size=#</code> |                                     |
| <b>System Variable</b>                                    | <b>Name</b>                             | <code>range_alloc_block_size</code> |
|   | <b>Variable Scope</b>                   | Global, Session                     |
|   | <b>Dynamic Variable</b>                 | Yes                                 |
| <b>Permitted Values</b> ( $\geq 5.7.9$ )                  | <b>Type</b>                             | integer                             |
|   | <b>Default</b>                          | 4096                                |
|   | <b>Min Value</b>                        | 4096                                |
|   | <b>Max Value</b>                        | 4294967295                          |
|   | <b>Block Size</b>                       | 1024                                |
| <b>Permitted Values</b> (32-bit platforms, $\leq 5.7.8$ ) | <b>Type</b>                             | integer                             |
|   | <b>Default</b>                          | 4096                                |
|   | <b>Min Value</b>                        | 4096                                |
|   | <b>Max Value</b>                        | 4294967295                          |
|   | <b>Block Size</b>                       | 1024                                |
| <b>Permitted Values</b> (64-bit platforms, $\leq 5.7.8$ ) | <b>Type</b>                             | integer                             |
|   | <b>Default</b>                          | 4096                                |
|   | <b>Min Value</b>                        | 4096                                |
|   | <b>Max Value</b>                        | 18446744073709551615                |
|   | <b>Block Size</b>                       | 1024                                |
| <b>Permitted Values</b> (64-bit platforms, $\geq 5.7.8$ ) | <b>Type</b>                             | integer                             |
|   | <b>Default</b>                          | 4096                                |
|   | <b>Min Value</b>                        | 4096                                |

|  |                   |                      |
|--|-------------------|----------------------|
|  | <b>Max Value</b>  | 18446744073709547520 |
|  | <b>Block Size</b> | 1024                 |

The size of blocks that are allocated when doing range optimization.

- `range_optimizer_max_mem_size`

|                                     |   |   |
|-------------------------------------|---|---|
| <b>Introduced</b>                   | 5.7.9   |   |
| <b>Command-Line Format</b>          | <code>--range_optimizer_max_mem_size=N</code> |   |
| <b>System Variable</b>              | <b>Name</b>                                   | <code>range_optimizer_max_mem_size</code> |
|                                     | <b>Variable Scope</b>                         | Global, Session                           |
|                                     | <b>Dynamic Variable</b>                       | Yes                                       |
| <b>Permitted Values</b> (<= 5.7.11) | <b>Type</b>                                   | integer                                   |
|                                     | <b>Default</b>                                | 1536000                                   |
| <b>Permitted Values</b> (>= 5.7.12) | <b>Type</b>                                   | integer                                   |
|                                     | <b>Default</b>                                | 8388608                                   |

The limit on memory consumption for the range optimizer. A value of 0 means “no limit.” If an execution plan considered by the optimizer uses the range access method but the optimizer estimates that the amount of memory needed for this method would exceed the limit, it abandons the plan and considers other plans. For more information, see [Limiting Memory Use for Range Optimization](#).

- `rbr_exec_mode`

|                         |                         |                            |
|-------------------------|-------------------------|----------------------------|
| <b>Introduced</b>       | 5.7.1                   |                            |
| <b>System Variable</b>  | <b>Name</b>             | <code>rbr_exec_mode</code> |
|                         | <b>Variable Scope</b>   | Session                    |
|                         | <b>Dynamic Variable</b> | Yes                        |
| <b>Permitted Values</b> | <b>Type</b>             | enumeration                |
|                         | <b>Default</b>          | STRICT                     |
|                         | <b>Valid Values</b>     | IDEMPOTENT                 |
|                         |                         | STRICT                     |

This variable switches the server between IDEMPOTENT mode and STRICT mode. IDEMPOTENT mode causes suppression of duplicate-key and no-key-found errors. This mode is useful when replaying a row-based binary log on a server that causes conflicts with existing data. `mysqlbinlog` uses this mode when you set the `--idempotent` option by writing the following to the output:

```
SET SESSION RBR_EXEC_MODE=IDEMPOTENT;
```

- `read_buffer_size`

|                            |                                   |                               |
|----------------------------|-----------------------------------|-------------------------------|
| <b>Command-Line Format</b> | <code>--read_buffer_size=#</code> |                               |
| <b>System Variable</b>     | <b>Name</b>                       | <code>read_buffer_size</code> |

|                         |                         |                 |
|-------------------------|-------------------------|-----------------|
| <b>Permitted Values</b> | <b>Variable Scope</b>   | Global, Session |
|                         | <b>Dynamic Variable</b> | Yes             |
|                         | <b>Type</b>             | integer         |
|                         | <b>Default</b>          | 131072          |
|                         | <b>Min Value</b>        | 8200            |
|                         | <b>Max Value</b>        | 2147479552      |

Each thread that does a sequential scan for a [MyISAM](#) table allocates a buffer of this size (in bytes) for each table it scans. If you do many sequential scans, you might want to increase this value, which defaults to 131072. The value of this variable should be a multiple of 4KB. If it is set to a value that is not a multiple of 4KB, its value will be rounded down to the nearest multiple of 4KB.

This option is also used in the following context for all storage engines:

- For caching the indexes in a temporary file (not a temporary table), when sorting rows for [ORDER BY](#).
- For bulk insert into partitions.
- For caching results of nested queries.

and in one other storage engine-specific way: to determine the memory block size for [MEMORY](#) tables.

The maximum permissible setting for [read\\_buffer\\_size](#) is 2GB.

For more information about memory use during different operations, see [Section 9.12.4.1, “How MySQL Uses Memory”](#).

- [read\\_only](#)

|                            |                             |                           |
|----------------------------|-----------------------------|---------------------------|
| <b>Command-Line Format</b> | <a href="#">--read_only</a> |                           |
| <b>System Variable</b>     | <b>Name</b>                 | <a href="#">read_only</a> |
|                            | <b>Variable Scope</b>       | Global                    |
|                            | <b>Dynamic Variable</b>     | Yes                       |
| <b>Permitted Values</b>    | <b>Type</b>                 | boolean                   |
|                            | <b>Default</b>              | <a href="#">OFF</a>       |

When the [read\\_only](#) system variable is enabled, the server permits no client updates except from users who have the [SUPER](#) privilege. This variable is disabled by default.

As of MySQL 5.7.8, the server also supports a [super\\_read\\_only](#) system variable (disabled by default), which has these effects:

- If [super\\_read\\_only](#) is enabled, the server prohibits client updates, even from users who have the [SUPER](#) privilege.
- Setting [super\\_read\\_only](#) to [ON](#) implicitly forces [read\\_only](#) to [ON](#).
- Setting [read\\_only](#) to [OFF](#) implicitly forces [super\\_read\\_only](#) to [OFF](#).

Even with `read_only` enabled, the server permits these operations:

- Updates performed by slave threads, if the server is a replication slave. In replication setups, it can be useful to enable `read_only` on slave servers to ensure that slaves accept updates only from the master server and not from clients.
- Use of `ANALYZE TABLE` or `OPTIMIZE TABLE` statements. The purpose of read-only mode is to prevent changes to table structure or contents. Analysis and optimization do not qualify as such changes. This means, for example, that consistency checks on read-only replication slaves can be performed with `mysqlcheck --all-databases --analyze`.
- Operations on `TEMPORARY` tables.
- Inserts into the log tables (`mysql.general_log` and `mysql.slow_log`); see [Section 6.4.1, “Selecting General Query and Slow Query Log Output Destinations”](#).
- As of MySQL 5.7.16, updates to Performance Schema tables, such as `UPDATE` or `TRUNCATE TABLE` operations.

Changes to `read_only` on a master server are not replicated to slave servers. The value can be set on a slave server independent of the setting on the master.

The following conditions apply to attempts to enable `read_only` (including implicit attempts resulting from enabling `super_read_only`):

- The attempt fails and an error occurs if you have any explicit locks (acquired with `LOCK TABLES`) or have a pending transaction.
- The attempt blocks while other clients hold explicit table locks or have pending transactions, until the locks are released and the transactions end. While the attempt to enable `read_only` is pending, requests by other clients for table locks or to begin transactions also block until `read_only` has been set.
- The attempt blocks if there are active transactions that hold metadata locks, until those transactions end.
- `read_only` can be enabled while you hold a global read lock (acquired with `FLUSH TABLES WITH READ LOCK`) because that does not involve table locks.
- `read_rnd_buffer_size`

|                            |                                       |                                   |
|----------------------------|---------------------------------------|-----------------------------------|
| <b>Command-Line Format</b> | <code>--read_rnd_buffer_size=#</code> |                                   |
| <b>System Variable</b>     | <b>Name</b>                           | <code>read_rnd_buffer_size</code> |
|                            | <b>Variable Scope</b>                 | Global, Session                   |
|                            | <b>Dynamic Variable</b>               | Yes                               |
| <b>Permitted Values</b>    | <b>Type</b>                           | integer                           |
|                            | <b>Default</b>                        | 262144                            |
|                            | <b>Min Value</b>                      | 1                                 |
|                            | <b>Max Value</b>                      | 2147483647                        |

This variable is used for reads from `MyISAM` tables, and, for any storage engine, for Multi-Range Read optimization.

When reading rows from a [MyISAM](#) table in sorted order following a key-sorting operation, the rows are read through this buffer to avoid disk seeks. See [Section 9.2.1.15, “ORDER BY Optimization”](#). Setting the variable to a large value can improve [ORDER BY](#) performance by a lot. However, this is a buffer allocated for each client, so you should not set the global variable to a large value. Instead, change the session variable only from within those clients that need to run large queries.

The maximum permissible setting for `read_rnd_buffer_size` is 2GB.

For more information about memory use during different operations, see [Section 9.12.4.1, “How MySQL Uses Memory”](#). For information about Multi-Range Read optimization, see [Section 9.2.1.13, “Multi-Range Read Optimization”](#).

- `relay_log_purge`

|                            |                                |                              |
|----------------------------|--------------------------------|------------------------------|
| <b>Command-Line Format</b> | <code>--relay_log_purge</code> |                              |
| <b>System Variable</b>     | <b>Name</b>                    | <code>relay_log_purge</code> |
|                            | <b>Variable Scope</b>          | Global                       |
|                            | <b>Dynamic Variable</b>        | Yes                          |
| <b>Permitted Values</b>    | <b>Type</b>                    | boolean                      |
|                            | <b>Default</b>                 | <code>TRUE</code>            |

Disables or enables automatic purging of relay log files as soon as they are not needed any more. The default value is 1 (`ON`).

- `relay_log_space_limit`

|  |  |                                    |
|--|--|------------------------------------|
| <b>Command-Line Format</b>                 | <code>--relay_log_space_limit=#</code> |                                    |
| <b>System Variable</b>                     | <b>Name</b>                            | <code>relay_log_space_limit</code> |
|  | <b>Variable Scope</b>                  | Global                             |
|  | <b>Dynamic Variable</b>                | No                                 |
| <b>Permitted Values</b> (32-bit platforms) | <b>Type</b>                            | integer                            |
|  | <b>Default</b>                         | 0                                  |
|  | <b>Min Value</b>                       | 0                                  |
|  | <b>Max Value</b>                       | 4294967295                         |
| <b>Permitted Values</b> (64-bit platforms) | <b>Type</b>                            | integer                            |
|  | <b>Default</b>                         | 0                                  |
|  | <b>Min Value</b>                       | 0                                  |
|  | <b>Max Value</b>                       | 18446744073709551615               |

The maximum amount of space to use for all relay logs.

- `report_host`

|                            |                                      |
|----------------------------|--------------------------------------|
| <b>Command-Line Format</b> | <code>--report-host=host_name</code> |
|----------------------------|--------------------------------------|

|                         |                         |                          |
|-------------------------|-------------------------|--------------------------|
| <b>System Variable</b>  | <b>Name</b>             | <code>report_host</code> |
|                         | <b>Variable Scope</b>   | Global                   |
|                         | <b>Dynamic Variable</b> | No                       |
| <b>Permitted Values</b> | <b>Type</b>             | string                   |

The value of the `--report-host` option.

- `report_password`

|                            |                                     |                              |
|----------------------------|-------------------------------------|------------------------------|
| <b>Command-Line Format</b> | <code>--report-password=name</code> |                              |
| <b>System Variable</b>     | <b>Name</b>                         | <code>report_password</code> |
|                            | <b>Variable Scope</b>               | Global                       |
|                            | <b>Dynamic Variable</b>             | No                           |
| <b>Permitted Values</b>    | <b>Type</b>                         | string                       |

The value of the `--report-password` option. Not the same as the password used for the MySQL replication user account.

- `report_port`

|                            |                              |                           |
|----------------------------|------------------------------|---------------------------|
| <b>Command-Line Format</b> | <code>--report-port=#</code> |                           |
| <b>System Variable</b>     | <b>Name</b>                  | <code>report_port</code>  |
|                            | <b>Variable Scope</b>        | Global                    |
|                            | <b>Dynamic Variable</b>      | No                        |
| <b>Permitted Values</b>    | <b>Type</b>                  | integer                   |
|                            | <b>Default</b>               | <code>[slave_port]</code> |
|                            | <b>Min Value</b>             | 0                         |
|                            | <b>Max Value</b>             | 65535                     |

The value of the `--report-port` option.

- `report_user`

|                            |                                 |                          |
|----------------------------|---------------------------------|--------------------------|
| <b>Command-Line Format</b> | <code>--report-user=name</code> |                          |
| <b>System Variable</b>     | <b>Name</b>                     | <code>report_user</code> |
|                            | <b>Variable Scope</b>           | Global                   |
|                            | <b>Dynamic Variable</b>         | No                       |
| <b>Permitted Values</b>    | <b>Type</b>                     | string                   |

The value of the `--report-user` option. Not the same as the name for the MySQL replication user account.

- `require_secure_transport`

|                            |  |                                       |
|----------------------------|--|---------------------------------------|
| <b>Introduced</b>          | 5.7.8  |                                       |
| <b>Command-Line Format</b> | <code>--require_secure_transport[={OFF ON}]</code> |                                       |
| <b>System Variable</b>     | <b>Name</b>  | <code>require_secure_transport</code> |
|                            | <b>Variable Scope</b>                              | Global                                |
|                            | <b>Dynamic Variable</b>                            | Yes                                   |
| <b>Permitted Values</b>    | <b>Type</b>  | boolean                               |
|                            | <b>Default</b>                                     | <code>OFF</code>                      |

Whether client connections to the server are required to use some form of secure transport. When this variable is enabled, the server permits only TCP/IP connections that use SSL, or connections that use a socket file (on Unix) or shared memory (on Windows). The server rejects nonsecure connection attempts, which fail with an `ER_SECURE_TRANSPORT_REQUIRED` error.

This capability supplements per-account SSL requirements, which take precedence. For example, if an account is defined with `REQUIRE SSL`, enabling `require_secure_transport` does not make it possible to use the account to connect using a Unix socket file.

It is possible for a server to have no secure transports available. For example, a server on Windows supports no secure transports if started without specifying any SSL certificate or key files and with the `shared_memory` system variable disabled. Under these conditions, attempts to enable `require_secure_transport` at startup cause the server to write a message to the error log and exit. Attempts to enable the variable at runtime fail with an `ER_NO_SECURE_TRANSPORTS_CONFIGURED` error.

- `rpl_semi_sync_master_enabled`

|                         |                         |   |
|-------------------------|-------------------------|---|
| <b>System Variable</b>  | <b>Name</b>             | <code>rpl_semi_sync_master_enabled</code> |
|                         | <b>Variable Scope</b>   | Global                                    |
|                         | <b>Dynamic Variable</b> | Yes                                       |
| <b>Permitted Values</b> | <b>Type</b>             | boolean                                   |
|                         | <b>Default</b>          | <code>OFF</code>                          |

Controls whether semisynchronous replication is enabled on the master. To enable or disable the plugin, set this variable to `ON` or `OFF` (or 1 or 0), respectively. The default is `OFF`.

This variable is available only if the master-side semisynchronous replication plugin is installed.

- `rpl_semi_sync_master_timeout`

|                         |                         |   |
|-------------------------|-------------------------|---|
| <b>System Variable</b>  | <b>Name</b>             | <code>rpl_semi_sync_master_timeout</code> |
|                         | <b>Variable Scope</b>   | Global                                    |
|                         | <b>Dynamic Variable</b> | Yes                                       |
| <b>Permitted Values</b> | <b>Type</b>             | integer                                   |
|                         | <b>Default</b>          | <code>10000</code>                        |

A value in milliseconds that controls how long the master waits on a commit for acknowledgment from a slave before timing out and reverting to asynchronous replication. The default value is 10000 (10 seconds).

This variable is available only if the master-side semisynchronous replication plugin is installed.

- `rpl_semi_sync_master_trace_level`

|                         |                         |   |
|-------------------------|-------------------------|---|
| <b>System Variable</b>  | <b>Name</b>             | <code>rpl_semi_sync_master_trace_level</code> |
|                         | <b>Variable Scope</b>   | Global  |
|                         | <b>Dynamic Variable</b> | Yes   |
| <b>Permitted Values</b> | <b>Type</b>             | integer                                       |
|                         | <b>Default</b>          | <code>32</code>                               |

The semisynchronous replication debug trace level on the master. Four levels are defined:

- 1 = general level (for example, time function failures)
- 16 = detail level (more verbose information)
- 32 = net wait level (more information about network waits)
- 64 = function level (information about function entry and exit)

This variable is available only if the master-side semisynchronous replication plugin is installed.

- `rpl_semi_sync_master_wait_for_slave_count`

|                         |                         |  |
|-------------------------|-------------------------|--|
| <b>Introduced</b>       | 5.7.3                   |  |
| <b>System Variable</b>  | <b>Name</b>             | <code>rpl_semi_sync_master_wait_for_slave_count</code> |
|                         | <b>Variable Scope</b>   | Global   |
|                         | <b>Dynamic Variable</b> | Yes  |
| <b>Permitted Values</b> | <b>Type</b>             | integer  |
|                         | <b>Default</b>          | <code>1</code>   |
|                         | <b>Min Value</b>        | <code>1</code>   |
|                         | <b>Max Value</b>        | <code>65535</code>                                     |

The number of slave acknowledgments the master must receive per transaction before proceeding. By default `rpl_semi_sync_master_wait_for_slave_count` is `1`, meaning that semisynchronous replication proceeds after receiving a single slave acknowledgment. Performance is best for small values of this variable.

For example, if `rpl_semi_sync_master_wait_for_slave_count` is `2`, then 2 slaves must acknowledge receipt of the transaction before the timeout period configured by `rpl_semi_sync_master_timeout` for semisynchronous replication to proceed. If less slaves acknowledge receipt of the transaction during the timeout period, the master reverts to normal replication.

**Note**

This behavior also depends on `rpl_semi_sync_master_wait_no_slave`

This variable is available only if the master-side semisynchronous replication plugin is installed.

- `rpl_semi_sync_master_wait_no_slave`

|                         |                         |   |
|-------------------------|-------------------------|---|
| <b>System Variable</b>  | <b>Name</b>             | <code>rpl_semi_sync_master_wait_no_slave</code> |
|                         | <b>Variable Scope</b>   | Global  |
|                         | <b>Dynamic Variable</b> | Yes   |
| <b>Permitted Values</b> | <b>Type</b>             | boolean   |
|                         | <b>Default</b>          | ON  |

Controls whether the master waits for the timeout period configured by `rpl_semi_sync_master_timeout` to expire, even if the slave count drops to less than the number of slaves configured by `rpl_semi_sync_master_wait_for_slave_count` during the timeout period.

When the value of `rpl_semi_sync_master_wait_no_slave` is `ON` (the default), it is permissible for the slave count to drop to less than `rpl_semi_sync_master_wait_for_slave_count` during the timeout period. As long as enough slaves acknowledge the transaction before the timeout period expires, semisynchronous replication continues.

When the value of `rpl_semi_sync_master_wait_no_slave` is `OFF`, if the slave count drops to less than the number configured in `rpl_semi_sync_master_wait_for_slave_count` at any time during the timeout period configured by `rpl_semi_sync_master_timeout`, the master reverts to normal replication.

This variable is available only if the master-side semisynchronous replication plugin is installed.

- `rpl_semi_sync_master_wait_point`

|                         |                         |  |
|-------------------------|-------------------------|--|
| <b>Introduced</b>       | 5.7.2                   |  |
| <b>System Variable</b>  | <b>Name</b>             | <code>rpl_semi_sync_master_wait_point</code> |
|                         | <b>Variable Scope</b>   | Global                                       |
|                         | <b>Dynamic Variable</b> | Yes  |
| <b>Permitted Values</b> | <b>Type</b>             | enumeration                                  |
|                         | <b>Default</b>          | <code>AFTER_SYNC</code>                      |
|                         | <b>Valid Values</b>     | <code>AFTER_SYNC</code>                      |
|                         |                         | <code>AFTER_COMMIT</code>                    |

This variable controls the point at which a semisynchronous replication master waits for slave acknowledgment of transaction receipt before returning a status to the client that committed the transaction. These values are permitted:

- `AFTER_SYNC` (the default): The master writes each transaction to its binary log and the slave, and syncs the binary log to disk. The master waits for slave acknowledgment of transaction receipt after the sync. Upon receiving acknowledgment, the master commits the transaction to the storage engine and returns a result to the client, which then can proceed.

- [AFTER\\_COMMIT](#): The master writes each transaction to its binary log and the slave, syncs the binary log, and commits the transaction to the storage engine. The master waits for slave acknowledgment of transaction receipt after the commit. Upon receiving acknowledgment, the master returns a result to the client, which then can proceed.

The replication characteristics of these settings differ as follows:

- With [AFTER\\_SYNC](#), all clients see the committed transaction at the same time: After it has been acknowledged by the slave and committed to the storage engine on the master. Thus, all clients see the same data on the master.

In the event of master failure, all transactions committed on the master have been replicated to the slave (saved to its relay log). A crash of the master and failover to the slave is lossless because the slave is up to date.

- With [AFTER\\_COMMIT](#), the client issuing the transaction gets a return status only after the server commits to the storage engine and receives slave acknowledgment. After the commit and before slave acknowledgment, other clients can see the committed transaction before the committing client.

If something goes wrong such that the slave does not process the transaction, then in the event of a master crash and failover to the slave, it is possible that such clients will see a loss of data relative to what they saw on the master.

This variable is available only if the master-side semisynchronous replication plugin is installed.

[rpl\\_semi\\_sync\\_master\\_wait\\_point](#) was added in MySQL 5.7.2. For older versions, semisynchronous master behavior is equivalent to a setting of [AFTER\\_COMMIT](#).

This change introduces a version compatibility constraint because it increments the semisynchronous interface version: Servers for MySQL 5.7.2 and up do not work with semisynchronous replication plugins from older versions, nor do servers from older versions work with semisynchronous replication plugins for MySQL 5.7.2 and up.

- [rpl\\_semi\\_sync\\_slave\\_enabled](#)

|                         |                         |   |
|-------------------------|-------------------------|---|
| <b>System Variable</b>  | <b>Name</b>             | <a href="#">rpl_semi_sync_slave_enabled</a> |
|                         | <b>Variable Scope</b>   | Global                                      |
|                         | <b>Dynamic Variable</b> | Yes   |
| <b>Permitted Values</b> | <b>Type</b>             | boolean                                     |
|                         | <b>Default</b>          | <a href="#">OFF</a>                         |

Controls whether semisynchronous replication is enabled on the slave. To enable or disable the plugin, set this variable to [ON](#) or [OFF](#) (or 1 or 0), respectively. The default is [OFF](#).

This variable is available only if the slave-side semisynchronous replication plugin is installed.

- [rpl\\_semi\\_sync\\_slave\\_trace\\_level](#)

|                        |                         |   |
|------------------------|-------------------------|---|

|                                       | <b>Default</b>             | ON                          |
|                                       | <b>Valid Values</b>        | OFF                         |
|                                       |                            | ON                          |
| <b>Permitted Values (&gt;= 5.7.5)</b> | <b>Type</b>                | boolean                     |
|                                       | <b>Default</b>             | ON                          |
|                                       | <b>Valid Values</b>        | ON                          |

If this variable is enabled, the server blocks connections by clients that attempt to use accounts that have passwords stored in the old (pre-4.1) format.

Enable this variable to prevent all use of passwords employing the old format (and hence insecure communication over the network).

As of MySQL 5.7.5, this variable is deprecated and will be removed in a future MySQL release. It is always enabled and attempting to disable it produces an error. Before MySQL 5.7.5, this variable is enabled by default but can be disabled.

Server startup fails with an error if this variable is enabled and the privilege tables are in pre-4.1 format. See [Section B.5.2.4, “Client does not support authentication protocol”](#).

#### Note

Passwords that use the pre-4.1 hashing method are less secure than passwords that use the native password hashing method and should be avoided. Pre-4.1 passwords are deprecated and support for them is removed in MySQL 5.7.5. For account upgrade instructions, see [Section 7.5.1.3, “Migrating Away from Pre-4.1 Password Hashing and the mysql\\_old\\_password Plugin”](#).

- [secure\\_file\\_priv](#)

|                            |  |                                  |
|----------------------------|--|----------------------------------|
| <b>Command-Line Format</b> | <code>--secure-file-priv=dir_name</code> |                                  |
| <b>System Variable</b>     | <b>Name</b>                              | <a href="#">secure_file_priv</a> |
|                            | <b>Variable Scope</b>                    | Global                           |

|                                    | Dynamic Variable    | No                |
|------------------------------------|---------------------|-------------------|
| <b>Permitted Values</b> (<= 5.7.5) | <b>Type</b>         | string            |
|                                    | <b>Default</b>      | empty             |
|                                    | <b>Valid Values</b> | empty             |
|                                    |                     | dirname           |
| <b>Permitted Values</b> (>= 5.7.6) | <b>Type</b>         | string            |
|                                    | <b>Default</b>      | platform specific |
|                                    | <b>Valid Values</b> | empty             |
|                                    |                     | dirname           |
|                                    |                     | NULL              |

This variable is used to limit the effect of data import and export operations, such as those performed by the `LOAD DATA` and `SELECT ... INTO OUTFILE` statements and the `LOAD_FILE()` function. These operations are permitted only to users who have the `FILE` privilege.

`secure_file_priv` may be set as follows:

- If empty, the variable has no effect. This is not a secure setting.
- If set to the name of a directory, the server limits import and export operations to work only with files in that directory. The directory must exist; the server will not create it.
- If set to `NULL`, the server disables import and export operations. This value is permitted as of MySQL 5.7.6.

Before MySQL 5.7.6, this variable is empty by default. As of 5.7.6, the default value is platform specific and depends on the value of the `INSTALL_LAYOUT CMake` option, as shown in the following table. To specify the default `secure_file_priv` value explicitly if you are building from source, use the `INSTALL_SECURE_FILE_PRIVDIR CMake` option.

| <code>INSTALL_LAYOUT</code> Value | Default <code>secure_file_priv</code> Value                   |
|-----------------------------------|---|
| STANDALONE, WIN                   | NULL (>= MySQL 5.7.16), empty (< MySQL 5.7.16)                |
| DEB, RPM, SLES, SVR4              | /var/lib/mysql-files  |
| Otherwise                         | mysql-files under the <code>CMAKE_INSTALL_PREFIX</code> value |

As of MySQL 5.7.8, to set the default `secure_file_priv` value for the `libmysqld` embedded server, use the `INSTALL_SECURE_FILE_PRIV_EMBEDDED CMake` option. The default value for this option is `NULL`.

As of MySQL 5.7.6, the server checks the value of `secure_file_priv` at startup and writes a warning to the error log if the value is insecure. A non-`NULL` value is considered insecure if it is empty, or the value is the data directory or a subdirectory of it, or a directory that is accessible by all users. If `secure_file_priv` is set to a nonexistent path, the server writes an error message to the error log and exits.

- `server_id`

|                            |                            |                        |
|----------------------------|----------------------------|------------------------|
| <b>Command-Line Format</b> | <code>--server-id=#</code> |                        |
| <b>System Variable</b>     | <b>Name</b>                | <code>server_id</code> |
|                            | <b>Variable Scope</b>      | Global                 |

|                         |                         |            |
|-------------------------|-------------------------|------------|
|                         | <b>Dynamic Variable</b> | Yes        |
| <b>Permitted Values</b> | <b>Type</b>             | integer    |
|                         | <b>Default</b>          | 0          |
|                         | <b>Min Value</b>        | 0          |
|                         | <b>Max Value</b>        | 4294967295 |

The server ID, used in replication to give each master and slave a unique identity. This variable is set by the `--server-id` option. For each server participating in replication, you should pick a positive integer in the range from 1 to  $2^{32} - 1$  to act as that server's ID.

- `session_track_gtids`

|                            |  |                                  |
|----------------------------|--|----------------------------------|
| <b>Introduced</b>          | 5.7.6                                      |                                  |
| <b>Command-Line Format</b> | <code>--session_track_gtids=[value]</code> |                                  |
| <b>System Variable</b>     | <b>Name</b>                                | <code>session_track_gtids</code> |
|                            | <b>Variable Scope</b>                      | Global, Session                  |
|                            | <b>Dynamic Variable</b>                    | Yes                              |
| <b>Permitted Values</b>    | <b>Type</b>                                | enumeration                      |
|                            | <b>Default</b>                             | OFF                              |
|                            | <b>Valid Values</b>                        | OFF                              |
|                            |  | OWN_GTID                         |
|                            |  | ALL_GTIDS                        |

Controls a tracker for capturing GTIDs and returning them in the OK packet. Depending on the value of this option, at the end of executing a transaction, the GTIDs specified are captured by the tracker and appended to the OK packet. The possible sets of GTIDs to track are:

- `OFF` means that no GTIDs are included in the OK packet. This is the same behavior as versions of MySQL prior to 5.7.6.
- `OWN_GTID` configures the tracker to collect GTIDs generated by successfully committed read/write transactions.
- `ALL_GTIDS` configures the tracker to collect all of the GTIDs in `gtid_executed` at the time the current transaction commits, regardless of whether the transaction is read/write or read-only.

For information about obtaining session state-change information within client programs, see [Section 26.8.7.65, “mysql\\_session\\_track\\_get\\_first\(\)”](#).

- `session_track_schema`

|                            |                                       |                                   |
|----------------------------|---------------------------------------|-----------------------------------|
| <b>Introduced</b>          | 5.7.4                                 |                                   |
| <b>Command-Line Format</b> | <code>--session_track_schema=#</code> |                                   |
| <b>System Variable</b>     | <b>Name</b>                           | <code>session_track_schema</code> |
|                            | <b>Variable Scope</b>                 | Global, Session                   |

|                         |                         |         |
|-------------------------|-------------------------|---------|
|                         | <b>Dynamic Variable</b> | Yes     |
| <b>Permitted Values</b> | <b>Type</b>             | boolean |
|                         | <b>Default</b>          | ON      |

Controls whether the server tracks changes to the default schema (database) name within the current session and makes this information available to the client when changes occur.

If notification is enabled, any setting of the default schema is reported, even if the new schema name is the same as the old.

For information about obtaining session state-change information within client programs, see [Section 26.8.7.65, “mysql\\_session\\_track\\_get\\_first\(\)”](#).

- `session_track_state_change`

|                            |   |   |
|----------------------------|---|---|
| <b>Introduced</b>          | 5.7.4                                       |   |
| <b>Command-Line Format</b> | <code>--session_track_state_change=#</code> |   |
| <b>System Variable</b>     | <b>Name</b>                                 | <code>session_track_state_change</code> |
|                            | <b>Variable Scope</b>                       | Global, Session                         |
|                            | <b>Dynamic Variable</b>                     | Yes                                     |
| <b>Permitted Values</b>    | <b>Type</b>                                 | boolean                                 |
|                            | <b>Default</b>                              | OFF                                     |

Controls whether the server tracks changes to the state of the current session and notifies the client when state changes occur. Session state consists of these values:

- The default schema (database)
- Session-specific values for system variables
- User-defined variables
- Temporary tables
- Prepared statements

If the session-state tracker is enabled, any assignments to session state values are reported, even if the new values are the same as the old.

The `session_track_state_change` variable controls only notification of when changes occur, not what the changes are. To receive notification for changes to the default schema name and session system variable values, use the `session_track_schema` and `session_track_system_variables` system variables.

For information about obtaining session state-change information within client programs, see [Section 26.8.7.65, “mysql\\_session\\_track\\_get\\_first\(\)”](#).

- `session_track_system_variables`

|                            |   |   |
|----------------------------|---|---|
| <b>Introduced</b>          | 5.7.4   |   |
| <b>Command-Line Format</b> | <code>--session_track_system_variables=#</code> |   |
| <b>System Variable</b>     | <b>Name</b>                                     | <code>session_track_system_variables</code> |

|                         |                         |   |
|-------------------------|-------------------------|---|
|                         | <b>Variable Scope</b>   | Global, Session   |
|                         | <b>Dynamic Variable</b> | Yes   |
| <b>Permitted Values</b> | <b>Type</b>             | string  |
|                         | <b>Default</b>          | <code>time_zone, autocommit, character_set_client, character_set_results, character_set_connection</code> |

Controls whether the server tracks changes to the session system variables and makes this information available to the client when changes occur. The variable value is a comma-separated list of variables for which to track changes. By default, notification is enabled for `time_zone`, `autocommit`, `character_set_client`, `character_set_results`, and `character_set_connection`. (The latter three variables are those affected by `SET NAMES`.)

The special value `*` causes the server to track changes to all session variables. If given, this value must be specified by itself without specific system variable names.

Notification occurs for all assignments to tracked session system variables, even if the new values are the same as the old.

For information about obtaining session state-change information within client programs, see [Section 26.8.7.65](#), “`mysql_session_track_get_first()`”.

- `sha256_password_auto_generate_rsa_keys`

|                            |  |   |
|----------------------------|--|---|
| <b>Introduced</b>          | 5.7.5  |   |
| <b>Command-Line Format</b> | <code>--sha256_password_auto_generate_rsa_keys[={OFF ON}]</code> |   |
| <b>System Variable</b>     | <b>Name</b>  | <code>sha256_password_auto_generate_rsa_keys</code> |
|                            | <b>Variable Scope</b>  | Global  |
|                            | <b>Dynamic Variable</b>  | No  |
| <b>Permitted Values</b>    | <b>Type</b>  | boolean   |
|                            | <b>Default</b>   | <code>ON</code>                                     |

This variable is available if the server was compiled using OpenSSL (see [Section 7.4.1](#), “[OpenSSL Versus yaSSL](#)”). It controls whether the server autogenerates RSA private/public key-pair files in the data directory, if they do not already exist.

At startup, the server automatically generates RSA private/public key-pair files in the data directory if the `sha256_password_auto_generate_rsa_keys` system variable is enabled, no RSA options are specified, and the RSA files are missing from the data directory. These files enable secure password exchange using RSA over unencrypted connections for accounts authenticated by the `sha256_password` plugin; see [Section 7.5.1.4](#), “[The SHA-256 Authentication Plugin](#)”.

For more information about RSA file autogeneration, including file names and characteristics, see [Section 7.4.6.1](#), “[Creating SSL and RSA Certificates and Keys using MySQL](#)”.

The `auto_generate_certs` system variable is related but controls autogeneration of SSL certificate and key files needed for secure connections using SSL.

- `sha256_password_private_key_path`

|                        |             |   |
|------------------------|-------------|---|
| <b>System Variable</b> | <b>Name</b> | <code>sha256_password_private_key_path</code> |
|------------------------|-------------|---|

|                         |                         |                              |
|-------------------------|-------------------------|------------------------------|
|                         | <b>Variable Scope</b>   | Global                       |
|                         | <b>Dynamic Variable</b> | No                           |
| <b>Permitted Values</b> | <b>Type</b>             | file name                    |
|                         | <b>Default</b>          | <code>private_key.pem</code> |

This variable is available if MySQL was compiled using OpenSSL (see [Section 7.4.1, “OpenSSL Versus yaSSL”](#)). Its value is the path name of the RSA private key file for the `sha256_password` authentication plugin. If the file is named as a relative path, it is interpreted relative to the server data directory. The file must be in PEM format. Because this file stores a private key, its access mode should be restricted so that only the MySQL server can read it.

For information about `sha256_password`, including instructions for creating the RSA key files, see [Section 7.5.1.4, “The SHA-256 Authentication Plugin”](#).

- `sha256_password_proxy_users`

|                            |   |  |
|----------------------------|---|--|
| <b>Introduced</b>          | 5.7.7   |  |
| <b>Command-Line Format</b> | <code>--sha256_password_proxy_users={OFF ON}</code> |  |
| <b>System Variable</b>     | <b>Name</b>   | <code>sha256_password_proxy_users</code> |
|                            | <b>Variable Scope</b>                               | Global                                   |
|                            | <b>Dynamic Variable</b>                             | Yes                                      |
| <b>Permitted Values</b>    | <b>Type</b>   | boolean                                  |
|                            | <b>Default</b>                                      | <code>OFF</code>                         |

This variable controls whether the `sha256_password` built-in authentication plugin supports proxy users. It has no effect unless the `check_proxy_users` system variable is enabled. For information about user proxying, see [Section 7.3.9, “Proxy Users”](#).

This variable was added in MySQL 5.7.7. Before 5.7.7, `sha256_password` does not support proxy users.

- `sha256_password_public_key_path`

|                         |                         |  |
|-------------------------|-------------------------|--|
| <b>System Variable</b>  | <b>Name</b>             | <code>sha256_password_public_key_path</code> |
|                         | <b>Variable Scope</b>   | Global                                       |
|                         | <b>Dynamic Variable</b> | No   |
| <b>Permitted Values</b> | <b>Type</b>             | file name                                    |
|                         | <b>Default</b>          | <code>public_key.pem</code>                  |

This variable is available if MySQL was compiled using OpenSSL (see [Section 7.4.1, “OpenSSL Versus yaSSL”](#)). Its value is the path name of the RSA public key file for the `sha256_password` authentication plugin. If the file is named as a relative path, it is interpreted relative to the server data directory. The file must be in PEM format. Because this file stores a public key, copies can be freely distributed to client users. (Clients that explicitly specify a public key when connecting to the server using RSA password encryption must use the same public key as that used by the server.)

For information about `sha256_password`, including instructions for creating the RSA key files and how clients specify the RSA public key, see [Section 7.5.1.4, “The SHA-256 Authentication Plugin”](#).

- `shared_memory`

|                            |                                      |                            |
|----------------------------|--------------------------------------|----------------------------|
| <b>Command-Line Format</b> | <code>--shared_memory[={0,1}]</code> |                            |
| <b>System Variable</b>     | <b>Name</b>                          | <code>shared_memory</code> |
|                            | <b>Variable Scope</b>                | Global                     |
|                            | <b>Dynamic Variable</b>              | No                         |
| <b>Platform Specific</b>   | Windows                              |                            |
| <b>Permitted Values</b>    | <b>Type</b>                          | boolean                    |
|                            | <b>Default</b>                       | <code>FALSE</code>         |

(Windows only.) Whether the server permits shared-memory connections.

- `shared_memory_base_name`

|                            |   |                                      |
|----------------------------|---|--------------------------------------|
| <b>Command-Line Format</b> | <code>--shared_memory_base_name=name</code> |                                      |
| <b>System Variable</b>     | <b>Name</b>                                 | <code>shared_memory_base_name</code> |
|                            | <b>Variable Scope</b>                       | Global                               |
|                            | <b>Dynamic Variable</b>                     | No                                   |
| <b>Platform Specific</b>   | Windows                                     |                                      |
| <b>Permitted Values</b>    | <b>Type</b>                                 | string                               |
|                            | <b>Default</b>                              | <code>MYSQL</code>                   |

(Windows only.) The name of shared memory to use for shared-memory connections. This is useful when running multiple MySQL instances on a single physical machine. The default name is `MYSQL`. The name is case sensitive.

- `show_compatibility_56`

|                                       |   |                                    |
|---------------------------------------|---|------------------------------------|
| <b>Introduced</b>                     | 5.7.6   |                                    |
| <b>Deprecated</b>                     | 5.7.6   |                                    |
| <b>Command-Line Format</b>            | <code>--show_compatibility_56[={OFF ON}]</code> |                                    |
| <b>System Variable</b>                | <b>Name</b>                                     | <code>show_compatibility_56</code> |
|                                       | <b>Variable Scope</b>                           | Global                             |
|                                       | <b>Dynamic Variable</b>                         | Yes                                |
| <b>Permitted Values (&lt;= 5.7.7)</b> | <b>Type</b>                                     | boolean                            |
|                                       | <b>Default</b>                                  | <code>ON</code>                    |
| <b>Permitted Values (&gt;= 5.7.8)</b> | <b>Type</b>                                     | boolean                            |
|                                       | <b>Default</b>                                  | <code>OFF</code>                   |

The `INFORMATION_SCHEMA` has tables that contain system and status variable information (see Section 23.10, “The `INFORMATION_SCHEMA` GLOBAL\_VARIABLES and SESSION\_VARIABLES Tables”, and Section 23.9, “The `INFORMATION_SCHEMA` GLOBAL\_STATUS and SESSION\_STATUS Tables”). As of MySQL 5.7.6, the Performance Schema also contains system and status variable tables (see Section 24.10.13, “Performance Schema System Variable Tables”,

and [Section 24.10.14, “Performance Schema Status Variable Tables”](#)). The Performance Schema tables are intended to replace the `INFORMATION_SCHEMA` tables, which are deprecated as of MySQL 5.7.6 and will be removed in a future MySQL release.

For advice on migrating away from the `INFORMATION_SCHEMA` tables to the Performance Schema tables, see [Section 24.18, “Migrating to Performance Schema System and Status Variable Tables”](#). To assist in the migration, you can use the `show_compatibility_56` system variable, which affects whether MySQL 5.6 compatibility is enabled with respect to how system and status variable information is provided by the `INFORMATION_SCHEMA` and Performance Schema tables, and also by the `SHOW VARIABLES` and `SHOW STATUS` statements.

**Note**

`show_compatibility_56` is deprecated because its only purpose is to permit control over deprecated system and status variable information sources that will be removed in a future MySQL release. When those sources are removed, `show_compatibility_56` will have no purpose and will be removed as well.

The following discussion describes the effects of `show_compatibility_56`:

- [Overview of show\\_compatibility\\_56 Effects](#)
- [Effect of show\\_compatibility\\_56 on SHOW Statements](#)
- [Effect of show\\_compatibility\\_56 on INFORMATION\\_SCHEMA Tables](#)
- [Effect of show\\_compatibility\\_56 on Performance Schema Tables](#)
- [Effect of show\\_compatibility\\_56 on Slave Status Variables](#)
- [Effect of show\\_compatibility\\_56 on FLUSH STATUS](#)

For better understanding, it is strongly recommended that you also read these sections:

- [Section 24.10.13, “Performance Schema System Variable Tables”](#)
- [Section 24.10.14, “Performance Schema Status Variable Tables”](#)
- [Section 24.10.15.10, “Status Variable Summary Tables”](#)

## Overview of show\_compatibility\_56 Effects

The `show_compatibility_56` system variable affects these aspects of server operation regarding system and status variables:

- Information available from the `SHOW VARIABLES` and `SHOW STATUS` statements
- Information available from the `INFORMATION_SCHEMA` tables that provide system and status variable information
- Information available from the Performance Schema tables that provide system and status variable information
- The effect of the `FLUSH STATUS` statement on status variables

This list summarizes the effects of `show_compatibility_56`, with additional details given later:

- When `show_compatibility_56` is `ON`, compatibility with MySQL 5.6 is enabled. Older variable information sources (`SHOW` statements, `INFORMATION_SCHEMA` tables) produce the same output as in MySQL 5.6.

- When `show_compatibility_56` is `OFF`, compatibility with MySQL 5.6 is disabled. Selecting from the `INFORMATION_SCHEMA` tables produces an error because the Performance Schema tables are intended to replace them. The `INFORMATION_SCHEMA` tables are deprecated as of MySQL 5.7.6 and will be removed in a future MySQL release.

To obtain system and status variable information When `show_compatibility_56=OFF`, use the Performance Schema tables or the `SHOW` statements.

**Note**

When `show_compatibility_56=OFF`, the `SHOW VARIABLES` and `SHOW STATUS` statements display rows from the Performance Schema `global_variables`, `session_variables`, `global_status`, and `session_status` tables.

As of MySQL 5.7.9, those tables are world readable and accessible without the `SELECT` privilege, which means that `SELECT` is not needed to use the `SHOW` statements, either. Before MySQL 5.7.9, the `SELECT` privilege is required to access those Performance Schema tables, either directly, or indirectly through the `SHOW` statements.

- Several `Slave_xxx` status variables are available from `SHOW STATUS` when `show_compatibility_56` is `ON`. When `show_compatibility_56` is `OFF`, some of those variables are not exposed to `SHOW STATUS`. The information they provide is available in replication-related Performance Schema tables, as described later.
- `show_compatibility_56` has no effect on system variable access using `@@` notation: `@@GLOBAL.var_name`, `@@SESSION.var_name`, `@@var_name`.
- `show_compatibility_56` has no effect for the embedded server, which produces 5.6-compatible output in all cases.

The following descriptions detail the effect of setting `show_compatibility_56` to `ON` or `OFF` in the contexts in which this variable applies.

## Effect of `show_compatibility_56` on `SHOW` Statements

`SHOW GLOBAL VARIABLES` statement:

- `ON`: MySQL 5.6 output.
- `OFF`: Output displays rows from the Performance Schema `global_variables` table.

`SHOW [SESSION | LOCAL] VARIABLES` statement:

- `ON`: MySQL 5.6 output.
- `OFF`: Output displays rows from the Performance Schema `session_variables` table. (In MySQL 5.7.6 and 5.7.7, `OFF` output does not fully reflect all system variable values in effect for the current session; it includes no rows for global variables that have no session counterpart. This is corrected in MySQL 5.7.8.)

`SHOW GLOBAL STATUS` statement:

- `ON`: MySQL 5.6 output.
- `OFF`: Output displays rows from the Performance Schema `global_status` table, plus the `Com_xxx` statement execution counters.

`OFF` output includes no rows for session variables that have no global counterpart, unlike `ON` output.

`SHOW [SESSION | LOCAL] STATUS` statement:

- `ON`: MySQL 5.6 output.
- `OFF`: Output displays rows from the Performance Schema `session_status` table, plus the `Com_xxx` statement execution counters. (In MySQL 5.7.6 and 5.7.7, `OFF` output does not fully reflect all status variable values in effect for the current session; it includes no rows for global variables that have no session counterpart. This is corrected in MySQL 5.7.8.)

In MySQL 5.7.6 and 5.7.7, for each of the `SHOW` statements just described, use of a `WHERE` clause produces a warning when `show_compatibility_56=ON` and an error when `show_compatibility_56=OFF`. (This applies to `WHERE` clauses that are not optimized away. For example, `WHERE 1` is trivially true, is optimized away, and thus produces no warning or error.) This behavior does not occur as of MySQL 5.7.8; `WHERE` is supported as before 5.7.6.

## Effect of `show_compatibility_56` on `INFORMATION_SCHEMA` Tables

`INFORMATION_SCHEMA` tables (`GLOBAL_VARIABLES`, `SESSION_VARIABLES`, `GLOBAL_STATUS`, and `SESSION_STATUS`):

- `ON`: MySQL 5.6 output, with a deprecation warning.
- `OFF`: Selecting from these tables produces an error. (Before 5.7.9, selecting from these tables produces no output, with a deprecation warning.)

## Effect of `show_compatibility_56` on Performance Schema Tables

Performance Schema system variable tables:

- `OFF`:
  - `global_variables`: Global system variables only.
  - `session_variables`: System variables in effect for the current session: A row for each session variable, and a row for each global variable that has no session counterpart. (In MySQL 5.7.6 and 5.7.7, the table does not fully reflect all system variable values in effect for the current session; it includes no rows for global variables that have no session counterpart. This is corrected in MySQL 5.7.8.)
  - `variables_by_thread`: Session system variables only, for each active session.
- `ON`: Same output as for `OFF`. (Before 5.7.8, these tables produce no output.)

Performance Schema status variable tables:

- `OFF`:
  - `global_status`: Global status variables only.
  - `session_status`: Status variables in effect the current session: A row for each session variable, and a row for each global variable that has no session counterpart. (In MySQL 5.7.6 and 5.7.7, the table does not fully reflect all status variable values in effect for the current session; it includes no rows for global variables that have no session counterpart. This is corrected in MySQL 5.7.8.)
  - `status_by_account` Session status variables only, aggregated per account.

- `status_by_host`: Session status variables only, aggregated per host name.
- `status_by_thread`: Session status variables only, for each active session.
- `status_by_user`: Session status variables only, aggregated per user name.
- `ON`: Same output as for `OFF`. (Before 5.7.9, these tables produce no output.)

## Effect of `show_compatibility_56` on Slave Status Variables

Slave status variables:

- `ON`: Several `Slave_xxx` status variables are available from `SHOW STATUS`.
- `OFF`: Some of those slave variables are not exposed to `SHOW STATUS` or the Performance Schema status variable tables. The information they provide is available in replication-related Performance Schema tables. The following table shows which `Slave_xxx` status variables become unavailable in `SHOW STATUS` and their locations in Performance Schema replication tables.

| Status Variable                         | Performance Schema Location  |
|---|--|
| <code>Slave_heartbeat_period</code>     | <code>replication_connection_configuration</code> table, <code>HEARTBEAT_INTERVAL</code> column                                  |
| <code>Slave_last_heartbeat</code>       | <code>replication_connection_status</code> table, <code>LAST_HEARTBEAT_TIMESTAMP</code> column                                   |
| <code>Slave_received_heartbeats</code>  | <code>replication_connection_status</code> table, <code>COUNT_RECEIVED_HEARTBEATS</code> column                                  |
| <code>Slave_retried_transactions</code> | <code>replication_applier_status</code> table, <code>COUNT_TRANSACTIONS_RETRIES</code> column                                    |
| <code>Slave_running</code>              | <code>replication_connection_status</code> and <code>replication_applier_status</code> tables, <code>SERVICE_STATE</code> column |

## Effect of `show_compatibility_56` on `FLUSH STATUS`

`FLUSH STATUS` statement:

- `ON`: This statement produces MySQL 5.6 behavior. It adds the current thread's session status variable values to the global values and resets the session values to zero. Some global variables may be reset to zero as well. It also resets the counters for key caches (default and named) to zero and sets `Max_used_connections` to the current number of open connections.
- `OFF`: This statement adds the session status from all active sessions to the global status variables, resets the status of all active sessions, and resets account, host, and user status values aggregated from disconnected sessions.
- `show_old_temporals`

|                            |  |                                 |
|----------------------------|--|---------------------------------|
| <b>Introduced</b>          | 5.7.6                                      |                                 |
| <b>Deprecated</b>          | 5.7.6                                      |                                 |
| <b>Command-Line Format</b> | <code>--show_old_temporals={OFF ON}</code> |                                 |
| <b>System Variable</b>     | <b>Name</b>                                | <code>show_old_temporals</code> |
|                            | <b>Variable Scope</b>                      | Global, Session                 |

|                         |                         |         |
|-------------------------|-------------------------|---------|
|                         | <b>Dynamic Variable</b> | Yes     |
| <b>Permitted Values</b> | <b>Type</b>             | boolean |
|                         | <b>Default</b>          | OFF     |

Whether `SHOW CREATE TABLE` output includes comments to flag temporal columns found to be in pre-5.6.4 format (`TIME`, `DATETIME`, and `TIMESTAMP` columns without support for fractional seconds precision). This variable is disabled by default. If enabled, `SHOW CREATE TABLE` output looks like this:

```
CREATE TABLE `mytbl` (
  `ts` timestamp /* 5.5 binary format */ NOT NULL DEFAULT CURRENT_TIMESTAMP,
  `dt` datetime /* 5.5 binary format */ DEFAULT NULL,
  `t` time /* 5.5 binary format */ DEFAULT NULL
) DEFAULT CHARSET=latin1
```

Output for the `COLUMN_TYPE` column of the `INFORMATION_SCHEMA.COLUMNS` table is affected similarly.

This variable is deprecated and will be removed in a future MySQL release.

- `skip_external_locking`

|                            |                                      |                                    |
|----------------------------|--------------------------------------|------------------------------------|
| <b>Command-Line Format</b> | <code>--skip-external-locking</code> |                                    |
| <b>System Variable</b>     | <b>Name</b>                          | <code>skip_external_locking</code> |
|                            | <b>Variable Scope</b>                | Global                             |
|                            | <b>Dynamic Variable</b>              | No                                 |
| <b>Permitted Values</b>    | <b>Type</b>                          | boolean                            |
|                            | <b>Default</b>                       | ON                                 |

This is `OFF` if `mysqld` uses external locking (system locking), `ON` if external locking is disabled. This affects only `MyISAM` table access.

This variable is set by the `--external-locking` or `--skip-external-locking` option. External locking is disabled by default.

External locking affects only `MyISAM` table access. For more information, including conditions under which it can and cannot be used, see [Section 9.11.5, “External Locking”](#).

- `skip_name_resolve`

|                            |                                  |                                |
|----------------------------|----------------------------------|--------------------------------|
| <b>Command-Line Format</b> | <code>--skip-name-resolve</code> |                                |
| <b>System Variable</b>     | <b>Name</b>                      | <code>skip_name_resolve</code> |
|                            | <b>Variable Scope</b>            | Global                         |
|                            | <b>Dynamic Variable</b>          | No                             |
| <b>Permitted Values</b>    | <b>Type</b>                      | boolean                        |
|                            | <b>Default</b>                   | OFF                            |

This variable is set from the value of the `--skip-name-resolve` option. If it is `OFF`, `mysqld` resolves host names when checking client connections. If it is `ON`, `mysqld` uses only IP numbers;

in this case, all `Host` column values in the grant tables must be IP addresses or `localhost`. See [Section 9.12.5.2, “DNS Lookup Optimization and the Host Cache”](#).

- `skip_networking`

|                            |                                |                              |
|----------------------------|--------------------------------|------------------------------|
| <b>Command-Line Format</b> | <code>--skip-networking</code> |                              |
| <b>System Variable</b>     | <b>Name</b>                    | <code>skip_networking</code> |
|                            | <b>Variable Scope</b>          | Global                       |
|                            | <b>Dynamic Variable</b>        | No                           |

This is `ON` if the server permits only local (non-TCP/IP) connections. On Unix, local connections use a Unix socket file. On Windows, local connections use a named pipe or shared memory. This variable can be set to `ON` with the `--skip-networking` option.

- `skip_show_database`

|                            |                                   |                                 |
|----------------------------|-----------------------------------|---------------------------------|
| <b>Command-Line Format</b> | <code>--skip-show-database</code> |                                 |
| <b>System Variable</b>     | <b>Name</b>                       | <code>skip_show_database</code> |
|                            | <b>Variable Scope</b>             | Global                          |
|                            | <b>Dynamic Variable</b>           | No                              |

This prevents people from using the `SHOW DATABASES` statement if they do not have the `SHOW DATABASES` privilege. This can improve security if you have concerns about users being able to see databases belonging to other users. Its effect depends on the `SHOW DATABASES` privilege: If the variable value is `ON`, the `SHOW DATABASES` statement is permitted only to users who have the `SHOW DATABASES` privilege, and the statement displays all database names. If the value is `OFF`, `SHOW DATABASES` is permitted to all users, but displays the names of only those databases for which the user has the `SHOW DATABASES` or other privilege. (Note that *any* global privilege is considered a privilege for the database.)

- `slow_launch_time`

|                            |                                   |                               |
|----------------------------|-----------------------------------|-------------------------------|
| <b>Command-Line Format</b> | <code>--slow_launch_time=#</code> |                               |
| <b>System Variable</b>     | <b>Name</b>                       | <code>slow_launch_time</code> |
|                            | <b>Variable Scope</b>             | Global                        |
|                            | <b>Dynamic Variable</b>           | Yes                           |
| <b>Permitted Values</b>    | <b>Type</b>                       | integer                       |
|                            | <b>Default</b>                    | 2                             |

If creating a thread takes longer than this many seconds, the server increments the `Slow_launch_threads` status variable.

- `slow_query_log`

|                            |                               |                             |
|----------------------------|-------------------------------|-----------------------------|
| <b>Command-Line Format</b> | <code>--slow-query-log</code> |                             |
| <b>System Variable</b>     | <b>Name</b>                   | <code>slow_query_log</code> |
|                            | <b>Variable Scope</b>         | Global                      |

|                         |                         |         |
|-------------------------|-------------------------|---------|
|                         | <b>Dynamic Variable</b> | Yes     |
| <b>Permitted Values</b> | <b>Type</b>             | boolean |
|                         | <b>Default</b>          | OFF     |

Whether the slow query log is enabled. The value can be 0 (or `OFF`) to disable the log or 1 (or `ON`) to enable the log. The default value depends on whether the `--slow_query_log` option is given. The destination for log output is controlled by the `log_output` system variable; if that value is `NONE`, no log entries are written even if the log is enabled.

“Slow” is determined by the value of the `long_query_time` variable. See [Section 6.4.5, “The Slow Query Log”](#).

- `slow_query_log_file`

|                            |  |                                  |
|----------------------------|--|----------------------------------|
| <b>Command-Line Format</b> | <code>--slow-query-log-file=file_name</code> |                                  |
| <b>System Variable</b>     | <b>Name</b>                                  | <code>slow_query_log_file</code> |
|                            | <b>Variable Scope</b>                        | Global                           |
|                            | <b>Dynamic Variable</b>                      | Yes                              |
| <b>Permitted Values</b>    | <b>Type</b>                                  | file name                        |
|                            | <b>Default</b>                               | <code>host_name-slow.log</code>  |

The name of the slow query log file. The default value is `host_name-slow.log`, but the initial value can be changed with the `--slow_query_log_file` option.

- `socket`

|                            |   |                              |
|----------------------------|---|------------------------------|
| <b>Command-Line Format</b> | <code>--socket={file_name pipe_name}</code> |                              |
| <b>System Variable</b>     | <b>Name</b>                                 | <code>socket</code>          |
|                            | <b>Variable Scope</b>                       | Global                       |
|                            | <b>Dynamic Variable</b>                     | No                           |
| <b>Permitted Values</b>    | <b>Type</b>                                 | string                       |
|                            | <b>Default</b>                              | <code>/tmp/mysql.sock</code> |

On Unix platforms, this variable is the name of the socket file that is used for local client connections. The default is `/tmp/mysql.sock`. (For some distribution formats, the directory might be different, such as `/var/lib/mysql` for RPMs.)

On Windows, this variable is the name of the named pipe that is used for local client connections. The default value is `MySQL` (not case sensitive).

- `sort_buffer_size`

|                            |                                   |                               |
|----------------------------|-----------------------------------|-------------------------------|
| <b>Command-Line Format</b> | <code>--sort_buffer_size=#</code> |                               |
| <b>System Variable</b>     | <b>Name</b>                       | <code>sort_buffer_size</code> |
|                            | <b>Variable Scope</b>             | Global, Session               |
|                            | <b>Dynamic Variable</b>           | Yes                           |

|   |                  |                      |
|---|------------------|----------------------|
| <b>Permitted Values</b><br>(Windows)              | <b>Type</b>      | integer              |
|   | <b>Default</b>   | 262144               |
|   | <b>Min Value</b> | 32768                |
|   | <b>Max Value</b> | 4294967295           |
| <b>Permitted Values</b> (Other, 32-bit platforms) | <b>Type</b>      | integer              |
|   | <b>Default</b>   | 262144               |
|   | <b>Min Value</b> | 32768                |
|   | <b>Max Value</b> | 4294967295           |
| <b>Permitted Values</b> (Other, 64-bit platforms) | <b>Type</b>      | integer              |
|   | <b>Default</b>   | 262144               |
|   | <b>Min Value</b> | 32768                |
|   | <b>Max Value</b> | 18446744073709551615 |

Each session that must perform a sort allocates a buffer of this size. `sort_buffer_size` is not specific to any storage engine and applies in a general manner for optimization. At minimum the `sort_buffer_size` value must be large enough to accommodate fifteen tuples in the sort buffer. Also, increasing the value of `max_sort_length` may require increasing the value of `sort_buffer_size`. For more information, see [Section 9.2.1.15, “ORDER BY Optimization”](#)

If you see many `Sort_merge_passes` per second in `SHOW GLOBAL STATUS` output, you can consider increasing the `sort_buffer_size` value to speed up `ORDER BY` or `GROUP BY` operations that cannot be improved with query optimization or improved indexing.

The optimizer tries to work out how much space is needed but can allocate more, up to the limit. Setting it larger than required globally will slow down most queries that sort. It is best to increase it as a session setting, and only for the sessions that need a larger size. On Linux, there are thresholds of 256KB and 2MB where larger values may significantly slow down memory allocation, so you should consider staying below one of those values. Experiment to find the best value for your workload. See [Section B.5.3.5, “Where MySQL Stores Temporary Files”](#).

The maximum permissible setting for `sort_buffer_size` is 4GB-1. Larger values are permitted for 64-bit platforms (except 64-bit Windows, for which large values are truncated to 4GB-1 with a warning).

- `sql_auto_is_null`

|                         |                         |                               |
|-------------------------|-------------------------|-------------------------------|
| <b>System Variable</b>  | <b>Name</b>             | <code>sql_auto_is_null</code> |
|                         | <b>Variable Scope</b>   | Global, Session               |
|                         | <b>Dynamic Variable</b> | Yes                           |
| <b>Permitted Values</b> | <b>Type</b>             | boolean                       |
|                         | <b>Default</b>          | 0                             |

If this variable is set to 1, then after a statement that successfully inserts an automatically generated `AUTO_INCREMENT` value, you can find that value by issuing a statement of the following form:

```
SELECT * FROM tbl_name WHERE auto_col IS NULL
```

If the statement returns a row, the value returned is the same as if you invoked the `LAST_INSERT_ID()` function. For details, including the return value after a multiple-row insert, see [Section 13.14, “Information Functions”](#). If no `AUTO_INCREMENT` value was successfully inserted, the `SELECT` statement returns no row.

The behavior of retrieving an `AUTO_INCREMENT` value by using an `IS NULL` comparison is used by some ODBC programs, such as Access. See [Obtaining Auto-Increment Values](#). This behavior can be disabled by setting `sql_auto_is_null` to 0.

The default value of `sql_auto_is_null` is 0.

- `sql_big_selects`

|                         |                         |                              |
|-------------------------|-------------------------|------------------------------|
| <b>System Variable</b>  | <b>Name</b>             | <code>sql_big_selects</code> |
|                         | <b>Variable Scope</b>   | Global, Session              |
|                         | <b>Dynamic Variable</b> | Yes                          |
| <b>Permitted Values</b> | <b>Type</b>             | boolean                      |
|                         | <b>Default</b>          | 1                            |

If set to 0, MySQL aborts `SELECT` statements that are likely to take a very long time to execute (that is, statements for which the optimizer estimates that the number of examined rows exceeds the value of `max_join_size`). This is useful when an inadvisable `WHERE` statement has been issued. The default value for a new connection is 1, which permits all `SELECT` statements.

If you set the `max_join_size` system variable to a value other than `DEFAULT`, `sql_big_selects` is set to 0.

- `sql_buffer_result`

|                         |                         |                                |
|-------------------------|-------------------------|--------------------------------|
| <b>System Variable</b>  | <b>Name</b>             | <code>sql_buffer_result</code> |
|                         | <b>Variable Scope</b>   | Global, Session                |
|                         | <b>Dynamic Variable</b> | Yes                            |
| <b>Permitted Values</b> | <b>Type</b>             | boolean                        |
|                         | <b>Default</b>          | 0                              |

If set to 1, `sql_buffer_result` forces results from `SELECT` statements to be put into temporary tables. This helps MySQL free the table locks early and can be beneficial in cases where it takes a long time to send results to the client. The default value is 0.

- `sql_log_bin`

|                         |                         |                          |
|-------------------------|-------------------------|--------------------------|
| <b>System Variable</b>  | <b>Name</b>             | <code>sql_log_bin</code> |
|                         | <b>Variable Scope</b>   | Session                  |
|                         | <b>Dynamic Variable</b> | Yes                      |
| <b>Permitted Values</b> | <b>Type</b>             | boolean                  |

This variable controls whether logging to the binary log is done. The default value is 1 (do logging). To change logging for the current session, change the session value of this variable. The session user must have the [SUPER](#) privilege to set this variable.

*Setting this variable to 0 prevents GTIDs from being assigned to transactions in the binary log. If you are using GTIDs for replication, this means that, even when binary logging is later enabled once again, the GTIDs written into the log from this point do not account for any transactions that occurred in the meantime—in effect, those transactions are lost.*

In MySQL 5.7, it is not possible to set @@session.sql\_log\_bin within a transaction or subquery. (Bug #53437)

- `sql_log_off`

|                         |                         |                          |
|-------------------------|-------------------------|--------------------------|
| <b>System Variable</b>  | <b>Name</b>             | <code>sql_log_off</code> |
|                         | <b>Variable Scope</b>   | Global, Session          |
|                         | <b>Dynamic Variable</b> | Yes                      |
| <b>Permitted Values</b> | <b>Type</b>             | boolean                  |
|                         | <b>Default</b>          | 0                        |

This variable controls whether logging to the general query log is done. The default value is 0 (do logging). To change logging for the current session, change the session value of this variable. The session user must have the [SUPER](#) privilege to set this option. The default value is 0.

|                                       |                     | NO_ZERO_IN_DATE  |                         |
|                                       |                     | ONLY_FULL_GROUP_BY   |                         |
|                                       |                     | PAD_CHAR_TO_FULL_LENGTH  |                         |
|                                       |                     | PIPES_AS_CONCAT  |                         |
|                                       |                     | REAL_AS_FLOAT  |                         |
|                                       |                     | STRICT_ALL_TABLES  |                         |

STRICT\_TRANS\_TABLES

The current server SQL mode, which can be set dynamically. For details, see [Section 6.1.8, “Server SQL Modes”](#).

**Note**

MySQL installation programs may configure the SQL mode during the installation process. For example, `mysql_install_db` creates a default option file named `my.cnf` in the base installation directory. This file contains a line that sets the SQL mode; see [Section 5.4.2, “mysql\\_install\\_db — Initialize MySQL Data Directory”](#).

If the SQL mode differs from the default or from what you expect, check for a setting in an option file that the server reads at startup.

- `sql_notes`

If set to 1 (the default), warnings of `Note` level increment `warning_count` and the server records them. If set to 0, `Note` warnings do not increment `warning_count` and the server does not record them. `mysqldump` includes output to set this variable to 0 so that reloading the dump file does not produce warnings for events that do not affect the integrity of the reload operation.

- `sql_quote_show_create`

If set to 1 (the default), the server quotes identifiers for `SHOW CREATE TABLE` and `SHOW CREATE DATABASE` statements. If set to 0, quoting is disabled. This option is enabled by default so that replication works for identifiers that require quoting. See [Section 14.7.5.10, “SHOW CREATE TABLE Syntax”](#), and [Section 14.7.5.6, “SHOW CREATE DATABASE Syntax”](#).

- `sql_safe_updates`

If set to 1, MySQL aborts `UPDATE` or `DELETE` statements that do not use a key in the `WHERE` clause or a `LIMIT` clause. (Specifically, `UPDATE` statements must have a `WHERE` clause that uses a key or a `LIMIT` clause, or both. `DELETE` statements must have both.) This makes it possible to catch `UPDATE` or `DELETE` statements where keys are not used properly and that would probably change or delete a large number of rows. The default value is 0.

- `sql_select_limit`

|                         |                         |                               |
|-------------------------|-------------------------|-------------------------------|
| <b>System Variable</b>  | <b>Name</b>             | <code>sql_select_limit</code> |
|                         | <b>Variable Scope</b>   | Global, Session               |
|                         | <b>Dynamic Variable</b> | Yes                           |
| <b>Permitted Values</b> | <b>Type</b>             | integer                       |

The maximum number of rows to return from `SELECT` statements. The default value for a new connection is the maximum number of rows that the server permits per table. Typical default values are  $(2^{32})-1$  or  $(2^{64})-1$ . If you have changed the limit, the default value can be restored by assigning a value of `DEFAULT`.

If a `SELECT` has a `LIMIT` clause, the `LIMIT` takes precedence over the value of `sql_select_limit`.

- `sql_warnings`

This variable controls whether single-row `INSERT` statements produce an information string if warnings occur. The default is 0. Set the value to 1 to produce an information string.

- `ssl_ca`

|                            |                                 |                     |
|----------------------------|---------------------------------|---------------------|
| <b>Command-Line Format</b> | <code>--ssl-ca=file_name</code> |                     |
| <b>System Variable</b>     | <b>Name</b>                     | <code>ssl_ca</code> |
|                            | <b>Variable Scope</b>           | Global              |
|                            | <b>Dynamic Variable</b>         | No                  |
| <b>Permitted Values</b>    | <b>Type</b>                     | file name           |

The path to a file with a list of trusted SSL CAs.

- `ssl_capath`

|                            |                                    |                         |
|----------------------------|------------------------------------|-------------------------|
| <b>Command-Line Format</b> | <code>--ssl-capath=dir_name</code> |                         |
| <b>System Variable</b>     | <b>Name</b>                        | <code>ssl_capath</code> |
|                            | <b>Variable Scope</b>              | Global                  |
|                            | <b>Dynamic Variable</b>            | No                      |
| <b>Permitted Values</b>    | <b>Type</b>                        | directory name          |

The path to a directory that contains trusted SSL CA certificates in PEM format.

- `ssl_cert`

|                            |                                   |                       |
|----------------------------|-----------------------------------|-----------------------|
| <b>Command-Line Format</b> | <code>--ssl-cert=file_name</code> |                       |
| <b>System Variable</b>     | <b>Name</b>                       | <code>ssl_cert</code> |
|                            | <b>Variable Scope</b>             | Global                |
|                            | <b>Dynamic Variable</b>           | No                    |
| <b>Permitted Values</b>    | <b>Type</b>                       | file name             |

The name of the SSL certificate file to use for establishing a secure connection.

- `ssl_cipher`

|                            |                                |                         |
|----------------------------|--------------------------------|-------------------------|
| <b>Command-Line Format</b> | <code>--ssl-cipher=name</code> |                         |
| <b>System Variable</b>     | <b>Name</b>                    | <code>ssl_cipher</code> |
|                            | <b>Variable Scope</b>          | Global                  |
|                            | <b>Dynamic Variable</b>        | No                      |
| <b>Permitted Values</b>    | <b>Type</b>                    | string                  |

A list of permissible ciphers to use for SSL encryption.

- `ssl_crl`

|                            |                                     |                      |
|----------------------------|-------------------------------------|----------------------|
| <b>Command-Line Format</b> | <code>--ssl-crl=800file_name</code> |                      |
| <b>System Variable</b>     | <b>Name</b>                         | <code>ssl_crl</code> |

|                         |                         |           |
|-------------------------|-------------------------|-----------|
|                         | <b>Variable Scope</b>   | Global    |
|                         | <b>Dynamic Variable</b> | No        |
| <b>Permitted Values</b> | <b>Type</b>             | file name |

The path to a file containing certificate revocation lists in PEM format. Revocation lists work for MySQL distributions compiled using OpenSSL (but not yaSSL). See [Section 7.4.1, “OpenSSL Versus yaSSL”](#).

- `ssl_crlpath`

|                            |                                     |                          |
|----------------------------|-------------------------------------|--------------------------|
| <b>Command-Line Format</b> | <code>--ssl-crlpath=dir_name</code> |                          |
| <b>System Variable</b>     | <b>Name</b>                         | <code>ssl_crlpath</code> |
|                            | <b>Variable Scope</b>               | Global                   |
|                            | <b>Dynamic Variable</b>             | No                       |
| <b>Permitted Values</b>    | <b>Type</b>                         | directory name           |

The path to a directory that contains files containing certificate revocation lists in PEM format. Revocation lists work for MySQL distributions compiled using OpenSSL (but not yaSSL). See [Section 7.4.1, “OpenSSL Versus yaSSL”](#).

- `ssl_key`

|                            |                                  |                      |
|----------------------------|----------------------------------|----------------------|
| <b>Command-Line Format</b> | <code>--ssl-key=file_name</code> |                      |
| <b>System Variable</b>     | <b>Name</b>                      | <code>ssl_key</code> |
|                            | <b>Variable Scope</b>            | Global               |
|                            | <b>Dynamic Variable</b>          | No                   |
| <b>Permitted Values</b>    | <b>Type</b>                      | file name            |

The name of the SSL key file to use for establishing a secure connection.

- `storage_engine`

|                         |                         |                             |
|-------------------------|-------------------------|-----------------------------|
| <b>Removed</b>          | 5.7.5                   |                             |
| <b>System Variable</b>  | <b>Name</b>             | <code>storage_engine</code> |
|                         | <b>Variable Scope</b>   | Global, Session             |
|                         | <b>Dynamic Variable</b> | Yes                         |
| <b>Permitted Values</b> | <b>Type</b>             | enumeration                 |
|                         | <b>Default</b>          | InnoDB                      |

This variable is deprecated and was removed in MySQL 5.7.5. Use `default_storage_engine` instead.

- `stored_program_cache`

|                            |                                       |
|----------------------------|---------------------------------------|
| <b>Command-Line Format</b> | <code>--stored-program-cache=#</code> |
|----------------------------|---------------------------------------|

|                                       |                         |                                   |
|---------------------------------------|-------------------------|-----------------------------------|
| <b>System Variable</b>                | <b>Name</b>             | <code>stored_program_cache</code> |
|                                       | <b>Variable Scope</b>   | Global                            |
|                                       | <b>Dynamic Variable</b> | Yes                               |
| <b>Permitted Values (&lt;= 5.7.5)</b> | <b>Type</b>             | integer                           |
|                                       | <b>Default</b>          | <code>256</code>                  |
|                                       | <b>Min Value</b>        | <code>256</code>                  |
|                                       | <b>Max Value</b>        | <code>524288</code>               |
| <b>Permitted Values (&gt;= 5.7.6)</b> | <b>Type</b>             | integer                           |
|                                       | <b>Default</b>          | <code>256</code>                  |
|                                       | <b>Min Value</b>        | <code>16</code>                   |
|                                       | <b>Max Value</b>        | <code>524288</code>               |

Sets a soft upper limit for the number of cached stored routines per connection. The value of this variable is specified in terms of the number of stored routines held in each of the two caches maintained by the MySQL Server for, respectively, stored procedures and stored functions.

Whenever a stored routine is executed this cache size is checked before the first or top-level statement in the routine is parsed; if the number of routines of the same type (stored procedures or stored functions according to which is being executed) exceeds the limit specified by this variable, the corresponding cache is flushed and memory previously allocated for cached objects is freed. This allows the cache to be flushed safely, even when there are dependencies between stored routines.

- `super_read_only`

|                            |  |                              |
|----------------------------|--|------------------------------|
| <b>Introduced</b>          | 5.7.8                                      |                              |
| <b>Command-Line Format</b> | <code>--super_read_only[={OFF ON} ]</code> |                              |
| <b>System Variable</b>     | <b>Name</b>                                | <code>super_read_only</code> |
|                            | <b>Variable Scope</b>                      | Global                       |
|                            | <b>Dynamic Variable</b>                    | Yes                          |
| <b>Permitted Values</b>    | <b>Type</b>                                | boolean                      |
|                            | <b>Default</b>                             | <code>OFF</code>             |

If the `read_only` system variable is enabled, the server permits client updates only from users who have the `SUPER` privilege. If the `super_read_only` system variable is also enabled, the server prohibits client updates even from users who have `SUPER`. See the description of the `read_only` system variable for a description of read-only mode and information about how `read_only` and `super_read_only` interact.

Changes to `super_read_only` on a master server are not replicated to slave servers. The value can be set on a slave server independent of the setting on the master.

- `sync_frm`

|                            |                         |                       |
|----------------------------|-------------------------|-----------------------|
| <b>Deprecated</b>          | 5.7.6                   |                       |
| <b>Command-Line Format</b> | <code>--sync_frm</code> |                       |
| <b>System Variable</b>     | <b>Name</b>             | <code>sync_frm</code> |
|                            | <b>Variable Scope</b>   | Global                |
|                            | <b>Dynamic Variable</b> | Yes                   |
| <b>Permitted Values</b>    | <b>Type</b>             | boolean               |
|                            | <b>Default</b>          | <code>TRUE</code>     |

If this variable is set to 1, when any nontemporary table is created its `.frm` file is synchronized to disk (using `fdatasync()`). This is slower but safer in case of a crash. The default is 1.

This variable is deprecated in MySQL 5.7.6 and will be removed in a future version of MySQL (when `.frm` files become obsolete).

- `system_time_zone`

|                         |                         |                               |
|-------------------------|-------------------------|-------------------------------|
| <b>System Variable</b>  | <b>Name</b>             | <code>system_time_zone</code> |
|                         | <b>Variable Scope</b>   | Global                        |
|                         | <b>Dynamic Variable</b> | No                            |
| <b>Permitted Values</b> | <b>Type</b>             | string                        |

The server system time zone. When the server begins executing, it inherits a time zone setting from the machine defaults, possibly modified by the environment of the account used for running the server or the startup script. The value is used to set `system_time_zone`. Typically the time zone is specified by the `TZ` environment variable. It also can be specified using the `--timezone` option of the `mysqld_safe` script.

The `system_time_zone` variable differs from `time_zone`. Although they might have the same value, the latter variable is used to initialize the time zone for each client that connects. See [Section 11.6, “MySQL Server Time Zone Support”](#).

- `table_definition_cache`

|                         |                         |                                     |
|-------------------------|-------------------------|-------------------------------------|
| <b>System Variable</b>  | <b>Name</b>             | <code>table_definition_cache</code> |
|                         | <b>Variable Scope</b>   | Global                              |
|                         | <b>Dynamic Variable</b> | Yes                                 |
| <b>Permitted Values</b> | <b>Type</b>             | integer                             |
|                         | <b>Default</b>          | <code>-1 (autosized)</code>         |
|                         | <b>Min Value</b>        | <code>400</code>                    |
|                         | <b>Max Value</b>        | <code>524288</code>                 |

The number of table definitions (from `.frm` files) that can be stored in the definition cache. If you use a large number of tables, you can create a large table definition cache to speed up opening of tables. The table definition cache takes less space and does not use file descriptors, unlike the normal table

cache. The minimum value is 400. The default value is based on the following formula, capped to a limit of 2000:

```
400 + (table_open_cache / 2)
```

For [InnoDB](#), [table\\_definition\\_cache](#) acts as a soft limit for the number of open table instances in the [InnoDB](#) data dictionary cache. If the number of open table instances exceeds the [table\\_definition\\_cache](#) setting, the LRU mechanism begins to mark table instances for eviction and eventually removes them from the data dictionary cache. The limit helps address situations in which significant amounts of memory would be used to cache rarely used table instances until the next server restart. The number of table instances with cached metadata could be higher than the limit defined by [table\\_definition\\_cache](#), because [InnoDB](#) system table instances and parent and child table instances with foreign key relationships are not placed on the LRU list and are not subject to eviction from memory.

Additionally, [table\\_definition\\_cache](#) defines a soft limit for the number of [InnoDB](#) file-per-table tablespaces that can be open at one time, which is also controlled by [innodb\\_open\\_files](#). If both [table\\_definition\\_cache](#) and [innodb\\_open\\_files](#) are set, the highest setting is used. If neither variable is set, [table\\_definition\\_cache](#), which has a higher default value, is used. If the number of open tablespace file handles exceeds the limit defined by [table\\_definition\\_cache](#) or [innodb\\_open\\_files](#), the LRU mechanism searches the tablespace file LRU list for files that are fully flushed and are not currently being extended. This process is performed each time a new tablespace is opened. If there are no “inactive” tablespaces, no tablespace files are closed.

- [table\\_open\\_cache](#)

|                         |                         |                                  |

| <b>System Variable</b>  | <b>Name</b>             | <a href="#">table_open_cache</a> |
|                         | <b>Variable Scope</b>   | Global                           |
|                         | <b>Dynamic Variable</b> | Yes                              |
| <b>Permitted Values</b> | <b>Type</b>             | integer                          |
|                         | <b>Default</b>          | <a href="#">2000</a>             |
|                         | <b>Min Value</b>        | <a href="#">1</a>                |
|                         | <b>Max Value</b>        | <a href="#">524288</a>           |

The number of open tables for all threads. Increasing this value increases the number of file descriptors that [mysqld](#) requires. You can check whether you need to increase the table cache by checking the [Opened\\_tables](#) status variable. See [Section 6.1.7, “Server Status Variables”](#). If the value of [Opened\\_tables](#) is large and you do not use [FLUSH TABLES](#) often (which just forces all tables to be closed and reopened), then you should increase the value of the [table\\_open\\_cache](#) variable. For more information about the table cache, see [Section 9.4.3.1, “How MySQL Opens and Closes Tables”](#).

- [table\\_open\\_cache\\_instances](#)

|                                       |                         |  |

|  | <b>Max Value</b>                      | 64      |
|  | <b>Permitted Values (&gt;= 5.7.8)</b> |         |
|  | <b>Type</b>                           | integer |
|  | <b>Default</b>                        | 16      |
|  | <b>Min Value</b>                      | 1       |
|  | <b>Max Value</b>                      | 64      |

The number of open tables cache instances. To improve scalability by reducing contention among sessions, the open tables cache can be partitioned into several smaller cache instances of size `table_open_cache / table_open_cache_instances`. A session needs to lock only one instance to access it for DML statements. This segments cache access among instances, permitting higher performance for operations that use the cache when there are many sessions accessing tables. (DDL statements still require a lock on the entire cache, but such statements are much less frequent than DML statements.)

A value of 8 or 16 is recommended on systems that routinely use 16 or more cores.

- `thread_cache_size`

|                            |                                    |                                |
|----------------------------|------------------------------------|--------------------------------|
| <b>Command-Line Format</b> | <code>--thread_cache_size=#</code> |                                |
| <b>System Variable</b>     | <b>Name</b>                        | <code>thread_cache_size</code> |
|                            | <b>Variable Scope</b>              | Global                         |
|                            | <b>Dynamic Variable</b>            | Yes                            |
| <b>Permitted Values</b>    | <b>Type</b>                        | integer                        |
|                            | <b>Default</b>                     | -1 (autosized)                 |
|                            | <b>Min Value</b>                   | 0                              |
|                            | <b>Max Value</b>                   | 16384                          |

How many threads the server should cache for reuse. When a client disconnects, the client's threads are put in the cache if there are fewer than `thread_cache_size` threads there. Requests for threads are satisfied by reusing threads taken from the cache if possible, and only when the cache is empty is a new thread created. This variable can be increased to improve performance if you have a lot of new connections. Normally, this does not provide a notable performance improvement if you have a good thread implementation. However, if your server sees hundreds of connections per second you should normally set `thread_cache_size` high enough so that most new connections use cached threads. By examining the difference between the `Connections` and `Threads_created` status variables, you can see how efficient the thread cache is. For details, see [Section 6.1.7, “Server Status Variables”](#).

The default value is based on the following formula, capped to a limit of 100:

```
8 + (max_connections / 100)
```

This variable has no effect for the embedded server (`libmysqld`) and as of MySQL 5.7.2 is no longer visible within the embedded server.

- `thread_concurrency`

|                            |                                     |                                 |
|----------------------------|-------------------------------------|---------------------------------|
| <b>Deprecated</b>          | 5.6.1                               |                                 |
| <b>Removed</b>             | 5.7.2                               |                                 |
| <b>Command-Line Format</b> | <code>--thread_concurrency=#</code> |                                 |
| <b>System Variable</b>     | <b>Name</b>                         | <code>thread_concurrency</code> |
|                            | <b>Variable Scope</b>               | Global                          |
|                            | <b>Dynamic Variable</b>             | No                              |
| <b>Permitted Values</b>    | <b>Type</b>                         | integer                         |
|                            | <b>Default</b>                      | 10                              |
|                            | <b>Min Value</b>                    | 1                               |
|                            | <b>Max Value</b>                    | 512                             |

This variable is specific to Solaris 8 and earlier systems, for which `mysqld` invokes the `thr_setconcurrency()` function with the variable value. This function enables applications to give the threads system a hint about the desired number of threads that should be run at the same time. Current Solaris versions document this as having no effect.

This variable was removed in MySQL 5.7.2.

- `thread_handling`

|                                       |                                     |  |
|---------------------------------------|-------------------------------------|--|
| <b>Command-Line Format</b>            | <code>--thread_handling=name</code> |  |
| <b>System Variable</b>                | <b>Name</b>                         | <code>thread_handling</code>           |
|                                       | <b>Variable Scope</b>               | Global                                 |
|                                       | <b>Dynamic Variable</b>             | No                                     |
| <b>Permitted Values (&lt;= 5.7.8)</b> | <b>Type</b>                         | enumeration                            |
|                                       | <b>Default</b>                      | <code>one-thread-per-connection</code> |
|                                       | <b>Valid Values</b>                 | <code>no-threads</code>                |
|                                       |                                     | <code>one-thread-per-connection</code> |
| <b>Permitted Values (&gt;= 5.7.9)</b> | <b>Type</b>                         | enumeration                            |
|                                       | <b>Default</b>                      | <code>one-thread-per-connection</code> |
|                                       | <b>Valid Values</b>                 | <code>no-threads</code>                |
|                                       |                                     | <code>one-thread-per-connection</code> |
|                                       |                                     | <code>dynamically-loaded</code>        |

The thread-handling model used by the server for connection threads. The permissible values are `no-threads` (the server uses a single thread to handle one connection) and `one-thread-per-connection` (the server uses one thread to handle each client connection). `no-threads` is useful for debugging under Linux; see [Section 27.5, “Debugging and Porting MySQL”](#).

This variable has no effect for the embedded server (`libmysqld`) and as of MySQL 5.7.2 is no longer visible within the embedded server.

- `thread_pool_algorithm`

|                            |  |                                    |
|----------------------------|--|------------------------------------|
| <b>Introduced</b>          | 5.7.9                                  |                                    |
| <b>Command-Line Format</b> | <code>--thread_pool_algorithm=#</code> |                                    |
| <b>System Variable</b>     | <b>Name</b>                            | <code>thread_pool_algorithm</code> |
|                            | <b>Variable Scope</b>                  | Global                             |
|                            | <b>Dynamic Variable</b>                | No                                 |
| <b>Permitted Values</b>    | <b>Type</b>                            | integer                            |
|                            | <b>Default</b>                         | 0                                  |
|                            | <b>Min Value</b>                       | 0                                  |
|                            | <b>Max Value</b>                       | 1                                  |

This variable controls which algorithm the thread pool plugin uses:

- A value of 0 (the default) uses a conservative low-concurrency algorithm which is most well tested and is known to produce very good results.
- A value of 1 increases the concurrency and uses a more aggressive algorithm which at times has been known to perform 5–10% better on optimal thread counts, but has degrading performance as the number of connections increases. Its use should be considered as experimental and not supported.

This variable was added in MySQL 5.7.9. It is available only if the thread pool plugin is enabled. See [Section 6.5.4, “MySQL Enterprise Thread Pool”](#)

- `thread_pool_high_priority_connection`

|                            |   |   |
|----------------------------|---|---|
| <b>Introduced</b>          | 5.7.9   |   |
| <b>Command-Line Format</b> | <code>--thread_pool_high_priority_connection=#</code> |   |
| <b>System Variable</b>     | <b>Name</b>   | <code>thread_pool_high_priority_connection</code> |
|                            | <b>Variable Scope</b>                                 | Global, Session                                   |
|                            | <b>Dynamic Variable</b>                               | Yes   |
| <b>Permitted Values</b>    | <b>Type</b>   | integer   |
|                            | <b>Default</b>  | 0   |
|                            | <b>Min Value</b>                                      | 0   |
|                            | <b>Max Value</b>                                      | 1   |

This variable affects queuing of new statements prior to execution. If the value is 0 (false, the default), statement queuing uses both the low-priority and high-priority queues. If the value is 1 (true), queued statements always go to the high-priority queue.

This variable was added in MySQL 5.7.9. It is available only if the thread pool plugin is enabled. See [Section 6.5.4, “MySQL Enterprise Thread Pool”](#)

- `thread_pool_max_unused_threads`

|                            |   |   |
|----------------------------|---|---|
| <b>Introduced</b>          | 5.7.9   |   |
| <b>Command-Line Format</b> | <code>--thread_pool_max_unused_threads=#</code> |   |
| <b>System Variable</b>     | <b>Name</b>                                     | <code>thread_pool_max_unused_threads</code> |
|                            | <b>Variable Scope</b>                           | Global                                      |
|                            | <b>Dynamic Variable</b>                         | Yes   |
| <b>Permitted Values</b>    | <b>Type</b>                                     | integer                                     |
|                            | <b>Default</b>                                  | 0   |
|                            | <b>Min Value</b>                                | 0   |
|                            | <b>Max Value</b>                                | 4096  |

The maximum permitted number of unused threads in the thread pool. This variable makes it possible to limit the amount of memory used by sleeping threads.

A value of 0 (the default) means no limit on the number of sleeping threads. A value of *N* where *N* is greater than 0 means 1 consumer thread and *N*−1 reserve threads. In this case, if a thread is ready to sleep but the number of sleeping threads is already at the maximum, the thread exits rather than going to sleep.

A sleeping thread is either sleeping as a consumer thread or a reserve thread. The thread pool permits one thread to be the consumer thread when sleeping. If a thread goes to sleep and there is no existing consumer thread, it will sleep as a consumer thread. When a thread must be woken up, a consumer thread is selected if there is one. A reserve thread is selected only when there is no consumer thread to wake up.

This variable was added in MySQL 5.7.9. It is available only if the thread pool plugin is enabled. See [Section 6.5.4, “MySQL Enterprise Thread Pool”](#)

- `thread_pool_prio_kickup_timer`

|                            |  |  |
|----------------------------|--|--|
| <b>Introduced</b>          | 5.7.9  |  |
| <b>Command-Line Format</b> | <code>--thread_pool_prio_kickup_timer=#</code> |  |
| <b>System Variable</b>     | <b>Name</b>                                    | <code>thread_pool_prio_kickup_timer</code> |
|                            | <b>Variable Scope</b>                          | Global, Session                            |
|                            | <b>Dynamic Variable</b>                        | Yes  |
| <b>Permitted Values</b>    | <b>Type</b>                                    | integer                                    |
|                            | <b>Default</b>                                 | 1000                                       |
|                            | <b>Min Value</b>                               | 0  |
|                            | <b>Max Value</b>                               | 4294967294                                 |

This variable affects statements waiting for execution in the low-priority queue. The value is the number of milliseconds before a waiting statement is moved to the high-priority queue. The default is 1000 (1 second). The range of values is 0 to  $2^{32} - 2$ .

This variable was added in MySQL 5.7.9. It is available only if the thread pool plugin is enabled. See [Section 6.5.4, “MySQL Enterprise Thread Pool”](#)

- `thread_pool_size`

|                            |                                   |                               |
|----------------------------|-----------------------------------|-------------------------------|
| <b>Introduced</b>          | 5.7.9                             |                               |
| <b>Command-Line Format</b> | <code>--thread_pool_size=#</code> |                               |
| <b>System Variable</b>     | <b>Name</b>                       | <code>thread_pool_size</code> |
|                            | <b>Variable Scope</b>             | Global                        |
|                            | <b>Dynamic Variable</b>           | No                            |
| <b>Permitted Values</b>    | <b>Type</b>                       | integer                       |
|                            | <b>Default</b>                    | 16                            |
|                            | <b>Min Value</b>                  | 1                             |
|                            | <b>Max Value</b>                  | 64                            |

The number of thread groups in the thread pool. This is the most important parameter controlling thread pool performance. It affects how many statements can execute simultaneously. The default value is 16, with a range from 1 to 64 of permissible values. If a value outside this range is specified, the thread pool plugin does not load and the server writes a message to the error log.

This variable was added in MySQL 5.7.9. It is available only if the thread pool plugin is enabled. See [Section 6.5.4, “MySQL Enterprise Thread Pool”](#)

- `thread_pool_stall_limit`

|                            |  |                                      |
|----------------------------|--|--------------------------------------|
| <b>Introduced</b>          | 5.7.9                                    |                                      |
| <b>Command-Line Format</b> | <code>--thread_pool_stall_limit=#</code> |                                      |
| <b>System Variable</b>     | <b>Name</b>                              | <code>thread_pool_stall_limit</code> |
|                            | <b>Variable Scope</b>                    | Global                               |
|                            | <b>Dynamic Variable</b>                  | Yes                                  |
| <b>Permitted Values</b>    | <b>Type</b>                              | integer                              |
|                            | <b>Default</b>                           | 6                                    |
|                            | <b>Min Value</b>                         | 4                                    |
|                            | <b>Max Value</b>                         | 600                                  |

This variable affects executing statements. The value is the amount of time a statement has to finish after starting to execute before it becomes defined as stalled, at which point the thread pool permits the thread group to begin executing another statement. The value is measured in 10 millisecond units, so a value of 6 (the default) means 60ms. The range of values is 4 to 600 (40ms to 6s). Short wait values permit threads to start more quickly. Short values are also better for avoiding deadlock

situations. Long wait values are useful for workloads that include long-running statements, to avoid starting too many new statements while the current ones execute.

This variable was added in MySQL 5.7.9. It is available only if the thread pool plugin is enabled. See [Section 6.5.4, “MySQL Enterprise Thread Pool”](#)

- `thread_stack`

|  |                               |                           |
|--|-------------------------------|---------------------------|
| <b>Command-Line Format</b>                 | <code>--thread_stack=#</code> |                           |
| <b>System Variable</b>                     | <b>Name</b>                   | <code>thread_stack</code> |
|  | <b>Variable Scope</b>         | Global                    |
|  | <b>Dynamic Variable</b>       | No                        |
| <b>Permitted Values</b> (32-bit platforms) | <b>Type</b>                   | integer                   |
|  | <b>Default</b>                | 196608                    |
|  | <b>Min Value</b>              | 131072                    |
|  | <b>Max Value</b>              | 4294967295                |
|  | <b>Block Size</b>             | 1024                      |
| <b>Permitted Values</b> (64-bit platforms) | <b>Type</b>                   | integer                   |
|  | <b>Default</b>                | 262144                    |
|  | <b>Min Value</b>              | 131072                    |
|  | <b>Max Value</b>              | 18446744073709551615      |
|  | <b>Block Size</b>             | 1024                      |

The stack size for each thread. The default of 192KB (256KB for 64-bit systems) is large enough for normal operation. If the thread stack size is too small, it limits the complexity of the SQL statements that the server can handle, the recursion depth of stored procedures, and other memory-consuming actions.

- `time_format`

This variable is unused. It is deprecated and will be removed in a future MySQL release.

- `time_zone`

|                         |                         |                        |
|-------------------------|-------------------------|------------------------|
| <b>System Variable</b>  | <b>Name</b>             | <code>time_zone</code> |
|                         | <b>Variable Scope</b>   | Global, Session        |
|                         | <b>Dynamic Variable</b> | Yes                    |
| <b>Permitted Values</b> | <b>Type</b>             | string                 |

The current time zone. This variable is used to initialize the time zone for each client that connects. By default, the initial value of this is `'SYSTEM'` (which means, “use the value of `system_time_zone`”). The value can be specified explicitly at server startup with the `--default-time-zone` option. See [Section 11.6, “MySQL Server Time Zone Support”](#).

- `timed_mutexes`

|                            |                              |                            |
|----------------------------|------------------------------|----------------------------|
| <b>Deprecated</b>          | 5.6.20                       |                            |
| <b>Removed</b>             | 5.7.5                        |                            |
| <b>Command-Line Format</b> | <code>--timed_mutexes</code> |                            |
| <b>System Variable</b>     | <b>Name</b>                  | <code>timed_mutexes</code> |
|                            | <b>Variable Scope</b>        | Global                     |
|                            | <b>Dynamic Variable</b>      | Yes                        |
| <b>Permitted Values</b>    | <b>Type</b>                  | boolean                    |
|                            | <b>Default</b>               | <code>OFF</code>           |

This deprecated variable has no use and was removed in MySQL 5.7.5.

- `timestamp`

|                         |                         |                        |
|-------------------------|-------------------------|------------------------|
| <b>System Variable</b>  | <b>Name</b>             | <code>timestamp</code> |
|                         | <b>Variable Scope</b>   | Session                |
|                         | <b>Dynamic Variable</b> | Yes                    |
| <b>Permitted Values</b> | <b>Type</b>             | numeric                |

Set the time for this client. This is used to get the original timestamp if you use the binary log to restore rows. `timestamp_value` should be a Unix epoch timestamp (a value like that returned by `UNIX_TIMESTAMP()`), not a value in 'YYYY-MM-DD hh:mm:ss' format) or `DEFAULT`.

Setting `timestamp` to a constant value causes it to retain that value until it is changed again. Setting `timestamp` to `DEFAULT` causes its value to be the current date and time as of the time it is accessed.

In MySQL 5.7, `timestamp` is a `DOUBLE` rather than `BIGINT` because its value includes a microseconds part.

`SET timestamp` affects the value returned by `NOW()` but not by `SYSDATE()`. This means that timestamp settings in the binary log have no effect on invocations of `SYSDATE()`. The server can be started with the `--sysdate-is-now` option to cause `SYSDATE()` to be an alias for `NOW()`, in which case `SET timestamp` affects both functions.

- `tls_version`

|                                      |  |                                    |
|--------------------------------------|--|------------------------------------|
| <b>Introduced</b>                    | 5.7.10                                   |                                    |
| <b>Command-Line Format</b>           | <code>--tls_version=protocol_list</code> |                                    |
| <b>System Variable</b>               | <b>Name</b>                              | <code>tls_version</code>           |
|                                      | <b>Variable Scope</b>                    | Global                             |
|                                      | <b>Dynamic Variable</b>                  | No                                 |
| <b>Permitted Values</b><br>(OpenSSL) | <b>Type</b>                              | string                             |
|                                      | <b>Default</b>                           | <code>TLSv1,TLSv1.1,TLSv1.2</code> |

|                                    |                |               |
|------------------------------------|----------------|---------------|
| <b>Permitted Values</b><br>(yaSSL) | <b>Type</b>    | string        |
|                                    | <b>Default</b> | TLSv1,TLSv1.1 |

The protocols permitted by the server for encrypted connections. The value is a comma-separated list containing one or more protocol names. The protocols that can be named for this variable depend on the SSL library used to compile MySQL. For details, see [Section 7.4.3, “Secure Connection Protocols and Ciphers”](#).

- `tmp_table_size`

|                            |                                 |                             |
|----------------------------|---------------------------------|-----------------------------|
| <b>Command-Line Format</b> | <code>--tmp_table_size=#</code> |                             |
| <b>System Variable</b>     | <b>Name</b>                     | <code>tmp_table_size</code> |
|                            | <b>Variable Scope</b>           | Global, Session             |
|                            | <b>Dynamic Variable</b>         | Yes                         |
| <b>Permitted Values</b>    | <b>Type</b>                     | integer                     |
|                            | <b>Default</b>                  | 16777216                    |
|                            | <b>Min Value</b>                | 1024                        |
|                            | <b>Max Value</b>                | 18446744073709551615        |

The maximum size of internal in-memory temporary tables. This variable does not apply to user-created `MEMORY` tables.

The actual limit is determined from whichever of the values of `tmp_table_size` and `max_heap_table_size` is smaller. If an in-memory temporary table exceeds the limit, MySQL automatically converts it to an on-disk temporary table. As of MySQL 5.7.5, the `internal_tmp_disk_storage_engine` option defines the storage engine used for on-disk temporary tables. Prior to MySQL 5.7.5, the `MyISAM` storage engine is used.

Increase the value of `tmp_table_size` (and `max_heap_table_size` if necessary) if you do many advanced `GROUP BY` queries and you have lots of memory.

You can compare the number of internal on-disk temporary tables created to the total number of internal temporary tables created by comparing the values of the `Created_tmp_disk_tables` and `Created_tmp_tables` variables.

See also [Section 9.4.4, “Internal Temporary Table Use in MySQL”](#).

- `tmpdir`

|                            |                                |                     |
|----------------------------|--------------------------------|---------------------|
| <b>Command-Line Format</b> | <code>--tmpdir=dir_name</code> |                     |
| <b>System Variable</b>     | <b>Name</b>                    | <code>tmpdir</code> |
|                            | <b>Variable Scope</b>          | Global              |
|                            | <b>Dynamic Variable</b>        | No                  |
| <b>Permitted Values</b>    | <b>Type</b>                    | directory name      |

The directory used for temporary files and temporary tables. This variable can be set to a list of several paths that are used in round-robin fashion. Paths should be separated by colon characters (:) on Unix and semicolon characters (;) on Windows.

The multiple-directory feature can be used to spread the load between several physical disks. If the MySQL server is acting as a replication slave, you should not set `tmpdir` to point to a directory on a memory-based file system or to a directory that is cleared when the server host restarts. A replication slave needs some of its temporary files to survive a machine restart so that it can replicate temporary tables or `LOAD DATA INFILE` operations. If files in the temporary file directory are lost when the server restarts, replication fails. You can set the slave's temporary directory using the `slave_load_tmpdir` variable. In that case, the slave will not use the general `tmpdir` value and you can set `tmpdir` to a nonpermanent location.

- `transaction_alloc_block_size`

|  |   |   |
|--|---|---|
| <b>Command-Line Format</b>                           | <code>--transaction_alloc_block_size=#</code> |   |
| <b>System Variable</b>                               | <b>Name</b>                                   | <code>transaction_alloc_block_size</code> |
|  | <b>Variable Scope</b>                         | Global, Session                           |
|  | <b>Dynamic Variable</b>                       | Yes                                       |
| <b>Permitted Values</b> (>= 5.7.6)                   | <b>Type</b>                                   | integer                                   |
|  | <b>Default</b>                                | 8192                                      |
|  | <b>Min Value</b>                              | 1024                                      |
|  | <b>Max Value</b>                              | 131072                                    |
|  | <b>Block Size</b>                             | 1024                                      |
| <b>Permitted Values</b> (32-bit platforms, <= 5.7.5) | <b>Type</b>                                   | integer                                   |
|  | <b>Default</b>                                | 8192                                      |
|  | <b>Min Value</b>                              | 1024                                      |
|  | <b>Max Value</b>                              | 4294967295                                |
|  | <b>Block Size</b>                             | 1024                                      |
| <b>Permitted Values</b> (64-bit platforms, <= 5.7.5) | <b>Type</b>                                   | integer                                   |
|  | <b>Default</b>                                | 8192                                      |
|  | <b>Min Value</b>                              | 1024                                      |
|  | <b>Max Value</b>                              | 18446744073709551615                      |
|  | <b>Block Size</b>                             | 1024                                      |

The amount in bytes by which to increase a per-transaction memory pool which needs memory. See the description of `transaction_prealloc_size`.

- `transaction_prealloc_size`

|                            |  |  |
|----------------------------|--|--|
| <b>Command-Line Format</b> | <code>--transaction_prealloc_size=#</code> |  |
| <b>System Variable</b>     | <b>Name</b>                                | <code>transaction_prealloc_size</code> |

|  |                         |                      |
|--|-------------------------|----------------------|
|  | <b>Variable Scope</b>   | Global, Session      |
|  | <b>Dynamic Variable</b> | Yes                  |
| <b>Permitted Values</b> ( $\geq$ 5.7.6)                  | <b>Type</b>             | integer              |
|  | <b>Default</b>          | 4096                 |
|  | <b>Min Value</b>        | 1024                 |
|  | <b>Max Value</b>        | 131072               |
|  | <b>Block Size</b>       | 1024                 |
| <b>Permitted Values</b> (32-bit platforms, $\leq$ 5.7.5) | <b>Type</b>             | integer              |
|  | <b>Default</b>          | 4096                 |
|  | <b>Min Value</b>        | 1024                 |
|  | <b>Max Value</b>        | 4294967295           |
|  | <b>Block Size</b>       | 1024                 |
| <b>Permitted Values</b> (64-bit platforms, $\leq$ 5.7.5) | <b>Type</b>             | integer              |
|  | <b>Default</b>          | 4096                 |
|  | <b>Min Value</b>        | 1024                 |
|  | <b>Max Value</b>        | 18446744073709551615 |
|  | <b>Block Size</b>       | 1024                 |

There is a per-transaction memory pool from which various transaction-related allocations take memory. The initial size of the pool in bytes is `transaction_prealloc_size`. For every allocation that cannot be satisfied from the pool because it has insufficient memory available, the pool is increased by `transaction_alloc_block_size` bytes. When the transaction ends, the pool is truncated to `transaction_prealloc_size` bytes.

By making `transaction_prealloc_size` sufficiently large to contain all statements within a single transaction, you can avoid many `malloc()` calls.

- `transaction_write_set_extraction`

|  |   |   |
|--|---|---|
| <b>Introduced</b>                        | 5.7.6   |   |
| <b>Command-Line Format</b>               | <code>--transaction_write_set_extraction=[value]</code> |   |
| <b>System Variable</b>                   | <b>Name</b>   | <code>transaction_write_set_extraction</code> |
|  | <b>Variable Scope</b>                                   | Global, Session                               |
|  | <b>Dynamic Variable</b>                                 | Yes   |
| <b>Permitted Values</b> ( $\leq$ 5.7.13) | <b>Type</b>   | enumeration                                   |
|  | <b>Default</b>  | OFF   |

|  |                     |             |
|--|---------------------|-------------|
| <b>Permitted Values</b> ( $\geq$ 5.7.14) | <b>Valid Values</b> | OFF         |
|  |                     | MURMUR32    |
|  | <b>Type</b>         | enumeration |
|  | <b>Default</b>      | OFF         |
|  | <b>Valid Values</b> | OFF         |
|  |                     | MURMUR32    |
|  |                     | XXHASH64    |

Defines the algorithm used to generate a hash identifying the writes associated with a transaction. If you are using [Chapter 19, Group Replication](#), the hash value is used for Group Replication's distributed conflict detection and handling and thus on 64 bit systems, we recommend setting this to [XXHASH64](#) in order to avoid unnecessary hash collisions which result in certification failures and the roll back of user transactions. See [Section 19.7.1, “Group Replication Requirements”](#).

- `tx_isolation`

|                         |                         |                           |
|-------------------------|-------------------------|---------------------------|
| <b>System Variable</b>  | <b>Name</b>             | <code>tx_isolation</code> |
|                         | <b>Variable Scope</b>   | Global, Session           |
|                         | <b>Dynamic Variable</b> | Yes                       |
| <b>Permitted Values</b> | <b>Type</b>             | enumeration               |
|                         | <b>Default</b>          | REPEATABLE-READ           |
|                         | <b>Valid Values</b>     | READ-UNCOMMITTED          |
|                         |                         | READ-COMMITTED            |
|                         |                         | REPEATABLE-READ           |
|                         |                         | SERIALIZABLE              |

The default transaction isolation level. Defaults to [REPEATABLE-READ](#).

This variable can be set directly, or indirectly using the `SET TRANSACTION` statement. See [Section 14.3.6, “SET TRANSACTION Syntax”](#). If you set `tx_isolation` directly to an isolation level name that contains a space, the name should be enclosed within quotation marks, with the space replaced by a dash. For example:

```
SET tx_isolation = 'READ-COMMITTED';
```

Any unique prefix of a valid value may be used to set the value of this variable.

The default transaction isolation level can also be set at startup using the `--transaction-isolation` server option.

- `tx_read_only`

|                         |                         |                           |
|-------------------------|-------------------------|---------------------------|
| <b>System Variable</b>  | <b>Name</b>             | <code>tx_read_only</code> |
|                         | <b>Variable Scope</b>   | Global, Session           |
|                         | <b>Dynamic Variable</b> | Yes                       |
| <b>Permitted Values</b> | <b>Type</b>             | boolean                   |
|                         | <b>Default</b>          | OFF                       |

The default transaction access mode. The value can be `OFF` (read/write, the default) or `ON` (read only).

This variable can be set directly, or indirectly using the `SET TRANSACTION` statement. See [Section 14.3.6, “SET TRANSACTION Syntax”](#).

To set the default transaction access mode at startup, use the `--transaction-read-only` server option.

- `unique_checks`

|                         |                         |                            |
|-------------------------|-------------------------|----------------------------|
| <b>System Variable</b>  | <b>Name</b>             | <code>unique_checks</code> |
|                         | <b>Variable Scope</b>   | Global, Session            |
|                         | <b>Dynamic Variable</b> | Yes                        |
| <b>Permitted Values</b> | <b>Type</b>             | boolean                    |
|                         | <b>Default</b>          | <code>1</code>             |

If set to 1 (the default), uniqueness checks for secondary indexes in `InnoDB` tables are performed. If set to 0, storage engines are permitted to assume that duplicate keys are not present in input data. If you know for certain that your data does not contain uniqueness violations, you can set this to 0 to speed up large table imports to `InnoDB`.

Setting this variable to 0 does not *require* storage engines to ignore duplicate keys. An engine is still permitted to check for them and issue duplicate-key errors if it detects them.

- `updatable_views_with_limit`

|                            |   |   |
|----------------------------|---|---|
| <b>Command-Line Format</b> | <code>--updatable_views_with_limit=#</code> |   |
| <b>System Variable</b>     | <b>Name</b>                                 | <code>updatable_views_with_limit</code> |
|                            | <b>Variable Scope</b>                       | Global, Session                         |
|                            | <b>Dynamic Variable</b>                     | Yes                                     |
| <b>Permitted Values</b>    | <b>Type</b>                                 | boolean                                 |
|                            | <b>Default</b>                              | <code>1</code>                          |

This variable controls whether updates to a view can be made when the view does not contain all columns of the primary key defined in the underlying table, if the update statement contains a `LIMIT` clause. (Such updates often are generated by GUI tools.) An update is an `UPDATE` or `DELETE` statement. Primary key here means a `PRIMARY KEY`, or a `UNIQUE` index in which no column can contain `NULL`.

The variable can have two values:

- `1` or `YES`: Issue a warning only (not an error message). This is the default value.
  - `0` or `NO`: Prohibit the update.
- `validate_password_xxx`

The `validate_password` plugin implements a set of system variables having names of the form `validate_password_xxx`. These variables affect password testing by that plugin; see [Section 7.5.3.2, “Password Validation Plugin Options and Variables”](#).

- `validate_user_plugins`

|                         |                         |                                    |
|-------------------------|-------------------------|------------------------------------|
| <b>System Variable</b>  | <b>Name</b>             | <code>validate_user_plugins</code> |
|                         | <b>Variable Scope</b>   | Global                             |
|                         | <b>Dynamic Variable</b> | No                                 |
| <b>Permitted Values</b> | <b>Type</b>             | boolean                            |
|                         | <b>Default</b>          | ON                                 |

If this variable is enabled (the default), the server checks each user account and produces a warning if conditions are found that would make the account unusable:

- The account requires an authentication plugin that is not loaded.
- The account requires the `sha256_password` authentication plugin but the server was started with neither SSL nor RSA enabled as required by this plugin.

Enabling `validate_user_plugins` slows down server initialization and `FLUSH PRIVILEGES`. If you do not require the additional checking, you can disable this variable at startup to avoid the performance decrement.

- `version`

The version number for the server. The value might also include a suffix indicating server build or configuration information. `-log` indicates that one or more of the general log, slow query log, or binary log are enabled. `-debug` indicates that the server was built with debugging support enabled.

- `version_comment`

|                         |                         |                              |
|-------------------------|-------------------------|------------------------------|
| <b>System Variable</b>  | <b>Name</b>             | <code>version_comment</code> |
|                         | <b>Variable Scope</b>   | Global                       |
|                         | <b>Dynamic Variable</b> | No                           |
| <b>Permitted Values</b> | <b>Type</b>             | string                       |

The `CMake` configuration program has a `COMPILATION_COMMENT` option that permits a comment to be specified when building MySQL. This variable contains the value of that comment. See [Section 2.9.4, “MySQL Source-Configuration Options”](#).

- `version_compile_machine`

|                         |                         |                                      |
|-------------------------|-------------------------|--------------------------------------|
| <b>System Variable</b>  | <b>Name</b>             | <code>version_compile_machine</code> |
|                         | <b>Variable Scope</b>   | Global                               |
|                         | <b>Dynamic Variable</b> | No                                   |
| <b>Permitted Values</b> | <b>Type</b>             | string                               |

The type of the server binary.

- `version_compile_os`

---

|                        |             |  |
|------------------------|-------------|--|
| <b>System Variable</b> | <b>Name</b> | 817<br><code>version_compile_os</code> |
|------------------------|-------------|--|

|                         |                         |        |
|-------------------------|-------------------------|--------|
|                         | <b>Variable Scope</b>   | Global |
|                         | <b>Dynamic Variable</b> | No     |
| <b>Permitted Values</b> | <b>Type</b>             | string |

The type of operating system on which MySQL was built.

- `wait_timeout`

|                                   |                               |                           |
|-----------------------------------|-------------------------------|---------------------------|
| <b>Command-Line Format</b>        | <code>--wait_timeout=#</code> |                           |
| <b>System Variable</b>            | <b>Name</b>                   | <code>wait_timeout</code> |
|                                   | <b>Variable Scope</b>         | Global, Session           |
|                                   | <b>Dynamic Variable</b>       | Yes                       |
| <b>Permitted Values (Windows)</b> | <b>Type</b>                   | integer                   |
|                                   | <b>Default</b>                | 28800                     |
|                                   | <b>Min Value</b>              | 1                         |
|                                   | <b>Max Value</b>              | 2147483                   |
| <b>Permitted Values (Other)</b>   | <b>Type</b>                   | integer                   |
|                                   | <b>Default</b>                | 28800                     |
|                                   | <b>Min Value</b>              | 1                         |
|                                   | <b>Max Value</b>              | 31536000                  |

The number of seconds the server waits for activity on a noninteractive connection before closing it.

On thread startup, the session `wait_timeout` value is initialized from the global `wait_timeout` value or from the global `interactive_timeout` value, depending on the type of client (as defined by the `CLIENT_INTERACTIVE` connect option to `mysql_real_connect()`). See also `interactive_timeout`.

- `warning_count`

The number of errors, warnings, and notes that resulted from the last statement that generated messages. This variable is read only. See [Section 14.7.5.40, “SHOW WARNINGS Syntax”](#).

## 6.1.6 Using System Variables

The MySQL server maintains many system variables that indicate how it is configured. [Section 6.1.5, “Server System Variables”](#), describes the meaning of these variables. Each system variable has a default value. System variables can be set at server startup using options on the command line or in an option file. Most of them can be changed dynamically while the server is running by means of the `SET` statement, which enables you to modify operation of the server without having to stop and restart it. You can also use system variable values in expressions.

There are two scopes in which system variables exist. Global variables affect the overall operation of the server. Session variables affect its operation for individual client connections. A given system variable can have both a global and a session value. Global and session system variables are related as follows:

- When the server starts, it initializes each global variable to its default value. These defaults can be changed by options specified on the command line or in an option file. (See [Section 5.2.3, “Specifying Program Options”](#).)
- The server also maintains a set of session variables for each client that connects. The client's session variables are initialized at connect time using the current values of the corresponding global variables. For example, a client's SQL mode is controlled by the session `sql_mode` value, which is initialized when the client connects to the value of the global `sql_mode` value.

For some system variables, the session value is not initialized from the corresponding global value; if so, that is indicated in the variable description.

System variable values can be set globally at server startup by using options on the command line or in an option file. When you use a startup option to set a variable that takes a numeric value, the value can be given with a suffix of `K`, `M`, or `G` (either uppercase or lowercase) to indicate a multiplier of 1024, 1024<sup>2</sup> or 1024<sup>3</sup>; that is, units of kilobytes, megabytes, or gigabytes, respectively. Thus, the following command starts the server with a query cache size of 16 megabytes and a maximum packet size of one gigabyte:

```
mysqld --query_cache_size=16M --max_allowed_packet=1G
```

Within an option file, those variables are set like this:

```
[mysqld]
query_cache_size=16M
max_allowed_packet=1G
```

The lettercase of suffix letters does not matter; `16M` and `16m` are equivalent, as are `1G` and `1g`.

To restrict the maximum value to which a system variable can be set at runtime with the `SET` statement, specify this maximum by using an option of the form `--maximum-var_name=value` at server startup. For example, to prevent the value of `query_cache_size` from being increased to more than 32MB at runtime, use the option `--maximum-query_cache_size=32M`.

Many system variables are dynamic and can be changed at runtime by using the `SET` statement. For a list, see [Section 6.1.6.2, “Dynamic System Variables”](#). To change a system variable with `SET`, refer to it by name, optionally preceded by a modifier:

- To indicate that a variable is a global variable, precede its name by the `GLOBAL` keyword or the `@@global.` qualifier:

```
SET GLOBAL max_connections = 1000;
SET @@global.max_connections = 1000;
```

The `SUPER` privilege is required to set global variables.

- To indicate that a variable is a session variable, precede its name by the `SESSION` keyword or either the `@@session.` or `@@` qualifier:

```
SET SESSION sql_mode = 'TRADITIONAL';
SET @@session.sql_mode = 'TRADITIONAL';
SET @@sql_mode = 'TRADITIONAL';
```

Setting a session variable normally requires no special privilege, although there are exceptions that require the `SUPER` privilege (such as `sql_log_bin`). A client can change its own session variables, but not those of any other client.

- `LOCAL` and `@@local.` are synonyms for `SESSION` and `@@session..`
- If no modifier is present, `SET` changes the session variable. If the variable has no session value, an error occurs.

```
mysql> SET max_connections = 1000;
ERROR 1229 (HY000): Variable 'max_connections' is a
GLOBAL variable and should be set with SET GLOBAL
```

- An error occurs under these circumstances:
  - Use of `SET GLOBAL` (or `@@global.`) when setting a variable that has only a session value
  - Omission of `GLOBAL` (or `@@global.`) when setting a variable that has only a global value
  - Use of `SET SESSION` (or `@@SESSION.`) when setting a variable that has only a global value

The preceding modifiers apply only to system variables. An error occurs for attempts to apply them to user-defined variables, stored procedure or function parameters, or stored program local variables.

A `SET` statement can contain multiple variable assignments, separated by commas. This statement assigns values to a user-defined variable and a system variable:

```
SET @x = 1, SESSION sql_mode = '';
```

If you set multiple system variables, the most recent `GLOBAL` or `SESSION` modifier in the statement is used for following assignments that have no modifier specified.

Examples of multiple-variable assignment:

```
SET GLOBAL sort_buffer_size = 1000000, SESSION sort_buffer_size = 1000000;
SET @@global.sort_buffer_size = 1000000, @@local.sort_buffer_size = 1000000;
SET GLOBAL max_connections = 1000, sort_buffer_size = 1000000;
```

If any variable assignment in a `SET` statement fails, the entire statement fails and no variables are changed.

If you change a session system variable, the value remains in effect within your session until you change the variable to a different value or the session ends. The change has no effect on other sessions.

If you change a global system variable, the value is remembered and used for new sessions until you change the variable to a different value or the server exits. The change is visible to any client that accesses the global variable. However, the change affects the corresponding session variable only for clients that connect after the change. The global variable change does not affect the session variable for any current client sessions (not even the session within which the `SET GLOBAL` statement occurred).

To make a global system variable setting permanent so that it applies across server restarts, you should also set it in an option file.

To set a `GLOBAL` value to the compiled-in MySQL default value or a `SESSION` variable to the current corresponding `GLOBAL` value, set the variable to the value `DEFAULT`. For example, the following two statements are identical in setting the session value of `max_join_size` to the current global value:

```
SET @@session.max_join_size=DEFAULT;
SET @@session.max_join_size=@@global.max_join_size;
```

Not all system variables can be set to `DEFAULT`. In such cases, assigning `DEFAULT` results in an error.

An error occurs for attempts to assign `DEFAULT` to user-defined variables, stored procedure or function parameters, or stored program local variables.

To refer to the value of a system variable in expressions, use one of the `@@`-modifiers. For example, you can retrieve values in a `SELECT` statement like this:

```
SELECT @@global.sql_mode, @@session.sql_mode, @@sql_mode;
```

For a reference to a system variable in an expression as `@@var_name` (rather than with `@@global.` or `@@session.`), MySQL returns the session value if it exists and the global value otherwise. This differs from `SET @@var_name = expr`, which always refers to the session value.

Suffixes for specifying a value multiplier can be used when setting a variable at server startup, but not to set the value with `SET` at runtime. On the other hand, with `SET` you can assign a variable's value using an expression, which is not true when you set a variable at server startup. For example, the first of the following lines is legal at server startup, but the second is not:

```
shell> mysql --max_allowed_packet=16M
shell> mysql --max_allowed_packet=16*1024*1024
```

Conversely, the second of the following lines is legal at runtime, but the first is not:

```
mysql> SET GLOBAL max_allowed_packet=16M;
mysql> SET GLOBAL max_allowed_packet=16*1024*1024;
```

### Note

Some system variables can be enabled with the `SET` statement by setting them to `ON` or `1`, or disabled by setting them to `OFF` or `0`. However, to set such a variable on the command line or in an option file, you must set it to `1` or `0`; setting it to `ON` or `OFF` will not work. For example, on the command line, `--delay_key_write=1` works but `--delay_key_write=ON` does not.

To display system variable names and values, use the `SHOW VARIABLES` statement:

```
mysql> SHOW VARIABLES;
```

| Variable_name               | Value                             |
|-----------------------------|-----------------------------------|
| auto_increment_increment    | 1                                 |
| auto_increment_offset       | 1                                 |
| automatic_sp_privileges     | ON                                |
| back_log                    | 50                                |
| basedir                     | /home/mysql/                      |
| binlog_cache_size           | 32768                             |
| bulk_insert_buffer_size     | 8388608                           |
| character_set_client        | latin1                            |
| character_set_connection    | latin1                            |
| character_set_database      | latin1                            |
| character_set_results       | latin1                            |
| character_set_server        | latin1                            |

| character_sets_dir          | /home/mysql/share/mysql/charsets/ |
| collation_connection        | latin1_swedish_ci                 |
| collation_database          | latin1_swedish_ci                 |
| collation_server            | latin1_swedish_ci                 |
| ...                         |                                   |
| innodb_autoextend_increment | 8                                 |
| innodb_buffer_pool_size     | 8388608                           |
| innodb_checksums            | ON                                |
| innodb_commit_concurrency   | 0                                 |
| innodb_concurrency_tickets  | 500                               |
| innodb_data_file_path       | ibdata1:10M:autoextend            |
| innodb_data_home_dir        |                                   |
| ...                         |                                   |
| version                     | 5.1.6-alpha-log                   |
| version_comment             | Source distribution               |
| version_compile_machine     | i686                              |
| version_compile_os          | suse-linux                        |
| wait_timeout                | 28800                             |

With a `LIKE` clause, the statement displays only those variables that match the pattern. To obtain a specific variable name, use a `LIKE` clause as shown:

```
SHOW VARIABLES LIKE 'max_join_size';
SHOW SESSION VARIABLES LIKE 'max_join_size';
```

To get a list of variables whose name match a pattern, use the `%` wildcard character in a `LIKE` clause:

```
SHOW VARIABLES LIKE '%size%';
SHOW GLOBAL VARIABLES LIKE '%size%';
```

Wildcard characters can be used in any position within the pattern to be matched. Strictly speaking, because `_` is a wildcard that matches any single character, you should escape it as `\_` to match it literally. In practice, this is rarely necessary.

For `SHOW VARIABLES`, if you specify neither `GLOBAL` nor `SESSION`, MySQL returns `SESSION` values.

The reason for requiring the `GLOBAL` keyword when setting `GLOBAL`-only variables but not when retrieving them is to prevent problems in the future. If we were to remove a `SESSION` variable that has the same name as a `GLOBAL` variable, a client with the `SUPER` privilege might accidentally change the `GLOBAL` variable rather than just the `SESSION` variable for its own connection. If we add a `SESSION` variable with the same name as a `GLOBAL` variable, a client that intends to change the `GLOBAL` variable might find only its own `SESSION` variable changed.

### 6.1.6.1 Structured System Variables

A structured variable differs from a regular system variable in two respects:

- Its value is a structure with components that specify server parameters considered to be closely related.
- There might be several instances of a given type of structured variable. Each one has a different name and refers to a different resource maintained by the server.

MySQL supports one structured variable type, which specifies parameters governing the operation of key caches. A key cache structured variable has these components:

- `key_buffer_size`
- `key_cache_block_size`
- `key_cache_division_limit`
- `key_cache_age_threshold`

This section describes the syntax for referring to structured variables. Key cache variables are used for syntax examples, but specific details about how key caches operate are found elsewhere, in [Section 9.10.2, “The MyISAM Key Cache”](#).

To refer to a component of a structured variable instance, you can use a compound name in `instance_name.component_name` format. Examples:

```
hot_cache.key_buffer_size
hot_cache.key_cache_block_size
cold_cache.key_cache_block_size
```

For each structured system variable, an instance with the name of `default` is always predefined. If you refer to a component of a structured variable without any instance name, the `default` instance is used. Thus, `default.key_buffer_size` and `key_buffer_size` both refer to the same system variable.

Structured variable instances and components follow these naming rules:

- For a given type of structured variable, each instance must have a name that is unique *within* variables of that type. However, instance names need not be unique *across* structured variable types. For example, each structured variable has an instance named `default`, so `default` is not unique across variable types.
- The names of the components of each structured variable type must be unique across all system variable names. If this were not true (that is, if two different types of structured variables could share component member names), it would not be clear which default structured variable to use for references to member names that are not qualified by an instance name.
- If a structured variable instance name is not legal as an unquoted identifier, refer to it as a quoted identifier using backticks. For example, `hot-cache` is not legal, but ``hot-cache`` is.
- `global`, `session`, and `local` are not legal instance names. This avoids a conflict with notation such as `@global.var_name` for referring to nonstructured system variables.

Currently, the first two rules have no possibility of being violated because the only structured variable type is the one for key caches. These rules will assume greater significance if some other type of structured variable is created in the future.

With one exception, you can refer to structured variable components using compound names in any context where simple variable names can occur. For example, you can assign a value to a structured variable using a command-line option:

```
shell> mysqld --hot_cache.key_buffer_size=64K
```

In an option file, use this syntax:

```
[mysqld]
hot_cache.key_buffer_size=64K
```

If you start the server with this option, it creates a key cache named `hot_cache` with a size of 64KB in addition to the default key cache that has a default size of 8MB.

Suppose that you start the server as follows:

```
shell> mysqld --key_buffer_size=256K \
          --extra_cache.key_buffer_size=128K \
          --extra_cache.key_cache_block_size=2048
```

In this case, the server sets the size of the default key cache to 256KB. (You could also have written `--default.key_buffer_size=256K`.) In addition, the server creates a second key cache named `extra_cache` that has a size of 128KB, with the size of block buffers for caching table index blocks set to 2048 bytes.

The following example starts the server with three different key caches having sizes in a 3:1:1 ratio:

```
shell> mysqld --key_buffer_size=6M \
          --hot_cache.key_buffer_size=2M \
          --cold_cache.key_buffer_size=2M
```

Structured variable values may be set and retrieved at runtime as well. For example, to set a key cache named `hot_cache` to a size of 10MB, use either of these statements:

```
mysql> SET GLOBAL hot_cache.key_buffer_size = 10*1024*1024;
mysql> SET @@global.hot_cache.key_buffer_size = 10*1024*1024;
```

To retrieve the cache size, do this:

```
mysql> SELECT @@global.hot_cache.key_buffer_size;
```

However, the following statement does not work. The variable is not interpreted as a compound name, but as a simple string for a `LIKE` pattern-matching operation:

```
mysql> SHOW GLOBAL VARIABLES LIKE 'hot_cache.key_buffer_size';
```

This is the exception to being able to use structured variable names anywhere a simple variable name may occur.

### 6.1.6.2 Dynamic System Variables

Many server system variables are dynamic and can be set at runtime using `SET GLOBAL` or `SET SESSION`. You can also obtain their values using `SELECT`. See [Section 6.1.6, “Using System Variables”](#).

The following table shows the full list of all dynamic system variables. The last column indicates for each variable whether `GLOBAL` or `SESSION` (or both) apply. The table also lists session options that can be set with the `SET` statement. [Section 6.1.5, “Server System Variables”](#), discusses these options.

Variables that have a type of “string” take a string value. Variables that have a type of “numeric” take a numeric value. Variables that have a type of “boolean” can be set to 0, 1, `ON` or `OFF`. Variables that are marked as “enumeration” normally should be set to one of the available values for the variable, but can also be set to the number that corresponds to the desired enumeration value. For enumerated system variables, the first enumeration value corresponds to 0. This differs from `ENUM` columns, for which the first enumeration value corresponds to 1.

**Table 6.3 Dynamic Variable Summary**

| Variable Name  | Variable Type | Variable Scope                             |
|--|---------------|--|
| <code>audit_log_connection_policy</code>             | enumeration   | <code>GLOBAL</code>                        |
| <code>audit_log_exclude_accounts</code>              | string        | <code>GLOBAL</code>                        |
| <code>audit_log_flush</code>                         | boolean       | <code>GLOBAL</code>                        |
| <code>audit_log_include_accounts</code>              | string        | <code>GLOBAL</code>                        |
| <code>audit_log_rotate_on_size</code>                | integer       | <code>GLOBAL</code>                        |
| <code>audit_log_statement_policy</code>              | enumeration   | <code>GLOBAL</code>                        |
| <code>auto_increment_increment</code>                | integer       | <code>GLOBAL</code>   <code>SESSION</code> |
| <code>auto_increment_offset</code>                   | integer       | <code>GLOBAL</code>   <code>SESSION</code> |
| <code>autocommit</code>                              | boolean       | <code>GLOBAL</code>   <code>SESSION</code> |
| <code>automatic_sp_privileges</code>                 | boolean       | <code>GLOBAL</code>                        |
| <code>avoid_temporal_upgrade</code>                  | boolean       | <code>GLOBAL</code>                        |
| <code>big_tables</code>                              | boolean       | <code>GLOBAL</code>   <code>SESSION</code> |
| <code>binlog_cache_size</code>                       | integer       | <code>GLOBAL</code>                        |
| <code>binlog_checksum</code>                         | string        | <code>GLOBAL</code>                        |
| <code>binlog_direct_non_transactional_updates</code> | boolean       | <code>GLOBAL</code>   <code>SESSION</code> |
| <code>binlog_error_action</code>                     | enumeration   | <code>GLOBAL</code>   <code>SESSION</code> |
| <code>binlog_format</code>                           | enumeration   | <code>GLOBAL</code>   <code>SESSION</code> |
| <code>binlog_group_commit_sync_delay</code>          | integer       | <code>GLOBAL</code>                        |
| <code>binlog_group_commit_sync_no_delay_count</code> | integer       | <code>GLOBAL</code>                        |
| <code>binlog_max_flush_queue_time</code>             | integer       | <code>GLOBAL</code>                        |
| <code>binlog_order_commits</code>                    | boolean       | <code>GLOBAL</code>                        |
| <code>binlog_row_image=image_type</code>             | enumeration   | <code>GLOBAL</code>   <code>SESSION</code> |
| <code>binlog_rows_query_log_events</code>            | boolean       | <code>GLOBAL</code>   <code>SESSION</code> |

| Variable Name  | Variable Type | Variable Scope   |
|--|---------------|------------------|
| <code>binlog_stmt_cache_size</code>                          | integer       | GLOBAL           |
| <code>binlogging_impossible_mode</code>                      | enumeration   | GLOBAL   SESSION |
| <code>block_encryption_mode</code>                           | string        | GLOBAL   SESSION |
| <code>bulk_insert_buffer_size</code>                         | integer       | GLOBAL   SESSION |
| <code>character_set_client</code>                            | string        | GLOBAL   SESSION |
| <code>character_set_connection</code>                        | string        | GLOBAL   SESSION |
| <code>character_set_database</code>                          | string        | GLOBAL   SESSION |
| <code>character_set_filesystem</code>                        | string        | GLOBAL   SESSION |

### 6.1.7 Server Status Variables

The MySQL server maintains many status variables that provide information about its operation. You can view these variables and their values by using the `SHOW [GLOBAL | SESSION] STATUS` statement (see [Section 14.7.5.35, “SHOW STATUS Syntax”](#)). The optional `GLOBAL` keyword aggregates the values over all connections, and `SESSION` shows the values for the current connection.

```
mysql> SHOW GLOBAL STATUS;
+-----+-----+
| Variable_name | Value |
+-----+-----+
| Aborted_clients | 0 |
| Aborted_connects | 0 |
| Bytes_received | 155372598 |
| Bytes_sent | 1176560426 |
| ... |
| Connections | 30023 |
| Created_tmp_disk_tables | 0 |
| Created_tmp_files | 3 |
| Created_tmp_tables | 2 |
| ... |
| Threads_created | 217 |
| Threads_running | 88 |
| Uptime | 1389872 |
+-----+-----+
```

Several status variables provide statement counts. To determine the number of statements executed, use these relationships:

```
SUM(Com_xxx) + Qcache_hits
= Questions + statements executed within stored programs
= Queries
```

Many status variables are reset to 0 by the `FLUSH STATUS` statement.

The following table lists all available server status variables:

**Table 6.4 Status Variable Summary**

| Variable Name                 | Variable Type | Variable Scope   |
|-------------------------------|---------------|------------------|
| Aborted_clients               | integer       | GLOBAL           |
| Aborted_connects              | integer       | GLOBAL           |
| Audit_log_current_size        | integer       | GLOBAL           |
| Audit_log_event_max_drop_size | integer       | GLOBAL           |
| Audit_log_events              | integer       | GLOBAL           |
| Audit_log_events_filtered     | integer       | GLOBAL           |
| Audit_log_events_lost         | integer       | GLOBAL           |
| Audit_log_events_written      | integer       | GLOBAL           |
| Audit_log_total_size          | integer       | GLOBAL           |
| Audit_log_write_waits         | integer       | GLOBAL           |
| Binlog_cache_disk_use         | integer       | GLOBAL           |
| Binlog_cache_use              | integer       | GLOBAL           |
| Binlog_stmt_cache_disk_use    | integer       | GLOBAL           |
| Binlog_stmt_cache_use         | integer       | GLOBAL           |
| Bytes_received                | integer       | GLOBAL   SESSION |
| Bytes_sent                    | integer       | GLOBAL   SESSION |

| <code>Uptime_since_flush_status</code>                       | integer       | GLOBAL           |
| <code>validate_password_dictionary_file_last_modified</code> | datetime      | GLOBAL           |
| <code>validate_password_dictionary_file_word_count</code>    | integer       | GLOBAL           |

The status variables have the meanings shown in the following list. For meanings of status variables specific to MySQL Cluster, see [NDB Cluster Status Variables](#).

- `Aborted_clients`

The number of connections that were aborted because the client died without closing the connection properly. See [Section B.5.2.11, “Communication Errors and Aborted Connections”](#).

- `Aborted_connects`

The number of failed attempts to connect to the MySQL server. See [Section B.5.2.11, “Communication Errors and Aborted Connections”](#).

For additional connection-related information, check the `Connection_errors_xxx` status variables and the `host_cache` table.

As of MySQL 5.7.3, `Aborted_connects` is not visible in the embedded server because for that server it is not updated and is not meaningful.

- `Binlog_cache_disk_use`

The number of transactions that used the temporary binary log cache but that exceeded the value of `binlog_cache_size` and used a temporary file to store statements from the transaction.

The number of nontransactional statements that caused the binary log transaction cache to be written to disk is tracked separately in the `Binlog_stmt_cache_disk_use` status variable.

- `Binlog_cache_use`

The number of transactions that used the binary log cache.

- `Binlog_stmt_cache_disk_use`

The number of nontransaction statements that used the binary log statement cache but that exceeded the value of `binlog_stmt_cache_size` and used a temporary file to store those statements.

- `Binlog_stmt_cache_use`

The number of nontransactional statements that used the binary log statement cache.

- `Bytes_received`

The number of bytes received from all clients.

- `Bytes_sent`

The number of bytes sent to all clients.

- `Com_xxx`

The `Com_xxx` statement counter variables indicate the number of times each `xxx` statement has been executed. There is one status variable for each type of statement. For example, `Com_delete` and `Com_update` count `DELETE` and `UPDATE` statements, respectively. `Com_delete_multi` and `Com_update_multi` are similar but apply to `DELETE` and `UPDATE` statements that use multiple-table syntax.

If a query result is returned from query cache, the server increments the `Qcache_hits` status variable, not `Com_select`. See [Section 9.10.3.4, “Query Cache Status and Maintenance”](#).

The discussion at the beginning of this section indicates how to relate these statement-counting status variables to other such variables.

All of the `Com_stmt_xxx` variables are increased even if a prepared statement argument is unknown or an error occurred during execution. In other words, their values correspond to the number of requests issued, not to the number of requests successfully completed.

The `Com_stmt_xxx` status variables are as follows:

- `Com_stmt_prepare`
- `Com_stmt_execute`

- `Com_stmt_fetch`
- `Com_stmt_send_long_data`
- `Com_stmt_reset`
- `Com_stmt_close`

Those variables stand for prepared statement commands. Their names refer to the `COM_xxx` command set used in the network layer. In other words, their values increase whenever prepared statement API calls such as `mysql_stmt_prepare()`, `mysql_stmt_execute()`, and so forth are executed. However, `Com_stmt_prepare`, `Com_stmt_execute` and `Com_stmt_close` also increase for `PREPARE`, `EXECUTE`, or `DEALLOCATE PREPARE`, respectively. Additionally, the values of the older statement counter variables `Com_prepare_sql`, `Com_execute_sql`, and `Com_dealloc_sql` increase for the `PREPARE`, `EXECUTE`, and `DEALLOCATE PREPARE` statements. `Com_stmt_fetch` stands for the total number of network round-trips issued when fetching from cursors.

`Com_stmt_reprepare` indicates the number of times statements were automatically reprepared by the server after metadata changes to tables or views referred to by the statement. A reprepare operation increments `Com_stmt_reprepare`, and also `Com_stmt_prepare`.

`Com_explain_other` indicates the number of `EXPLAIN FOR CONNECTION` statements executed. See [Section 9.8.4, “Obtaining Execution Plan Information for a Named Connection”](#). It was introduced in MySQL 5.7.2.

`Com_change_repl_filter` indicates the number of `CHANGE REPLICATION FILTER` statements executed. It was introduced in MySQL 5.7.3.

- `Compression`

Whether the client connection uses compression in the client/server protocol.

- `Connection_errors_xxx`

These variables provide information about errors that occur during the client connection process. They are global only and represent error counts aggregated across connections from all hosts. These variables track errors not accounted for by the host cache (see [Section 9.12.5.2, “DNS Lookup Optimization and the Host Cache”](#)), such as errors that are not associated with TCP connections, occur very early in the connection process (even before an IP address is known), or are not specific to any particular IP address (such as out-of-memory conditions).

As of MySQL 5.7.3, the `Connection_errors_xxx` status variables are not visible in the embedded server because for that server they are not updated and are not meaningful.

- `Connection_errors_accept`

The number of errors that occurred during calls to `accept()` on the listening port.

- `Connection_errors_internal`

The number of connections refused due to internal errors in the server, such as failure to start a new thread or an out-of-memory condition.

- `Connection_errors_max_connections`

The number of connections refused because the server `max_connections` limit was reached.

- `Connection_errors_peer_addr`

The number of errors that occurred while searching for connecting client IP addresses.

- [Connection\\_errors\\_select](#)

The number of errors that occurred during calls to [select\(\)](#) or [poll\(\)](#) on the listening port. (Failure of this operation does not necessarily mean a client connection was rejected.)

- [Connection\\_errors\\_tcpwrap](#)

The number of connections refused by the [libwrap](#) library.

- [Connections](#)

The number of connection attempts (successful or not) to the MySQL server.

- [Created\\_tmp\\_disk\\_tables](#)

The number of internal on-disk temporary tables created by the server while executing statements.

If an internal temporary table is created initially as an in-memory table but becomes too large, MySQL automatically converts it to an on-disk table. The maximum size for in-memory temporary tables is the minimum of the [tmp\\_table\\_size](#) and [max\\_heap\\_table\\_size](#) values. If [Created\\_tmp\\_disk\\_tables](#) is large, you may want to increase the [tmp\\_table\\_size](#) or [max\\_heap\\_table\\_size](#) value to lessen the likelihood that internal temporary tables in memory will be converted to on-disk tables.

You can compare the number of internal on-disk temporary tables created to the total number of internal temporary tables created by comparing the values of the [Created\\_tmp\\_disk\\_tables](#) and [Created\\_tmp\\_tables](#) variables.

See also [Section 9.4.4, “Internal Temporary Table Use in MySQL”](#).

- [Created\\_tmp\\_files](#)

How many temporary files [mysqld](#) has created.

- [Created\\_tmp\\_tables](#)

The number of internal temporary tables created by the server while executing statements.

You can compare the number of internal on-disk temporary tables created to the total number of internal temporary tables created by comparing the values of the [Created\\_tmp\\_disk\\_tables](#) and [Created\\_tmp\\_tables](#) variables.

See also [Section 9.4.4, “Internal Temporary Table Use in MySQL”](#).

Each invocation of the [SHOW STATUS](#) statement uses an internal temporary table and increments the global [Created\\_tmp\\_tables](#) value.

- [Delayed\\_errors](#)

This status variable is deprecated (because [DELAYED](#) inserts are not supported), and will be removed in a future release.

- [Delayed\\_insert\\_threads](#)

This status variable is deprecated (because [DELAYED](#) inserts are not supported), and will be removed in a future release.

- [Delayed\\_writes](#)

This status variable is deprecated (because `DELAYED` inserts are not supported), and will be removed in a future release.

- `Flush_commands`

The number of times the server flushes tables, whether because a user executed a `FLUSH TABLES` statement or due to internal server operation. It is also incremented by receipt of a `COM_REFRESH` packet. This is in contrast to `Com_flush`, which indicates how many `FLUSH` statements have been executed, whether `FLUSH TABLES`, `FLUSH LOGS`, and so forth.

- `Handler_commit`

The number of internal `COMMIT` statements.

- `Handler_delete`

The number of times that rows have been deleted from tables.

- `Handler_external_lock`

The server increments this variable for each call to its `external_lock()` function, which generally occurs at the beginning and end of access to a table instance. There might be differences among storage engines. This variable can be used, for example, to discover for a statement that accesses a partitioned table how many partitions were pruned before locking occurred: Check how much the counter increased for the statement, subtract 2 (2 calls for the table itself), then divide by 2 to get the number of partitions locked.

- `Handler_mrr_init`

The number of times the server uses a storage engine's own Multi-Range Read implementation for table access.

- `Handler_prepare`

A counter for the prepare phase of two-phase commit operations.

- `Handler_read_first`

The number of times the first entry in an index was read. If this value is high, it suggests that the server is doing a lot of full index scans; for example, `SELECT col1 FROM foo`, assuming that `col1` is indexed.

- `Handler_read_key`

The number of requests to read a row based on a key. If this value is high, it is a good indication that your tables are properly indexed for your queries.

- `Handler_read_last`

The number of requests to read the last key in an index. With `ORDER BY`, the server will issue a first-key request followed by several next-key requests, whereas with `ORDER BY DESC`, the server will issue a last-key request followed by several previous-key requests.

- `Handler_read_next`

The number of requests to read the next row in key order. This value is incremented if you are querying an index column with a range constraint or if you are doing an index scan.

- `Handler_read_prev`

The number of requests to read the previous row in key order. This read method is mainly used to optimize `ORDER BY ... DESC`.

- `Handler_read_rnd`

The number of requests to read a row based on a fixed position. This value is high if you are doing a lot of queries that require sorting of the result. You probably have a lot of queries that require MySQL to scan entire tables or you have joins that do not use keys properly.

- `Handler_read_rnd_next`

The number of requests to read the next row in the data file. This value is high if you are doing a lot of table scans. Generally this suggests that your tables are not properly indexed or that your queries are not written to take advantage of the indexes you have.

- `Handler_rollback`

The number of requests for a storage engine to perform a rollback operation.

- `Handler_savepoint`

The number of requests for a storage engine to place a savepoint.

- `Handler_savepoint_rollback`

The number of requests for a storage engine to roll back to a savepoint.

- `Handler_update`

The number of requests to update a row in a table.

- `Handler_write`

The number of requests to insert a row in a table.

- `InnoDB_available_undo_logs`

The total number of available [InnoDB rollback segments](#). Supplements the `innodb_undo_logs` system variable, which defines the number of active rollback segments.

One rollback segment always resides in the system tablespace, and as of MySQL 5.7.2, 32 rollback segments are reserved for use by temporary tables and are hosted in the temporary tablespace (`ibtmp1`). See [Section 15.4.12.1, “InnoDB Temporary Table Undo Logs”](#).

If you initiate a MySQL instance with 32 or fewer rollback segments, [InnoDB](#) still assigns one rollback segment to the system tablespace and 32 rollback segments to the temporary tablespace. In this case, `InnoDB_available_undo_logs` reports 33 available rollback segments even though the instance was initialized with a lesser `innodb_undo_logs` value.

- `InnoDB_buffer_pool_dump_status`

The progress of an operation to record the [pages](#) held in the [InnoDB buffer pool](#), triggered by the setting of `innodb_buffer_pool_dump_at_shutdown` or `innodb_buffer_pool_dump_now`.

For related information and examples, see [Section 15.6.3.8, “Saving and Restoring the Buffer Pool State”](#).

- `InnoDB_buffer_pool_load_status`

The progress of an operation to [warm up](#) the [InnoDB buffer pool](#) by reading in a set of [pages](#) corresponding to an earlier point in time, triggered by the setting of `innodb_buffer_pool_load_at_startup` or `innodb_buffer_pool_load_now`. If the operation introduces too much overhead, you can cancel it by setting `innodb_buffer_pool_load_abort`.

For related information and examples, see [Section 15.6.3.8, “Saving and Restoring the Buffer Pool State”](#).

- `Innodb_buffer_pool_bytes_data`

The total number of bytes in the [InnoDB buffer pool](#) containing data. The number includes both [dirty](#) and clean pages. For more accurate memory usage calculations than with `Innodb_buffer_pool_pages_data`, when [compressed](#) tables cause the buffer pool to hold pages of different sizes.

- `Innodb_buffer_pool_pages_data`

The number of [pages](#) in the [InnoDB buffer pool](#) containing data. The number includes both [dirty](#) and clean pages. When using [compressed tables](#), the reported `Innodb_buffer_pool_pages_data` value may be larger than `Innodb_buffer_pool_pages_total` (Bug #59550).

- `Innodb_buffer_pool_bytes_dirty`

The total current number of bytes held in [dirty pages](#) in the [InnoDB buffer pool](#). For more accurate memory usage calculations than with `Innodb_buffer_pool_pages_dirty`, when [compressed](#) tables cause the buffer pool to hold pages of different sizes.

- `Innodb_buffer_pool_pages_dirty`

The current number of [dirty pages](#) in the [InnoDB buffer pool](#).

- `Innodb_buffer_pool_pages_flushed`

The number of requests to [flush pages](#) from the [InnoDB buffer pool](#).

- `Innodb_buffer_pool_pages_free`

The number of free [pages](#) in the [InnoDB buffer pool](#).

- `Innodb_buffer_pool_pages_latched`

The number of latched [pages](#) in the [InnoDB buffer pool](#). These are pages currently being read or written, or that cannot be [flushed](#) or removed for some other reason. Calculation of this variable is expensive, so it is available only when the `UNIV_DEBUG` system is defined at server build time.

- `Innodb_buffer_pool_pages_misc`

The number of [pages](#) in the [InnoDB buffer pool](#) that are busy because they have been allocated for administrative overhead, such as [row locks](#) or the [adaptive hash index](#). This value can also be calculated as `Innodb_buffer_pool_pages_total - Innodb_buffer_pool_pages_free - Innodb_buffer_pool_pages_data`. When using [compressed tables](#), `Innodb_buffer_pool_pages_misc` may report an out-of-bounds value (Bug #59550).

- `Innodb_buffer_pool_pages_total`

The total size of the [InnoDB buffer pool](#), in [pages](#). When using [compressed tables](#), the reported `Innodb_buffer_pool_pages_data` value may be larger than `Innodb_buffer_pool_pages_total` (Bug #59550)

- `Innodb_buffer_pool_read_ahead`

The number of [pages](#) read into the [InnoDB buffer pool](#) by the [read-ahead](#) background thread.

- `Innodb_buffer_pool_read_ahead_evicted`

The number of [pages](#) read into the [InnoDB buffer pool](#) by the [read-ahead](#) background thread that were subsequently [evicted](#) without having been accessed by queries.

- [Innodb\\_buffer\\_pool\\_read\\_ahead\\_rnd](#)

The number of “random” read-aheads initiated by [InnoDB](#). This happens when a query scans a large portion of a table but in random order.

- [Innodb\\_buffer\\_pool\\_read\\_requests](#)

The number of logical read requests.

- [Innodb\\_buffer\\_pool\\_reads](#)

The number of logical reads that [InnoDB](#) could not satisfy from the [buffer pool](#), and had to read directly from disk.

- [Innodb\\_buffer\\_pool\\_resize\\_status](#)

The status of an operation to resize the [InnoDB buffer pool](#) dynamically, triggered by setting the [innodb\\_buffer\\_pool\\_size](#) parameter dynamically. As of MySQL 5.7.5, the [innodb\\_buffer\\_pool\\_size](#) parameter is dynamic, which allows you to resize the buffer pool without restarting the server. See [Configuring InnoDB Buffer Pool Size Online](#) for related information.

- [Innodb\\_buffer\\_pool\\_wait\\_free](#)

Normally, writes to the [InnoDB buffer pool](#) happen in the background. When [InnoDB](#) needs to read or create a [page](#) and no clean pages are available, [InnoDB](#) flushes some [dirty pages](#) first and waits for that operation to finish. This counter counts instances of these waits. If [innodb\\_buffer\\_pool\\_size](#) has been set properly, this value should be small.

- [Innodb\\_buffer\\_pool\\_write\\_requests](#)

The number of writes done to the [InnoDB buffer pool](#).

- [Innodb\\_data\\_fsyncs](#)

The number of `fsync()` operations so far. The frequency of `fsync()` calls is influenced by the setting of the [innodb\\_flush\\_method](#) configuration option.

- [Innodb\\_data\\_pending\\_fsyncs](#)

The current number of pending `fsync()` operations. The frequency of `fsync()` calls is influenced by the setting of the [innodb\\_flush\\_method](#) configuration option.

- [Innodb\\_data\\_pending\\_reads](#)

The current number of pending reads.

- [Innodb\\_data\\_pending\\_writes](#)

The current number of pending writes.

- [Innodb\\_data\\_read](#)

The amount of data read since the server was started (in bytes).

- [Innodb\\_data\\_reads](#)

The total number of data reads (OS file reads).

- [Innodb\\_data\\_writes](#)

The total number of data writes.

- `Innodb_data_written`

The amount of data written so far, in bytes.

- `Innodb_dblwr_pages_written`

The number of [pages](#) that have been written to the [doublewrite buffer](#). See [Section 15.12.1, “InnoDB Disk I/O”](#).

- `Innodb_dblwr_writes`

The number of doublewrite operations that have been performed. See [Section 15.12.1, “InnoDB Disk I/O”](#).

- `Innodb_have_atomic_builtins`

Indicates whether the server was built with [atomic instructions](#).

- `Innodb_log_waits`

The number of times that the [log buffer](#) was too small and a [wait](#) was required for it to be [flushed](#) before continuing.

- `Innodb_log_write_requests`

The number of write requests for the [InnoDB redo log](#).

- `Innodb_log_writes`

The number of physical writes to the [InnoDB redo log](#) file.

- `Innodb_num_open_files`

The number of files [InnoDB](#) currently holds open.

- `Innodb_os_log_fsyncs`

The number of `fsync()` writes done to the [InnoDB redo log](#) files.

- `Innodb_os_log_pending_fsyncs`

The number of pending `fsync()` operations for the [InnoDB redo log](#) files.

- `Innodb_os_log_pending_writes`

The number of pending writes to the [InnoDB redo log](#) files.

- `Innodb_os_log_written`

The number of bytes written to the [InnoDB redo log](#) files.

- `Innodb_page_size`

[InnoDB](#) page size (default 16KB). Many values are counted in pages; the page size enables them to be easily converted to bytes.

- `Innodb_pages_created`

The number of pages created by operations on [InnoDB](#) tables.

- `Innodb_pages_read`

The number of pages read from the [InnoDB](#) buffer pool by operations on [InnoDB](#) tables.

- [Innodb\\_pages\\_written](#)

The number of pages written by operations on [InnoDB](#) tables.

- [Innodb\\_row\\_lock\\_current\\_waits](#)

The number of [row locks](#) currently being waited for by operations on [InnoDB](#) tables.

- [Innodb\\_row\\_lock\\_time](#)

The total time spent in acquiring [row locks](#) for [InnoDB](#) tables, in milliseconds.

- [Innodb\\_row\\_lock\\_time\\_avg](#)

The average time to acquire a [row lock](#) for [InnoDB](#) tables, in milliseconds.

- [Innodb\\_row\\_lock\\_time\\_max](#)

The maximum time to acquire a [row lock](#) for [InnoDB](#) tables, in milliseconds.

- [Innodb\\_row\\_lock\\_waits](#)

The number of times operations on [InnoDB](#) tables had to wait for a [row lock](#).

- [Innodb\\_rows\\_deleted](#)

The number of rows deleted from [InnoDB](#) tables.

- [Innodb\\_rows\\_inserted](#)

The number of rows inserted into [InnoDB](#) tables.

- [Innodb\\_rows\\_read](#)

The number of rows read from [InnoDB](#) tables.

- [Innodb\\_rows\\_updated](#)

The number of rows updated in [InnoDB](#) tables.

- [Innodb\\_truncated\\_status\\_writes](#)

The number of times output from the `SHOW ENGINE INNODB STATUS` statement has been truncated.

- [Key\\_blocks\\_not\\_flushed](#)

The number of key blocks in the [MyISAM](#) key cache that have changed but have not yet been flushed to disk.

- [Key\\_blocks\\_unused](#)

The number of unused blocks in the [MyISAM](#) key cache. You can use this value to determine how much of the key cache is in use; see the discussion of [key\\_buffer\\_size](#) in [Section 6.1.5, “Server System Variables”](#).

- [Key\\_blocks\\_used](#)

The number of used blocks in the [MyISAM](#) key cache. This value is a high-water mark that indicates the maximum number of blocks that have ever been in use at one time.

- [Key\\_read\\_requests](#)

The number of requests to read a key block from the [MyISAM](#) key cache.

- [Key\\_reads](#)

The number of physical reads of a key block from disk into the [MyISAM](#) key cache. If [Key\\_reads](#) is large, then your [key\\_buffer\\_size](#) value is probably too small. The cache miss rate can be calculated as  $\text{Key\_reads} / \text{Key\_read\_requests}$ .

- [Key\\_write\\_requests](#)

The number of requests to write a key block to the [MyISAM](#) key cache.

- [Key\\_writes](#)

The number of physical writes of a key block from the [MyISAM](#) key cache to disk.

- [Last\\_query\\_cost](#)

The total cost of the last compiled query as computed by the query optimizer. This is useful for comparing the cost of different query plans for the same query. The default value of 0 means that no query has been compiled yet. The default value is 0. [Last\\_query\\_cost](#) has session scope.

The [Last\\_query\\_cost](#) value can be computed accurately only for simple “flat” queries, not complex queries such as those with subqueries or [UNION](#). For the latter, the value is set to 0.

- [Last\\_query\\_partial\\_plans](#)

The number of iterations the query optimizer made in execution plan construction for the previous query. [Last\\_query\\_cost](#) has session scope.

- [Locked\\_connects](#)

The number of attempts to connect to locked user accounts. For information about account locking and unlocking, see [Section 7.3.10, “User Account Locking”](#).

This variable was added in MySQL 5.7.6.

- [Max\\_execution\\_time\\_exceeded](#)

The number of [SELECT](#) statements for which the execution timeout was exceeded. This variable was added in MySQL 5.7.8. Previously, it was named [Max\\_statement\\_time\\_exceeded](#).

- [Max\\_execution\\_time\\_set](#)

The number of [SELECT](#) statements for which a nonzero execution timeout was set. This includes statements that include a nonzero [MAX\\_EXECUTION\\_TIME](#) optimizer hint, and statements that include no such hint but execute while the timeout indicated by the [max\\_execution\\_time](#) system variable is nonzero. This variable was added in MySQL 5.7.8. Previously, it was named [Max\\_statement\\_time\\_set](#).

- [Max\\_execution\\_time\\_set\\_failed](#)

The number of [SELECT](#) statements for which the attempt to set an execution timeout failed. This variable was added in MySQL 5.7.8. Previously, it was named [Max\\_statement\\_time\\_set\\_failed](#).

- [Max\\_statement\\_time\\_exceeded](#)

The number of [SELECT](#) statements for which the execution timeout was exceeded. This variable was added in MySQL 5.7.4 and renamed to [Max\\_execution\\_time\\_exceeded](#) in MySQL 5.7.8.

- [Max\\_statement\\_time\\_set](#)

The number of [SELECT](#) statements for which a nonzero execution timeout was set. This includes statements that include a nonzero [MAX\\_STATEMENT\\_TIME](#) option, and statements that include no such option but execute while the timeout indicated by the [max\\_statement\\_time](#) system variable is nonzero. This variable was added in MySQL 5.7.4 and renamed to [Max\\_execution\\_time\\_set](#) in MySQL 5.7.8.

- [Max\\_statement\\_time\\_set\\_failed](#)

The number of [SELECT](#) statements for which the attempt to set an execution timeout failed. This variable was added in MySQL 5.7.4 and renamed to [Max\\_execution\\_time\\_set\\_failed](#) in MySQL 5.7.8.

- [Max\\_used\\_connections](#)

The maximum number of connections that have been in use simultaneously since the server started.

- [Max\\_used\\_connections\\_time](#)

The time at which [Max\\_used\\_connections](#) reached its current value. This variable was added in MySQL 5.7.5.

- [Not\\_flushed\\_delayed\\_rows](#)

This status variable is deprecated (because [DELAYED](#) inserts are not supported), and will be removed in a future release.

- [mecab\\_charset](#)

The character set currently used by the MeCab full-text parser plugin. For related information, see [Section 13.9.9, “MeCab Full-Text Parser Plugin”](#).

- [Ongoing\\_anonymous\\_transaction\\_count](#)

Shows the number of ongoing transactions which have been marked as anonymous. This can be used to ensure that no further transactions are waiting to be processed. This variable was added in MySQL 5.7.6.

- [Ongoing\\_anonymous\\_gtid\\_violating\\_transaction\\_count](#)

This status variable is only available in debug builds. Shows the number of ongoing transactions which use [gtid\\_next=ANONYMOUS](#) and that violate GTID consistency. This variable was added in MySQL 5.7.6.

- [Ongoing\\_automatic\\_gtid\\_violating\\_transaction\\_count](#)

This status variable is only available in debug builds. Shows the number of ongoing transactions which use [gtid\\_next=AUTOMATIC](#) and that violate GTID consistency. This variable was added in MySQL 5.7.6.

- [Open\\_files](#)

The number of files that are open. This count includes regular files opened by the server. It does not include other types of files such as sockets or pipes. Also, the count does not include files that storage engines open using their own internal functions rather than asking the server level to do so.

- [Open\\_streams](#)

The number of streams that are open (used mainly for logging).

- [Open\\_table\\_definitions](#)

The number of cached [.frm](#) files.

- `Open_tables`

The number of tables that are open.

- `Opened_files`

The number of files that have been opened with `my_open()` (a `mysys` library function). Parts of the server that open files without using this function do not increment the count.

- `Opened_table_definitions`

The number of `.frm` files that have been cached.

- `Opened_tables`

The number of tables that have been opened. If `Opened_tables` is big, your `table_open_cache` value is probably too small.

- `Performance_schema_xxx`

Performance Schema status variables are listed in [Section 24.14, “Performance Schema Status Variables”](#). These variables provide information about instrumentation that could not be loaded or created due to memory constraints.

- `Prepared_stmt_count`

The current number of prepared statements. (The maximum number of statements is given by the `max_prepared_stmt_count` system variable.)

- `Qcache_free_blocks`

The number of free memory blocks in the query cache.

- `Qcache_free_memory`

The amount of free memory for the query cache.

- `Qcache_hits`

The number of query cache hits.

The discussion at the beginning of this section indicates how to relate this statement-counting status variable to other such variables.

- `Qcache_inserts`

The number of queries added to the query cache.

- `Qcache_lowmem_prunes`

The number of queries that were deleted from the query cache because of low memory.

- `Qcache_not_cached`

The number of noncached queries (not cacheable, or not cached due to the `query_cache_type` setting).

- `Qcache_queries_in_cache`

The number of queries registered in the query cache.

- `Qcache_total_blocks`

The total number of blocks in the query cache.

- `Queries`

The number of statements executed by the server. This variable includes statements executed within stored programs, unlike the `Questions` variable. It does not count `COM_PING` or `COM_STATISTICS` commands.

The discussion at the beginning of this section indicates how to relate this statement-counting status variable to other such variables.

- `Questions`

The number of statements executed by the server. This includes only statements sent to the server by clients and not statements executed within stored programs, unlike the `Queries` variable. This variable does not count `COM_PING`, `COM_STATISTICS`, `COM_STMT_PREPARE`, `COM_STMT_CLOSE`, or `COM_STMT_RESET` commands.

The discussion at the beginning of this section indicates how to relate this statement-counting status variable to other such variables.

- `Rpl_semi_sync_master_clients`

The number of semisynchronous slaves.

This variable is available only if the master-side semisynchronous replication plugin is installed.

- `Rpl_semi_sync_master_net_avg_wait_time`

The average time in microseconds the master waited for a slave reply. In MySQL 5.7.4 and later this variable is always 0. In MySQL 5.7.8 and later it is deprecated and it will be removed in a future version.

This variable is available only if the master-side semisynchronous replication plugin is installed.

- `Rpl_semi_sync_master_net_wait_time`

The total time in microseconds the master waited for slave replies. In MySQL 5.7.4 and later this variable is always 0. In MySQL 5.7.8 and later it is deprecated and it will be removed in a future version.

This variable is available only if the master-side semisynchronous replication plugin is installed.

- `Rpl_semi_sync_master_net_waits`

The total number of times the master waited for slave replies.

This variable is available only if the master-side semisynchronous replication plugin is installed.

- `Rpl_semi_sync_master_no_times`

The number of times the master turned off semisynchronous replication.

This variable is available only if the master-side semisynchronous replication plugin is installed.

- `Rpl_semi_sync_master_no_tx`

The number of commits that were not acknowledged successfully by a slave.

This variable is available only if the master-side semisynchronous replication plugin is installed.

- `Rpl_semi_sync_master_status`

Whether semisynchronous replication currently is operational on the master. The value is `ON` if the plugin has been enabled and a commit acknowledgment has occurred. It is `OFF` if the plugin is not

enabled or the master has fallen back to asynchronous replication due to commit acknowledgment timeout.

This variable is available only if the master-side semisynchronous replication plugin is installed.

- `Rpl_semi_sync_master_timefunc_failures`

The number of times the master failed when calling time functions such as `gettimeofday()`.

This variable is available only if the master-side semisynchronous replication plugin is installed.

- `Rpl_semi_sync_master_tx_avg_wait_time`

The average time in microseconds the master waited for each transaction.

This variable is available only if the master-side semisynchronous replication plugin is installed.

- `Rpl_semi_sync_master_tx_wait_time`

The total time in microseconds the master waited for transactions.

This variable is available only if the master-side semisynchronous replication plugin is installed.

- `Rpl_semi_sync_master_tx_waits`

The total number of times the master waited for transactions.

This variable is available only if the master-side semisynchronous replication plugin is installed.

- `Rpl_semi_sync_master_wait_pos_backtraverse`

The total number of times the master waited for an event with binary coordinates lower than events waited for previously. This can occur when the order in which transactions start waiting for a reply is different from the order in which their binary log events are written.

This variable is available only if the master-side semisynchronous replication plugin is installed.

- `Rpl_semi_sync_master_wait_sessions`

The number of sessions currently waiting for slave replies.

This variable is available only if the master-side semisynchronous replication plugin is installed.

- `Rpl_semi_sync_master_yes_tx`

The number of commits that were acknowledged successfully by a slave.

This variable is available only if the master-side semisynchronous replication plugin is installed.

- `Rpl_semi_sync_slave_status`

Whether semisynchronous replication currently is operational on the slave. This is `ON` if the plugin has been enabled and the slave I/O thread is running, `OFF` otherwise.

This variable is available only if the slave-side semisynchronous replication plugin is installed.

- `Rsa_public_key`

This variable is available if MySQL was using OpenSSL (see [Section 7.4.1, “OpenSSL Versus yaSSL”](#)). Its value is the RSA public key value used by the `sha256_password` authentication plugin. The value is nonempty only if the server successfully initializes the private and public keys in the files named by the `sha256_password_private_key_path` and `sha256_password_public_key_path` system variables. The value of `Rsa_public_key` comes from the latter file.

For information about `sha256_password`, see [Section 7.5.1.4, “The SHA-256 Authentication Plugin”](#).

- `Select_full_join`

The number of joins that perform table scans because they do not use indexes. If this value is not 0, you should carefully check the indexes of your tables.

- `Select_full_range_join`

The number of joins that used a range search on a reference table.

- `Select_range`

The number of joins that used ranges on the first table. This is normally not a critical issue even if the value is quite large.

- `Select_range_check`

The number of joins without keys that check for key usage after each row. If this is not 0, you should carefully check the indexes of your tables.

- `Select_scan`

The number of joins that did a full scan of the first table.

- `Slave_heartbeat_period`

Shows the replication heartbeat interval (in seconds) on a replication slave.

This variable is affected by the value of the `show_compatibility_56` system variable. For details, see [Effect of show\\_compatibility\\_56 on Slave Status Variables](#).

**Note**

This variable only shows the status of the default replication channel. To monitor multiple replication channels use the `HEARTBEAT_INTERVAL` column in the `replication_connection_status` table for the replication channel.

- `Slave_last_heartbeat`

Shows when the most recent heartbeat signal was received by a replication slave, as a `TIMESTAMP` value.

This variable is affected by the value of the `show_compatibility_56` system variable. For details, see [Effect of show\\_compatibility\\_56 on Slave Status Variables](#).

**Note**

This variable only shows the status of the default replication channel. To monitor multiple replication channels use the `LAST_HEARTBEAT_TIMESTAMP` column in the `replication_connection_status` table for the replication channel.

- `Slave_open_temp_tables`

The number of temporary tables that the slave SQL thread currently has open. If the value is greater than zero, it is not safe to shut down the slave; see [Section 18.4.1.24, “Replication and Temporary Tables”](#). This variable reports the total count of open temporary tables for *all* replication channels.

- `Slave_received_heartbeats`

This counter increments with each replication heartbeat received by a replication slave since the last time that the slave was restarted or reset, or a `CHANGE MASTER TO` statement was issued.

This variable is affected by the value of the `show_compatibility_56` system variable. For details, see [Effect of show\\_compatibility\\_56 on Slave Status Variables](#).

**Note**

This variable only shows the status of the default replication channel. To monitor multiple replication channels use the `COUNT_RECEIVED_HEARTBEATS` column in the `replication_connection_status` table for the replication channel.

- `Slave_retried_transactions`

The total number of times since startup that the replication slave SQL thread has retried transactions.

This variable is affected by the value of the `show_compatibility_56` system variable. For details, see [Effect of show\\_compatibility\\_56 on Slave Status Variables](#).

**Note**

This variable only shows the status of the default replication channel. To monitor multiple replication channels use the `COUNT_TRANSACTIONS_RETRIES` column in the `replication_applier_status` table for the replication channel.

- `Slave_running`

This is `ON` if this server is a replication slave that is connected to a replication master, and both the I/O and SQL threads are running; otherwise, it is `OFF`.

This variable is affected by the value of the `show_compatibility_56` system variable. For details, see [Effect of show\\_compatibility\\_56 on Slave Status Variables](#).

**Note**

This variable only shows the status of the default replication channel. To monitor multiple replication channels use the `SERVICE_STATE` column in the `replication_applier_status` or `replication_connection_status` tables of the replication channel.

- `Slow_launch_threads`

The number of threads that have taken more than `slow_launch_time` seconds to create.

This variable is not meaningful in the embedded server (`libmysqld`) and as of MySQL 5.7.2 is no longer visible within the embedded server.

- `Slow_queries`

The number of queries that have taken more than `long_query_time` seconds. This counter increments regardless of whether the slow query log is enabled. For information about that log, see [Section 6.4.5, “The Slow Query Log”](#).

- `Sort_merge_passes`

The number of merge passes that the sort algorithm has had to do. If this value is large, you should consider increasing the value of the `sort_buffer_size` system variable.

- `Sort_range`

The number of sorts that were done using ranges.

- `Sort_rows`

The number of sorted rows.

- `Sort_scan`

The number of sorts that were done by scanning the table.

- `Ssl_accept_renegotiates`

The number of negotiates needed to establish the connection.

- `Ssl_accepts`

The number of accepted SSL connections.

- `Ssl_callback_cache_hits`

The number of callback cache hits.

- `Ssl_cipher`

The current encryption cipher (empty for unencrypted connections).

- `Ssl_cipher_list`

The list of possible SSL ciphers (empty for non-SSL connections).

- `Ssl_client_connects`

The number of SSL connection attempts to an SSL-enabled master.

- `Ssl_connect_renegotiates`

The number of negotiates needed to establish the connection to an SSL-enabled master.

- `Ssl_ctx_verify_depth`

The SSL context verification depth (how many certificates in the chain are tested).

- `Ssl_ctx_verify_mode`

The SSL context verification mode.

- `Ssl_default_timeout`

The default SSL timeout.

- `Ssl_finished_accepts`

The number of successful SSL connections to the server.

- `Ssl_finished_connects`

The number of successful slave connections to an SSL-enabled master.

- `Ssl_server_not_after`

The last date for which the SSL certificate is valid. To check SSL certificate expiration information, use this statement:

```
mysql> SHOW STATUS LIKE 'Ssl_server_not%';
```

| Variable_name         | Value                    |
|-----------------------|--------------------------|
| Ssl_server_not_after  | Apr 28 14:16:39 2025 GMT |
| Ssl_server_not_before | May 1 14:16:39 2015 GMT  |

- `Ssl_server_not_before`

The first date for which the SSL certificate is valid.

- `Ssl_session_cache_hits`

The number of SSL session cache hits.

- `Ssl_session_cache_misses`

The number of SSL session cache misses.

- `Ssl_session_cache_mode`

The SSL session cache mode.

- `Ssl_session_cache_overflows`

The number of SSL session cache overflows.

- `Ssl_session_cache_size`

The SSL session cache size.

- `Ssl_session_cache_timeouts`

The number of SSL session cache timeouts.

- `Ssl_sessions_reused`

How many SSL connections were reused from the cache.

- `Ssl_used_session_cache_entries`

How many SSL session cache entries were used.

- `Ssl_verify_depth`

The verification depth for replication SSL connections.

- `Ssl_verify_mode`

The verification mode for replication SSL connections.

- `Ssl_version`

The SSL protocol version of the connection; for example, TLSv1. If the connection is not encrypted, the value is empty.

- `Table_locks_immediate`

The number of times that a request for a table lock could be granted immediately.

- `Table_locks_waited`

The number of times that a request for a table lock could not be granted immediately and a wait was needed. If this is high and you have performance problems, you should first optimize your queries, and then either split your table or tables or use replication.

- `Table_open_cache_hits`

The number of hits for open tables cache lookups.

- `Table_open_cache_misses`

The number of misses for open tables cache lookups.

- `Table_open_cache_overflows`

The number of overflows for the open tables cache. This is the number of times, after a table is opened or closed, a cache instance has an unused entry and the size of the instance is larger than `table_open_cache / table_open_cache_instances`.

- `Tc_log_max_pages_used`

For the memory-mapped implementation of the log that is used by `mysqld` when it acts as the transaction coordinator for recovery of internal XA transactions, this variable indicates the largest number of pages used for the log since the server started. If the product of `Tc_log_max_pages_used` and `Tc_log_page_size` is always significantly less than the log size, the size is larger than necessary and can be reduced. (The size is set by the `--log-tc-size` option. This variable is unused: It is unneeded for binary log-based recovery, and the memory-mapped recovery log method is not used unless the number of storage engines that are capable of two-phase commit and that support XA transactions is greater than one. (`InnoDB` is the only applicable engine.)

- `Tc_log_page_size`

The page size used for the memory-mapped implementation of the XA recovery log. The default value is determined using `getpagesize()`. This variable is unused for the same reasons as described for `Tc_log_max_pages_used`.

- `Tc_log_page_waits`

For the memory-mapped implementation of the recovery log, this variable increments each time the server was not able to commit a transaction and had to wait for a free page in the log. If this value is large, you might want to increase the log size (with the `--log-tc-size` option). For binary log-based recovery, this variable increments each time the binary log cannot be closed because there are two-phase commits in progress. (The close operation waits until all such transactions are finished.)

- `Threads_cached`

The number of threads in the thread cache.

This variable is not meaningful in the embedded server (`libmysqld`) and as of MySQL 5.7.2 is no longer visible within the embedded server.

- `Threads_connected`

The number of currently open connections.

- `Threads_created`

The number of threads created to handle connections. If `Threads_created` is big, you may want to increase the `thread_cache_size` value. The cache miss rate can be calculated as `Threads_created/Connections`.

- `Threads_running`

The number of threads that are not sleeping.

- `Uptime`

The number of seconds that the server has been up.

- [Uptime\\_since\\_flush\\_status](#)

The number of seconds since the most recent [FLUSH STATUS](#) statement.

## 6.1.8 Server SQL Modes

The MySQL server can operate in different SQL modes, and can apply these modes differently for different clients, depending on the value of the [sql\\_mode](#) system variable. DBAs can set the global SQL mode to match site server operating requirements, and each application can set its session SQL mode to its own requirements.

Modes affect the SQL syntax MySQL supports and the data validation checks it performs. This makes it easier to use MySQL in different environments and to use MySQL together with other database servers.

- [Setting the SQL Mode](#)
- [The Most Important SQL Modes](#)
- [Full List of SQL Modes](#)
- [Combination SQL Modes](#)
- [Strict SQL Mode](#)
- [Comparison of the IGNORE Keyword and Strict SQL Mode](#)
- [SQL Mode Changes in MySQL 5.7](#)

For answers to questions often asked about server SQL modes in MySQL, see [Section A.3, “MySQL 5.7 FAQ: Server SQL Mode”](#).

When working with [InnoDB](#) tables, consider also the [innodb\\_strict\\_mode](#) system variable. It enables additional error checks for [InnoDB](#) tables.

### Setting the SQL Mode

The default SQL mode in MySQL 5.7 includes these modes: [ONLY\\_FULL\\_GROUP\\_BY](#), [STRICT\\_TRANS\\_TABLES](#), [NO\\_ZERO\\_IN\\_DATE](#), [NO\\_ZERO\\_DATE](#), [ERROR\\_FOR\\_DIVISION\\_BY\\_ZERO](#), [NO\\_AUTO\\_CREATE\\_USER](#), and [NO\\_ENGINE\\_SUBSTITUTION](#).

The [ONLY\\_FULL\\_GROUP\\_BY](#) and [STRICT\\_TRANS\\_TABLES](#) modes were added in MySQL 5.7.5. The [NO\\_AUTO\\_CREATE\\_USER](#) mode was added in MySQL 5.7.7. The [ERROR\\_FOR\\_DIVISION\\_BY\\_ZERO](#), [NO\\_ZERO\\_DATE](#), and [NO\\_ZERO\\_IN\\_DATE](#) modes were added in MySQL 5.7.8. For additional discussion regarding these changes to the default SQL mode value, see [SQL Mode Changes in MySQL 5.7](#).

To set the SQL mode at server startup, use the `--sql-mode="modes"` option on the command line, or `sql-mode="modes"` in an option file such as `my.cnf` (Unix operating systems) or `my.ini` (Windows). *modes* is a list of different modes separated by commas. To clear the SQL mode explicitly, set it to an empty string using `--sql-mode=""` on the command line, or `sql-mode=""` in an option file.

#### Note

MySQL installation programs may configure the SQL mode during the installation process. For example, `mysql_install_db` creates a default option file named `my.cnf` in the base installation directory. This file contains a line that sets the SQL mode; see [Section 5.4.2, “mysql\\_install\\_db — Initialize MySQL Data Directory”](#).

If the SQL mode differs from the default or from what you expect, check for a setting in an option file that the server reads at startup.

To change the SQL mode at runtime, set the global or session `sql_mode` system variable using a `SET` statement:

```
SET GLOBAL sql_mode = 'modes';
SET SESSION sql_mode = 'modes';
```

Setting the `GLOBAL` variable requires the `SUPER` privilege and affects the operation of all clients that connect from that time on. Setting the `SESSION` variable affects only the current client. Each client can change its session `sql_mode` value at any time.

To determine the current global or session `sql_mode` value, use the following statements:

```
SELECT @@GLOBAL.sql_mode;
SELECT @@SESSION.sql_mode;
```

### Important

**SQL mode and user-defined partitioning.** Changing the server SQL mode after creating and inserting data into partitioned tables can cause major changes in the behavior of such tables, and could lead to loss or corruption of data. It is strongly recommended that you never change the SQL mode once you have created tables employing user-defined partitioning.

When replicating partitioned tables, differing SQL modes on master and slave can also lead to problems. For best results, you should always use the same server SQL mode on the master and on the slave.

See [Section 21.6, “Restrictions and Limitations on Partitioning”](#), for more information.

## The Most Important SQL Modes

The most important `sql_mode` values are probably these:

- `ANSI`

This mode changes syntax and behavior to conform more closely to standard SQL. It is one of the special [combination modes](#) listed at the end of this section.

- `STRICT_TRANS_TABLES`

If a value could not be inserted as given into a transactional table, abort the statement. For a nontransactional table, abort the statement if the value occurs in a single-row statement or the first row of a multiple-row statement. More details are given later in this section.

As of MySQL 5.7.5, the default SQL mode includes `STRICT_TRANS_TABLES`.

- `TRADITIONAL`

Make MySQL behave like a “traditional” SQL database system. A simple description of this mode is “give an error instead of a warning” when inserting an incorrect value into a column. It is one of the special [combination modes](#) listed at the end of this section.

### Note

The `INSERT` or `UPDATE` aborts as soon as the error is noticed. This may not be what you want if you are using a nontransactional storage engine,

because data changes made prior to the error may not be rolled back, resulting in a “partially done” update.

When this manual refers to “strict mode,” it means a mode with either or both [STRICT\\_TRANS\\_TABLES](#) or [STRICT\\_ALL\\_TABLES](#) enabled.

## Full List of SQL Modes

The following list describes all supported SQL modes:

- [ALLOW\\_INVALID\\_DATES](#)

Do not perform full checking of dates. Check only that the month is in the range from 1 to 12 and the day is in the range from 1 to 31. This is very convenient for Web applications where you obtain year, month, and day in three different fields and you want to store exactly what the user inserted (without date validation). This mode applies to [DATE](#) and [DATETIME](#) columns. It does not apply [TIMESTAMP](#) columns, which always require a valid date.

The server requires that month and day values be legal, and not merely in the range 1 to 12 and 1 to 31, respectively. With strict mode disabled, invalid dates such as `'2004-04-31'` are converted to `'0000-00-00'` and a warning is generated. With strict mode enabled, invalid dates generate an error. To permit such dates, enable [ALLOW\\_INVALID\\_DATES](#).

- [ANSI\\_QUOTES](#)

Treat `"` as an identifier quote character (like the ``` quote character) and not as a string quote character. You can still use ``` to quote identifiers with this mode enabled. With [ANSI\\_QUOTES](#) enabled, you cannot use double quotation marks to quote literal strings, because it is interpreted as an identifier.

- [ERROR\\_FOR\\_DIVISION\\_BY\\_ZERO](#)

The [ERROR\\_FOR\\_DIVISION\\_BY\\_ZERO](#) mode affects handling of division by zero, which includes `MOD(N, 0)`. For data-change operations ([INSERT](#), [UPDATE](#)), its effect also depends on whether strict SQL mode is enabled.

- If this mode is not enabled, division by zero inserts [NULL](#) and produces no warning.
- If this mode is enabled, division by zero inserts [NULL](#) and produces a warning.
- If this mode and strict mode are enabled, division by zero produces an error, unless [IGNORE](#) is given as well. For [INSERT IGNORE](#) and [UPDATE IGNORE](#), division by zero inserts [NULL](#) and produces a warning.

For [SELECT](#), division by zero returns [NULL](#). Enabling [ERROR\\_FOR\\_DIVISION\\_BY\\_ZERO](#) causes a warning to be produced as well, regardless of whether strict mode is enabled.

As of MySQL 5.7.4, [ERROR\\_FOR\\_DIVISION\\_BY\\_ZERO](#) is deprecated. In MySQL 5.7.4 through 5.7.7, [ERROR\\_FOR\\_DIVISION\\_BY\\_ZERO](#) does nothing when named explicitly. Instead, its effect is included in the effects of strict SQL mode. In MySQL 5.7.8 and later, [ERROR\\_FOR\\_DIVISION\\_BY\\_ZERO](#) does have an effect when named explicitly and is not part of strict mode, as before MySQL 5.7.4. However, it should be used in conjunction with strict mode and is enabled by default. A warning occurs if [ERROR\\_FOR\\_DIVISION\\_BY\\_ZERO](#) is enabled without also enabling strict mode or vice versa. For additional discussion, see [SQL Mode Changes in MySQL 5.7](#).

Because [ERROR\\_FOR\\_DIVISION\\_BY\\_ZERO](#) is deprecated, it will be removed in a future MySQL release as a separate mode name and its effect included in the effects of strict SQL mode.

- [HIGH\\_NOT\\_PRECEDENCE](#)

The precedence of the `NOT` operator is such that expressions such as `NOT a BETWEEN b AND c` are parsed as `NOT (a BETWEEN b AND c)`. In some older versions of MySQL, the expression was parsed as `(NOT a) BETWEEN b AND c`. The old higher-precedence behavior can be obtained by enabling the `HIGH_NOT_PRECEDENCE` SQL mode.

```
mysql> SET sql_mode = '';
mysql> SELECT NOT 1 BETWEEN -5 AND 5;
      -> 0
mysql> SET sql_mode = 'HIGH_NOT_PRECEDENCE';
mysql> SELECT NOT 1 BETWEEN -5 AND 5;
      -> 1
```

- `IGNORE_SPACE`

Permit spaces between a function name and the `(` character. This causes built-in function names to be treated as reserved words. As a result, identifiers that are the same as function names must be quoted as described in [Section 10.2, “Schema Object Names”](#). For example, because there is a `COUNT()` function, the use of `count` as a table name in the following statement causes an error:

```
mysql> CREATE TABLE count (i INT);
ERROR 1064 (42000): You have an error in your SQL syntax
```

The table name should be quoted:

```
mysql> CREATE TABLE `count` (i INT);
Query OK, 0 rows affected (0.00 sec)
```

The `IGNORE_SPACE` SQL mode applies to built-in functions, not to user-defined functions or stored functions. It is always permissible to have spaces after a UDF or stored function name, regardless of whether `IGNORE_SPACE` is enabled.

For further discussion of `IGNORE_SPACE`, see [Section 10.2.4, “Function Name Parsing and Resolution”](#).

- `NO_AUTO_CREATE_USER`

Prevent the `GRANT` statement from automatically creating new user accounts if it would otherwise do so, unless authentication information is specified. The statement must specify a nonempty password using `IDENTIFIED BY` or an authentication plugin using `IDENTIFIED WITH`.

It is preferable to create MySQL accounts with `CREATE USER` rather than `GRANT`. As of MySQL 5.7.6, `NO_AUTO_CREATE_USER` is deprecated. As of 5.7.7 the default SQL mode includes `NO_AUTO_CREATE_USER` and assignments to `sql_mode` that change the `NO_AUTO_CREATE_USER` mode state produce a warning, except assignments that set `sql_mode` to `DEFAULT`. `NO_AUTO_CREATE_USER` will be removed in a future MySQL release, at which point its effect will be enabled at all times (`GRANT` will not create accounts).

- `NO_AUTO_VALUE_ON_ZERO`

`NO_AUTO_VALUE_ON_ZERO` affects handling of `AUTO_INCREMENT` columns. Normally, you generate the next sequence number for the column by inserting either `NULL` or `0` into it. `NO_AUTO_VALUE_ON_ZERO` suppresses this behavior for `0` so that only `NULL` generates the next sequence number.

This mode can be useful if `0` has been stored in a table's `AUTO_INCREMENT` column. (Storing `0` is not a recommended practice, by the way.) For example, if you dump the table with `mysqldump` and then reload it, MySQL normally generates new sequence numbers when it encounters the `0` values, resulting in a table with contents different from the one that was dumped. Enabling `NO_AUTO_VALUE_ON_ZERO` before reloading the dump file solves this problem. `mysqldump` now

automatically includes in its output a statement that enables `NO_AUTO_VALUE_ON_ZERO`, to avoid this problem.

- `NO_BACKSLASH_ESCAPES`

Disable the use of the backslash character (`\`) as an escape character within strings. With this mode enabled, backslash becomes an ordinary character like any other.

- `NO_DIR_IN_CREATE`

When creating a table, ignore all `INDEX DIRECTORY` and `DATA DIRECTORY` directives. This option is useful on slave replication servers.

- `NO_ENGINE_SUBSTITUTION`

Control automatic substitution of the default storage engine when a statement such as `CREATE TABLE` or `ALTER TABLE` specifies a storage engine that is disabled or not compiled in.

The default SQL mode includes `NO_ENGINE_SUBSTITUTION`.

Because storage engines can be pluggable at runtime, unavailable engines are treated the same way:

With `NO_ENGINE_SUBSTITUTION` disabled, for `CREATE TABLE` the default engine is used and a warning occurs if the desired engine is unavailable. For `ALTER TABLE`, a warning occurs and the table is not altered.

With `NO_ENGINE_SUBSTITUTION` enabled, an error occurs and the table is not created or altered if the desired engine is unavailable.

- `NO_FIELD_OPTIONS`

Do not print MySQL-specific column options in the output of `SHOW CREATE TABLE`. This mode is used by `mysqldump` in portability mode.

- `NO_KEY_OPTIONS`

Do not print MySQL-specific index options in the output of `SHOW CREATE TABLE`. This mode is used by `mysqldump` in portability mode.

- `NO_TABLE_OPTIONS`

Do not print MySQL-specific table options (such as `ENGINE`) in the output of `SHOW CREATE TABLE`. This mode is used by `mysqldump` in portability mode.

- `NO_UNSIGNED_SUBTRACTION`

Subtraction between integer values, where one is of type `UNSIGNED`, produces an unsigned result by default. If the result would otherwise have been negative, an error results:

```
mysql> SET sql_mode = '';
Query OK, 0 rows affected (0.00 sec)

mysql> SELECT CAST(0 AS UNSIGNED) - 1;
ERROR 1690 (22003): BIGINT UNSIGNED value is out of range in '(cast(0 as unsigned) - 1)'
```

If the `NO_UNSIGNED_SUBTRACTION` SQL mode is enabled, the result is negative:

```
mysql> SET sql_mode = 'NO UNSIGNED SUBTRACTION';
mysql> SELECT CAST(0 AS UNSIGNED) - 1;
+-----+
| CAST(0 AS UNSIGNED) - 1 |
+-----+
```

```
| -1 |
+-----+
```

If the result of such an operation is used to update an `UNSIGNED` integer column, the result is clipped to the maximum value for the column type, or clipped to 0 if `NO_UNSIGNED_SUBTRACTION` is enabled. If strict SQL mode is enabled, an error occurs and the column remains unchanged.

When `NO_UNSIGNED_SUBTRACTION` is enabled, the subtraction result is signed, *even if any operand is unsigned*. For example, compare the type of column `c2` in table `t1` with that of column `c2` in table `t2`:

```
mysql> SET sql_mode='';
mysql> CREATE TABLE test (c1 BIGINT UNSIGNED NOT NULL);
mysql> CREATE TABLE t1 SELECT c1 - 1 AS c2 FROM test;
mysql> DESCRIBE t1;
+-----+-----+-----+-----+-----+-----+
| Field | Type                | Null | Key | Default | Extra |
+-----+-----+-----+-----+-----+-----+
| c2    | bigint(21) unsigned | NO   |     | 0       |       |
+-----+-----+-----+-----+-----+-----+

mysql> SET sql_mode='NO_UNSIGNED_SUBTRACTION';
mysql> CREATE TABLE t2 SELECT c1 - 1 AS c2 FROM test;
mysql> DESCRIBE t2;
+-----+-----+-----+-----+-----+-----+
| Field | Type                | Null | Key | Default | Extra |
+-----+-----+-----+-----+-----+-----+
| c2    | bigint(21)          | NO   |     | 0       |       |
+-----+-----+-----+-----+-----+-----+
```

This means that `BIGINT UNSIGNED` is not 100% usable in all contexts. See [Section 13.10, “Cast Functions and Operators”](#).

- `NO_ZERO_DATE`

The `NO_ZERO_DATE` mode affects whether the server permits `'0000-00-00'` as a valid date. Its effect also depends on whether strict SQL mode is enabled.

- If this mode is not enabled, `'0000-00-00'` is permitted and inserts produce no warning.
- If this mode is enabled, `'0000-00-00'` is permitted and inserts produce a warning.
- If this mode and strict mode are enabled, `'0000-00-00'` is not permitted and inserts produce an error, unless `IGNORE` is given as well. For `INSERT IGNORE` and `UPDATE IGNORE`, `'0000-00-00'` is permitted and inserts produce a warning.

As of MySQL 5.7.4, `NO_ZERO_DATE` is deprecated. In MySQL 5.7.4 through 5.7.7, `NO_ZERO_DATE` does nothing when named explicitly. Instead, its effect is included in the effects of strict SQL mode. In MySQL 5.7.8 and later, `NO_ZERO_DATE` does have an effect when named explicitly and is not part of strict mode, as before MySQL 5.7.4. However, it should be used in conjunction with strict mode and is enabled by default. A warning occurs if `NO_ZERO_DATE` is enabled without also enabling strict mode or vice versa. For additional discussion, see [SQL Mode Changes in MySQL 5.7](#).

Because `NO_ZERO_DATE` is deprecated, it will be removed in a future MySQL release as a separate mode name and its effect included in the effects of strict SQL mode.

- `NO_ZERO_IN_DATE`

The `NO_ZERO_IN_DATE` mode affects whether the server permits dates in which the year part is nonzero but the month or day part is 0. (This mode affects dates such as `'2010-00-01'` or `'2010-01-00'`, but not `'0000-00-00'`. To control whether the server permits `'0000-00-00'`,

use the `NO_ZERO_DATE` mode.) The effect of `NO_ZERO_IN_DATE` also depends on whether strict SQL mode is enabled.

- If this mode is not enabled, dates with zero parts are permitted and inserts produce no warning.
- If this mode is enabled, dates with zero parts are inserted as `'0000-00-00'` and produce a warning.
- If this mode and strict mode are enabled, dates with zero parts are not permitted and inserts produce an error, unless `IGNORE` is given as well. For `INSERT IGNORE` and `UPDATE IGNORE`, dates with zero parts are inserted as `'0000-00-00'` and produce a warning.

As of MySQL 5.7.4, `NO_ZERO_IN_DATE` is deprecated. In MySQL 5.7.4 through 5.7.7, `NO_ZERO_IN_DATE` does nothing when named explicitly. Instead, its effect is included in the effects of strict SQL mode. In MySQL 5.7.8 and later, `NO_ZERO_IN_DATE` does have an effect when named explicitly and is not part of strict mode, as before MySQL 5.7.4. However, it should be used in conjunction with strict mode and is enabled by default. A warning occurs if `NO_ZERO_IN_DATE` is enabled without also enabling strict mode or vice versa. For additional discussion, see [SQL Mode Changes in MySQL 5.7](#).

Because `NO_ZERO_IN_DATE` is deprecated, it will be removed in a future MySQL release as a separate mode name and its effect included in the effects of strict SQL mode.

- `ONLY_FULL_GROUP_BY`

Reject queries for which the select list, `HAVING` condition, or `ORDER BY` list refer to nonaggregated columns that are neither named in the `GROUP BY` clause nor are functionally dependent on (uniquely determined by) `GROUP BY` columns.

As of MySQL 5.7.5, the default SQL mode includes `ONLY_FULL_GROUP_BY`. (Before 5.7.5, MySQL does not detect functional dependency and `ONLY_FULL_GROUP_BY` is not enabled by default. For a description of pre-5.7.5 behavior, see the [MySQL 5.6 Reference Manual](#).)

A MySQL extension to standard SQL permits references in the `HAVING` clause to aliased expressions in the select list. Before MySQL 5.7.5, enabling `ONLY_FULL_GROUP_BY` disables this extension, thus requiring the `HAVING` clause to be written using unaliased expressions. As of MySQL 5.7.5, this restriction is lifted so that the `HAVING` clause can refer to aliases regardless of whether `ONLY_FULL_GROUP_BY` is enabled.

For additional discussion and examples, see [Section 13.19.3, “MySQL Handling of GROUP BY”](#).

- `PAD_CHAR_TO_FULL_LENGTH`

By default, trailing spaces are trimmed from `CHAR` column values on retrieval. If `PAD_CHAR_TO_FULL_LENGTH` is enabled, trimming does not occur and retrieved `CHAR` values are padded to their full length. This mode does not apply to `VARCHAR` columns, for which trailing spaces are retained on retrieval.

```
mysql> CREATE TABLE t1 (c1 CHAR(10));
Query OK, 0 rows affected (0.37 sec)

mysql> INSERT INTO t1 (c1) VALUES('xy');
Query OK, 1 row affected (0.01 sec)

mysql> SET sql_mode = '';
Query OK, 0 rows affected (0.00 sec)

mysql> SELECT c1, CHAR_LENGTH(c1) FROM t1;
+-----+-----+
| c1    | CHAR_LENGTH(c1) |
+-----+-----+
```

```

| xy |          2 |
+-----+-----+
1 row in set (0.00 sec)

mysql> SET sql_mode = 'PAD_CHAR_TO_FULL_LENGTH';
Query OK, 0 rows affected (0.00 sec)

mysql> SELECT c1, CHAR_LENGTH(c1) FROM t1;
+-----+-----+
| c1      | CHAR_LENGTH(c1) |
+-----+-----+
| xy      |          10     |
+-----+-----+
1 row in set (0.00 sec)

```

- [PIPES\\_AS\\_CONCAT](#)

Treat `||` as a string concatenation operator (same as `CONCAT()`) rather than as a synonym for `OR`.

- [REAL\\_AS\\_FLOAT](#)

Treat `REAL` as a synonym for `FLOAT`. By default, MySQL treats `REAL` as a synonym for `DOUBLE`.

- [STRICT\\_ALL\\_TABLES](#)

Enable strict SQL mode for all storage engines. Invalid data values are rejected. For details, see [Strict SQL Mode](#).

From MySQL 5.7.4 through 5.7.7, [STRICT\\_ALL\\_TABLES](#) includes the effect of the [ERROR\\_FOR\\_DIVISION\\_BY\\_ZERO](#), [NO\\_ZERO\\_DATE](#), and [NO\\_ZERO\\_IN\\_DATE](#) modes. For additional discussion, see [SQL Mode Changes in MySQL 5.7](#).

- [STRICT\\_TRANS\\_TABLES](#)

Enable strict SQL mode for transactional storage engines, and when possible for nontransactional storage engines. For details, see [Strict SQL Mode](#).

From MySQL 5.7.4 through 5.7.7, [STRICT\\_TRANS\\_TABLES](#) includes the effect of the [ERROR\\_FOR\\_DIVISION\\_BY\\_ZERO](#), [NO\\_ZERO\\_DATE](#), and [NO\\_ZERO\\_IN\\_DATE](#) modes. For additional discussion, see [SQL Mode Changes in MySQL 5.7](#).

## Combination SQL Modes

The following special modes are provided as shorthand for combinations of mode values from the preceding list.

- [ANSI](#)

Equivalent to [REAL\\_AS\\_FLOAT](#), [PIPES\\_AS\\_CONCAT](#), [ANSI\\_QUOTES](#), [IGNORE\\_SPACE](#), and (as of MySQL 5.7.5) [ONLY\\_FULL\\_GROUP\\_BY](#).

[ANSI](#) mode also causes the server to return an error for queries where a set function `S` with an outer reference `S(outer_ref)` cannot be aggregated in the outer query against which the outer reference has been resolved. This is such a query:

```
SELECT * FROM t1 WHERE t1.a IN (SELECT MAX(t1.b) FROM t2 WHERE ...);
```

Here, `MAX(t1.b)` cannot be aggregated in the outer query because it appears in the `WHERE` clause of that query. Standard SQL requires an error in this situation. If [ANSI](#) mode is not enabled, the server treats `S(outer_ref)` in such queries the same way that it would interpret `S(const)`.

See [Section 1.8, “MySQL Standards Compliance”](#).

- [DB2](#)

Equivalent to `PIPES_AS_CONCAT`, `ANSI_QUOTES`, `IGNORE_SPACE`, `NO_KEY_OPTIONS`, `NO_TABLE_OPTIONS`, `NO_FIELD_OPTIONS`.

- `MAXDB`

Equivalent to `PIPES_AS_CONCAT`, `ANSI_QUOTES`, `IGNORE_SPACE`, `NO_KEY_OPTIONS`, `NO_TABLE_OPTIONS`, `NO_FIELD_OPTIONS`, `NO_AUTO_CREATE_USER`.

- `MSSQL`

Equivalent to `PIPES_AS_CONCAT`, `ANSI_QUOTES`, `IGNORE_SPACE`, `NO_KEY_OPTIONS`, `NO_TABLE_OPTIONS`, `NO_FIELD_OPTIONS`.

- `MYSQL323`

Equivalent to `MYSQL323`, `HIGH_NOT_PRECEDENCE`. This means `HIGH_NOT_PRECEDENCE` plus some `SHOW CREATE TABLE` behaviors specific to `MYSQL323`:

- `TIMESTAMP` column display does not include `DEFAULT` or `ON UPDATE` attributes that were introduced in MySQL 4.1.
- String column display does not include character set and collation attributes that were introduced in MySQL 4.1. For `CHAR` and `VARCHAR` columns, if the collation is binary, `BINARY` is appended to the column type.
- The `ENGINE=engine_name` table option displays as `TYPE=engine+name`.
- For `MEMORY` tables, the storage engine is displayed as `HEAP`.
- `MYSQL40`

Equivalent to `MYSQL40`, `HIGH_NOT_PRECEDENCE`. This means `HIGH_NOT_PRECEDENCE` plus some behaviors specific to `MYSQL40`. These are the same as for `MYSQL323`, except that `SHOW CREATE TABLE` does not display `HEAP` as the storage engine for `MEMORY` tables.

- `ORACLE`

Equivalent to `PIPES_AS_CONCAT`, `ANSI_QUOTES`, `IGNORE_SPACE`, `NO_KEY_OPTIONS`, `NO_TABLE_OPTIONS`, `NO_FIELD_OPTIONS`, `NO_AUTO_CREATE_USER`.

- `POSTGRESQL`

Equivalent to `PIPES_AS_CONCAT`, `ANSI_QUOTES`, `IGNORE_SPACE`, `NO_KEY_OPTIONS`, `NO_TABLE_OPTIONS`, `NO_FIELD_OPTIONS`.

- `TRADITIONAL`

Before MySQL 5.7.4, and in MySQL 5.7.8 and later, `TRADITIONAL` is equivalent to `STRICT_TRANS_TABLES`, `STRICT_ALL_TABLES`, `NO_ZERO_IN_DATE`, `NO_ZERO_DATE`, `ERROR_FOR_DIVISION_BY_ZERO`, `NO_AUTO_CREATE_USER`, and `NO_ENGINE_SUBSTITUTION`.

From MySQL 5.7.4 though 5.7.7, `TRADITIONAL` is equivalent to `STRICT_TRANS_TABLES`, `STRICT_ALL_TABLES`, `NO_AUTO_CREATE_USER`, and `NO_ENGINE_SUBSTITUTION`. The `NO_ZERO_IN_DATE`, `NO_ZERO_DATE`, and `ERROR_FOR_DIVISION_BY_ZERO` modes are not named because in those versions their effects are included in the effects of strict SQL mode (`STRICT_ALL_TABLES` or `STRICT_TRANS_TABLES`). Thus, the effects of `TRADITIONAL` are the same in all MySQL 5.7 versions (and the same as in MySQL 5.6). For additional discussion, see [SQL Mode Changes in MySQL 5.7](#).

## Strict SQL Mode

Strict mode controls how MySQL handles invalid or missing values in data-change statements such as `INSERT` or `UPDATE`. A value can be invalid for several reasons. For example, it might have the wrong data type for the column, or it might be out of range. A value is missing when a new row to be inserted does not contain a value for a non-`NULL` column that has no explicit `DEFAULT` clause in its definition. (For a `NULL` column, `NULL` is inserted if the value is missing.) Strict mode also affects DDL statements such as `CREATE TABLE`.

If strict mode is not in effect, MySQL inserts adjusted values for invalid or missing values and produces warnings (see [Section 14.7.5.40, “SHOW WARNINGS Syntax”](#)). In strict mode, you can produce this behavior by using `INSERT IGNORE` or `UPDATE IGNORE`.

For statements such as `SELECT` that do not change data, invalid values generate a warning in strict mode, not an error.

Strict mode produces an error for attempts to create a key that exceeds the maximum key length. When strict mode is not enabled, this results in a warning and truncation of the key to the maximum key length.

Strict mode does not affect whether foreign key constraints are checked. `foreign_key_checks` can be used for that. (See [Section 6.1.5, “Server System Variables”](#).)

Strict SQL mode is in effect if either `STRICT_ALL_TABLES` or `STRICT_TRANS_TABLES` is enabled, although the effects of these modes differ somewhat:

- For transactional tables, an error occurs for invalid or missing values in a data-change statement when either `STRICT_ALL_TABLES` or `STRICT_TRANS_TABLES` is enabled. The statement is aborted and rolled back.
- For nontransactional tables, the behavior is the same for either mode if the bad value occurs in the first row to be inserted or updated: The statement is aborted and the table remains unchanged. If the statement inserts or modifies multiple rows and the bad value occurs in the second or later row, the result depends on which strict mode is enabled:
  - For `STRICT_ALL_TABLES`, MySQL returns an error and ignores the rest of the rows. However, because the earlier rows have been inserted or updated, the result is a partial update. To avoid this, use single-row statements, which can be aborted without changing the table.
  - For `STRICT_TRANS_TABLES`, MySQL converts an invalid value to the closest valid value for the column and inserts the adjusted value. If a value is missing, MySQL inserts the implicit default value for the column data type. In either case, MySQL generates a warning rather than an error and continues processing the statement. Implicit defaults are described in [Section 12.7, “Data Type Default Values”](#).

Strict mode affects handling of division by zero, zero dates, and zeros in dates as follows:

- Strict mode affects handling of division by zero, which includes `MOD(N, 0)`:

For data-change operations (`INSERT`, `UPDATE`):

- If strict mode is not enabled, division by zero inserts `NULL` and produces no warning.
- If strict mode is enabled, division by zero produces an error, unless `IGNORE` is given as well. For `INSERT IGNORE` and `UPDATE IGNORE`, division by zero inserts `NULL` and produces a warning.

For `SELECT`, division by zero returns `NULL`. Enabling strict mode causes a warning to be produced as well.

- Strict mode affects whether the server permits `'0000-00-00'` as a valid date:
  - If strict mode is not enabled, `'0000-00-00'` is permitted and inserts produce no warning.

- If strict mode is enabled, '0000-00-00' is not permitted and inserts produce an error, unless `IGNORE` is given as well. For `INSERT IGNORE` and `UPDATE IGNORE`, '0000-00-00' is permitted and inserts produce a warning.
- Strict mode affects whether the server permits dates in which the year part is nonzero but the month or day part is 0 (dates such as '2010-00-01' or '2010-01-00'):
- If strict mode is not enabled, dates with zero parts are permitted and inserts produce no warning.
- If strict mode is enabled, dates with zero parts are not permitted and inserts produce an error, unless `IGNORE` is given as well. For `INSERT IGNORE` and `UPDATE IGNORE`, dates with zero parts are inserted as '0000-00-00' (which is considered valid with `IGNORE`) and produce a warning.

For more information about strict mode with respect to `IGNORE`, see [Comparison of the IGNORE Keyword and Strict SQL Mode](#).

Before MySQL 5.7.4, and in MySQL 5.7.8 and later, strict mode affects handling of division by zero, zero dates, and zeros in dates in conjunction with the `ERROR_FOR_DIVISION_BY_ZERO`, `NO_ZERO_DATE`, and `NO_ZERO_IN_DATE` modes. From MySQL 5.7.4 through 5.7.7, the `ERROR_FOR_DIVISION_BY_ZERO`, `NO_ZERO_DATE`, and `NO_ZERO_IN_DATE` modes do nothing when named explicitly and their effects are included in the effects of strict mode. For additional discussion, see [SQL Mode Changes in MySQL 5.7](#).

## Comparison of the IGNORE Keyword and Strict SQL Mode

This section compares the effect on statement execution of the `IGNORE` keyword (which downgrades errors to warnings) and strict SQL mode (which upgrades warnings to errors). It describes which statements they affect, and which errors they apply to.

The following table presents a summary comparison of statement behavior when the default is to produce an error versus a warning. An example of when the default is to produce an error is inserting a `NULL` into a `NOT NULL` column. An example of when the default is to produce a warning is inserting a value of the wrong data type into a column (such as inserting the string 'abc' into an integer column).

| Operational Mode                               | When Statement Default is Error                                | When Statement Default is Warning                                |
|--|--|--|
| Without <code>IGNORE</code> or strict SQL mode | Error  | Warning  |
| With <code>IGNORE</code>                       | Warning  | Warning (same as without <code>IGNORE</code> or strict SQL mode) |
| With strict SQL mode                           | Error (same as without <code>IGNORE</code> or strict SQL mode) | Error  |
| With <code>IGNORE</code> and strict SQL mode   | Warning  | Warning  |

One conclusion to draw from the table is that when the `IGNORE` keyword and strict SQL mode are both in effect, `IGNORE` takes precedence. This means that, although `IGNORE` and strict SQL mode can be considered to have opposite effects on error handling, they do not cancel when used together.

## The Effect of IGNORE on Statement Execution

Several statements in MySQL support an optional `IGNORE` keyword. This keyword causes the server to downgrade certain types of errors and generate warnings instead. For a multiple-row statement, `IGNORE` causes the statement to skip to the next row instead of aborting.

For example, if the table `t` has a primary key column `i`, attempting to insert the same value of `i` into multiple rows normally produces a duplicate-key error:

```
mysql> INSERT INTO t (i) VALUES(1),(1);
ERROR 1062 (23000): Duplicate entry '1' for key 'PRIMARY'
```

With `IGNORE`, the row containing the duplicate key still is not inserted, but a warning occurs instead of an error:

```
mysql> INSERT IGNORE INTO t (i) VALUES(1),(1);
Query OK, 1 row affected, 1 warning (0.01 sec)
Records: 2  Duplicates: 1  Warnings: 1

mysql> SHOW WARNINGS;
+-----+-----+-----+
| Level | Code | Message |
+-----+-----+-----+
| Warning | 1062 | Duplicate entry '1' for key 'PRIMARY' |
+-----+-----+-----+
1 row in set (0.00 sec)
```

These statements support the `IGNORE` keyword:

- `CREATE TABLE ... SELECT`: `IGNORE` does not apply to the `CREATE TABLE` or `SELECT` parts of the statement but to inserts into the table of rows produced by the `SELECT`. Rows that duplicate an existing row on a unique key value are discarded.
- `DELETE`: `IGNORE` causes MySQL to ignore errors during the process of deleting rows.
- `INSERT`: With `IGNORE`, rows that duplicate an existing row on a unique key value are discarded. Rows set to values that would cause data conversion errors are set to the closest valid values instead.

For partitioned tables where no partition matching a given value is found, `IGNORE` causes the insert operation to fail silently for rows containing the unmatched value.

- `LOAD DATA`, `LOAD XML`: With `IGNORE`, rows that duplicate an existing row on a unique key value are discarded.
- `UPDATE`: With `IGNORE`, rows for which duplicate-key conflicts occur on a unique key value are not updated. Rows updated to values that would cause data conversion errors are updated to the closest valid values instead.

The `IGNORE` keyword applies to the following errors:

```
ER_BAD_NULL_ERROR
ER_DUP_ENTRY
ER_DUP_ENTRY_WITH_KEY_NAME
ER_DUP_KEY
ER_NO_PARTITION_FOR_GIVEN_VALUE
ER_NO_PARTITION_FOR_GIVEN_VALUE_SILENT
ER_NO_REFERENCED_ROW_2
ER_ROW_DOES_NOT_MATCH_GIVEN_PARTITION_SET
ER_ROW_IS_REFERENCED_2
ER_SUBQUERY_NO_1_ROW
ER_VIEW_CHECK_FAILED
```

## The Effect of Strict SQL Mode on Statement Execution

The MySQL server can operate in different SQL modes, and can apply these modes differently for different clients, depending on the value of the `sql_mode` system variable. In “strict” SQL mode, the server upgrades certain warnings to errors.

For example, in non-strict SQL mode, inserting the string `'abc'` into an integer column results in conversion of the value to 0 and a warning:

```
mysql> SET sql_mode = '';
```

```
Query OK, 0 rows affected (0.00 sec)

mysql> INSERT INTO t (i) VALUES('abc');
Query OK, 1 row affected, 1 warning (0.01 sec)

mysql> SHOW WARNINGS;
+-----+-----+-----+
| Level   | Code | Message                                     |
+-----+-----+-----+
| Warning | 1366 | Incorrect integer value: 'abc' for column 'i' at row 1 |
+-----+-----+-----+
1 row in set (0.00 sec)
```

In strict SQL mode, the invalid value is rejected with an error:

```
mysql> SET sql_mode = 'STRICT_ALL_TABLES';
Query OK, 0 rows affected (0.00 sec)

mysql> INSERT INTO t (i) VALUES('abc');
ERROR 1366 (HY000): Incorrect integer value: 'abc' for column 'i' at row 1
```

For more information about possible settings of the `sql_mode` system variable, see [Section 6.1.8, “Server SQL Modes”](#).

Strict SQL mode applies to the following statements under conditions for which some value might be out of range or an invalid row is inserted into or deleted from a table:

- `ALTER TABLE`
- `CREATE TABLE`
- `CREATE TABLE ... SELECT`
- `DELETE` (both single table and multiple table)
- `INSERT`
- `LOAD DATA`
- `LOAD XML`
- `SELECT SLEEP( )`
- `UPDATE` (both single table and multiple table)

Within stored programs, individual statements of the types just listed execute in strict SQL mode if the program was defined while strict mode was in effect.

Strict SQL mode applies to the following errors, represent a class of errors in which an input value is either invalid or missing. A value is invalid if it has the wrong data type for the column or might be out of range. A value is missing if a new row to be inserted does not contain a value for a `NOT NULL` column that has no explicit `DEFAULT` clause in its definition.

```
ER_BAD_NULL_ERROR
ER_CUT_VALUE_GROUP_CONCAT
ER_DATA_TOO_LONG
ER_DATETIME_FUNCTION_OVERFLOW
ER_DIVISION_BY_ZERO
ER_INVALID_ARGUMENT_FOR_LOGARITHM
ER_NO_DEFAULT_FOR_FIELD
ER_NO_DEFAULT_FOR_VIEW_FIELD
ER_TOO_LONG_KEY
ER_TRUNCATED_WRONG_VALUE
ER_TRUNCATED_WRONG_VALUE_FOR_FIELD
ER_WARN_DATA_OUT_OF_RANGE
ER_WARN_NULL_TO_NOTNULL
ER_WARN_TOO_FEW_RECORDS
```

```
ER_WRONG_ARGUMENTS
ER_WRONG_VALUE_FOR_TYPE
WARN_DATA_TRUNCATED
```

## SQL Mode Changes in MySQL 5.7

In MySQL 5.7.5, the `ONLY_FULL_GROUP_BY` SQL mode is enabled by default because `GROUP BY` processing has become more sophisticated to include detection of functional dependencies. However, if you find that having `ONLY_FULL_GROUP_BY` enabled causes queries for existing applications to be rejected, either of these actions should restore operation:

- If it is possible to modify an offending query, do so, either so that nonaggregated columns are functionally dependent on `GROUP BY` columns, or by referring to nonaggregated columns using `ANY_VALUE()`.
- If it is not possible to modify an offending query (for example, if it is generated by a third-party application), set the `sql_mode` system variable at server startup to not enable `ONLY_FULL_GROUP_BY`.

As of MySQL 5.7.4, the `ERROR_FOR_DIVISION_BY_ZERO`, `NO_ZERO_DATE`, and `NO_ZERO_IN_DATE` SQL modes are deprecated. From MySQL 5.7.4 through 5.7.7, these modes do nothing when named explicitly. Instead, their effects are included in the effects of strict SQL mode (`STRICT_ALL_TABLES` or `STRICT_TRANS_TABLES`). In other words, strict mode means the same thing in those versions as the pre-5.7.4 meaning of strict mode plus `ERROR_FOR_DIVISION_BY_ZERO`, `NO_ZERO_DATE`, and `NO_ZERO_IN_DATE`.

The MySQL 5.7.4 change to make strict mode more strict by including `ERROR_FOR_DIVISION_BY_ZERO`, `NO_ZERO_DATE`, and `NO_ZERO_IN_DATE` caused some problems. For example, in MySQL 5.6 with strict mode but not `NO_ZERO_DATE` enabled, `TIMESTAMP` columns can be defined with `DEFAULT '0000-00-00 00:00:00'`. In MySQL 5.7.4 with the same mode settings, strict mode includes the effect of `NO_ZERO_DATE` and `TIMESTAMP` columns cannot be defined with `DEFAULT '0000-00-00 00:00:00'`. This causes replication of `CREATE TABLE` statements from 5.6 to 5.7.4 to fail if they contain such `TIMESTAMP` columns.

The long term plan is still to have the three affected modes be included in strict SQL mode and to remove them as explicit modes in a future MySQL release. But to restore compatibility in MySQL 5.7 with MySQL 5.6 strict mode and to provide additional time for affected applications to be modified, the following changes were made in MySQL 5.7.8:

- `ERROR_FOR_DIVISION_BY_ZERO`, `NO_ZERO_DATE`, and `NO_ZERO_IN_DATE` have an effect when named explicitly. This reverts a change made in MySQL 5.7.4.
- `ERROR_FOR_DIVISION_BY_ZERO`, `NO_ZERO_DATE`, and `NO_ZERO_IN_DATE` are not part of strict SQL mode. This reverts a change made in MySQL 5.7.4.
- `ERROR_FOR_DIVISION_BY_ZERO`, `NO_ZERO_DATE`, and `NO_ZERO_IN_DATE` are included in the default `sql_mode` value, which as a result includes these modes: `ONLY_FULL_GROUP_BY`, `STRICT_TRANS_TABLES`, `NO_ZERO_IN_DATE`, `NO_ZERO_DATE`, `ERROR_FOR_DIVISION_BY_ZERO`, `NO_AUTO_CREATE_USER`, and `NO_ENGINE_SUBSTITUTION`.

With the preceding changes, stricter data checking is still enabled by default, but the individual modes can be disabled in environments where it is currently desirable or necessary to do so.

Although in MySQL 5.7.8 and later `ERROR_FOR_DIVISION_BY_ZERO`, `NO_ZERO_DATE`, and `NO_ZERO_IN_DATE` can be used separately from strict mode, it is intended that they be used together. As a reminder, a warning occurs if they are enabled without also enabling strict mode or vice versa.

### Important

The following discussion applies only for MySQL versions 5.7.4 through 5.7.7. For upgrades from a version older than MySQL 5.7.4, we recommend upgrading to MySQL 5.7.8 or later, which renders this discussion unnecessary.

The remainder of this section describes the SQL mode settings to use in MySQL 5.7.4 through 5.7.7 to achieve the same statement execution as before 5.7.4, including the cases for `INSERT` and `UPDATE` in which `IGNORE` is given. It also provides guidelines for determining whether applications need modification to behave the same before and after the SQL mode changes.

The following table shows how to control handling of division by zero for versions other than MySQL 5.7.4 through 5.7.7 and for MySQL 5.7.4 through 5.7.7.

| Desired Behavior                              | MySQL 5.7.x Versions Except 5.7.4 Through 5.7.7  | MySQL 5.7.4 Through 5.7.7         |
|---|--|-----------------------------------|
| insert <code>NULL</code> , produce no warning | <code>ERROR_FOR_DIVISION_BY_ZERO</code> not enabled  | strict mode not enabled           |
| insert <code>NULL</code> , produce warning    | <code>ERROR_FOR_DIVISION_BY_ZERO</code> , or <code>ERROR_FOR_DIVISION_BY_ZERO</code> + strict mode + <code>IGNORE</code> | strict mode + <code>IGNORE</code> |
| error   | <code>ERROR_FOR_DIVISION_BY_ZERO</code> + strict mode  | strict mode                       |

The following table shows how to control whether the server permits '`0000-00-00`' as a valid date for versions other than MySQL 5.7.4 through 5.7.7 and for MySQL 5.7.4 through 5.7.7.

| Desired Behavior                                       | MySQL 5.7.x Versions Except 5.7.4 Through 5.7.7  | MySQL 5.7.4 Through 5.7.7         |
|--|--|-----------------------------------|
| insert ' <code>0000-00-00</code> ', produce no warning | <code>NO_ZERO_DATE</code> not enabled  | strict mode not enabled           |
| insert ' <code>0000-00-00</code> ', produce warning    | <code>NO_ZERO_DATE</code> , or <code>NO_ZERO_DATE</code> + strict mode + <code>IGNORE</code> | strict mode + <code>IGNORE</code> |
| error  | <code>NO_ZERO_DATE</code> + strict mode  | strict mode                       |

The following table shows how to control whether the server permits dates with zero parts for versions other than MySQL 5.7.4 through 5.7.7 and for MySQL 5.7.4 through 5.7.7.

| Desired Behavior                                    | MySQL 5.7.x Versions Except 5.7.4 Through 5.7.7  | MySQL 5.7.4 Through 5.7.7         |
|---|--|-----------------------------------|
| insert date, produce no warning                     | <code>NO_ZERO_IN_DATE</code> not enabled   | strict mode not enabled           |
| insert ' <code>0000-00-00</code> ', produce warning | <code>NO_ZERO_IN_DATE</code> , or <code>NO_ZERO_IN_DATE</code> + strict mode + <code>IGNORE</code> | strict mode + <code>IGNORE</code> |
| error   | <code>NO_ZERO_IN_DATE</code> + strict mode   | strict mode                       |

The following discussion describes the conditions under which a given statement produces the same or different result under the SQL mode changes in MySQL 5.7.4 through 5.7.7. It considers only strict mode (`STRICT_ALL_TABLES` or `STRICT_TRANS_TABLES`) and the three deprecated modes (`ERROR_FOR_DIVISION_BY_ZERO`, `NO_ZERO_DATE`, and `NO_ZERO_IN_DATE`). Other SQL modes such as `ANSI_QUOTES` or `ONLY_FULL_GROUP_BY` are assumed to be held constant before and after an upgrade.

This discussion also describes how to prepare for an upgrade to 5.7.4 through 5.7.7 from a version older than 5.7.4. *Any modifications should be made before upgrading.*

There is no change in behavior between MySQL 5.6 and 5.7 for the following SQL mode settings. A statement that executes under one of these settings needs no modification to produce the same result in 5.6 and 5.7:

- Strict mode and the three deprecated modes are all not enabled.
- Strict mode and the three deprecated modes are all enabled.

A change from warnings in MySQL 5.6 to no warnings in MySQL 5.7 occurs for the following SQL mode settings. The result of statement execution is the same in 5.6 and 5.7, so statements need no modification unless warnings are considered significant:

- Strict mode is not enabled, but either of the deprecated `ERROR_FOR_DIVISION_BY_ZERO` and `NO_ZERO_DATE` modes are enabled.

A behavior change occurs under the following SQL mode settings. A statement that executes under one of these settings must be modified to produce the same result in 5.6 and 5.7:

- Strict mode is not enabled, `NO_ZERO_IN_DATE` is enabled. For this mode setting, expect these differences in statement execution:
  - In 5.6, the server inserts dates with zero parts as `'0000-00-00'` and produces a warning.
  - In 5.7, the server inserts dates with zero parts as is and produces no warning.
- Strict mode is enabled, with some but not all of the three deprecated modes enabled. For this mode setting, expect these differences in statement execution:

Statements that would be affected by enabling the not-enabled deprecated modes produce errors in 5.7 but not in 5.6. Suppose that strict mode, `NO_ZERO_DATE`, and `NO_ZERO_IN_DATE` are enabled, and a data-change statement performs division by zero:

- In 5.6, the statement inserts `NULL` and produces no warning. Enabling `ERROR_FOR_DIVISION_BY_ZERO` would cause an error instead.
- In 5.7, an error occurs because strict mode implicitly includes the effect of `ERROR_FOR_DIVISION_BY_ZERO`. Enabling `ERROR_FOR_DIVISION_BY_ZERO` explicitly would not change that.

To prepare for an upgrade to MySQL 5.7.4 through 5.7.7, the main principle is to make sure that your applications will operate the same way in MySQL 5.6 and 5.7. For example, you can adopt either of these approaches to application compatibility:

- Modify the application to set the SQL mode on a version-specific basis. If we assume that an application will not be used with development versions of MySQL 5.7 prior to 5.7.4, it is possible to set the `sql_mode` value for the application based on the current server version as follows:

```
SET sql_mode = IF(LEFT(VERSION(),3)<'5.7',5.6 mode,5.7 mode);
```

The tables shown earlier in this section serve as a guide to the appropriate equivalent modes for MySQL 5.6 and 5.7.

- Modify the application to execute under an SQL mode for which statements produce the same result in MySQL 5.6 and 5.7.

#### Tip

`TRADITIONAL` SQL mode in MySQL 5.6 includes strict mode and the three deprecated modes. If you write applications to operate in `TRADITIONAL` mode in MySQL 5.6, there is no change to make for MySQL 5.7.

When assessing SQL mode compatibility between MySQL 5.6 and 5.7, consider particularly these statement execution contexts:

- Replication. You will encounter replication incompatibility related to the SQL mode changes under the following conditions:

- MySQL 5.6 master and 5.7 slave
- Statement-based replication
- An SQL mode setting for which statements produce different results in MySQL 5.6 and 5.7, as described earlier

To handle this incompatibility, use one of these workarounds:

- Use row-based replication
- Use `IGNORE`
- Use an SQL mode for which statements do not produce different results in MySQL 5.6 and 5.7
- Stored programs (stored procedures and functions, triggers, and events). Each stored program executes using the SQL mode in effect at the time it was created. To identify stored programs that may be affected by differences between MySQL 5.6 and 5.7 in SQL mode handling, use these queries:

```
SELECT ROUTINE_SCHEMA, ROUTINE_NAME, ROUTINE_TYPE, SQL_MODE
FROM INFORMATION_SCHEMA.ROUTINES
WHERE SQL_MODE LIKE '%STRICT%'
OR SQL_MODE LIKE '%DIVISION%'
OR SQL_MODE LIKE '%NO_ZERO%';

SELECT TRIGGER_SCHEMA, TRIGGER_NAME, SQL_MODE
FROM INFORMATION_SCHEMA.TRIGGERS
WHERE SQL_MODE LIKE '%STRICT%'
OR SQL_MODE LIKE '%DIVISION%'
OR SQL_MODE LIKE '%NO_ZERO%';

SELECT EVENT_SCHEMA, EVENT_NAME, SQL_MODE
FROM INFORMATION_SCHEMA.EVENTS
WHERE SQL_MODE LIKE '%STRICT%'
OR SQL_MODE LIKE '%DIVISION%'
OR SQL_MODE LIKE '%NO_ZERO%';
```

## 6.1.9 IPv6 Support

Support for IPv6 in MySQL includes these capabilities:

- MySQL Server can accept TCP/IP connections from clients connecting over IPv6. For example, this command connects over IPv6 to the MySQL server on the local host:

```
shell> mysql -h ::1
```

To use this capability, two things must be true:

- Your system must be configured to support IPv6. See [Section 6.1.9.1, “Verifying System Support for IPv6”](#).
- The default MySQL server configuration permits IPv6 connections in addition to IPv4 connections. To change the default configuration, start the server with an appropriate `--bind-address` option. See [Section 6.1.5, “Server System Variables”](#).
- MySQL account names permit IPv6 addresses to enable DBAs to specify privileges for clients that connect to the server over IPv6. See [Section 7.2.3, “Specifying Account Names”](#). IPv6 addresses can be specified in account names in statements such as `CREATE USER`, `GRANT`, and `REVOKE`. For example:

```
mysql> CREATE USER 'bill'@':::1' IDENTIFIED BY 'secret';
mysql> GRANT SELECT ON mydb.* TO 'bill'@':::1';
```

- IPv6 functions enable conversion between string and internal format IPv6 address formats, and checking whether values represent valid IPv6 addresses. For example, `INET6_ATON()` and `INET6_NTOA()` are similar to `INET_ATON()` and `INET_NTOA()`, but handle IPv6 addresses in addition to IPv4 addresses. See [Section 13.20, “Miscellaneous Functions”](#).

The following sections describe how to set up MySQL so that clients can connect to the server over IPv6.

### 6.1.9.1 Verifying System Support for IPv6

Before MySQL Server can accept IPv6 connections, the operating system on your server host must support IPv6. As a simple test to determine whether that is true, try this command:

```
shell> ping6 ::1
16 bytes from ::1, icmp_seq=0 hlim=64 time=0.171 ms
16 bytes from ::1, icmp_seq=1 hlim=64 time=0.077 ms
...
```

To produce a description of your system's network interfaces, invoke `ifconfig -a` and look for IPv6 addresses in the output.

If your host does not support IPv6, consult your system documentation for instructions on enabling it. It might be that you need only reconfigure an existing network interface to add an IPv6 address. Or a more extensive change might be needed, such as rebuilding the kernel with IPv6 options enabled.

These links may be helpful in setting up IPv6 on various platforms:

- [Windows](#)
- [Gentoo Linux](#)
- [Ubuntu Linux](#)
- [Linux \(Generic\)](#)
- [OS X](#)

### 6.1.9.2 Configuring the MySQL Server to Permit IPv6 Connections

The MySQL server listens on a single network socket for TCP/IP connections. This socket is bound to a single address, but it is possible for an address to map onto multiple network interfaces. To specify an address, use the `--bind-address=addr` option at server startup, where `addr` is an IPv4 or IPv6 address or a host name. (IPv6 addresses are not supported before MySQL 5.5.3.) If `addr` is a host name, the server resolves the name to an IP address and binds to that address.

The server treats different types of addresses as follows:

- If the address is `*`, the server accepts TCP/IP connections on all server host IPv6 and IPv4 interfaces if the server host supports IPv6, or accepts TCP/IP connections on all IPv4 addresses otherwise. Use this address to permit both IPv4 and IPv6 connections on all server interfaces. This value is the default.
- If the address is `0.0.0.0`, the server accepts TCP/IP connections on all server host IPv4 interfaces.
- If the address is `::`, the server accepts TCP/IP connections on all server host IPv4 and IPv6 interfaces. Use this address to permit both IPv4 and IPv6 connections on all server interfaces.
- If the address is an IPv4-mapped address, the server accepts TCP/IP connections for that address, in either IPv4 or IPv6 format. For example, if the server is bound to `::ffff:127.0.0.1`, clients can connect using `--host=127.0.0.1` or `--host>::ffff:127.0.0.1`.

- If the address is a “regular” IPv4 or IPv6 address (such as `127.0.0.1` or `::1`), the server accepts TCP/IP connections only for that IPv4 or IPv6 address.

If you intend to bind the server to a specific address, be sure that the `mysql.user` grant table contains an account with administrative privileges that you can use to connect to that address. Otherwise, you will not be able to shut down the server. For example, if you bind the server to `*`, you can connect to it using all existing accounts. But if you bind the server to `::1`, it accepts connections only on that address. In that case, first make sure that the `'root'@'::1'` account is present in the `mysql.user` table so you can still connect to the server to shut it down.

### 6.1.9.3 Connecting Using the IPv6 Local Host Address

The following procedure shows how to configure MySQL to permit IPv6 connections by clients that connect to the local server using the `::1` local host address. The instructions given here assume that your system supports IPv6.

1. Start the MySQL server with an appropriate `--bind-address` option to permit it to accept IPv6 connections. For example, put the following lines in your server option file and restart the server:

```
[mysqld]
bind-address = *
```

Alternatively, you can bind the server to `::1`, but that makes the server more restrictive for TCP/IP connections. It accepts only IPv6 connections for that single address and rejects IPv4 connections. For more information, see [Section 6.1.9.2, “Configuring the MySQL Server to Permit IPv6 Connections”](#).

2. As an administrator, connect to the server and create an account for a local user who will connect from the `::1` local IPv6 host address:

```
mysql> CREATE USER 'ipv6user'@'::1' IDENTIFIED BY 'ipv6pass';
```

For the permitted syntax of IPv6 addresses in account names, see [Section 7.2.3, “Specifying Account Names”](#). In addition to the `CREATE USER` statement, you can issue `GRANT` statements that give specific privileges to the account, although that is not necessary for the remaining steps in this procedure.

3. Invoke the `mysql` client to connect to the server using the new account:

```
shell> mysql -h ::1 -u ipv6user -pipv6pass
```

4. Try some simple statements that show connection information:

```
mysql> STATUS
...
Connection:      ::1 via TCP/IP
...

mysql> SELECT CURRENT_USER(), @@bind_address;
+-----+-----+
| CURRENT_USER() | @@bind_address |
+-----+-----+
| ipv6user@::1   | ::             |
+-----+-----+
```

### 6.1.9.4 Connecting Using IPv6 Nonlocal Host Addresses

The following procedure shows how to configure MySQL to permit IPv6 connections by remote clients. It is similar to the preceding procedure for local clients, but the server and client hosts are distinct and each has its own nonlocal IPv6 address. The example uses these addresses:

```
Server host: 2001:db8:0:f101::1
Client host: 2001:db8:0:f101::2
```

These addresses are chosen from the nonroutable address range recommended by [IANA](#) for documentation purposes and suffice for testing on your local network. To accept IPv6 connections from clients outside the local network, the server host must have a public address. If your network provider assigns you an IPv6 address, you can use that. Otherwise, another way to obtain an address is to use an IPv6 broker; see [Section 6.1.9.5, “Obtaining an IPv6 Address from a Broker”](#).

1. Start the MySQL server with an appropriate `--bind-address` option to permit it to accept IPv6 connections. For example, put the following lines in your server option file and restart the server:

```
[mysqld]
bind-address = *
```

Alternatively, you can bind the server to `2001:db8:0:f101::1`, but that makes the server more restrictive for TCP/IP connections. It accepts only IPv6 connections for that single address and rejects IPv4 connections. For more information, see [Section 6.1.9.2, “Configuring the MySQL Server to Permit IPv6 Connections”](#).

2. On the server host (`2001:db8:0:f101::1`), create an account for a user who will connect from the client host (`2001:db8:0:f101::2`):

```
mysql> CREATE USER 'remoteipv6user'@'2001:db8:0:f101::2' IDENTIFIED BY 'remoteipv6pass';
```

3. On the client host (`2001:db8:0:f101::2`), invoke the `mysql` client to connect to the server using the new account:

```
shell> mysql -h 2001:db8:0:f101::1 -u remoteipv6user -premoteipv6pass
```

4. Try some simple statements that show connection information:

```
mysql> STATUS
...
Connection: 2001:db8:0:f101::1 via TCP/IP
...

mysql> SELECT CURRENT_USER(), @@bind_address;
+-----+-----+
| CURRENT_USER() | @@bind_address |
+-----+-----+
| remoteipv6user@2001:db8:0:f101::2 | :: |
+-----+-----+
```

### 6.1.9.5 Obtaining an IPv6 Address from a Broker

If you do not have a public IPv6 address that enables your system to communicate over IPv6 outside your local network, you can obtain one from an IPv6 broker. The [Wikipedia IPv6 Tunnel Broker page](#) lists several brokers and their features, such as whether they provide static addresses and the supported routing protocols.

After configuring your server host to use a broker-supplied IPv6 address, start the MySQL server with an appropriate `--bind-address` option to permit the server to accept IPv6 connections. For example, put the following lines in the server option file and restart the server:

```
[mysqld]
bind-address = *
```

Alternatively, you can bind the server to the specific IPv6 address provided by the broker, but that makes the server more restrictive for TCP/IP connections. It accepts only IPv6 connections for that

single address and rejects IPv4 connections. For more information, see [Section 6.1.9.2, “Configuring the MySQL Server to Permit IPv6 Connections”](#). In addition, if the broker allocates dynamic addresses, the address provided for your system might change the next time you connect to the broker. If so, any accounts you create that name the original address become invalid. To bind to a specific address but avoid this change-of-address problem, you may be able to arrange with the broker for a static IPv6 address.

The following example shows how to use Freenet6 as the broker and the `gogoc` IPv6 client package on Gentoo Linux.

1. Create an account at Freenet6 by visiting this URL and signing up:

```
http://gogonet.gogo6.com
```

2. After creating the account, go to this URL, sign in, and create a user ID and password for the IPv6 broker:

```
http://gogonet.gogo6.com/page/freenet6-registration
```

3. As `root`, install `gogoc`:

```
shell> emerge gogoc
```

4. Edit `/etc/gogoc/gogoc.conf` to set the `userid` and `password` values. For example:

```
userid=gogouser  
passwd=gogopass
```

5. Start `gogoc`:

```
shell> /etc/init.d/gogoc start
```

To start `gogoc` each time your system boots, execute this command:

```
shell> rc-update add gogoc default
```

6. Use `ping6` to try to ping a host:

```
shell> ping6 ipv6.google.com
```

7. To see your IPv6 address:

```
shell> ifconfig tun
```

## 6.1.10 Server-Side Help

MySQL Server supports a `HELP` statement that returns information from the MySQL Reference manual (see [Section 14.8.3, “HELP Syntax”](#)). Several tables in the `mysql` system database contain the information needed to support this statement (see [Section 6.3, “The mysql System Database”](#)). The proper operation of this statement requires that these help tables be initialized, which is done by processing the contents of the `fill_help_tables.sql` script.

If you install MySQL using a binary or source distribution on Unix, help table content initialization occurs when you initialize the data directory (see [Section 2.10.1, “Initializing the Data Directory”](#)). For an RPM distribution on Linux or binary distribution on Windows, content initialization occurs as part of the MySQL installation process.

If you upgrade MySQL using a binary distribution, help table content is not upgraded automatically, but you can upgrade it manually. Locate the `fill_help_tables.sql` file in the `share` or `share/mysql` directory. Change location into that directory and process the file with the `mysql` client as follows:

```
shell> mysql -u root mysql < fill_help_tables.sql
```

You can also obtain the latest `fill_help_tables.sql` at any time to upgrade your help tables. Download the proper file for your version of MySQL from <http://dev.mysql.com/doc/index-other.html>. After downloading and uncompressing the file, process it with `mysql` as described previously.

If you are working with Git and a MySQL development source tree, you must use a downloaded copy of the `fill_help_tables.sql` file because the source tree contains only a “stub” version.

#### Note

For a server that participates in replication, the help table content upgrade process involves multiple servers. For details, see [Section 18.4.1.29](#), “Replication of Server-Side Help Tables”.

## 6.1.11 Server Response to Signals

On Unix, signals can be sent to processes. `mysqld` responds to signals sent to it as follows:

- `SIGTERM` causes the server to shut down.
- `SIGHUP` causes the server to reload the grant tables and to flush tables, logs, the thread cache, and the host cache. These actions are like various forms of the `FLUSH` statement. The server also writes a status report to the error log that has this format:

```
Status information:

Current dir: /var/mysql/data/
Running threads: 0  Stack size: 196608
Current locks:

Key caches:
default
Buffer_size:      8388600
Block_size:       1024
Division_limit:   100
Age_limit:        300
blocks used:      0
not flushed:      0
w_requests:       0
writes:           0
r_requests:       0
reads:            0

handler status:
read_key:         0
read_next:        0
read_rnd          0
read_first:       1
write:            0
delete            0
update:           0

Table status:
Opened tables:    5
Open tables:      0
Open files:       7
Open streams:     0

Alarm status:
Active alarms:    1
Max used alarms:  2
```

```
Next alarm time: 67
```

## 6.1.12 The Server Shutdown Process

The server shutdown process takes place as follows:

1. The shutdown process is initiated.

This can occur initiated several ways. For example, a user with the `SHUTDOWN` privilege can execute a `mysqladmin shutdown` command. `mysqladmin` can be used on any platform supported by MySQL. Other operating system-specific shutdown initiation methods are possible as well: The server shuts down on Unix when it receives a `SIGTERM` signal. A server running as a service on Windows shuts down when the services manager tells it to.

2. The server creates a shutdown thread if necessary.

Depending on how shutdown was initiated, the server might create a thread to handle the shutdown process. If shutdown was requested by a client, a shutdown thread is created. If shutdown is the result of receiving a `SIGTERM` signal, the signal thread might handle shutdown itself, or it might create a separate thread to do so. If the server tries to create a shutdown thread and cannot (for example, if memory is exhausted), it issues a diagnostic message that appears in the error log:

```
Error: Can't create thread to kill server
```

3. The server stops accepting new connections.

To prevent new activity from being initiated during shutdown, the server stops accepting new client connections by closing the handlers for the network interfaces to which it normally listens for connections: the TCP/IP port, the Unix socket file, the Windows named pipe, and shared memory on Windows.

4. The server terminates current activity.

For each thread associated with a client connection, the server breaks the connection to the client and marks the thread as killed. Threads die when they notice that they are so marked. Threads for idle connections die quickly. Threads that currently are processing statements check their state periodically and take longer to die. For additional information about thread termination, see [Section 14.7.6.4, "KILL Syntax"](#), in particular for the instructions about killed `REPAIR TABLE` or `OPTIMIZE TABLE` operations on `MyISAM` tables.

For threads that have an open transaction, the transaction is rolled back. If a thread is updating a nontransactional table, an operation such as a multiple-row `UPDATE` or `INSERT` may leave the table partially updated because the operation can terminate before completion.

If the server is a master replication server, it treats threads associated with currently connected slaves like other client threads. That is, each one is marked as killed and exits when it next checks its state.

If the server is a slave replication server, it stops the I/O and SQL threads, if they are active, before marking client threads as killed. The SQL thread is permitted to finish its current statement (to avoid causing replication problems), and then stops. If the SQL thread is in the middle of a transaction at this point, the server waits until the current replication event group (if any) has finished executing, or until the user issues a `KILL QUERY` or `KILL CONNECTION` statement. See also [Section 14.4.2.7, "STOP SLAVE Syntax"](#). Since nontransactional statements cannot be rolled back, in order to guarantee crash-safe replication, only transactional tables should be used.

### Note

To guarantee crash safety on the slave, you must run the slave with `--relay-log-recovery` enabled.

See also [Section 18.2.4, “Replication Relay and Status Logs”](#)).

5. The server shuts down or closes storage engines.

At this stage, the server flushes the table cache and closes all open tables.

Each storage engine performs any actions necessary for tables that it manages. [InnoDB](#) flushes its buffer pool to disk (unless `innodb_fast_shutdown` is 2), writes the current LSN to the tablespace, and terminates its own internal threads. [MyISAM](#) flushes any pending index writes for a table.

6. The server exits.

To provide information to management processes, the server returns one of the exit codes described in the following list. The phrase in parentheses indicates the action taken by `systemd` in response to the code, for platforms on which `systemd` is used to manage the server.

- 0 = successful termination (no restart done)
- 1 = unsuccessful termination (no restart done)
- 2 = unsuccessful termination (restart done)

**Note**

The server returns the codes just described as of MySQL 5.7.6. Any management script written for older servers should be revised to handle three exit values if it checks only for 1 as a failure exit value.

## 6.2 The MySQL Data Directory

Information managed by the MySQL server is stored under a directory known as the data directory. The following list briefly describes the items typically found in the data directory, with cross references for additional information:

- Data directory subdirectories. Each subdirectory of the data directory is a database directory and corresponds to a database managed by the server. All MySQL installations have certain standard databases:
  - The `mysql` directory corresponds to the `mysql` system database, which contains information required by the MySQL server as it runs. See [Section 6.3, “The mysql System Database”](#).
  - The `performance_schema` directory corresponds to the Performance Schema, which provides information used to inspect the internal execution of the server at runtime. See [Chapter 24, MySQL Performance Schema](#).
  - The `sys` directory corresponds to the `sys` schema, which provides a set of objects to help interpret Performance Schema information more easily. See [Chapter 25, MySQL sys Schema](#).
  - The `ndbinfo` directory corresponds to the `ndbinfo` database that stores information specific to MySQL Cluster (present only for installations built to include MySQL Cluster). See [Section 20.5.10, “The ndbinfo NDB Cluster Information Database”](#).

Other subdirectories correspond to databases created by users or applications.

**Note**

`INFORMATION_SCHEMA` is a standard database, but its implementation uses no corresponding database directory.

- Log files written by the server. See [Section 6.4, “MySQL Server Logs”](#).
- [InnoDB](#) tablespace and log files. See [Chapter 15, \*The InnoDB Storage Engine\*](#).
- Default/autogenerated SSL and RSA certificate and key files. See [Section 7.4.6, “Creating SSL and RSA Certificates and Keys”](#).
- The server process ID file (while the server is running).

Some items in the preceding list can be relocated elsewhere by reconfiguring the server. In addition, the `--datadir` option enables the location of the data directory itself to be changed. For a given MySQL installation, check the server configuration to determine whether items have been moved.

## 6.3 The mysql System Database

The `mysql` database is the system database. It contains tables that store information required by the MySQL server as it runs.

Tables in the `mysql` database fall into these categories:

- [Grant System Tables](#)
- [Object Information System Tables](#)
- [Log System Tables](#)
- [Server-Side Help System Tables](#)
- [Time Zone System Tables](#)
- [Replication System Tables](#)
- [Optimizer System Tables](#)
- [Miscellaneous System Tables](#)

The remainder of this section enumerates the tables in each category, with cross references for additional information. System tables use the `MyISAM` storage engine unless otherwise indicated.

### Grant System Tables

These system tables contain grant information about user accounts and the privileges held by them:

- `user`: User accounts, global privileges, and other non-privilege columns.
- `db`: Database-level privileges.
- `tables_priv`: Table-level privileges.
- `columns_priv`: Column-level privileges.
- `procs_priv`: Stored procedure and function privileges.
- `proxies_priv`: Proxy-user privileges.

For more information about the structure, contents, and purpose of the grant tables, see [Section 7.2.2, “Grant Tables”](#).

### Object Information System Tables

These system tables contain information about stored programs, user-defined functions, and server-side plugins:

- `event`: Information about Event Scheduler events. See [Section 22.4, “Using the Event Scheduler”](#). The server loads events listed in this table during its startup sequence, unless started with the `--skip-grant-tables` option.
- `func`: Information about user-defined functions (UDFs). See [Section 27.4, “Adding New Functions to MySQL”](#). The server loads UDFs listed in this table during its startup sequence, unless started with the `--skip-grant-tables` option.
- `plugin`: Information about server-side plugins. See [Section 6.5.2, “Installing and Uninstalling Plugins”](#), and [Section 27.2, “The MySQL Plugin API”](#). The server loads plugins listed in this table during its startup sequence, unless started with the `--skip-grant-tables` option.

The `plugin` table uses the `InnoDB` storage engine as of MySQL 5.7.6, `MyISAM` before that.

- `proc`: Information about stored procedures and functions. See [Section 22.2, “Using Stored Routines \(Procedures and Functions\)”](#).

## Log System Tables

The server uses these system tables for logging:

- `general_log`: The general query log table.
- `slow_log`: The slow query log table.

Log tables use the `CSV` storage engine.

For more information, see [Section 6.4, “MySQL Server Logs”](#).

## Server-Side Help System Tables

These system tables contain server-side help information:

- `help_category`: Information about help categories.
- `help_keyword`: Keywords associated with help topics.
- `help_relation`: Mappings between help keywords and topics.
- `help_topic`: Help topic contents.

These tables use the `InnoDB` storage engine as of MySQL 5.7.5, `MyISAM` before that.

For more information, see [Section 6.1.10, “Server-Side Help”](#).

## Time Zone System Tables

These system tables contain time zone information:

- `time_zone`: Time zone IDs and whether they use leap seconds.
- `time_zone_leap_second`: When leap seconds occur.
- `time_zone_name`: Mappings between time zone IDs and names.
- `time_zone_transition`, `time_zone_transition_type`: Time zone descriptions.

These tables use the `InnoDB` storage engine as of MySQL 5.7.5, `MyISAM` before that.

For more information, see [Section 11.6, “MySQL Server Time Zone Support”](#).

## Replication System Tables

The server uses these system tables to support replication:

- `gtid_executed`: Table for storing GTID values. See [mysql.gtid\\_executed Table](#).

The `gtid_executed` table uses the `InnoDB` storage engine.

- `ndb_binlog_index`: Binary log information for MySQL Cluster replication. See [Section 20.6.4, “NDB Cluster Replication Schema and Tables”](#).
- `slave_master_info`, `slave_relay_log_info`, `slave_worker_info`: Used to store replication information on slave servers. See [Section 18.2.4, “Replication Relay and Status Logs”](#).

These tables use the `InnoDB` storage engine.

## Optimizer System Tables

These system tables are for use by the optimizer:

- `innodb_index_stats`, `innodb_table_stats`: Used for `InnoDB` persistent optimizer statistics. See [Section 15.6.11.1, “Configuring Persistent Optimizer Statistics Parameters”](#).
- `server_cost`, `engine_cost`: The optimizer cost model uses tables that contain cost estimate information about operations that occur during query execution. `server_cost` contains optimizer cost estimates for general server operations. `engine_cost` contains estimates for operations specific to particular storage engines. See [Section 9.9.5, “The Optimizer Cost Model”](#).

These tables use the `InnoDB` storage engine.

## Miscellaneous System Tables

Other system tables do not fall into the preceding categories:

- `audit_log_filter`, `audit_log_user`: If MySQL Enterprise Audit is installed, these tables provide persistent storage of audit log filter definitions and user accounts. See [Audit Log Tables](#).
- `firewall_users`, `firewall_whitelist`: If MySQL Enterprise Firewall is installed, these tables provide persistent storage for information used by the firewall. See [Section 7.5.6, “MySQL Enterprise Firewall”](#).
- `servers`: Used by the `FEDERATED` storage engine. See [Section 16.8.2.2, “Creating a FEDERATED Table Using CREATE SERVER”](#).

The `servers` table uses the `InnoDB` storage engine as of MySQL 5.7.6, `MyISAM` before that.

## 6.4 MySQL Server Logs

MySQL Server has several logs that can help you find out what activity is taking place.

| Log Type               | Information Written to Log  |
|------------------------|---|
| Error log              | Problems encountered starting, running, or stopping <code>mysqld</code>     |
| General query log      | Established client connections and statements received from clients         |
| Binary log             | Statements that change data (also used for replication)                     |
| Relay log              | Data changes received from a replication master server                      |
| Slow query log         | Queries that took more than <code>long_query_time</code> seconds to execute |
| DDL log (metadata log) | Metadata operations performed by DDL statements                             |

By default, no logs are enabled, except the error log on Windows. (The DDL log is always created when required, and has no user-configurable options; see [Section 6.4.6, “The DDL Log”](#).) The following log-specific sections provide information about the server options that enable logging.

By default, the server writes files for all enabled logs in the data directory. You can force the server to close and reopen the log files (or in some cases switch to a new log file) by flushing the logs. Log flushing occurs when you issue a `FLUSH LOGS` statement; execute `mysqladmin` with a `flush-logs` or `refresh` argument; or execute `mysqldump` with a `--flush-logs` or `--master-data` option. See [Section 14.7.6.3, “FLUSH Syntax”](#), [Section 5.5.2, “mysqladmin — Client for Administering a MySQL Server”](#), and [Section 5.5.4, “mysqldump — A Database Backup Program”](#). In addition, the binary log is flushed when its size reaches the value of the `max_binlog_size` system variable.

You can control the general query and slow query logs during runtime. You can enable or disable logging, or change the log file name. You can tell the server to write general query and slow query entries to log tables, log files, or both. For details, see [Section 6.4.1, “Selecting General Query and Slow Query Log Output Destinations”](#), [Section 6.4.3, “The General Query Log”](#), and [Section 6.4.5, “The Slow Query Log”](#).

The relay log is used only on slave replication servers, to hold data changes from the master server that must also be made on the slave. For discussion of relay log contents and configuration, see [Section 18.2.4.1, “The Slave Relay Log”](#).

For information about log maintenance operations such as expiration of old log files, see [Section 6.4.7, “Server Log Maintenance”](#).

For information about keeping logs secure, see [Section 7.1.2.3, “Passwords and Logging”](#).

## 6.4.1 Selecting General Query and Slow Query Log Output Destinations

MySQL Server provides flexible control over the destination of output to the general query log and the slow query log, if those logs are enabled. Possible destinations for log entries are log files or the `general_log` and `slow_log` tables in the `mysql` database. Either or both destinations can be selected.

**Log control at server startup.** The `--log-output` option specifies the destination for log output. This option does not in itself enable the logs. Its syntax is `--log-output[=value,...]`:

- If `--log-output` is given with a value, the value should be a comma-separated list of one or more of the words `TABLE` (log to tables), `FILE` (log to files), or `NONE` (do not log to tables or files). `NONE`, if present, takes precedence over any other specifiers.
- If `--log-output` is omitted, the default logging destination is `FILE`.

The `general_log` system variable controls logging to the general query log for the selected log destinations. If specified at server startup, `general_log` takes an optional argument of 1 or 0 to enable or disable the log. To specify a file name other than the default for file logging, set the `general_log_file` variable. Similarly, the `slow_query_log` variable controls logging to the slow query log for the selected destinations and setting `slow_query_log_file` specifies a file name for file logging. If either log is enabled, the server opens the corresponding log file and writes startup messages to it. However, further logging of queries to the file does not occur unless the `FILE` log destination is selected.

Examples:

- To write general query log entries to the log table and the log file, use `--log-output=TABLE,FILE` to select both log destinations and `--general_log` to enable the general query log.
- To write general and slow query log entries only to the log tables, use `--log-output=TABLE` to select tables as the log destination and `--general_log` and `--slow_query_log` to enable both logs.

- To write slow query log entries only to the log file, use `--log-output=FILE` to select files as the log destination and `--slow_query_log` to enable the slow query log. (In this case, because the default log destination is `FILE`, you could omit the `--log-output` option.)

**Log control at runtime.** The system variables associated with log tables and files enable runtime control over logging:

- The global `log_output` system variable indicates the current logging destination. It can be modified at runtime to change the destination.
- The global `general_log` and `slow_query_log` variables indicate whether the general query log and slow query log are enabled (`ON`) or disabled (`OFF`). You can set these variables at runtime to control whether the logs are enabled.
- The global `general_log_file` and `slow_query_log_file` variables indicate the names of the general query log and slow query log files. You can set these variables at server startup or at runtime to change the names of the log files.
- To disable or enable general query logging for the current connection, set the session `sql_log_off` variable to `ON` or `OFF`.

The use of tables for log output offers the following benefits:

- Log entries have a standard format. To display the current structure of the log tables, use these statements:

```
SHOW CREATE TABLE mysql.general_log;
SHOW CREATE TABLE mysql.slow_log;
```

- Log contents are accessible through SQL statements. This enables the use of queries that select only those log entries that satisfy specific criteria. For example, to select log contents associated with a particular client (which can be useful for identifying problematic queries from that client), it is easier to do this using a log table than a log file.
- Logs are accessible remotely through any client that can connect to the server and issue queries (if the client has the appropriate log table privileges). It is not necessary to log in to the server host and directly access the file system.

The log table implementation has the following characteristics:

- In general, the primary purpose of log tables is to provide an interface for users to observe the runtime execution of the server, not to interfere with its runtime execution.
- `CREATE TABLE`, `ALTER TABLE`, and `DROP TABLE` are valid operations on a log table. For `ALTER TABLE` and `DROP TABLE`, the log table cannot be in use and must be disabled, as described later.
- By default, the log tables use the `CSV` storage engine that writes data in comma-separated values format. For users who have access to the `.CSV` files that contain log table data, the files are easy to import into other programs such as spreadsheets that can process CSV input.

The log tables can be altered to use the `MyISAM` storage engine. You cannot use `ALTER TABLE` to alter a log table that is in use. The log must be disabled first. No engines other than `CSV` or `MyISAM` are legal for the log tables.

- To disable logging so that you can alter (or drop) a log table, you can use the following strategy. The example uses the general query log; the procedure for the slow query log is similar but uses the `slow_log` table and `slow_query_log` system variable.

```
SET @old_log_state = @@global.general_log;
SET GLOBAL general_log = 'OFF';
ALTER TABLE mysql.general_log ENGINE = MyISAM;
```

```
SET GLOBAL general_log = @old_log_state;
```

- `TRUNCATE TABLE` is a valid operation on a log table. It can be used to expire log entries.
- `RENAME TABLE` is a valid operation on a log table. You can atomically rename a log table (to perform log rotation, for example) using the following strategy:

```
USE mysql;  
DROP TABLE IF EXISTS general_log2;  
CREATE TABLE general_log2 LIKE general_log;  
RENAME TABLE general_log TO general_log_backup, general_log2 TO general_log;
```

- `CHECK TABLE` is a valid operation on a log table.
- `LOCK TABLES` cannot be used on a log table.
- `INSERT`, `DELETE`, and `UPDATE` cannot be used on a log table. These operations are permitted only internally to the server itself.
- `FLUSH TABLES WITH READ LOCK` and the state of the `read_only` system variable have no effect on log tables. The server can always write to the log tables.
- Entries written to the log tables are not written to the binary log and thus are not replicated to slave servers.
- To flush the log tables or log files, use `FLUSH TABLES` or `FLUSH LOGS`, respectively.
- Partitioning of log tables is not permitted.
- A `mysqldump` dump includes statements to recreate those tables so that they are not missing after reloading the dump file. Log table contents are not dumped.

## 6.4.2 The Error Log

The error log contains information indicating when `mysqld` was started and stopped and also any critical errors that occur while the server is running. If `mysqld` notices a table that needs to be automatically checked or repaired, it writes a message to the error log.

On some operating systems, the error log contains a stack trace if `mysqld` exits abnormally. The trace can be used to determine where `mysqld` exited. See [Section 27.5, “Debugging and Porting MySQL”](#).

If `mysqld_safe` is used to start `mysqld` and `mysqld` exits abnormally, `mysqld_safe` notices this, restarts `mysqld`, and writes a `mysqld restarted` message to the error log.

In the following discussion, “console” means `stderr`, the standard error output; this is your terminal or console window unless the standard error output has been redirected.

On Windows, the `--log-error`, `--pid-file`, and `--console` options affect error logging:

- Without `--log-error`, `mysqld` writes error messages to the default log file.
- With `--log-error[=file_name]`, `mysqld` writes error messages to an error log file. If no file is named, `mysqld` writes to the default log file. If a file is named, `mysqld` writes to it, creating it in the data directory unless an absolute path name is given to specify a different directory.
- The default log file is `host_name.err` in the data directory, unless the `--pid-file` option is specified. In that case, the default name is the PID file base name with a suffix of `.err` in the data directory. This default is used if `--log-error` is not given, or is given without naming a log file.
- With `--console`, `mysqld` writes error messages to the console. `--log-error`, if given, is ignored and has no effect. If both options are present, their order does not matter: `--console` takes

precedence and error messages go to the console. (In MySQL 5.5 and 5.6, the precedence is reversed: `--log-error` causes `--console` to be ignored.)

In addition, on Windows, the server by default writes events and error messages to the Windows Event Log within the Application log. Entries marked as **Error**, **Warning**, and **Note** are written to the Event Log, but not informational messages such as information statements from individual storage engines. These log entries have a source of **MySQL**. As of MySQL 5.7.5, information written to the Windows Event Log can be controlled using the `log_syslog` system variable, as described later.

On Unix and Unix-like systems, `mysqld` writes error log messages as follows:

- Without `--log-error`, `mysqld` writes error messages to the console.
- With `--log-error[=file_name]`, `mysqld` writes error messages to an error log file. If no file is named, `mysqld` writes to the default log file. If a file is named, `mysqld` writes to it, creating it in the data directory unless an absolute path name is given to specify a different directory.
- The default log file is `host_name.err` in the data directory. This default is used if `--log-error` is given without naming a log file.

**Note**

It is common for Yum or APT package installations to configure an error log location under `/var/log` with an entry like `log-error=/var/log/mysqld.log` in a server configuration file. Removing the file name from the entry causes the default log file to be used, which is written to the data directory.

If the server writes error messages to the console, it sets the `log_error` system variable to `stderr`. Otherwise, `log_error` indicates the error log file name. In particular, on Windows, `--console` overrides use of an error log file and sends error messages to the console, so the server sets `log_error` to `stderr`. This occurs even if `--log-error` is also given.

If you specify `--log-error` in an option file in a `[mysqld]`, `[server]`, or `[mysqld_safe]` section, `mysqld_safe` finds and uses the option.

## Using Syslog for the Error Log

As of MySQL 5.7.5, it is possible to have `mysqld` write the error log to `syslog` on Unix and Unix-like systems, and to the Windows Event Log on Windows. To do so, use these system variables:

- `log_syslog`: Enable this variable to send the error log to `syslog`. In this case, the following system variables can also be used for finer control.
- `log_syslog_facility`: The default facility for `syslog` messages is `daemon`. Set this variable to specify a different facility.
- `log_syslog_include_pid`: Whether to include the server process ID in each line of `syslog` output.
- `log_syslog_tag`: This variable defines a tag to add to the server identifier (`mysqld`) in `syslog` messages. If defined, the tag is appended to the identifier with a leading hyphen.

Before MySQL 5.7.5, control of output to `syslog` on Unix and Unix-like systems is handled by `mysqld_safe`, which captures server error output and passes it to `syslog`. On Windows, logging to the Event Log is enabled by default and cannot be disabled.

**Note**

As of MySQL 5.7.5, using `mysqld_safe` for `syslog` error logging is deprecated; you should use the server system variables instead.

`mysqld_safe` has three error-logging options, `--syslog`, `--skip-syslog`, and `--log-error`. The default with no logging options or with `--skip-syslog` is to use the default log file. To explicitly specify use of an error log file, specify `--log-error=file_name` to `mysqld_safe`, and `mysqld_safe` will arrange for `mysqld` to write messages to a log file. To use `syslog` instead, specify the `--syslog` option. For `syslog` output, a tag can be specified with `--syslog-tag=tag_val`; this is appended to the `mysqld` server identifier with a leading hyphen.

## Error Log Verbosity

As of MySQL 5.7.2, the `log_error_verbosity` system variable controls server verbosity for writing error, warning, and note messages to the error log. Permitted values are 1 (errors only), 2 (errors and warnings), 3 (errors, warnings, and notes), with a default of 3. If the value is greater than 2, the server logs aborted connections and access-denied errors for new connection attempts. See [Section B.5.2.11, “Communication Errors and Aborted Connections”](#).

Before MySQL 5.7.2, the `log_warnings` system variable controls warning logging to the error log. By default, `log_warnings` is enabled (nonzero). To disable warning logging, set `log_warnings` to 0. The server logs messages about statements that are unsafe for statement-based logging if the value is greater than 0, and logs aborted connections and access-denied errors for new connection attempts if the value is greater than 1. See [Section B.5.2.11, “Communication Errors and Aborted Connections”](#).

## Error Log Message Format

As of MySQL 5.7.2, the `log_timestamps` system variable controls the timestamp time zone of messages written to the error log (as well as to general query log and slow query log files). Permitted values are `UTC` (the default) and `SYSTEM` (local system time zone). Before MySQL 5.7.2, messages use the local system time zone.

As of MySQL 5.7.2, the ID included in error log messages is that of the thread within `mysqld` responsible for writing the message. This indicates which part of the server produced the message, and is consistent with general query log and slow query log messages, which include the connection thread ID. Before MySQL 5.7.2, the ID in error log messages is that of the `mysqld` process ID.

## Flushing and Renaming the Error Log File

If you flush the logs using `FLUSH LOGS` or `mysqladmin flush-logs` and `mysqld` is writing the error log to a file (for example, if it was started with the `--log-error` option), the server closes and reopens the log file. To rename the file, do so manually before flushing. Flushing the logs then reopens a new file with the original file name. For example, to rename the file and create a new one, use the following commands (assuming a log file name of `host_name.err`):

```
shell> mv host_name.err host_name.err-old
shell> mysqladmin flush-logs
shell> mv host_name.err-old backup-directory
```

On Windows, use `rename` rather than `mv`.

If the server is not writing to a named file, no error log renaming occurs when the logs are flushed.

## 6.4.3 The General Query Log

The general query log is a general record of what `mysqld` is doing. The server writes information to this log when clients connect or disconnect, and it logs each SQL statement received from clients. The general query log can be very useful when you suspect an error in a client and want to know exactly what the client sent to `mysqld`.

As of MySQL 5.7.8, each line that shows when a client connects also includes `using connection_type` to indicate the protocol used to establish the connection. `connection_type` is one of `TCP/IP` (TCP/IP connection established without SSL), `SSL/TLS` (TCP/IP connection

established with SSL), [Socket](#) (Unix socket file connection), [Named Pipe](#) (Windows named pipe connection), or [Shared Memory](#) (Windows shared memory connection).

`mysqld` writes statements to the query log in the order that it receives them, which might differ from the order in which they are executed. This logging order is in contrast with that of the binary log, for which statements are written after they are executed but before any locks are released. In addition, the query log may contain statements that only select data while such statements are never written to the binary log.

When using statement-based binary logging on a replication master server, statements received by its slaves are written to the query log of each slave. Statements are written to the query log of the master server if a client reads events with the `mysqlbinlog` utility and passes them to the server.

However, when using row-based binary logging, updates are sent as row changes rather than SQL statements, and thus these statements are never written to the query log when `binlog_format` is `ROW`. A given update also might not be written to the query log when this variable is set to `MIXED`, depending on the statement used. See [Section 18.2.1.1, “Advantages and Disadvantages of Statement-Based and Row-Based Replication”](#), for more information.

By default, the general query log is disabled. To specify the initial general query log state explicitly, use `--general_log[={0|1}]`. With no argument or an argument of 1, `--general_log` enables the log. With an argument of 0, this option disables the log. To specify a log file name, use `--general_log_file=file_name`. To specify the log destination, use `--log-output` (as described in [Section 6.4.1, “Selecting General Query and Slow Query Log Output Destinations”](#)).

If you specify no name for the general query log file, the default name is `host_name.log`. The server creates the file in the data directory unless an absolute path name is given to specify a different directory.

To disable or enable the general query log or change the log file name at runtime, use the global `general_log` and `general_log_file` system variables. Set `general_log` to 0 (or `OFF`) to disable the log or to 1 (or `ON`) to enable it. Set `general_log_file` to specify the name of the log file. If a log file already is open, it is closed and the new file is opened.

When the general query log is enabled, the server writes output to any destinations specified by the `--log-output` option or `log_output` system variable. If you enable the log, the server opens the log file and writes startup messages to it. However, further logging of queries to the file does not occur unless the `FILE` log destination is selected. If the destination is `NONE`, the server writes no queries even if the general log is enabled. Setting the log file name has no effect on logging if the log destination value does not contain `FILE`.

Server restarts and log flushing do not cause a new general query log file to be generated (although flushing closes and reopens it). To rename the file and create a new one, use the following commands:

```
shell> mv host_name.log host_name-old.log
shell> mysqladmin flush-logs
shell> mv host_name-old.log backup-directory
```

On Windows, use `rename` rather than `mv`.

You can also rename the general query log file at runtime by disabling the log:

```
SET GLOBAL general_log = 'OFF';
```

With the log disabled, rename the log file externally; for example, from the command line. Then enable the log again:

```
SET GLOBAL general_log = 'ON';
```

This method works on any platform and does not require a server restart.

The session `sql_log_off` variable can be set to `ON` or `OFF` to disable or enable general query logging for the current connection.

Passwords in statements written to the general query log are rewritten by the server not to occur literally in plain text. Password rewriting can be suppressed for the general query log by starting the server with the `--log-raw` option. This option may be useful for diagnostic purposes, to see the exact text of statements as received by the server, but for security reasons is not recommended for production use. See also [Section 7.1.2.3, “Passwords and Logging”](#).

An implication of password rewriting is that statements that cannot be parsed (due, for example, to syntax errors) are not written to the general query log because they cannot be known to be password free. Use cases that require logging of all statements including those with errors should use the `--log-raw` option, bearing in mind that this also bypasses password rewriting.

Password rewriting occurs only when plain text passwords are expected. For statements with syntax that expect a password hash value, no rewriting occurs. If a plain text password is supplied erroneously for such syntax, the password is logged as given, without rewriting. For example, the following statement is logged as shown because a password hash value is expected:

```
CREATE USER 'user1'@'localhost' IDENTIFIED BY PASSWORD 'not-so-secret';
```

As of MySQL 5.7.2, the `log_timestamps` system variable controls the timestamp time zone of messages written to the general query log file (as well as to the slow query log file and the error log). It does not affect the time zone of general query log and slow query log messages written to log tables, but rows retrieved from those tables can be converted from the local system time zone to any desired time zone with `CONVERT_TZ()` or by setting the session `time_zone` system variable. Before MySQL 5.7.2, messages use the local system time zone.

## 6.4.4 The Binary Log

The binary log contains “events” that describe database changes such as table creation operations or changes to table data. It also contains events for statements that potentially could have made changes (for example, a `DELETE` which matched no rows), unless row-based logging is used. The binary log also contains information about how long each statement took that updated data. The binary log has two important purposes:

- For replication, the binary log on a master replication server provides a record of the data changes to be sent to slave servers. The master server sends the events contained in its binary log to its slaves, which execute those events to make the same data changes that were made on the master. See [Section 18.2, “Replication Implementation”](#).
- Certain data recovery operations require use of the binary log. After a backup has been restored, the events in the binary log that were recorded after the backup was made are re-executed. These events bring databases up to date from the point of the backup. See [Section 8.5, “Point-in-Time \(Incremental\) Recovery Using the Binary Log”](#).

The binary log is not used for statements such as `SELECT` or `SHOW` that do not modify data. To log all statements (for example, to identify a problem query), use the general query log. See [Section 6.4.3, “The General Query Log”](#).

Running a server with binary logging enabled makes performance slightly slower. However, the benefits of the binary log in enabling you to set up replication and for restore operations generally outweigh this minor performance decrement.

The binary log is generally resilient to unexpected halts because only complete transactions are logged or read back. See [Section 18.3.2, “Handling an Unexpected Halt of a Replication Slave”](#) for more information.

Passwords in statements written to the binary log are rewritten by the server not to occur literally in plain text. See also [Section 7.1.2.3, “Passwords and Logging”](#).

The following discussion describes some of the server options and variables that affect the operation of binary logging. For a complete list, see [Section 18.1.6.4, “Binary Logging Options and Variables”](#).

To enable the binary log, start the server with the `--log-bin[=base_name]` option. If no *base\_name* value is given, the default name is the value of the `pid-file` option (which by default is the name of host machine) followed by `-bin`. If the base name is given, the server writes the file in the data directory unless the base name is given with a leading absolute path name to specify a different directory. It is recommended that you specify a base name explicitly rather than using the default of the host name; see [Section B.5.7, “Known Issues in MySQL”](#), for the reason.

If you supply an extension in the log name (for example, `--log-bin=base_name.extension`), the extension is silently removed and ignored.

`mysqld` appends a numeric extension to the binary log base name to generate binary log file names. The number increases each time the server creates a new log file, thus creating an ordered series of files. The server creates a new file in the series each time it starts or flushes the logs. The server also creates a new binary log file automatically after the current log's size reaches `max_binlog_size`. A binary log file may become larger than `max_binlog_size` if you are using large transactions because a transaction is written to the file in one piece, never split between files.

To keep track of which binary log files have been used, `mysqld` also creates a binary log index file that contains the names of all used binary log files. By default, this has the same base name as the binary log file, with the extension `'.index'`. You can change the name of the binary log index file with the `--log-bin-index[=file_name]` option. You should not manually edit this file while `mysqld` is running; doing so would confuse `mysqld`.

The term “binary log file” generally denotes an individual numbered file containing database events. The term “binary log” collectively denotes the set of numbered binary log files plus the index file.

A client that has the `SUPER` privilege can disable binary logging of its own statements by using a `SET sql_log_bin=0` statement. See [Section 6.1.5, “Server System Variables”](#).

By default, the server logs the length of the event as well as the event itself and uses this to verify that the event was written correctly. You can also cause the server to write checksums for the events by setting the `binlog_checksum` system variable. When reading back from the binary log, the master uses the event length by default, but can be made to use checksums if available by enabling the `master_verify_checksum` system variable. The slave I/O thread also verifies events received from the master. You can cause the slave SQL thread to use checksums if available when reading from the relay log by enabling the `slave_sql_verify_checksum` system variable.

The format of the events recorded in the binary log is dependent on the binary logging format. Three format types are supported, row-based logging, statement-based logging and mixed-base logging. The binary logging format used depends on the MySQL version. For general descriptions of the logging formats, see [Section 6.4.4.1, “Binary Logging Formats”](#). For detailed information about the format of the binary log, see [MySQL Internals: The Binary Log](#).

The server evaluates the `--binlog-do-db` and `--binlog-ignore-db` options in the same way as it does the `--replicate-do-db` and `--replicate-ignore-db` options. For information about how this is done, see [Section 18.2.5.1, “Evaluation of Database-Level Replication and Binary Logging Options”](#).

A replication slave server by default does not write to its own binary log any data modifications that are received from the replication master. To log these modifications, start the slave with the `--log-slave-updates` option in addition to the `--log-bin` option (see [Section 18.1.6.3, “Replication Slave Options and Variables”](#)). This is done when a slave is also to act as a master to other slaves in chained replication.

You can delete all binary log files with the `RESET MASTER` statement, or a subset of them with `PURGE BINARY LOGS`. See [Section 14.7.6.6, “RESET Syntax”](#), and [Section 14.4.1.1, “PURGE BINARY LOGS Syntax”](#).

If you are using replication, you should not delete old binary log files on the master until you are sure that no slave still needs to use them. For example, if your slaves never run more than three days behind, once a day you can execute `mysqladmin flush-logs` on the master and then remove any logs that are more than three days old. You can remove the files manually, but it is preferable to use `PURGE BINARY LOGS`, which also safely updates the binary log index file for you (and which can take a date argument). See [Section 14.4.1.1, “PURGE BINARY LOGS Syntax”](#).

You can display the contents of binary log files with the `mysqlbinlog` utility. This can be useful when you want to reprocess statements in the log for a recovery operation. For example, you can update a MySQL server from the binary log as follows:

```
shell> mysqlbinlog log_file | mysql -h server_name
```

`mysqlbinlog` also can be used to display replication slave relay log file contents because they are written using the same format as binary log files. For more information on the `mysqlbinlog` utility and how to use it, see [Section 5.6.7, “mysqlbinlog — Utility for Processing Binary Log Files”](#). For more information about the binary log and recovery operations, see [Section 8.5, “Point-in-Time \(Incremental\) Recovery Using the Binary Log”](#).

Binary logging is done immediately after a statement or transaction completes but before any locks are released or any commit is done. This ensures that the log is logged in commit order.

Updates to nontransactional tables are stored in the binary log immediately after execution.

Within an uncommitted transaction, all updates (`UPDATE`, `DELETE`, or `INSERT`) that change transactional tables such as `InnoDB` tables are cached until a `COMMIT` statement is received by the server. At that point, `mysqld` writes the entire transaction to the binary log before the `COMMIT` is executed.

Modifications to nontransactional tables cannot be rolled back. If a transaction that is rolled back includes modifications to nontransactional tables, the entire transaction is logged with a `ROLLBACK` statement at the end to ensure that the modifications to those tables are replicated.

When a thread that handles the transaction starts, it allocates a buffer of `binlog_cache_size` to buffer statements. If a statement is bigger than this, the thread opens a temporary file to store the transaction. The temporary file is deleted when the thread ends.

The `Binlog_cache_use` status variable shows the number of transactions that used this buffer (and possibly a temporary file) for storing statements. The `Binlog_cache_disk_use` status variable shows how many of those transactions actually had to use a temporary file. These two variables can be used for tuning `binlog_cache_size` to a large enough value that avoids the use of temporary files.

The `max_binlog_cache_size` system variable (default 4GB, which is also the maximum) can be used to restrict the total size used to cache a multiple-statement transaction. If a transaction is larger than this many bytes, it fails and rolls back. The minimum value is 4096.

If you are using the binary log and row based logging, concurrent inserts are converted to normal inserts for `CREATE ... SELECT` or `INSERT ... SELECT` statements. This is done to ensure that you can re-create an exact copy of your tables by applying the log during a backup operation. If you are using statement-based logging, the original statement is written to the log.

The binary log format has some known limitations that can affect recovery from backups. See [Section 18.4.1, “Replication Features and Issues”](#).

Binary logging for stored programs is done as described in [Section 22.7, “Binary Logging of Stored Programs”](#).

Note that the binary log format differs in MySQL 5.7 from previous versions of MySQL, due to enhancements in replication. See [Section 18.4.2, “Replication Compatibility Between MySQL Versions”](#).

Writes to the binary log file and binary log index file are handled in the same way as writes to [MyISAM](#) tables. See [Section B.5.3.4, “How MySQL Handles a Full Disk”](#).

As of MySQL 5.7.7, the binary log is synchronized to disk at each write by default (`sync_binlog=1`). Prior to MySQL 5.7.7, it is not (`sync_binlog=0`). So, prior to MySQL 5.7.7, if the operating system or machine (not only the MySQL server) crashes, there is a chance that the last statements of the binary log are lost. To prevent this, use the `sync_binlog` system variable to synchronize the binary log to disk after every *N* commit groups. See [Section 6.1.5, “Server System Variables”](#). The safest value for `sync_binlog` is 1, but this is also the slowest. Even with `sync_binlog` set to 1, there is still the chance of inconsistency between the table content and binary log content in case of a crash.

For example, if you are using [InnoDB](#) tables and the MySQL server processes a `COMMIT` statement, it writes many prepared transactions to the binary log in sequence, synchronizes the binary log, and then commits this transaction into [InnoDB](#). If the server crashes between those two operations, the transaction is rolled back by [InnoDB](#) at restart but still exists in the binary log. Such an issue is resolved assuming `--innodb_support_xa` is set to 1, the default. Although this option is related to the support of XA transactions in [InnoDB](#), it also ensures that the binary log and [InnoDB](#) data files are synchronized. For this option to provide a greater degree of safety, the MySQL server should also be configured to synchronize the binary log and the [InnoDB](#) logs to disk before committing the transaction. The [InnoDB](#) logs are synchronized by default, and `sync_binlog=1` can be used to synchronize the binary log. The effect of this option is that at restart after a crash, after doing a rollback of transactions, the MySQL server removes rolled back [InnoDB](#) transactions from the binary log. This ensures that the binary log reflects the exact data of [InnoDB](#) tables, and therefore the slave remains in synchrony with the master because it does not receive a statement which has been rolled back.

**Note**

`innodb_support_xa` is deprecated and will be removed in a future release. [InnoDB](#) support for two-phase commit in XA transactions is always enabled as of MySQL 5.7.10.

If the MySQL server discovers at crash recovery that the binary log is shorter than it should have been, it lacks at least one successfully committed [InnoDB](#) transaction. This should not happen if `sync_binlog=1` and the disk/file system do an actual sync when they are requested to (some do not), so the server prints an error message `The binary log file_name is shorter than its expected size`. In this case, this binary log is not correct and replication should be restarted from a fresh snapshot of the master's data.

The session values of the following system variables are written to the binary log and honored by the replication slave when parsing the binary log:

- `sql_mode` (except that the `NO_DIR_IN_CREATE` mode is not replicated; see [Section 18.4.1.38, “Replication and Variables”](#))
- `foreign_key_checks`
- `unique_checks`
- `character_set_client`
- `collation_connection`
- `collation_database`
- `collation_server`
- `sql_auto_is_null`

#### 6.4.4.1 Binary Logging Formats

The server uses several logging formats to record information in the binary log. The exact format employed depends on the version of MySQL being used. There are three logging formats:

- Replication capabilities in MySQL originally were based on propagation of SQL statements from master to slave. This is called *statement-based logging*. You can cause this format to be used by starting the server with `--binlog-format=STATEMENT`.
- In *row-based logging*, the master writes events to the binary log that indicate how individual table rows are affected. It is important therefore that tables always use a primary key to ensure rows can be efficiently identified. You can cause the server to use row-based logging by starting it with `--binlog-format=ROW`.
- A third option is also available: *mixed logging*. With mixed logging, statement-based logging is used by default, but the logging mode switches automatically to row-based in certain cases as described below. You can cause MySQL to use mixed logging explicitly by starting `mysqld` with the option `--binlog-format=MIXED`.

Prior to MySQL 5.7.7, statement-based logging format was the default. In MySQL 5.7.7 and later, row-based logging format is the default.

The logging format can also be set or limited by the storage engine being used. This helps to eliminate issues when replicating certain statements between a master and slave which are using different storage engines.

With statement-based replication, there may be issues with replicating nondeterministic statements. In deciding whether or not a given statement is safe for statement-based replication, MySQL determines whether it can guarantee that the statement can be replicated using statement-based logging. If MySQL cannot make this guarantee, it marks the statement as potentially unreliable and issues the warning, *Statement may not be safe to log in statement format*.

You can avoid these issues by using MySQL's row-based replication instead.

#### 6.4.4.2 Setting The Binary Log Format

You can select the binary logging format explicitly by starting the MySQL server with `--binlog-format=type`. The supported values for *type* are:

- `STATEMENT` causes logging to be statement based.
- `ROW` causes logging to be row based.
- `MIXED` causes logging to use mixed format.

Prior to MySQL 5.7.7, statement-based logging format was the default. In MySQL 5.7.7 and later, row-based logging format is the default.

The logging format also can be switched at runtime. To specify the format globally for all clients, set the global value of the `binlog_format` system variable:

```
mysql> SET GLOBAL binlog_format = 'STATEMENT';
mysql> SET GLOBAL binlog_format = 'ROW';
mysql> SET GLOBAL binlog_format = 'MIXED';
```

An individual client can control the logging format for its own statements by setting the session value of `binlog_format`:

```
mysql> SET SESSION binlog_format = 'STATEMENT';
mysql> SET SESSION binlog_format = 'ROW';
mysql> SET SESSION binlog_format = 'MIXED';
```

#### Note

Each MySQL Server can set its own and only its own binary logging format (true whether `binlog_format` is set with global or session scope). This means

that changing the logging format on a replication master does not cause a slave to change its logging format to match. (When using `STATEMENT` mode, the `binlog_format` system variable is not replicated; when using `MIXED` or `ROW` logging mode, it is replicated but is ignored by the slave.) Changing the binary logging format on the master while replication is ongoing, or without also changing it on the slave can cause replication to fail with errors such as `Error executing row event: 'Cannot execute statement: impossible to write to binary log since statement is in row format and BINLOG_FORMAT = STATEMENT.'`

To change the global or session `binlog_format` value, you must have the `SUPER` privilege.

There are several reasons why a client might want to set binary logging on a per-session basis:

- A session that makes many small changes to the database might want to use row-based logging.
- A session that performs updates that match many rows in the `WHERE` clause might want to use statement-based logging because it will be more efficient to log a few statements than many rows.
- Some statements require a lot of execution time on the master, but result in just a few rows being modified. It might therefore be beneficial to replicate them using row-based logging.

There are exceptions when you cannot switch the replication format at runtime:

- From within a stored function or a trigger
- If the `NDB` storage engine is enabled
- If the session is currently in row-based replication mode and has open temporary tables

Trying to switch the format in any of these cases results in an error.

If you are using `InnoDB` tables and the transaction isolation level is `READ COMMITTED` or `READ UNCOMMITTED`, only row-based logging can be used. It is *possible* to change the logging format to `STATEMENT`, but doing so at runtime leads very rapidly to errors because `InnoDB` can no longer perform inserts.

Switching the replication format at runtime is not recommended when any temporary tables exist, because temporary tables are logged only when using statement-based replication, whereas with row-based replication they are not logged. With mixed replication, temporary tables are usually logged; exceptions happen with user-defined functions (UDFs) and with the `UUID()` function.

With the binary log format set to `ROW`, many changes are written to the binary log using the row-based format. Some changes, however, still use the statement-based format. Examples include all DDL (data definition language) statements such as `CREATE TABLE`, `ALTER TABLE`, or `DROP TABLE`.

The `--binlog-row-event-max-size` option is available for servers that are capable of row-based replication. Rows are stored into the binary log in chunks having a size in bytes not exceeding the value of this option. The value must be a multiple of 256. The default value is 8192.

### Warning

When using *statement-based logging* for replication, it is possible for the data on the master and slave to become different if a statement is designed in such a way that the data modification is *nondeterministic*; that is, it is left to the will of the query optimizer. In general, this is not a good practice even outside of replication. For a detailed explanation of this issue, see [Section B.5.7, “Known Issues in MySQL”](#).

For information about logs kept by replication slaves, see [Section 18.2.4, “Replication Relay and Status Logs”](#).

### 6.4.4.3 Mixed Binary Logging Format

When running in `MIXED` logging format, the server automatically switches from statement-based to row-based logging under the following conditions:

- When a function contains `UUID()`.
- When one or more tables with `AUTO_INCREMENT` columns are updated and a trigger or stored function is invoked. Like all other unsafe statements, this generates a warning if `binlog_format = STATEMENT`.

For more information, see [Section 18.4.1.1, “Replication and AUTO\\_INCREMENT”](#).

- When the body of a view requires row-based replication, the statement creating the view also uses it. For example, this occurs when the statement creating a view uses the `UUID()` function.
- When a call to a UDF is involved.
- If a statement is logged by row and the session that executed the statement has any temporary tables, logging by row is used for all subsequent statements (except for those accessing temporary tables) until all temporary tables in use by that session are dropped.

This is true whether or not any temporary tables are actually logged.

Temporary tables cannot be logged using row-based format; thus, once row-based logging is used, all subsequent statements using that table are unsafe. The server approximates this condition by treating all statements executed during the session as unsafe until the session no longer holds any temporary tables.

- When `FOUND_ROWS()` or `ROW_COUNT()` is used. (Bug #12092, Bug #30244)
- When `USER()`, `CURRENT_USER()`, or `CURRENT_USER` is used. (Bug #28086)
- When a statement refers to one or more system variables. (Bug #31168)

**Exception.** The following system variables, when used with session scope (only), do not cause the logging format to switch:

- `auto_increment_increment`
- `auto_increment_offset`
- `character_set_client`
- `character_set_connection`
- `character_set_database`
- `character_set_server`
- `collation_connection`
- `collation_database`
- `collation_server`
- `foreign_key_checks`
- `identity`
- `last_insert_id`
- `lc_time_names`

- `pseudo_thread_id`
- `sql_auto_is_null`
- `time_zone`
- `timestamp`
- `unique_checks`

For information about determining system variable scope, see [Section 6.1.6, “Using System Variables”](#).

For information about how replication treats `sql_mode`, see [Section 18.4.1.38, “Replication and Variables”](#).

- When one of the tables involved is a log table in the `mysql` database.
- When the `LOAD_FILE()` function is used. (Bug #39701)

#### Note

A warning is generated if you try to execute a statement using statement-based logging that should be written using row-based logging. The warning is shown both in the client (in the output of `SHOW WARNINGS`) and through the `mysqld` error log. A warning is added to the `SHOW WARNINGS` table each time such a statement is executed. However, only the first statement that generated the warning for each client session is written to the error log to prevent flooding the log.

In addition to the decisions above, individual engines can also determine the logging format used when information in a table is updated. The logging capabilities of an individual engine can be defined as follows:

- If an engine supports row-based logging, the engine is said to be *row-logging capable*.
- If an engine supports statement-based logging, the engine is said to be *statement-logging capable*.

A given storage engine can support either or both logging formats. The following table lists the formats supported by each engine.

| Storage Engine         | Row Logging Supported | Statement Logging Supported   |
|------------------------|-----------------------|---|
| <code>ARCHIVE</code>   | Yes                   | Yes   |
| <code>BLACKHOLE</code> | Yes                   | Yes   |
| <code>CSV</code>       | Yes                   | Yes   |
| <code>EXAMPLE</code>   | Yes                   | No  |
| <code>FEDERATED</code> | Yes                   | Yes   |
| <code>HEAP</code>      | Yes                   | Yes   |
| <code>InnoDB</code>    | Yes                   | Yes when the transaction isolation level is <code>REPEATABLE READ</code> or <code>SERIALIZABLE</code> ; No otherwise. |
| <code>MyISAM</code>    | Yes                   | Yes   |
| <code>MERGE</code>     | Yes                   | Yes   |

| Storage Engine | Row Logging Supported | Statement Logging Supported |
|----------------|-----------------------|-----------------------------|
| NDB            | Yes                   | No                          |

Whether a statement is to be logged and the logging mode to be used is determined according to the type of statement (safe, unsafe, or binary injected), the binary logging format ([STATEMENT](#), [ROW](#), or [MIXED](#)), and the logging capabilities of the storage engine (statement capable, row capable, both, or neither). (Binary injection refers to logging a change that must be logged using [ROW](#) format.)

Statements may be logged with or without a warning; failed statements are not logged, but generate errors in the log. This is shown in the following decision table, where **SLC** stands for “statement-logging capable” and **RLC** stands for “row-logging capable”.

| Condition |               |     |     | Action  |           |
|-----------|---------------|-----|-----|---|-----------|
| Type      | binlog_format | SLC | RLC | Error / Warning   | Logged as |
| *         | *             | No  | No  | Error: Cannot execute statement:<br>Binary logging is impossible since at least one engine is involved that is both row-incapable and statement-incapable.  | -         |
| Safe      | STATEMENT     | Yes | No  | -   | STATEMENT |
| Safe      | MIXED         | Yes | No  | -   | STATEMENT |
| Safe      | ROW           | Yes | No  | Error: Cannot execute statement:<br>Binary logging is impossible since <a href="#">BINLOG_FORMAT</a> = <a href="#">ROW</a> and at least one table uses a storage engine that is not capable of row-based logging. | -         |
| Unsafe    | STATEMENT     | Yes | No  | Warning:<br>Unsafe statement binlogged in statement format, since <a href="#">BINLOG_FORMAT</a> = <a href="#">STATEMENT</a>   | STATEMENT |
| Unsafe    | MIXED         | Yes | No  | Error: Cannot execute statement:<br>Binary logging of an unsafe statement is impossible when the storage engine is limited to   | -         |

| Condition     |               |     |     | Action   |           |
|---------------|---------------|-----|-----|--|-----------|
| Type          | binlog_format | SLC | RLC | Error / Warning  | Logged as |
|               |               |     |     | statement-based logging, even if <code>BINLOG_FORMAT = MIXED</code> .  |           |
| Unsafe        | ROW           | Yes | No  | Error: Cannot execute statement:<br>Binary logging is impossible since <code>BINLOG_FORMAT = ROW</code> and at least one table uses a storage engine that is not capable of row-based logging. | -         |
| Row Injection | STATEMENT     | Yes | No  | Error: Cannot execute row injection:<br>Binary logging is not possible since at least one table uses a storage engine that is not capable of row-based logging.                                | -         |
| Row Injection | MIXED         | Yes | No  | Error: Cannot execute row injection:<br>Binary logging is not possible since at least one table uses a storage engine that is not capable of row-based logging.                                | -         |
| Row Injection | ROW           | Yes | No  | Error: Cannot execute row injection:<br>Binary logging is not possible since at least one table uses a storage engine that is not capable of row-based logging.                                | -         |
| Safe          | STATEMENT     | No  | Yes | Error: Cannot execute statement:<br>Binary logging is impossible since <code>BINLOG_FORMAT = STATEMENT</code> and at least one table   | -         |

| Condition     |               |     |     | Action   |           |
|---------------|---------------|-----|-----|--|-----------|
| Type          | binlog_format | SLC | RLC | Error / Warning  | Logged as |
|               |               |     |     | uses a storage engine that is not capable of statement-based logging.  |           |
| Safe          | MIXED         | No  | Yes | -  | ROW       |
| Safe          | ROW           | No  | Yes | -  | ROW       |
| Unsafe        | STATEMENT     | No  | Yes | Error: Cannot execute statement: Binary logging is impossible since BINLOG_FORMAT = STATEMENT and at least one table uses a storage engine that is not capable of statement-based logging. | -         |
| Unsafe        | MIXED         | No  | Yes | -  | ROW       |
| Unsafe        | ROW           | No  | Yes | -  | ROW       |
| Row Injection | STATEMENT     | No  | Yes | Error: Cannot execute row injection: Binary logging is not possible since BINLOG_FORMAT = STATEMENT.   | -         |
| Row Injection | MIXED         | No  | Yes | -  | ROW       |
| Row Injection | ROW           | No  | Yes | -  | ROW       |

| Safe          | ROW           | Yes | Yes | -  | ROW       |
| Unsafe        | STATEMENT     | Yes | Yes | Warning: Unsafe statement binlogged in statement format since BINLOG_FORMAT = STATEMENT.   | STATEMENT |
| Unsafe        | MIXED         | Yes | Yes | -  | ROW       |
| Unsafe        | ROW           | Yes | Yes | -  | ROW       |
| Row Injection | STATEMENT     | Yes | Yes | Error: Cannot execute row injection:   | -         |

| Condition     |                            |     |     | Action  |                  |
|---------------|----------------------------|-----|-----|---|------------------|
| Type          | <code>binlog_format</code> | SLC | RLC | Error / Warning   | Logged as        |
|               |                            |     |     | Binary logging is not possible because <code>BINLOG_FORMAT = STATEMENT</code> . |                  |
| Row Injection | <code>MIXED</code>         | Yes | Yes | -   | <code>ROW</code> |
| Row Injection | <code>ROW</code>           | Yes | Yes | -   | <code>ROW</code> |

When a warning is produced by the determination, a standard MySQL warning is produced (and is available using `SHOW WARNINGS`). The information is also written to the `mysqld` error log. Only one error for each error instance per client connection is logged to prevent flooding the log. The log message includes the SQL statement that was attempted.

If a slave server was started with `log_error_verbosity` set to display warnings, the slave prints messages to the error log to provide information about its status, such as the binary log and relay log coordinates where it starts its job, when it is switching to another relay log, when it reconnects after a disconnect, statements that are unsafe for statement-based logging, and so forth.

#### 6.4.4.4 Logging Format for Changes to `mysql` Database Tables

The contents of the grant tables in the `mysql` database can be modified directly (for example, with `INSERT` or `DELETE`) or indirectly (for example, with `GRANT` or `CREATE USER`). Statements that affect `mysql` database tables are written to the binary log using the following rules:

- Data manipulation statements that change data in `mysql` database tables directly are logged according to the setting of the `binlog_format` system variable. This pertains to statements such as `INSERT`, `UPDATE`, `DELETE`, `REPLACE`, `DO`, `LOAD DATA INFILE`, `SELECT`, and `TRUNCATE TABLE`.
- Statements that change the `mysql` database indirectly are logged as statements regardless of the value of `binlog_format`. This pertains to statements such as `GRANT`, `REVOKE`, `SET PASSWORD`, `RENAME USER`, `CREATE` (all forms except `CREATE TABLE ... SELECT`), `ALTER` (all forms), and `DROP` (all forms).

`CREATE TABLE ... SELECT` is a combination of data definition and data manipulation. The `CREATE TABLE` part is logged using statement format and the `SELECT` part is logged according to the value of `binlog_format`.

#### 6.4.5 The Slow Query Log

The slow query log consists of SQL statements that took more than `long_query_time` seconds to execute and required at least `min_examined_row_limit` rows to be examined. The minimum and default values of `long_query_time` are 0 and 10, respectively. The value can be specified to a resolution of microseconds. For logging to a file, times are written including the microseconds part. For logging to tables, only integer times are written; the microseconds part is ignored.

By default, administrative statements are not logged, nor are queries that do not use indexes for lookups. This behavior can be changed using `log_slow_admin_statements` and `log_queries_not_using_indexes`, as described later.

The time to acquire the initial locks is not counted as execution time. `mysqld` writes a statement to the slow query log after it has been executed and after all locks have been released, so log order might differ from execution order.

By default, the slow query log is disabled. To specify the initial slow query log state explicitly, use `--slow_query_log[={0|1}]`. With no argument or an argument of 1, `--slow_query_log`

enables the log. With an argument of 0, this option disables the log. To specify a log file name, use `--slow_query_log_file=file_name`. To specify the log destination, use `--log-output` (as described in [Section 6.4.1, “Selecting General Query and Slow Query Log Output Destinations”](#)).

If you specify no name for the slow query log file, the default name is `host_name-slow.log`. The server creates the file in the data directory unless an absolute path name is given to specify a different directory.

To disable or enable the slow query log or change the log file name at runtime, use the global `slow_query_log` and `slow_query_log_file` system variables. Set `slow_query_log` to 0 (or OFF) to disable the log or to 1 (or ON) to enable it. Set `slow_query_log_file` to specify the name of the log file. If a log file already is open, it is closed and the new file is opened.

When the slow query log is enabled, the server writes output to any destinations specified by the `--log-output` option or `log_output` system variable. If you enable the log, the server opens the log file and writes startup messages to it. However, further logging of queries to the file does not occur unless the `FILE` log destination is selected. If the destination is `NONE`, the server writes no queries even if the slow query log is enabled. Setting the log file name has no effect on logging if the log destination value does not contain `FILE`.

The server writes less information to the slow query log if you use the `--log-short-format` option.

To include slow administrative statements in the statements written to the slow query log, use the `log_slow_admin_statements` system variable. Administrative statements include `ALTER TABLE`, `ANALYZE TABLE`, `CHECK TABLE`, `CREATE INDEX`, `DROP INDEX`, `OPTIMIZE TABLE`, and `REPAIR TABLE`.

To include queries that do not use indexes for row lookups in the statements written to the slow query log, enable the `log_queries_not_using_indexes` system variable. When such queries are logged, the slow query log may grow quickly. It is possible to put a rate limit on these queries by setting the `log_throttle_queries_not_using_indexes` system variable. By default, this variable is 0, which means there is no limit. Positive values impose a per-minute limit on logging of queries that do not use indexes. The first such query opens a 60-second window within which the server logs queries up to the given limit, then suppresses additional queries. If there are suppressed queries when the window ends, the server logs a summary that indicates how many there were and the aggregate time spent in them. The next 60-second window begins when the server logs the next query that does not use indexes.

The server uses the controlling parameters in the following order to determine whether to write a query to the slow query log:

1. The query must either not be an administrative statement, or `log_slow_admin_statements` must be enabled.
2. The query must have taken at least `long_query_time` seconds, or `log_queries_not_using_indexes` must be enabled and the query used no indexes for row lookups.
3. The query must have examined at least `min_examined_row_limit` rows.
4. The query must not be suppressed according to the `log_throttle_queries_not_using_indexes` setting.

As of MySQL 5.7.2, the `log_timestamps` system variable controls the timestamp time zone of messages written to the slow query log file (as well as to the general query log file and the error log). It does not affect the time zone of general query log and slow query log messages written to log tables, but rows retrieved from those tables can be converted from the local system time zone to any desired time zone with `CONVERT_TZ()` or by setting the session `time_zone` system variable. Before MySQL 5.7.2, messages use the local system time zone.

As of MySQL 5.7.2, all log lines contain a timestamp. Previously, for lines falling in the same second, only the first contained a timestamp.

The server does not write queries handled by the query cache to the slow query log, nor queries that would not benefit from the presence of an index because the table has zero rows or one row.

By default, a replication slave does not write replicated queries to the slow query log. To change this, use the `log_slow_slave_statements` system variable.

Passwords in statements written to the slow query log are rewritten by the server not to occur literally in plain text. See also [Section 7.1.2.3, “Passwords and Logging”](#).

The slow query log can be used to find queries that take a long time to execute and are therefore candidates for optimization. However, examining a long slow query log can become a difficult task. To make this easier, you can process a slow query log file using the `mysqldumpslow` command to summarize the queries that appear in the log. See [Section 5.6.8, “mysqldumpslow — Summarize Slow Query Log Files”](#).

## 6.4.6 The DDL Log

The DDL log, or metadata log, records metadata operations generated by data definition statements such as `DROP TABLE` and `ALTER TABLE`. MySQL uses this log to recover from crashes occurring in the middle of a metadata operation. When executing the statement `DROP TABLE t1, t2`, we need to ensure that both `t1` and `t2` are dropped, and that each table drop is complete. Another example of this type of SQL statement is `ALTER TABLE t3 DROP PARTITION p2`, where we must make certain that the partition is completely dropped and that its definition is removed from the list of partitions for table `t3`.

A record of metadata operations such as those just described are written to the file `ddl_log.log`, in the MySQL data directory. This is a binary file; it is not intended to be human-readable, and you should not attempt to modify its contents in any way.

`ddl_log.log` is not created until it is actually needed for recording metadata statements, and is removed following a successful start of `mysqld`. Thus, it is possible for this file not to be present on a MySQL server that is functioning in a completely normal manner.

Currently, `ddl_log.log` can hold up to 1048573 entries, equivalent 4 GB in size. Once this limit is exceeded, you must rename or remove the file before it is possible to execute any additional DDL statements. This is a known issue which we are working to resolve (Bug #83708).

There are no user-configurable server options or variables associated with this file.

## 6.4.7 Server Log Maintenance

As described in [Section 6.4, “MySQL Server Logs”](#), MySQL Server can create several different log files to help you see what activity is taking place. However, you must clean up these files regularly to ensure that the logs do not take up too much disk space.

When using MySQL with logging enabled, you may want to back up and remove old log files from time to time and tell MySQL to start logging to new files. See [Section 8.2, “Database Backup Methods”](#).

On a Linux (Red Hat) installation, you can use the `mysql-log-rotate` script for this. If you installed MySQL from an RPM distribution, this script should have been installed automatically. Be careful with this script if you are using the binary log for replication. You should not remove binary logs until you are certain that their contents have been processed by all slaves.

On other systems, you must install a short script yourself that you start from `cron` (or its equivalent) for handling log files.

For the binary log, you can set the `expire_logs_days` system variable to expire binary log files automatically after a given number of days (see [Section 6.1.5, “Server System Variables”](#)). If you are using replication, you should set the variable no lower than the maximum number of days your

slaves might lag behind the master. To remove binary logs on demand, use the `PURGE BINARY LOGS` statement (see [Section 14.4.1.1, “PURGE BINARY LOGS Syntax”](#)).

You can force MySQL to start using new log files by flushing the logs. Log flushing occurs when you issue a `FLUSH LOGS` statement or execute a `mysqladmin flush-logs`, `mysqladmin refresh`, `mysqldump --flush-logs`, or `mysqldump --master-data` command. See [Section 14.7.6.3, “FLUSH Syntax”](#), [Section 5.5.2, “mysqladmin — Client for Administering a MySQL Server”](#), and [Section 5.5.4, “mysqldump — A Database Backup Program”](#). In addition, the binary log is flushed when its size reaches the value of the `max_binlog_size` system variable.

`FLUSH LOGS` supports optional modifiers to enable selective flushing of individual logs (for example, `FLUSH BINARY LOGS`).

A log-flushing operation does the following:

- If general query logging or slow query logging to a log file is enabled, the server closes and reopens the general query log file or slow query log file.
- If binary logging is enabled, the server closes the current binary log file and opens a new log file with the next sequence number.
- If the server was started with the `--log-error` option to cause the error log to be written to a file, the server closes and reopens the log file.

The server creates a new binary log file when you flush the logs. However, it just closes and reopens the general and slow query log files. To cause new files to be created on Unix, rename the current log files before flushing them. At flush time, the server opens new log files with the original names. For example, if the general and slow query log files are named `mysql.log` and `mysql-slow.log`, you can use a series of commands like this:

```
shell> cd mysql-data-directory
shell> mv mysql.log mysql.old
shell> mv mysql-slow.log mysql-slow.old
shell> mysqladmin flush-logs
```

On Windows, use `rename` rather than `mv`.

At this point, you can make a backup of `mysql.old` and `mysql-slow.old` and then remove them from disk.

A similar strategy can be used to back up the error log file, if there is one.

You can rename the general query log or slow query log at runtime by disabling the log:

```
SET GLOBAL general_log = 'OFF';
SET GLOBAL slow_query_log = 'OFF';
```

With the logs disabled, rename the log files externally; for example, from the command line. Then enable the logs again:

```
SET GLOBAL general_log = 'ON';
SET GLOBAL slow_query_log = 'ON';
```

This method works on any platform and does not require a server restart.

## 6.5 MySQL Server Plugins

MySQL supports a plugin API that enables creation of server components. Plugins can be loaded at server startup, or loaded and unloaded at runtime without restarting the server. The components

supported by this interface include, but are not limited to, storage engines, [INFORMATION\\_SCHEMA](#) tables, full-text parser plugins, partitioning support, and server extensions.

## 6.5.1 Server Plugins Available

MySQL distributions include several plugins that implement server extensions:

- Plugins for authenticating attempts by clients to connect to MySQL Server. Plugins are available for several authentication protocols. See [Section 7.3.8, “Pluggable Authentication”](#).
- A connection-control plugin that enables administrators to introduce an increasing delay after a certain number of consecutive failed client connection attempts. See [Section 7.5.2, “The Connection-Control Plugin”](#).
- A password-validation plugin implements password strength policies and assesses the strength of potential passwords. See [Section 7.5.3, “The Password Validation Plugin”](#).
- Group Replication enables you to create a highly available distributed MySQL service across a group of MySQL server instances, with data consistency, conflict detection and resolution, and group membership services all built-in. See [Chapter 19, Group Replication](#).
- MySQL Enterprise Edition includes a thread pool plugin that manages connection threads to increase server performance by efficiently managing statement execution threads for large numbers of client connections. See [Section 6.5.4, “MySQL Enterprise Thread Pool”](#).
- MySQL Enterprise Edition includes an audit plugin for monitoring and logging of connection and query activity. See [Section 7.5.5, “MySQL Enterprise Audit”](#).
- MySQL Enterprise Edition includes a firewall plugin that implements an application-level firewall to enable database administrators to permit or deny SQL statement execution based on matching against whitelists of accepted statement patterns. See [Section 7.5.6, “MySQL Enterprise Firewall”](#).
- A query rewrite plugin examines statements received by MySQL Server and possibly rewrites them before the server executes them. See [Section 6.5.5, “The Rewriter Query Rewrite Plugin”](#).
- Version Tokens enables creation of and synchronization around server tokens that applications can use to prevent accessing incorrect or out-of-date data. Version Tokens is based on a plugin library that implements a [version\\_tokens](#) plugin and a set of user-defined functions. See [Section 6.5.6, “Version Tokens”](#).
- Keyring plugins provide secure storage for sensitive information. See [Section 7.5.4, “The MySQL Keyring”](#).
- X Plugin extends MySQL Server to be able to function as a document store. Running X Plugin enables MySQL Server to communicate with clients using the X Protocol, which is designed to expose the ACID compliant storage abilities of MySQL as a document store. See [Section 3.7, “X Plugin”](#).
- Semisynchronous replication plugins implement an interface to replication capabilities that permit the master to proceed as long as at least one slave has responded to each transaction. See [Section 18.3.9, “Semisynchronous Replication”](#).
- Plugins for testing server services. For information about these plugins, see [Plugins for Testing Plugin Services](#), in [The MySQL Test Framework, Version 2.0](#).

The following sections describe how to install and uninstall plugins, and how to determine at runtime which plugins are installed and obtain information about them. For information about writing plugins, see [Section 27.2, “The MySQL Plugin API”](#).

## 6.5.2 Installing and Uninstalling Plugins

Server plugins must be loaded into the server before they can be used. MySQL supports plugin loading at server startup and runtime. It is also possible to control the activation state of loaded plugins at startup, and to unload them at runtime.

- [Installing plugins](#)
- [Controlling plugin activation state](#)
- [Uninstalling plugins](#)

While a plugin is loaded, information about it is available at runtime from the `INFORMATION_SCHEMA.PLUGINS` table and the `SHOW PLUGINS` statement. See [Section 6.5.3](#), “Obtaining Server Plugin Information”.

## Installing Plugins

Before a server plugin can be used, it must be installed using one of the following methods. In the descriptions, *plugin\_name* stands for a plugin name such as `innodb`, `csv`, or `validate_password`.

### Built-in plugins:

A built-in plugin is known by the server automatically. Normally, the server enables the plugin at startup. Some built-in plugins permit this to be changed with the `--plugin_name[=activation_state]` option.

### Plugins registered in the `mysql.plugin` system table:

The `mysql.plugin` table serves as a registry of plugins (other than built-in plugins, which need not be registered). At startup, the server loads each plugin listed in the table. Normally, for a plugin loaded from the `mysql.plugin` table, the server also enables the plugin. This can be changed with the `--plugin_name[=activation_state]` option.

If the server is started with the `--skip-grant-tables` option, it does not consult the `mysql.plugin` table and does not load the plugins listed there.

### Plugins named with command-line options:

A plugin located in a plugin library file can be loaded at server startup with the `--plugin-load`, `--plugin-load-add`, or (as of MySQL 5.7.11) `--early-plugin-load` option. Normally, for a plugin loaded at startup, the server also enables the plugin. This can be changed with the `--plugin_name[=activation_state]` option.

The `--plugin-load` and `--plugin-load-add` options load plugins after built-in plugins and storage engines have initialized during the server startup sequence. The `--early-plugin-load` option is used to load plugins that must be available prior to initialization of built-in plugins and storage engines.

The value of each plugin-loading option is a semicolon-separated list of `name=plugin_library` and `plugin_library` values. Each *name* is the name of a plugin to load, and *plugin\_library* is the name of the library file that contains the plugin code. If a plugin library is named without any preceding plugin name, the server loads all plugins in the library. The server looks for plugin library files in the directory named by the `plugin_dir` system variable.

Plugin-loading options do not register any plugin in the `mysql.plugin` table. For subsequent restarts, the server loads the plugin again only if `--plugin-load`, `--plugin-load-add`, or `--early-plugin-load` is given again. That is, the option produces a one-time plugin-installation operation that persists for a single server invocation.

`--plugin-load`, `--plugin-load-add`, and `--early-plugin-load` enable plugins to be loaded even when `--skip-grant-tables` is given (which causes the server to ignore the `mysql.plugin` table). `--plugin-load`, `--plugin-load-add`, and `--early-plugin-load` also enable plugins to be loaded at startup that cannot be loaded at runtime.

The `--plugin-load-add` option complements the `--plugin-load` option:

- `--plugin-load-add` adds a plugin or plugins to the set of plugins to be loaded at startup.
- The argument format is the same as for `--plugin-load`, but `--plugin-load-add` can be used to avoid specifying a large set of plugins as a single long unwieldy `--plugin-load` argument.
- `--plugin-load-add` can be given in the absence of `--plugin-load`, but any instance of `--plugin-load-add` that appears before `--plugin-load` has no effect because `--plugin-load` resets the set of plugins to load.

For example, these options:

```
--plugin-load=x --plugin-load-add=y
```

are equivalent to this option:

```
--plugin-load="x;y"
```

But these options:

```
--plugin-load-add=y --plugin-load=x
```

are equivalent to this option:

```
--plugin-load=x
```

### Plugins installed with the `INSTALL PLUGIN` statement:

A plugin located in a plugin library file can be loaded at runtime with the `INSTALL PLUGIN` statement. The statement also registers the plugin in the `mysql.plugin` table to cause the server to load it on subsequent restarts. For this reason, `INSTALL PLUGIN` requires the `INSERT` privilege for the `mysql.plugin` table.

The plugin library file base name depends on your platform. Common suffixes are `.so` for Unix and Unix-like systems, `.dll` for Windows.

Example: The `--plugin-load` option installs a plugin at server startup. To install a plugin named `myplugin` from a plugin library file named `somepluglib.so`, use these lines in a `my.cnf` file:

```
[mysqld]
plugin-load=myplugin=somepluglib.so
```

In this case, the plugin is not registered in `mysql.plugin`. Restarting the server without the `--plugin-load` option causes the plugin not to be loaded at startup.

Alternatively, the `INSTALL PLUGIN` statement causes the server to load the plugin code from the library file at runtime:

```
INSTALL PLUGIN myplugin SONAME 'somepluglib.so';
```

`INSTALL PLUGIN` also causes “permanent” plugin registration: The plugin is listed in the `mysql.plugin` table to ensure that the server loads it on subsequent restarts.

Many plugins can be loaded either at server startup or at runtime. However, if a plugin is designed such that it must be loaded and initialized during server startup, attempts to load it at runtime using `INSTALL PLUGIN` produce an error:

```
mysql> INSTALL PLUGIN myplugin SONAME 'somepluglib.so';
ERROR 1721 (HY000): Plugin 'myplugin' is marked as not dynamically
installable. You have to stop the server to install it.
```

In this case, you must use `--plugin-load`, `--plugin-load-add`, or `--early-plugin-load`.

If a plugin is named both using a `--plugin-load`, `--plugin-load-add`, or `--early-plugin-load` option and (as a result of an earlier `INSTALL PLUGIN` statement) in the `mysql.plugin` table, the server starts but writes these messages to the error log:

```
[ERROR] Function 'plugin_name' already exists
[Warning] Couldn't load plugin named 'plugin_name'
with soname 'plugin_object_file'.
```

## Controlling Plugin Activation State

If the server knows about a plugin when it starts (for example, because the plugin is named using a `--plugin-load` option or is registered in the `mysql.plugin` table), the server loads and enables the plugin by default. It is possible to control activation state for such a plugin using a `--plugin_name[=activation_state]` startup option, where `plugin_name` is the name of the plugin to affect, such as `innodb`, `csv`, or `validate_password`. As with other options, dashes and underscores are interchangeable in option names. Also, activation state values are not case sensitive. For example, `--my_plugin=ON` and `--my-plugin=on` are equivalent.

- `--plugin_name=OFF`

Tells the server to disable the plugin. This may not be possible for certain built-in plugins, such as `mysql_native_password`.

- `--plugin_name[=ON]`

Tells the server to enable the plugin. (Specifying the option as `--plugin_name` without a value has the same effect.) If the plugin fails to initialize, the server runs with the plugin disabled.

- `--plugin_name=FORCE`

Tells the server to enable the plugin, but if plugin initialization fails, the server does not start. In other words, this option forces the server to run with the plugin enabled or not at all.

- `--plugin_name=FORCE_PLUS_PERMANENT`

Like `FORCE`, but in addition prevents the plugin from being unloaded at runtime. If a user attempts to do so with `UNINSTALL PLUGIN`, an error occurs.

Plugin activation states are visible in the `LOAD_OPTION` column of the `INFORMATION_SCHEMA.PLUGINS` table.

Suppose that `CSV`, `BLACKHOLE`, and `ARCHIVE` are built-in pluggable storage engines and that you want the server to load them at startup, subject to these conditions: The server is permitted to run if `CSV` initialization fails, must require that `BLACKHOLE` initialization succeeds, and should disable `ARCHIVE`. To accomplish that, use these lines in an option file:

```
[mysqld]
csv=ON
blackhole=FORCE
archive=OFF
```

The `--enable-plugin_name` option format is a synonym for `--plugin_name=ON`. The `--disable-plugin_name` and `--skip-plugin_name` option formats are synonyms for `--plugin_name=OFF`.

If a plugin is disabled, either explicitly with `OFF` or implicitly because it was enabled with `ON` but failed to initialize, aspects of server operation that require the plugin will change. For example, if the plugin implements a storage engine, existing tables for the storage engine become inaccessible, and attempts to create new tables for the storage engine result in tables that use the default storage engine unless the `NO_ENGINE_SUBSTITUTION` SQL mode is enabled to cause an error to occur instead.

Disabling a plugin may require adjustment to other options. For example, if you start the server using `--skip-innodb` to disable InnoDB, other `innodb_xxx` options likely will need to be omitted at startup. In addition, because InnoDB is the default storage engine, it will not start unless you specify another available storage engine with `--default_storage_engine`. You must also set `--default_tmp_storage_engine`.

## Uninstalling Plugins

At runtime, the `UNINSTALL PLUGIN` statement disables and uninstalls a plugin known to the server. The statement unloads the plugin and removes it from the `mysql.plugin` table, if it is registered there. For this reason, `UNINSTALL PLUGIN` statement requires the `DELETE` privilege for the `mysql.plugin` table. With the plugin no longer registered in the table, the server will not load the plugin automatically for subsequent restarts.

`UNINSTALL PLUGIN` can unload a plugin regardless of whether it was loaded at runtime with `INSTALL PLUGIN` or at startup with a plugin-loading option, subject to these conditions:

- It cannot unload plugins that are built in to the server. These can be identified as those that have a library name of `NULL` in the output from `INFORMATION_SCHEMA.PLUGINS` or `SHOW PLUGINS`.
- It cannot unload plugins for which the server was started with `--plugin_name=FORCE_PLUS_PERMANENT`, which prevents plugin unloading at runtime. These can be identified from the `LOAD_OPTION` column of the `INFORMATION_SCHEMA.PLUGINS` table.

To uninstall a plugin that currently is loaded at server startup with a plugin-loading option, use this procedure.

1. Remove any options related to the plugin from the `my.cnf` file.
2. Restart the server.
3. Plugins normally are installed using either a plugin-loading option at startup or with `INSTALL PLUGIN` at runtime, but not both. However, removing options for a plugin from the `my.cnf` file may not be sufficient to uninstall it if at some point `INSTALL PLUGIN` has also been used. If the plugin still appears in the output from `INFORMATION_SCHEMA.PLUGINS` or `SHOW PLUGINS`, use `UNINSTALL PLUGIN` to remove it from the `mysql.plugin` table. Then restart the server again.

## 6.5.3 Obtaining Server Plugin Information

There are several ways to determine which plugins are installed in the server:

- The `INFORMATION_SCHEMA.PLUGINS` table contains a row for each loaded plugin. Any that have a `PLUGIN_LIBRARY` value of `NULL` are built in and cannot be unloaded.

```
mysql> SELECT * FROM information_schema.PLUGINS\G
***** 1. row *****
      PLUGIN_NAME: binlog
      PLUGIN_VERSION: 1.0
      PLUGIN_STATUS: ACTIVE
      PLUGIN_TYPE: STORAGE ENGINE
      PLUGIN_TYPE_VERSION: 50158.0
      PLUGIN_LIBRARY: NULL
      PLUGIN_LIBRARY_VERSION: NULL
```

```

        PLUGIN_AUTHOR: MySQL AB
        PLUGIN_DESCRIPTION: This is a pseudo storage engine to represent the binlog in a transaction
        PLUGIN_LICENSE: GPL
        LOAD_OPTION: FORCE
    ...
***** 10. row *****
        PLUGIN_NAME: InnoDB
        PLUGIN_VERSION: 1.0
        PLUGIN_STATUS: ACTIVE
        PLUGIN_TYPE: STORAGE ENGINE
        PLUGIN_TYPE_VERSION: 50158.0
        PLUGIN_LIBRARY: ha_innodb_plugin.so
    PLUGIN_LIBRARY_VERSION: 1.0
        PLUGIN_AUTHOR: Innobase Oy
        PLUGIN_DESCRIPTION: Supports transactions, row-level locking,
                           and foreign keys
        PLUGIN_LICENSE: GPL
        LOAD_OPTION: ON
    ...

```

- The `SHOW PLUGINS` statement displays a row for each loaded plugin. Any that have a `Library` value of `NULL` are built in and cannot be unloaded.

```

mysql> SHOW PLUGINS\G
***** 1. row *****
    Name: binlog
    Status: ACTIVE
    Type: STORAGE ENGINE
    Library: NULL
    License: GPL
    ...
***** 10. row *****
    Name: InnoDB
    Status: ACTIVE
    Type: STORAGE ENGINE
    Library: ha_innodb_plugin.so
    License: GPL
    ...

```

- The `mysql.plugin` table shows which plugins have been registered with `INSTALL PLUGIN`. The table contains only plugin names and library file names, so it does not provide as much information as the `PLUGINS` table or the `SHOW PLUGINS` statement.

## 6.5.4 MySQL Enterprise Thread Pool

### Note

MySQL Enterprise Thread Pool is an extension included in MySQL Enterprise Edition, a commercial product. To learn more about commercial products, <http://www.mysql.com/products/>.

As of MySQL 5.7.9, MySQL Enterprise Edition includes MySQL Enterprise Thread Pool, implemented using a server plugin. The default thread-handling model in MySQL Server executes statements using one thread per client connection. As more clients connect to the server and execute statements, overall performance degrades. The thread pool plugin provides an alternative thread-handling model designed to reduce overhead and improve performance. The plugin implements a thread pool that increases server performance by efficiently managing statement execution threads for large numbers of client connections.

The thread pool addresses several problems of the one thread per connection model:

- Too many thread stacks make CPU caches almost useless in highly parallel execution workloads. The thread pool promotes thread stack reuse to minimize the CPU cache footprint.
- With too many threads executing in parallel, context switching overhead is high. This also presents a challenging task to the operating system scheduler. The thread pool controls the number of active

threads to keep the parallelism within the MySQL server at a level that it can handle and that is appropriate for the server host on which MySQL is executing.

- Too many transactions executing in parallel increases resource contention. In [InnoDB](#), this increases the time spent holding central mutexes. The thread pool controls when transactions start to ensure that not too many execute in parallel.

The thread pool plugin is included only in MySQL Enterprise Edition. It is not included in MySQL community distributions.

On Windows, the thread pool plugin requires Windows Vista or newer. On Linux, the plugin requires kernel 2.6.9 or higher.

## Additional Resources

[Section A.14, “MySQL 5.7 FAQ: MySQL Enterprise Thread Pool”](#)

### 6.5.4.1 Thread Pool Components

The thread pool feature comprises these components:

- A plugin library file contains a plugin for the thread pool code and plugins for several [INFORMATION\\_SCHEMA](#) tables.

For a detailed description of how the thread pool works, see [Section 6.5.4.3, “Thread Pool Operation”](#).

The [INFORMATION\\_SCHEMA](#) tables are named [TP\\_THREAD\\_STATE](#), [TP\\_THREAD\\_GROUP\\_STATE](#), and [TP\\_THREAD\\_GROUP\\_STATS](#). These tables provide information about thread pool operation. For more information, see [Section 23.32, “Thread Pool INFORMATION\\_SCHEMA Tables”](#).

- Several system variables are related to the thread pool. The [thread\\_handling](#) system variable has a value of [loaded-dynamically](#) when the server successfully loads the thread pool plugin.

The other related variables are implemented by the thread pool plugin; they are not available unless it is enabled:

- [thread\\_pool\\_algorithm](#): The concurrency algorithm to use for scheduling.
- [thread\\_pool\\_high\\_priority\\_connection](#): How to schedule statement execution for a session.
- [thread\\_pool\\_prio\\_kickup\\_timer](#): How long before the thread pool moves a statement awaiting execution from the low-priority queue to the high-priority queue.
- [thread\\_pool\\_max\\_unused\\_threads](#): How many sleeping threads to permit.
- [thread\\_pool\\_size](#): The number of thread groups in the thread pool. This is the most important parameter controlling thread pool performance.
- [thread\\_pool\\_stall\\_limit](#): The time before an executing statement is considered to be stalled.

If any variable implemented by the plugin is set to an illegal value at startup, plugin initialization fails and the plugin does not load.

For information about setting thread pool parameters, see [Section 6.5.4.4, “Thread Pool Tuning”](#).

- The Performance Schema exposes information about the thread pool and may be used to investigate operational performance. For more information, see [Chapter 24, MySQL Performance Schema](#).

### 6.5.4.2 Thread Pool Installation

This section describes how to install MySQL Enterprise Thread Pool. For general information about installing plugins, see [Section 6.5.2, “Installing and Uninstalling Plugins”](#).

To be usable by the server, the plugin library file must be located in the MySQL plugin directory (the directory named by the `plugin_dir` system variable). If necessary, set the value of `plugin_dir` at server startup to tell the server the plugin directory location.

The plugin library file base name is `thread_pool`. The file name suffix differs per platform (for example, `.so` for Unix and Unix-like systems, `.dll` for Windows).

To enable thread pool capability, load the plugins to be used by starting the server with the `--plugin-load` option. For example, if you name just the plugin library file, the server loads all plugins that it contains (that is, the thread pool plugin and all the `INFORMATION_SCHEMA` tables). To do this, put these lines in your `my.cnf` file (adjust the `.so` suffix for your platform as necessary):

```
[mysqld]
plugin-load=thread_pool.so
```

That is equivalent to loading all thread pool plugins by naming them individually:

```
[mysqld]
plugin-load=thread_pool=thread_pool.so;tp_thread_state=thread_pool.so;tp_thread_group_state=thread_pool.so
```

With `--plugin-load`, all plugins must be named on a single line. To make the option file easier to read, use `--plugin-load-add`, which enables naming plugins individually:

```
[mysqld]
plugin-load-add=thread_pool=thread_pool.so
plugin-load-add=tp_thread_state=thread_pool.so
plugin-load-add=tp_thread_group_state=thread_pool.so
plugin-load-add=tp_thread_group_stats=thread_pool.so
```

If desired, you can load individual plugins from the library file. To load the thread pool plugin but not the `INFORMATION_SCHEMA` tables, use an option like this:

```
[mysqld]
plugin-load=thread_pool=thread_pool.so
```

To load the thread pool plugin and only the `TP_THREAD_STATE INFORMATION_SCHEMA` table, use an option like this:

```
[mysqld]
plugin-load=thread_pool=thread_pool.so;tp_thread_state=thread_pool.so
```

#### Note

If you do not load all the `INFORMATION_SCHEMA` tables, some or all MySQL Enterprise Monitor thread pool graphs will be empty.

To verify plugin installation, examine the `INFORMATION_SCHEMA.PLUGINS` table or use the `SHOW PLUGINS` statement (see [Section 6.5.3, “Obtaining Server Plugin Information”](#)). For example:

```
mysql> SELECT PLUGIN_NAME, PLUGIN_STATUS FROM INFORMATION_SCHEMA.PLUGINS
-> WHERE PLUGIN_NAME LIKE 'thread%' OR PLUGIN_NAME LIKE 'tp%';
+-----+-----+
| PLUGIN_NAME | PLUGIN_STATUS |
+-----+-----+
| thread_pool | ACTIVE        |
| TP_THREAD_STATE | ACTIVE        |
```

|                       |        |  |
|-----------------------|--------|--|
| TP_THREAD_GROUP_STATE | ACTIVE |  |
| TP_THREAD_GROUP_STATS | ACTIVE |  |
| +-----+-----+         |        |  |

If the server loads the thread pool plugin successfully, it sets the `thread_handling` system variable to `dynamically-loaded`. If the plugin fails to load, the server writes a message to the error log.

### 6.5.4.3 Thread Pool Operation

The thread pool consists of a number of thread groups, each of which manages a set of client connections. As connections are established, the thread pool assigns them to thread groups in round-robin fashion.

The number of thread groups is configurable using the `thread_pool_size` system variable. The default number of groups is 16. For guidelines on setting this variable, see [Section 6.5.4.4, “Thread Pool Tuning”](#).

The maximum number of threads per group is 4096 (or 4095 on some systems where one thread is used internally).

The thread pool separates connections and threads, so there is no fixed relationship between connections and the threads that execute statements received from those connections. This differs from the default thread-handling model that associates one thread with one connection such that the thread executes all statements from the connection.

The thread pool tries to ensure a maximum of one thread executing in each group at any time, but sometimes permits more threads to execute temporarily for best performance. The algorithm works in the following manner:

- Each thread group has a listener thread that listens for incoming statements from the connections assigned to the group. When a statement arrives, the thread group either begins executing it immediately or queues it for later execution:
  - Immediate execution occurs if the statement is the only one received and no statements are queued or currently executing.
  - Queuing occurs if the statement cannot begin executing immediately.
- If immediate execution occurs, execution is performed by the listener thread. (This means that temporarily no thread in the group is listening.) If the statement finishes quickly, the executing thread returns to listening for statements. Otherwise, the thread pool considers the statement stalled and starts another thread as a listener thread (creating it if necessary). To ensure that no thread group becomes blocked by stalled statements, the thread pool has a background thread that regularly monitors thread group states.

By using the listening thread to execute a statement that can begin immediately, there is no need to create an additional thread if the statement finishes quickly. This ensures the most efficient execution possible in the case of a low number of concurrent threads.

When the thread pool plugin starts, it creates one thread per group (the listener thread), plus the background thread. Additional threads are created as necessary to execute statements.

- The value of the `thread_pool_stall_limit` system variable determines the meaning of “finishes quickly” in the previous item. The default time before threads are considered stalled is 60ms but can be set to a maximum of 6s. This parameter is configurable to enable you to strike a balance appropriate for the server work load. Short wait values permit threads to start more quickly. Short values are also better for avoiding deadlock situations. Long wait values are useful for workloads that include long-running statements, to avoid starting too many new statements while the current ones execute.
- The thread pool focuses on limiting the number of concurrent short-running statements. Before an executing statement reaches the stall time, it prevents other statements from beginning to execute.

If the statement executes past the stall time, it is permitted to continue but no longer prevents other statements from starting. In this way, the thread pool tries to ensure that in each thread group there is never more than one short-running statement, although there might be multiple long-running statements. It is undesirable to let long-running statements prevent other statements from executing because there is no limit on the amount of waiting that might be necessary. For example, on a replication master, a thread that is sending binary log events to a slave effectively runs forever.

- A statement becomes blocked if it encounters a disk I/O operation or a user level lock (row lock or table lock). The block would cause the thread group to become unused, so there are callbacks to the thread pool to ensure that the thread pool can immediately start a new thread in this group to execute another statement. When a blocked thread returns, the thread pool permits it to restart immediately.
- There are two queues, a high-priority queue and a low-priority queue. The first statement in a transaction goes to the low-priority queue. Any following statements for the transaction go to the high-priority queue if the transaction is ongoing (statements for it have begun executing), or to the low-priority queue otherwise. Queue assignment can be affected by enabling the `thread_pool_high_priority_connection` system variable, which causes all queued statements for a session to go into the high-priority queue.

Statements for a nontransactional storage engine, or a transactional engine if `autocommit` is enabled, are treated as low-priority statements because in this case each statement is a transaction. Thus, given a mix of statements for `InnoDB` and `MyISAM` tables, the thread pool prioritizes those for `InnoDB` over those for `MyISAM` unless `autocommit` is enabled. With `autocommit` enabled, all statements will be low priority.

- When the thread group selects a queued statement for execution, it first looks in the high-priority queue, then in the low-priority queue. If a statement is found, it is removed from its queue and begins to execute.
- If a statement stays in the low-priority queue too long, the thread pool moves to the high-priority queue. The value of the `thread_pool_prio_kickup_timer` system variable controls the time before movement. For each thread group, a maximum of one statement per 10ms or 100 per second will be moved from the low-priority queue to the high-priority queue.
- The thread pool reuses the most active threads to obtain a much better use of CPU caches. This is a small adjustment that has a great impact on performance.
- While a thread executes a statement from a user connection, Performance Schema instrumentation accounts thread activity to the user connection. Otherwise, Performance Schema accounts activity to the thread pool.

Here are examples of conditions under which a thread group might have multiple threads started to execute statements:

- One thread begins executing a statement, but runs long enough to be considered stalled. The thread group permits another thread to begin executing another statement even though the first thread is still executing.
- One thread begins executing a statement, then becomes blocked and reports this back to the thread pool. The thread group permits another thread to begin executing another statement.
- One thread begins executing a statement, becomes blocked, but does not report back that it is blocked because the block does not occur in code that has been instrumented with thread pool callbacks. In this case, the thread appears to the thread group to be still running. If the block lasts long enough for the statement to be considered stalled, the group permits another thread to begin executing another statement.

The thread pool is designed to be scalable across an increasing number of connections. It is also designed to avoid deadlocks that can arise from limiting the number of actively executing statements. It is important that threads that do not report back to the thread pool do not prevent other statements

from executing and thus cause the thread pool to become deadlocked. Examples of such statements follow:

- Long-running statements. These would lead to all resources used by only a few statements and they could prevent all others from accessing the server.
- Binary log dump threads that read the binary log and send it to slaves. This is a kind of long-running “statement” that runs for a very long time, and that should not prevent other statements from executing.
- Statements blocked on a row lock, table lock, sleep, or any other blocking activity that has not been reported back to the thread pool by MySQL Server or a storage engine.

In each case, to prevent deadlock, the statement is moved to the stalled category when it does not complete quickly, so that the thread group can permit another statement to begin executing. With this design, when a thread executes or becomes blocked for an extended time, the thread pool moves the thread to the stalled category and for the rest of the statement's execution, it does not prevent other statements from executing.

The maximum number of threads that can occur is the sum of `max_connections` and `thread_pool_size`. This can happen in a situation where all connections are in execution mode and an extra thread is created per group to listen for more statements. This is not necessarily a state that happens often, but it is theoretically possible.

#### 6.5.4.4 Thread Pool Tuning

This section provides guidelines on setting thread pool system variables for best performance, measured using a metric such as transactions per second.

`thread_pool_size` is the most important parameter controlling thread pool performance. It can be set only at server startup. Our experience in testing the thread pool indicates the following:

- If the primary storage engine is `InnoDB`, the optimal `thread_pool_size` setting is likely to be between 16 and 36, with the most common optimal values tending to be from 24 to 36. We have not seen any situation where the setting has been optimal beyond 36. There may be special cases where a value smaller than 16 is optimal.

For workloads such as DBT2 and Sysbench, the optimum for `InnoDB` seems to be usually around 36. For very write-intensive workloads, the optimal setting can sometimes be lower.

- If the primary storage engine is `MyISAM`, the `thread_pool_size` setting should be fairly low. We tend to get optimal performance for values from 4 to 8. Higher values tend to have a slightly negative but not dramatic impact on performance.

Another system variable, `thread_pool_stall_limit`, is important for handling of blocked and long-running statements. If all calls that block the MySQL Server are reported to the thread pool, it would always know when execution threads are blocked. However, this may not always be true. For example, blocks could occur in code that has not been instrumented with thread pool callbacks. For such cases, the thread pool must be able to identify threads that appear to be blocked. This is done by means of a timeout, the length of which can be tuned using the `thread_pool_stall_limit` system variable. This parameter ensures that the server does not become completely blocked. The value of `thread_pool_stall_limit` has an upper limit of 6 seconds to prevent the risk of a deadlocked server.

`thread_pool_stall_limit` also enables the thread pool to handle long-running statements. If a long-running statement was permitted to block a thread group, all other connections assigned to the group would be blocked and unable to start execution until the long-running statement completed. In the worst case, this could take hours or even days.

The value of `thread_pool_stall_limit` should be chosen such that statements that execute longer than its value are considered stalled. Stalled statements generate a lot of extra overhead since

they involve extra context switches and in some cases even extra thread creations. On the other hand, setting the `thread_pool_stall_limit` parameter too high means that long-running statements will block a number of short-running statements for longer than necessary. Short wait values permit threads to start more quickly. Short values are also better for avoiding deadlock situations. Long wait values are useful for workloads that include long-running statements, to avoid starting too many new statements while the current ones execute.

Suppose a server executes a workload where 99.9% of the statements complete within 100ms even when the server is loaded, and the remaining statements take between 100ms and 2 hours fairly evenly spread. In this case, it would make sense to set `thread_pool_stall_limit` to 10 (meaning 100ms). The default value of 60ms is okay for servers that primarily execute very simple statements.

The `thread_pool_stall_limit` parameter can be changed at runtime to enable you to strike a balance appropriate for the server work load. Assuming that the `TP_THREAD_GROUP_STATS` table is enabled, you can use the following query to determine the fraction of executed statements that stalled:

```
SELECT SUM(STALLED_QUERIES_EXECUTED) / SUM(QUERIES_EXECUTED)
FROM information_schema.TP_THREAD_GROUP_STATS;
```

This number should be as low as possible. To decrease the likelihood of statements stalling, increase the value of `thread_pool_stall_limit`.

When a statement arrives, what is the maximum time it can be delayed before it actually starts executing? Suppose that the following conditions apply:

- There are 200 statements queued in the low-priority queue.
- There are 10 statements queued in the high-priority queue.
- `thread_pool_prio_kickup_timer` is set to 10000 (10 seconds).
- `thread_pool_stall_limit` is set to 100 (1 second).

In the worst case, the 10 high-priority statements represent 10 transactions that continue executing for a long time. Thus, in the worst case, no statements will be moved to the high-priority queue because it will always already contain statements awaiting execution. After 10 seconds, the new statement is eligible to be moved to the high-priority queue. However, before it can be moved, all the statements before it must be moved as well. This could take another 2 seconds because a maximum of 100 statements per second are moved to the high-priority queue. Now when the statement reaches the high-priority queue, there could potentially be many long-running statements ahead of it. In the worst case, every one of those will become stalled and it will take 1 second for each statement before the next statement is retrieved from the high-priority queue. Thus, in this scenario, it will take 222 seconds before the new statement starts executing.

This example shows a worst case for an application. How to handle it depends on the application. If the application has high requirements for the response time, it should most likely throttle users at a higher level itself. Otherwise, it can use the thread pool configuration parameters to set some kind of a maximum waiting time.

## 6.5.5 The Rewriter Query Rewrite Plugin

As of MySQL 5.7.6, MySQL Server supports query rewrite plugins that can examine and possibly modify statements received by the server before the server executes them. See [Query Rewrite Plugins](#).

MySQL distributions include a postparse query rewrite plugin named `Rewriter` and scripts for installing the plugin and its associated components. These components work together to provide `SELECT` rewriting capability:

- A server-side plugin named `Rewriter` examines `SELECT` statements and may rewrite them, based on its in-memory cache of rewrite rules. Standalone `SELECT` statements and `SELECT` statements in

prepared statements are subject to rewriting. `SELECT` statements occurring within view definitions or stored programs are not subject to rewriting.

- The `Rewriter` plugin uses a database named `query_rewrite` containing a table named `rewrite_rules`. The table provides persistent storage for the rules that the plugin uses to decide whether to rewrite statements. Users communicate with the plugin by modifying the set of rules stored in this table. The plugin communicates with users by setting the `message` column of table rows.
- The `query_rewrite` database contains a stored procedure named `flush_rewrite_rules()` that loads the contents of the rules table into the plugin.
- A user-defined function named `load_rewrite_rules()` is used by the `flush_rewrite_rules()` stored procedure.
- The `Rewriter` plugin exposes system variables that enable plugin configuration and status variables that provide runtime operational information.

The following sections describe how to install and use the `Rewriter` plugin, and provide reference information for its associated components.

### 6.5.5.1 Installing or uninstalling the Rewriter Query Rewrite Plugin

#### Note

If installed, the `Rewriter` plugin involves some overhead even when disabled. To avoid this overhead, do not install the plugin unless you plan to use it.

To install or uninstall the `Rewriter` query rewrite plugin, choose the appropriate script located in the `share` directory of your MySQL installation:

- `install_rewriter.sql`: Choose this script to install the `Rewriter` plugin and its associated components.

#### Note

Before MySQL 5.7.8, there are two installation scripts, `install_rewriter.sql` and `install_rewriter_with_optional_columns.sql`, which differ in whether they create the `pattern_digest` and `normalized_columns` columns of the `rewrite_rules` table. As of 5.7.8, the installation script always creates these columns. (For details about the table columns, see [Rewriter Query Rewrite Plugin Rules Table](#).)

- `uninstall_rewriter.sql`: Choose this script to uninstall the `Rewriter` plugin and its associated components.

Run the chosen script as follows:

```
shell> mysql -u root -p < install_rewriter.sql
Enter password: (enter root password here)
```

The example here uses the `install_rewriter.sql` installation script. Make the appropriate substitution if you choose a different script.

Running an installation script should install and enable the plugin. To verify that, connect to the server and execute this statement:

```
mysql> SHOW GLOBAL VARIABLES LIKE 'rewriter_enabled';
+-----+-----+
```

| Variable_name    | Value |
|------------------|-------|
| rewriter_enabled | ON    |

For usage instructions, see [Section 6.5.5.2, “Using the Rewriter Query Rewrite Plugin”](#). For reference information, see [Section 6.5.5.3, “Rewriter Query Rewrite Plugin Reference”](#).

### 6.5.5.2 Using the Rewriter Query Rewrite Plugin

To enable or disable the plugin, enable or disable the `rewriter_enabled` system variable. By default, the `Rewriter` plugin is enabled when you install it (see [Section 6.5.5.1, “Installing or uninstalling the Rewriter Query Rewrite Plugin”](#)). To set the initial plugin state explicitly, you can set the variable at server startup. For example, to enable the plugin in an option file, use these lines:

```
[mysqld]
rewriter_enabled=ON
```

It is also possible to enable or disable the plugin at runtime:

```
mysql> SET GLOBAL rewriter_enabled = ON;
mysql> SET GLOBAL rewriter_enabled = OFF;
```

Assuming that the `Rewriter` plugin is enabled, it examines and possibly modifies each `SELECT` statement received by the server. The plugin determines whether to rewrite statements based on its in-memory cache of rewriting rules, which are loaded from the `rewrite_rules` table in the `query_rewrite` database.

### Adding Rewrite Rules

To add rules for the `Rewriter` plugin, add rows to the `rewrite_rules` table, then invoke the `flush_rewrite_rules()` stored procedure to load the rules from the table into the plugin. The following example creates a simple rule to match statements that select a single literal value:

```
mysql> INSERT INTO query_rewrite.rewrite_rules (pattern, replacement)
-> VALUES('SELECT ?', 'SELECT ? + 1');
```

The resulting table contents look like this:

```
mysql> SELECT * FROM query_rewrite.rewrite_rules\G
***** 1. row *****
      id: 1
    pattern: SELECT ?
pattern_database: NULL
  replacement: SELECT ? + 1
      enabled: YES
      message: NULL
pattern_digest: NULL
normalized_pattern: NULL
```

The rule specifies a pattern template indicating which `SELECT` statements to match, and a replacement template indicating how to rewrite matching statements. However, adding the rule to the `rewrite_rules` table is not sufficient to cause the `Rewriter` plugin to use the rule. You must invoke `flush_rewrite_rules()` to load the table contents into the plugin in-memory cache:

```
mysql> CALL query_rewrite.flush_rewrite_rules();
```

#### Tip

If your rewrite rules seem not to be working properly, make sure that you have reloaded the rules table by calling `flush_rewrite_rules()`.

When the plugin reads each rule from the rules table, it computes a normalized form (digest) from the pattern and a digest hash value, and updates the `normalized_pattern` and `pattern_digest` columns:

```
mysql> SELECT * FROM query_rewrite.rewrite_rules\G
***** 1. row *****
      id: 1
      pattern: SELECT ?
      pattern_database: NULL
      replacement: SELECT ? + 1
      enabled: YES
      message: NULL
      pattern_digest: 46b876e64cd5c41009d91c754921fld4
      normalized_pattern: select ?
```

For information about statement digesting and normalized statements, see [Section 24.8, “Performance Schema Statement Digests”](#).

Patterns use the same syntax as prepared statements (see [Section 14.5.1, “PREPARE Syntax”](#)). Within a pattern template, `?` characters act as parameter markers that match data values. Parameter markers can be used only where data values should appear, not for SQL keywords, identifiers, and so forth. The `?` characters should not be enclosed within quotation marks.

Like the pattern, the replacement can contain `?` characters. For a statement that matches a pattern template, the plugin rewrites it, replacing `?` parameter markers in the replacement using data values matched by the corresponding markers in the pattern. The result is a complete statement string. The plugin asks the server to parse it, and returns the result to the server as the representation of the rewritten statement.

After adding and loading the rule, check whether rewriting occurs according to whether statements match the rule pattern:

```
mysql> SELECT PI();
+-----+
| PI()   |
+-----+
| 3.141593 |
+-----+
1 row in set (0.01 sec)

mysql> SELECT 10;
+-----+
| 10 + 1 |
+-----+
|      11 |
+-----+
1 row in set, 1 warning (0.00 sec)
```

No rewriting occurs for the first `SELECT` statement, but does for the second. The second statement illustrates that when the `Rewriter` plugin rewrites a statement, it produces a warning message. To view the message, use `SHOW WARNINGS`:

```
mysql> SHOW WARNINGS\G
***** 1. row *****
      Level: Note
      Code: 1105
      Message: Query 'SELECT 10' rewritten to 'SELECT 10 + 1' by a query rewrite plugin
```

To enable or disable an existing rule, modify its `enabled` column and reload the table into the plugin. To disable rule 1:

```
mysql> UPDATE query_rewrite.rewrite_rules SET enabled = 'NO' WHERE id = 1;
mysql> CALL query_rewrite.flush_rewrite_rules();
```

This enables you to deactivate a rule without removing it from the table.

To re-enable rule 1:

```
mysql> UPDATE query_rewrite.rewrite_rules SET enabled = 'YES' WHERE id = 1;
mysql> CALL query_rewrite.flush_rewrite_rules();
```

The `rewrite_rules` table contains a `pattern_database` column that `Rewriter` uses for matching table names that are not qualified with a database name:

- Qualified table names in statements match qualified names in the pattern if corresponding database and table names are identical.
- Unqualified table names in statements match unqualified names in the pattern only if the default database is the same as `pattern_database` and the table names are identical.

Suppose that a table named `appdb.users` has a column named `id` and that applications are expected to select rows from the table using a query of one of these forms, where the second can be used only if `appdb` is the default database:

```
SELECT * FROM users WHERE appdb.id = id_value;
SELECT * FROM users WHERE id = id_value;
```

Suppose also that the `id` column is renamed to `user_id` (perhaps the table must be modified to add another type of ID and it is necessary to indicate more specifically what type of ID the `id` column represents).

The change means that applications must refer to `user_id` rather than `id` in the `WHERE` clause. But if there are old applications that cannot be written to change the `SELECT` queries they generate, they will no longer work properly. The `Rewriter` plugin can solve this problem. To match and rewrite statements whether or not they qualify the table name, add the following two rules and reload the rules table:

```
mysql> INSERT INTO query_rewrite.rewrite_rules
-> (pattern, replacement) VALUES(
-> 'SELECT * FROM appdb.users WHERE id = ?',
-> 'SELECT * FROM appdb.users WHERE user_id = ?'
-> );
mysql> INSERT INTO query_rewrite.rewrite_rules
-> (pattern, replacement, pattern_database) VALUES(
-> 'SELECT * FROM users WHERE id = ?',
-> 'SELECT * FROM users WHERE user_id = ?',
-> 'appdb'
-> );
mysql> CALL query_rewrite.flush_rewrite_rules();
```

`Rewriter` uses the first rule to match statements that use the qualified table name. It uses the second to match statements that used the unqualified name, but only if the default database is `appdb` (the value in `pattern_database`).

## How Statement Matching Works

The `Rewriter` plugin uses statement digests to match incoming statements against rewrite rules in stages. The `max_digest_length` system variable determines the size of the buffer used for computing statement digests. Larger values enable computation of digests that distinguish longer statements. Smaller values use less memory but increase the likelihood of longer statements colliding with the same digest value.

The plugin matches each statement to the rewrite rules as follows:

1. Compute the statement digest hash value and compare it to the rule digest hash values. This is subject to false positives, but serves as a quick rejection test.

2. If the statement digest hash value matches any pattern digest hash values, match the normalized form of the statement to the normalized form of the matching rule patterns.
3. If the normalized statement matches a rule, compare the literal values in the statement and the pattern. A `?` in the pattern matches any literal value in the statement. If the statement prepares a `SELECT` statement, `?` in the pattern also matches `?` in the statement. Otherwise, corresponding literals must be the same.

If multiple rules match a statement, it is indeterminate which one the plugin uses to rewrite the statement.

If a pattern contains more markers than the replacement, the plugin discards excess data values. If a pattern contains fewer markers than the replacement, it is an error. The plugin notices this when the rules table is loaded, writes an error message to the `message` column of the rule row to communicate the problem, and sets the `Rewriter_reload_error` status variable to `ON`.

## Rewriting Prepared Statements

Prepared statements are rewritten at parse time (that is, when they are prepared), not when they are executed later.

Prepared statements differ from nonprepared statements in that they may contain `?` characters as parameter markers. To match a `?` in a prepared statement, a `Rewriter` pattern must contain `?` in the same location. Suppose that a rewrite rule has this pattern:

```
SELECT ?, 3
```

The following table shows several prepared `SELECT` statements and whether the rule pattern matches them.

| Prepared Statement                      | Whether Pattern Matches Statement |
|---|-----------------------------------|
| <code>PREPARE s AS 'SELECT 3, 3'</code> | Yes                               |
| <code>PREPARE s AS 'SELECT ?, 3'</code> | Yes                               |
| <code>PREPARE s AS 'SELECT 3, ?'</code> | No                                |
| <code>PREPARE s AS 'SELECT ?, ?'</code> | No                                |

## Rewriter Plugin Operational Information

The `Rewriter` plugin makes information available about its operation by means of several status variables:

```
mysql> SHOW GLOBAL STATUS LIKE 'Rewriter%';
+-----+
| Variable_name | Value |
+-----+
| Rewriter_number_loaded_rules | 1 |
| Rewriter_number_reloads | 5 |
| Rewriter_number_rewritten_queries | 1 |
| Rewriter_reload_error | ON |
+-----+
```

For descriptions of these variables, see [Rewriter Query Rewrite Plugin Status Variables](#).

When you load the rules table by calling the `flush_rewrite_rules()` stored procedure, if an error occurs for some rule, the `CALL` statement produces an error, and the plugin sets the `Rewriter_reload_error` status variable to `ON`:

```
mysql> CALL query_rewrite.flush_rewrite_rules();
```

```
ERROR 1644 (45000): Loading of some rule(s) failed.

mysql> SHOW GLOBAL STATUS LIKE 'Rewriter_reload_error';
+-----+-----+
| Variable_name | Value |
+-----+-----+
| Rewriter_reload_error | ON    |
+-----+-----+
```

In this case, check the `message` column of `rewrite_rules` table rows for non-NULL values to see what the problem was.

## Rewriter Plugin Use of Character Sets

When the `rewrite_rules` table is loaded into the `Rewriter` plugin, the plugin interprets statements using the current global value of the `character_set_client` system variable. If the global `character_set_client` value is changed subsequently, the rules table must be reloaded.

A client must have a session `character_set_client` value identical to what the global value was when the rules table was loaded or rule matching will not work for that client.

### 6.5.5.3 Rewriter Query Rewrite Plugin Reference

The following discussion serves as a reference to these components associated with the `Rewriter` query rewrite plugin:

- The `Rewriter` rules table in the `query_rewrite` database
- `Rewriter` procedures and functions
- `Rewriter` system and status variables

## Rewriter Query Rewrite Plugin Rules Table

The `rewrite_rules` table in the `query_rewrite` database provides persistent storage for the rules that the `Rewriter` plugin uses to decide whether to rewrite statements.

Users communicate with the plugin by modifying the set of rules stored in this table. The plugin communicates with users by setting the table's `message` column.

#### Note

The rules table is loaded into the plugin by the `flush_rewrite_rules` stored procedure. Unless that procedure has been called following the most recent table modification, the table contents do not necessarily correspond to the set of rules the plugin is using.

The `rewrite_rules` table has these columns:

- `id`

The rule ID. This column is the table primary key. You can use the ID to uniquely identify any rule.

- `pattern`

The template that indicates the pattern for statements that the rule matches. Use `?` to represent parameter markers that match data values.

- `pattern_database`

The database used to match unqualified table names in statements. Qualified table names in statements match qualified names in the pattern if corresponding database and table names are

identical. Unqualified table names in statements match unqualified names in the pattern only if the default database is the same as `pattern_database` and the table names are identical.

- `replacement`

The template that indicates how to rewrite statements matching the `pattern` column value. Use `?` to represent parameter markers that match data values. In rewritten statements, the plugin replaces `?` parameter markers in `replacement` using data values matched by the corresponding markers in `pattern`.

- `enabled`

Whether the rule is enabled. Load operations (performed by invoking the `flush_rewrite_rules()` stored procedure) load the rule from the table into the `Rewriter` in-memory cache only if this column is `YES` (`Y` before MySQL 5.7.8).

This column makes it possible to deactivate a rule without removing it: Set the column to a value other than `YES` and reload the table into the plugin.

- `message`

The plugin uses this column for communicating with users. If no error occurs when the rules table is loaded into memory, the plugin sets the `message` column to `NULL`. A non-`NULL` value indicates an error and the column contents are the error message. Errors can occur under these circumstances:

- Either the pattern or the replacement is an incorrect SQL statement that produces syntax errors.
- The replacement contains more `?` parameter markers than the pattern.

If a load error occurs, the plugin also sets the `Rewriter_reload_error` status variable to `ON`.

- `pattern_digest`

This column is used for debugging and diagnostics. If the column exists when the rules table is loaded into memory, the plugin updates it with the pattern digest. This column may be useful if you are trying to determine why some statement fails to be rewritten.

- `normalized_pattern`

This column is used for debugging and diagnostics. If the column exists when the rules table is loaded into memory, the plugin updates it with the normalized form of the pattern. This column may be useful if you are trying to determine why some statement fails to be rewritten.

**Note**

Before MySQL 5.7.8, the `pattern_digest` and `normalized_pattern` columns are optional: They are created if you install the `Rewriter` plugin using the `install_rewriter_with_optional_columns.sql`, but not if you use `install_rewriter.sql`.

## Rewriter Query Rewrite Plugin Procedures and Functions

`Rewriter` plugin operation uses a stored procedure that loads the rules table into its in-memory cache, and a helper user-defined function (UDF). Under normal operation, users invoke only the stored procedure. The UDF is intended to be invoked by the stored procedure, not directly by users.

- `flush_rewrite_rules()`

This stored procedure uses the `load_rewrite_rules()` UDF to load the contents of the `rewrite_rules` table into the `Rewriter` in-memory cache. After loading the table, it also clears the query cache.

Calling `flush_rewrite_rules()` implies `COMMIT`.

Invoke this procedure after you modify the rules table to cause the plugin to update its cache from the new table contents. If any errors occur, the plugin sets the `message` column for the appropriate rule rows in the table and sets the `Rewriter_reload_error` status variable to `ON`.

- `load_rewrite_rules()`

This UDF is a helper routine used by the `flush_rewrite_rules()` stored procedure.

## Rewriter Query Rewrite Plugin System Variables

The `Rewriter` query rewrite plugin supports the following system variables. These variables are available only if the plugin is installed (see [Section 6.5.5.1, “Installing or uninstalling the Rewriter Query Rewrite Plugin”](#)).

- `rewriter_enabled`

|                         |                         |                               |
|-------------------------|-------------------------|-------------------------------|
| <b>Introduced</b>       | 5.7.6                   |                               |
| <b>System Variable</b>  | <b>Name</b>             | <code>rewriter_enabled</code> |
|                         | <b>Variable Scope</b>   | Global                        |
|                         | <b>Dynamic Variable</b> | Yes                           |
| <b>Permitted Values</b> | <b>Type</b>             | boolean                       |
|                         | <b>Default</b>          | <code>ON</code>               |

Whether the `Rewriter` query rewrite plugin is enabled.

- `rewriter_verbose`

|                         |                         |                               |
|-------------------------|-------------------------|-------------------------------|
| <b>Introduced</b>       | 5.7.6                   |                               |
| <b>System Variable</b>  | <b>Name</b>             | <code>rewriter_verbose</code> |
|                         | <b>Variable Scope</b>   | Global                        |
|                         | <b>Dynamic Variable</b> | Yes                           |
| <b>Permitted Values</b> | <b>Type</b>             | integer                       |

For internal use.

## Rewriter Query Rewrite Plugin Status Variables

The `Rewriter` query rewrite plugin supports the following status variables. These variables are available only if the plugin is installed (see [Section 6.5.5.1, “Installing or uninstalling the Rewriter Query Rewrite Plugin”](#)).

- `Rewriter_number_loaded_rules`

The number of rewrite plugin rewrite rules successfully loaded from the `rewrite_rules` table into memory for use by the `Rewriter` plugin.

- `Rewriter_number_reloads`

The number of times the `rewrite_rules` table has been loaded into the in-memory cache used by the `Rewriter` plugin.

- `Rewriter_number_rewritten_queries`

The number of queries rewritten by the `Rewriter` query rewrite plugin since it was loaded.

- `Rewriter_reload_error`

Whether an error occurred the most recent time that the `rewrite_rules` table was loaded into the in-memory cache used by the `Rewriter` plugin. If the value is `OFF`, no error occurred. If the value is `ON`, an error occurred; check the `message` column of the `rewriter_rules` table for error messages.

## 6.5.6 Version Tokens

Distributions of MySQL 5.7.8 or higher include Version Tokens, a feature that enables creation of and synchronization around server tokens that applications can use to prevent accessing incorrect or out-of-date data.

The Version Tokens interface has these characteristics:

- Version tokens are pairs consisting of a name that serves as a key or identifier, plus a value.
- Version tokens can be locked. An application can use token locks to indicate to other cooperating applications that tokens are in use and should not be modified.
- Version token lists are established per server; for example, to specify the server assignment or operational state. In addition, an application that communicates with a server can register its own list of tokens that indicate the state it requires the server to be in. An SQL statement sent by the application to a server not in the required state produces an error. This is a signal to the application that it should seek a different server in the required state to receive the SQL statement.

The following sections describe the components of Version Tokens, discuss how to install and use it, and provide reference information for its components.

### 6.5.6.1 Version Tokens Components

Version Tokens is based on a plugin library that implements these components:

- A server-side plugin named `version_tokens` holds the list of version tokens associated with the server and subscribes to notifications for statement execution events. The `version_tokens` plugin uses the [audit plugin API](#) to monitor incoming statements from clients and matches each client's session-specific version token list against the server version token list. If there is a match, the plugin lets the statement through and the server continues to process it. Otherwise, the plugin returns an error to the client and the statement fails.
- A set of user-defined functions (UDFs) provides an SQL-level API for manipulating and inspecting the list of server version tokens maintained by the plugin.
- A system variable enables clients to specify the list of version tokens that register the required server state. If the server has a different state when a client sends a statement, the client receives an error.

### 6.5.6.2 Installing or Uninstalling Version Tokens

#### Note

If installed, Version Tokens involves some overhead. To avoid this overhead, do not install it unless you plan to use it.

This section describes how to install or uninstall Version Tokens, which is implemented in a plugin library file containing a plugin and user-defined functions. For general information about installing or uninstalling plugins and UDFs, see [Section 6.5.2, “Installing and Uninstalling Plugins”](#), and [Section 27.4.2.5, “UDF Compiling and Installing”](#).

To be usable by the server, the plugin library file must be located in the MySQL plugin directory (the directory named by the `plugin_dir` system variable). If necessary, set the value of `plugin_dir` at server startup to tell the server the plugin directory location.

The plugin library file base name is `version_tokens`. The file name suffix differs per platform (for example, `.so` for Unix and Unix-like systems, `.dll` for Windows).

To install the Version Tokens plugin and UDFs, use the `INSTALL PLUGIN` and `CREATE FUNCTION` statements (adjust the `.so` suffix for your platform as necessary):

```
INSTALL PLUGIN version_tokens SONAME 'version_token.so';
CREATE FUNCTION version_tokens_set RETURNS STRING SONAME 'version_token.so';
CREATE FUNCTION version_tokens_show RETURNS STRING SONAME 'version_token.so';
CREATE FUNCTION version_tokens_edit RETURNS STRING SONAME 'version_token.so';
CREATE FUNCTION version_tokens_delete RETURNS STRING SONAME 'version_token.so';
CREATE FUNCTION version_tokens_lock_shared RETURNS INT SONAME 'version_token.so';
CREATE FUNCTION version_tokens_lock_exclusive RETURNS INT SONAME 'version_token.so';
CREATE FUNCTION version_tokens_unlock RETURNS INT SONAME 'version_token.so';
```

You must install the UDFs to manage the server's version token list, but you must also install the plugin because the UDFs will not work correctly without it.

If the plugin and UDFs are used on a master replication server, install them on all slave servers as well to avoid replication problems.

Once installed as just described, the Version Tokens plugin and UDFs remain installed until uninstalled. To remove them, use the `UNINSTALL PLUGIN` and `DROP FUNCTION` statements:

```
UNINSTALL PLUGIN version_tokens;
DROP FUNCTION version_tokens_set;
DROP FUNCTION version_tokens_show;
DROP FUNCTION version_tokens_edit;
DROP FUNCTION version_tokens_delete;
DROP FUNCTION version_tokens_lock_shared;
DROP FUNCTION version_tokens_lock_exclusive;
DROP FUNCTION version_tokens_unlock;
```

### 6.5.6.3 Using Version Tokens

Before using Version Tokens, install it according to the instructions provided at [Section 6.5.6.2, “Installing or Uninstalling Version Tokens”](#).

A scenario in which Version Tokens can be useful is a system that accesses a collection of MySQL servers but needs to manage them for load balancing purposes by monitoring them and adjusting server assignments according to load changes. Such a system comprises these components:

- The collection of MySQL servers to be managed.
- An administrative or management application that communicates with the servers and organizes them into high-availability groups. Groups serve different purposes, and servers within each group may have different assignments. Assignment of a server within a certain group can change at any time.
- Client applications that access the servers to retrieve and update data, choosing servers according to the purposes assigned them. For example, a client should not send an update to a read-only server.

Version Tokens permit server access to be managed according to assignment without requiring clients to repeatedly query the servers about their assignments:

- The management application performs server assignments and establishes version tokens on each server to reflect its assignment. The application caches this information to provide a central access point to it.

If at some point the management application needs to change a server assignment (for example, to change it from permitting writes to read only), it changes the server's version token list and updates its cache.

- To improve performance, client applications obtain cache information from the management application, enabling them to avoid having to retrieve information about server assignments for each statement. Based on the type of statements it will issue (for example, reads versus writes), a client selects an appropriate server and connects to it.
- In addition, the client sends to the server its own client-specific version tokens to register the assignment it requires of the server. For each statement sent by the client to the server, the server compares its own token list with the client token list. If the server token list contains all tokens present in the client token list with the same values, there is a match and the server executes the statement.

On the other hand, perhaps the management application has changed the server assignment and its version token list. In this case, the new server assignment may now be incompatible with the client requirements. A token mismatch between the server and client token lists occurs and the server returns an error in reply to the statement. This is an indication to the client to refresh its version token information from the management application cache, and to select a new server to communicate with.

The client-side logic for detecting version token errors and selecting a new server can be implemented different ways:

- The client can handle all version token registration, mismatch detection, and connection switching itself.
- The logic for those actions can be implemented in a connector that manages connections between clients and MySQL servers. Such a connector might handle mismatch error detection and statement resending itself, or it might pass the error to the application and leave it to the application to resend the statement.

The following example illustrates the preceding discussion in more concrete form.

When Version Tokens initializes on a given server, the server's version token list is empty. Token list maintenance is performed by calling user-defined functions (UDFs). The `SUPER` privilege is required to call any of the Version Token UDFs, so token list modification is expected to be done by a management or administrative application that has that privilege.

Suppose that a management application communicates with a set of servers that are queried by clients to access employee and product databases (named `emp` and `prod`, respectively). All servers are permitted to process data retrieval statements, but only some of them are permitted to make database updates. To handle this on a database-specific basis, the management application establishes a list of version tokens on each server. In the token list for a given server, token names represent database names and token values are `read` or `write` depending on whether the database must be used in read-only fashion or whether it can take reads and writes.

Client applications register a list of version tokens they require the server to match by setting a system variable. Variable setting occurs on a client-specific basis, so different clients can register different requirements. By default, the client token list is empty, which matches any server token list. When a client sets its token list to a nonempty value, matching may succeed or fail, depending on the server version token list.

To define the version token list for a server, the management application calls the `version_token_set()` UDF. (There are also UDFs for modifying and displaying the token list, described later.) For example, the application might send these statements to a group of three servers:

Server 1:

```
mysql> SELECT version_tokens_set('emp=read;prod=read');
+-----+
| version_tokens_set('emp=read;prod=read') |
+-----+
| 2 version tokens set.                    |
+-----+
```

Server 2:

```
mysql> SELECT version_tokens_set('emp=write;prod=read');
+-----+
| version_tokens_set('emp=write;prod=read') |
+-----+
| 2 version tokens set.                    |
+-----+
```

Server 3:

```
mysql> SELECT version_tokens_set('emp=read;prod=write');
+-----+
| version_tokens_set('emp=read;prod=write') |
+-----+
| 2 version tokens set.                    |
+-----+
```

The token list in each case is specified as a semicolon-separated list of *name=value* pairs. The resulting token list values result in these server assignments:

- Any server accepts reads for either database.
- Only server 2 accepts updates for the *emp* database.
- Only server 3 accepts updates for the *prod* database.

In addition to assigning each server a version token list, the management application also maintains a cache that reflects the server assignments.

Before communicating with the servers, a client application contacts the management application and retrieves information about server assignments. Then the client selects a server based on those assignments. Suppose that a client wants to perform both reads and writes on the *emp* database. Based on the preceding assignments, only server 2 qualifies. The client connects to server 2 and registers its server requirements there by setting its *version\_tokens\_session* system variable:

```
mysql> SET @@session.version_tokens_session = 'emp=write';
```

For subsequent statements sent by the client to server 2, the server compares its own version token list to the client list to check whether they match. If so, statements execute normally:

```
mysql> UPDATE emp.employee SET salary = salary * 1.1 WHERE id = 4981;
Query OK, 1 row affected (0.07 sec)
Rows matched: 1  Changed: 1  Warnings: 0

mysql> SELECT last_name, first_name FROM emp.employee WHERE id = 4981;
+-----+-----+
| last_name | first_name |
+-----+-----+
| Smith    | Abe       |
+-----+-----+
1 row in set (0.01 sec)
```

Discrepancies between the server and client version token lists can occur two ways:

- A token name in the `version_tokens_session` value is not present in the server token list. In this case, an `ER_VTOKEN_PLUGIN_TOKEN_NOT_FOUND` error occurs.
- A token value in the `version_tokens_session` value differs from the value of the corresponding token in the server token list. In this case, an `ER_VTOKEN_PLUGIN_TOKEN_MISMATCH` error occurs.

As long as the assignment of server 2 does not change, the client continues to use it for reads and writes. But suppose that the management application wants to change server assignments so that writes for the `emp` database must be sent to server 1 instead of server 2. To do this, it uses `version_tokens_edit()` to modify the `emp` token value on the two servers (and updates its cache of server assignments):

Server 1:

```
mysql> SELECT version_tokens_edit('emp=write');
+-----+
| version_tokens_edit('emp=write') |
+-----+
| 1 version tokens updated.         |
+-----+
```

Server 2:

```
mysql> SELECT version_tokens_edit('emp=read');
+-----+
| version_tokens_edit('emp=read') |
+-----+
| 1 version tokens updated.        |
+-----+
```

`version_tokens_edit()` modifies the named tokens in the server token list and leaves other tokens unchanged.

The next time the client sends a statement to server 2, its own token list no longer matches the server token list and an error occurs:

```
mysql> UPDATE emp.employee SET salary = salary * 1.1 WHERE id = 4982;
ERROR 3136 (42000): Version token mismatch for emp. Correct value read
```

In this case, the client should contact the management application to obtain updated information about server assignments, select a new server, and send the failed statement to the new server.

#### Note

Each client must cooperate with Version Tokens by sending only statements in accordance with the token list that it registers with a given server. For example, if a client registers a token list of `'emp=read'`, there is nothing in Version Tokens to prevent the client from sending updates for the `emp` database. The client itself must refrain from doing so.

For each statement received from a client, the server implicitly uses locking, as follows:

- Take a shared lock for each token named in the client token list (that is, in the `version_tokens_session` value)
- Perform the comparison between the server and client token lists
- Execute the statement or produce an error depending on the comparison result
- Release the locks

The server uses shared locks so that comparisons for multiple sessions can occur without blocking, while preventing changes to the tokens for any session that attempts to acquire an exclusive lock before it manipulates tokens of the same names in the server token list.

The preceding example uses only a few of the user-defined included in the Version Tokens plugin library, but there are others. One set of UDFs permits the server's list of version tokens to be manipulated and inspected. Another set of UDFs permits version tokens to be locked and unlocked.

These UDFs permit the server's list of version tokens to be created, changed, removed, and inspected:

- `version_tokens_set()` completely replaces the current list and assigns a new list. The argument is a semicolon-separated list of `name=value` pairs.
- `version_tokens_edit()` enables partial modifications to the current list. It can add new tokens or change the values of existing tokens. The argument is a semicolon-separated list of `name=value` pairs.
- `version_tokens_delete()` deletes tokens from the current list. The argument is a semicolon-separated list of token names.
- `version_tokens_show()` displays the current token list. It takes no argument.

Each of those functions, if successful, returns a binary string indicating what action occurred. The following example establishes the server token list, modifies it by adding a new token, deletes some tokens, and displays the resulting token list:

```
mysql> SELECT version_tokens_set('tok1=a;tok2=b');
+-----+
| version_tokens_set('tok1=a;tok2=b') |
+-----+
| 2 version tokens set.                |
+-----+
mysql> SELECT version_tokens_edit('tok3=c');
+-----+
| version_tokens_edit('tok3=c') |
+-----+
| 1 version tokens updated.      |
+-----+
mysql> SELECT version_tokens_delete('tok2;tok1');
+-----+
| version_tokens_delete('tok2;tok1') |
+-----+
| 2 version tokens deleted.          |
+-----+
mysql> SELECT version_tokens_show();
+-----+
| version_tokens_show() |
+-----+
| tok3=c;               |
+-----+
```

Warnings occur if a token list is malformed:

```
mysql> SELECT version_tokens_set('tok1=a; =c');
+-----+
| version_tokens_set('tok1=a; =c') |
+-----+
| 1 version tokens set.            |
+-----+
1 row in set, 1 warning (0.00 sec)

mysql> SHOW WARNINGS\G
***** 1. row *****
Level: Warning
Code: 42000
Message: Invalid version token pair encountered. The list provided
```

```
is only partially updated.
1 row in set (0.00 sec)
```

As mentioned previously, version tokens are defined using a semicolon-separated list of *name=value* pairs. Consider this invocation of `version_tokens_set()`:

```
mysql> SELECT version_tokens_set('tok1=b;;; tok2= a = b ; tok1 = 1\'2 3\'4')
+-----+
| version_tokens_set('tok1=b;;; tok2= a = b ; tok1 = 1\'2 3\'4') |
+-----+
| 3 version tokens set. |
+-----+
```

Version Tokens interprets the argument as follows:

- Whitespace around names and values is ignored. Whitespace within names and values is permitted. (For `version_tokens_delete()`, which takes a list of names without values, whitespace around names is ignored.)
- There is no quoting mechanism.
- Order of tokens is not significant except that if a token list contains multiple instances of a given token name, the last value takes precedence over earlier values.

Given those rules, the preceding `version_tokens_set()` call results in a token list with two tokens: `tok1` has the value `1\'2 3\'4`, and `tok2` has the value `a = b`. To verify this, call `version_tokens_show()`:

```
mysql> SELECT version_tokens_show();
+-----+
| version_tokens_show() |
+-----+
| tok2=a = b;tok1=1\'2 3\'4; |
+-----+
```

If the token list contains two tokens, why did `version_tokens_set()` return the value `3 version tokens set`? That occurred because the original token list contained two definitions for `tok1`, and the second definition replaced the first.

The Version Tokens token-manipulation UDFs place these constraints on token names and values:

- Token names cannot contain `=` or `;` characters and have a maximum length of 64 characters.
- Token values cannot contain `;` characters. Length of values is constrained by the value of the `max_allowed_packet` system variable.
- Version Tokens treats token names and values as binary strings, so comparisons are case sensitive.

Version Tokens also includes a set of UDFs enabling tokens to be locked and unlocked:

- `version_tokens_lock_exclusive()` acquires exclusive version token locks. It takes a list of one or more lock names and a timeout value.
- `version_tokens_lock_shared()` acquires shared version token locks. It takes a list of one or more lock names and a timeout value.
- `version_tokens_unlock()` releases version token locks (exclusive and shared). It takes no argument.

Each locking function returns nonzero for success. Otherwise, an error occurs:

```
mysql> SELECT version_tokens_lock_shared('lock1', 'lock2', 0);
```

```

+-----+
| version_tokens_lock_shared('lock1', 'lock2', 0) |
+-----+
| 1 |
+-----+

mysql> SELECT version_tokens_lock_shared(NULL, 0);
ERROR 3131 (42000): Incorrect locking service lock name '(null)'.

```

Locking using Version Tokens locking functions is advisory; applications must agree to cooperate.

It is possible to lock nonexistent token names. This does not create the tokens.

#### Note

Version Tokens locking functions are based on the locking service described at [Section 27.3.1, “The Locking Service”](#), and thus have the same semantics for shared and exclusive locks. (Version Tokens uses the locking service routines built into the server, not the locking service UDF interface, so those UDFs need not be installed to use Version Tokens.) Locks acquired by Version Tokens use a locking service namespace of `version_token_locks`. Locking service locks can be monitored using the Performance Schema, so this is also true for Version Tokens locks. For details, see [Locking Service Monitoring](#).

For the Version Tokens locking functions, token name arguments are used exactly as specified. Surrounding whitespace is not ignored and `=` and `;` characters are permitted. This is because Version Tokens simply passes the token names to be locked as is to the locking service.

### 6.5.6.4 Version Tokens Reference

The following discussion serves as a reference to these Version Tokens components:

- Version Tokens user-defined functions
- Version Tokens system variables

#### Version Tokens Functions

The Version Tokens plugin library includes several user-defined functions. One set of UDFs permits the server's list of version tokens to be manipulated and inspected. Another set of UDFs permits version tokens to be locked and unlocked. The `SUPER` privilege is required to invoke any Version Tokens UDF.

The following UDFs permit the server's list of version tokens to be created, changed, removed, and inspected. Interpretation of `name_list` and `token_list` arguments (including whitespace handling) occurs as described in [Section 6.5.6.3, “Using Version Tokens”](#), which provides details about the syntax for specifying tokens, as well as additional examples.

- `version_tokens_delete(name_list)`

Deletes tokens from the server's list of version tokens using the `name_list` argument and returns a binary string that indicates the outcome of the operation. `name_list` is a semicolon-separated list of version token names to delete.

```

mysql> SELECT version_tokens_delete('tok1;tok3');
+-----+
| version_tokens_delete('tok1;tok3') |
+-----+
| 2 version tokens deleted.          |
+-----+

```

As of MySQL 5.7.9, an argument of `NULL` is treated as an empty string, which has no effect on the token list.

`version_tokens_delete()` deletes the tokens named in its argument, if they exist. (It is not an error to delete nonexistent tokens.) To clear the token list entirely without knowing which tokens are in the list, pass `NULL` or a string containing no tokens to `version_tokens_set()`:

```
mysql> SELECT version_tokens_set(NULL);
+-----+
| version_tokens_set(NULL) |
+-----+
| Version tokens list cleared. |
+-----+
mysql> SELECT version_tokens_set('');
```

- `version_tokens_edit(token_list)`

Modifies the server's list of version tokens using the `token_list` argument and returns a binary string that indicates the outcome of the operation. `token_list` is a semicolon-separated list of `name=value` pairs specifying the name of each token to be defined and its value. If a token exists, its value is updated with the given value. If a token does not exist, it is created with the given value. If the argument is `NULL` or a string containing no tokens, the token list remains unchanged.

```
mysql> SELECT version_tokens_set('tok1=value1;tok2=value2');
+-----+
| version_tokens_set('tok1=value1;tok2=value2') |
+-----+
| 2 version tokens set. |
+-----+
mysql> SELECT version_tokens_edit('tok2=new_value2;tok3=new_value3');
```

- `version_tokens_set(token_list)`

Replaces the server's list of version tokens with the tokens defined in the `token_list` argument and returns a binary string that indicates the outcome of the operation. `token_list` is a semicolon-separated list of `name=value` pairs specifying the name of each token to be defined and its value. If the argument is `NULL` or a string containing no tokens, the token list is cleared.

```
mysql> SELECT version_tokens_set('tok1=value1;tok2=value2');
+-----+
| version_tokens_set('tok1=value1;tok2=value2') |
+-----+
| 2 version tokens set. |
+-----+
```

- `version_tokens_show()`

Returns the server's list of version tokens as a binary string containing a semicolon-separated list of `name=value` pairs.

```
mysql> SELECT version_tokens_show();
+-----+
| version_tokens_show() |
+-----+
| tok2=value2;tok1=value1; |
+-----+
```

The following UDFs permit version tokens to be locked and unlocked:

- `version_tokens_lock_exclusive(token_name[, token_name] ..., timeout)`

Acquires exclusive locks on one or more version tokens, specified by name as strings, timing out with an error if the locks are not acquired within the given timeout value.

```
mysql> SELECT version_tokens_lock_exclusive('lock1', 'lock2', 10);
+-----+
| version_tokens_lock_exclusive('lock1', 'lock2', 10) |
+-----+
| 1 |
+-----+
```

This function was added in MySQL 5.7.8 with the name `vtoken_get_write_locks()` and renamed to `version_tokens_lock_exclusive()` in 5.7.9.

- `version_tokens_lock_shared(token_name[, token_name] ..., timeout)`

Acquires shared locks on one or more version tokens, specified by name as strings, timing out with an error if the locks are not acquired within the given timeout value.

```
mysql> SELECT version_tokens_lock_shared('lock1', 'lock2', 10);
+-----+
| version_tokens_lock_shared('lock1', 'lock2', 10) |
+-----+
| 1 |
+-----+
```

This function was added in MySQL 5.7.8 with the name `vtoken_get_read_locks()` and renamed to `version_tokens_lock_shared()` in 5.7.9.

- `version_tokens_unlock()`

Releases all locks that were acquired within the current session using `version_tokens_lock_exclusive()` and `version_tokens_lock_shared()`.

```
mysql> SELECT version_tokens_unlock();
+-----+
| version_tokens_unlock() |
+-----+
| 1 |
+-----+
```

This function was added in MySQL 5.7.8 with the name `vtoken_release_locks()` and renamed to `version_tokens_unlock()` in 5.7.9.

The locking functions share these characteristics:

- The return value is nonzero for success. Otherwise, an error occurs.
- Token names are strings.
- In contrast to argument handling for the UDFs that manipulate the server token list, whitespace surrounding token name arguments is not ignored and `=` and `;` characters are permitted.
- It is possible to lock nonexistent token names. This does not create the tokens.
- Timeout values are nonnegative integers representing the time in seconds to wait to acquire locks before timing out with an error. If the timeout is 0, there is no waiting and the function produces an error if locks cannot be acquired immediately.
- Version Tokens locking functions are based on the locking service described at [Section 27.3.1, “The Locking Service”](#).

## Version Tokens System Variables

Version Tokens supports the following system variables. These variables are unavailable unless the Version Tokens plugin is installed (see [Section 6.5.6.2, “Installing or Uninstalling Version Tokens”](#)).

System variables:

- `version_tokens_session`

|                            |   |                                     |
|----------------------------|---|-------------------------------------|
| <b>Introduced</b>          | 5.7.8                                       |                                     |
| <b>Command-Line Format</b> | <code>--version_tokens_session=value</code> |                                     |
| <b>System Variable</b>     | <b>Name</b>                                 | <code>version_tokens_session</code> |
|                            | <b>Variable Scope</b>                       | Global, Session                     |
|                            | <b>Dynamic Variable</b>                     | Yes                                 |
| <b>Permitted Values</b>    | <b>Type</b>                                 | string                              |
|                            | <b>Default</b>                              | <code>NULL</code>                   |

The session value of this variable specifies the client version token list and indicates the tokens that the client session requires the server version token list to have.

If the `version_tokens_session` variable is `NULL` (the default) or has an empty value, any server version token list matches. (In effect, an empty value disables matching requirements.)

If the `version_tokens_session` variable has a nonempty value, any mismatch between its value and the server version token list results in an error for any statement the session sends to the server. A mismatch occurs under these conditions:

- A token name in the `version_tokens_session` value is not present in the server token list. In this case, an `ER_VTOKEN_PLUGIN_TOKEN_NOT_FOUND` error occurs.
- A token value in the `version_tokens_session` value differs from the value of the corresponding token in the server token list. In this case, an `ER_VTOKEN_PLUGIN_TOKEN_MISMATCH` error occurs.

It is not a mismatch for the server version token list to include a token not named in the `version_tokens_session` value.

Suppose that a management application has set the server token list as follows:

```
mysql> SELECT version_tokens_set('tok1=a;tok2=b;tok3=c');
+-----+
| version_tokens_set('tok1=a;tok2=b;tok3=c') |
+-----+
| 3 version tokens set.                      |
+-----+
```

A client registers the tokens it requires the server to match by setting its `version_tokens_session` value. Then, for each subsequent statement sent by the client, the server checks its token list against the client `version_tokens_session` value and produces an error if there is a mismatch:

```
mysql> SET @@session.version_tokens_session = 'tok1=a;tok2=b';
mysql> SELECT 1;
+----+
| 1 |
+----+
| 1 |
```

```
+----+
mysql> SET @@session.version_tokens_session = 'tok1=b';
mysql> SELECT 1;
ERROR 3136 (42000): Version token mismatch for tok1. Correct value a
```

The first `SELECT` succeeds because the client tokens `tok1` and `tok2` are present in the server token list and each token has the same value in the server list. The second `SELECT` fails because, although `tok1` is present in the server token list, it has a different value than specified by the client.

At this point, any statement sent by the client fails, unless the server token list changes such that it matches again. Suppose that the management application changes the server token list as follows:

```
mysql> SELECT version_tokens_edit('tok1=b');
+-----+
| version_tokens_edit('tok1=b') |
+-----+
| 1 version tokens updated.      |
+-----+
mysql> SELECT version_tokens_show();
+-----+
| version_tokens_show() |
+-----+
| tok3=c;tok1=b;tok2=b; |
+-----+
```

Now the client `version_tokens_session` value matches the server token list and the client can once again successfully execute statements:

```
mysql> SELECT 1;
+----+
| 1 |
+----+
| 1 |
+----+
```

This variable was added in MySQL 5.7.8.

- `version_tokens_session_number`

|                            |  |  |
|----------------------------|--|--|
| <b>Introduced</b>          | 5.7.8  |  |
| <b>Command-Line Format</b> | <code>--version_tokens_session_number=N</code> |  |
| <b>System Variable</b>     | <b>Name</b>                                    | <code>version_tokens_session_number</code> |
|                            | <b>Variable Scope</b>                          | Global, Session                            |
|                            | <b>Dynamic Variable</b>                        | No   |
| <b>Permitted Values</b>    | <b>Type</b>                                    | integer                                    |
|                            | <b>Default</b>                                 | 0  |

This variable is for internal use.

This variable was added in MySQL 5.7.8.

## 6.6 Running Multiple MySQL Instances on One Machine

In some cases, you might want to run multiple instances of MySQL on a single machine. You might want to test a new MySQL release while leaving an existing production setup undisturbed. Or you might want to give different users access to different `mysqld` servers that they manage themselves.

(For example, you might be an Internet Service Provider that wants to provide independent MySQL installations for different customers.)

It is possible to use a different MySQL server binary per instance, or use the same binary for multiple instances, or any combination of the two approaches. For example, you might run a server from MySQL 5.6 and one from MySQL 5.7, to see how different versions handle a given workload. Or you might run multiple instances of the current production version, each managing a different set of databases.

Whether or not you use distinct server binaries, each instance that you run must be configured with unique values for several operating parameters. This eliminates the potential for conflict between instances. Parameters can be set on the command line, in option files, or by setting environment variables. See [Section 5.2.3, “Specifying Program Options”](#). To see the values used by a given instance, connect to it and execute a `SHOW VARIABLES` statement.

The primary resource managed by a MySQL instance is the data directory. Each instance should use a different data directory, the location of which is specified using the `--datadir=dir_name` option. For methods of configuring each instance with its own data directory, and warnings about the dangers of failing to do so, see [Section 6.6.1, “Setting Up Multiple Data Directories”](#).

In addition to using different data directories, several other options must have different values for each server instance:

- `--port=port_num`

`--port` controls the port number for TCP/IP connections. Alternatively, if the host has multiple network addresses, you can use `--bind-address` to cause each server to listen to a different address.

- `--socket={file_name|pipe_name}`

`--socket` controls the Unix socket file path on Unix or the named pipe name on Windows. On Windows, it is necessary to specify distinct pipe names only for those servers configured to permit named-pipe connections.

- `--shared-memory-base-name=name`

This option is used only on Windows. It designates the shared-memory name used by a Windows server to permit clients to connect using shared memory. It is necessary to specify distinct shared-memory names only for those servers configured to permit shared-memory connections.

- `--pid-file=file_name`

This option indicates the path name of the file in which the server writes its process ID.

If you use the following log file options, their values must differ for each server:

- `--general_log_file=file_name`
- `--log-bin[=file_name]`
- `--slow_query_log_file=file_name`
- `--log-error[=file_name]`

For further discussion of log file options, see [Section 6.4, “MySQL Server Logs”](#).

To achieve better performance, you can specify the following option differently for each server, to spread the load between several physical disks:

- `--tmpdir=dir_name`

Having different temporary directories also makes it easier to determine which MySQL server created any given temporary file.

If you have multiple MySQL installations in different locations, you can specify the base directory for each installation with the `--basedir=dir_name` option. This causes each instance to automatically use a different data directory, log files, and PID file because the default for each of those parameters is relative to the base directory. In that case, the only other options you need to specify are the `--socket` and `--port` options. Suppose that you install different versions of MySQL using `tar` file binary distributions. These install in different locations, so you can start the server for each installation using the command `bin/mysqld_safe` under its corresponding base directory. `mysqld_safe` determines the proper `--basedir` option to pass to `mysqld`, and you need specify only the `--socket` and `--port` options to `mysqld_safe`.

As discussed in the following sections, it is possible to start additional servers by specifying appropriate command options or by setting environment variables. However, if you need to run multiple servers on a more permanent basis, it is more convenient to use option files to specify for each server those option values that must be unique to it. The `--defaults-file` option is useful for this purpose.

## 6.6.1 Setting Up Multiple Data Directories

Each MySQL Instance on a machine should have its own data directory. The location is specified using the `--datadir=dir_name` option.

There are different methods of setting up a data directory for a new instance:

- Create a new data directory.
- Copy an existing data directory.

The following discussion provides more detail about each method.

### Warning

Normally, you should never have two servers that update data in the same databases. This may lead to unpleasant surprises if your operating system does not support fault-free system locking. If (despite this warning) you run multiple servers using the same data directory and they have logging enabled, you must use the appropriate options to specify log file names that are unique to each server. Otherwise, the servers try to log to the same files.

Even when the preceding precautions are observed, this kind of setup works only with `MyISAM` and `MERGE` tables, and not with any of the other storage engines. Also, this warning against sharing a data directory among servers always applies in an NFS environment. Permitting multiple MySQL servers to access a common data directory over NFS is a *very bad idea*. The primary problem is that NFS is the speed bottleneck. It is not meant for such use. Another risk with NFS is that you must devise a way to ensure that two or more servers do not interfere with each other. Usually NFS file locking is handled by the `lockd` daemon, but at the moment there is no platform that performs locking 100% reliably in every situation.

### Create a New Data Directory

With this method, the data directory will be in the same state as when you first install MySQL. It will have the default set of MySQL accounts and no user data.

On Unix, initialize the data directory. See [Section 2.10, “Postinstallation Setup and Testing”](#).

On Windows, the data directory is included in the MySQL distribution:

- MySQL Zip archive distributions for Windows contain an unmodified data directory. You can unpack such a distribution into a temporary location, then copy it `data` directory to where you are setting up the new instance.

- Windows MSI package installers create and set up the data directory that the installed server will use, but also create a pristine “template” data directory named `data` under the installation directory. After an installation has been performed using an MSI package, the template data directory can be copied to set up additional MySQL instances.

## Copy an Existing Data Directory

With this method, any MySQL accounts or user data present in the data directory are carried over to the new data directory.

1. Stop the existing MySQL instance using the data directory. This must be a clean shutdown so that the instance flushes any pending changes to disk.
2. Copy the data directory to the location where the new data directory should be.
3. Copy the `my.cnf` or `my.ini` option file used by the existing instance. This serves as a basis for the new instance.
4. Modify the new option file so that any pathnames referring to the original data directory refer to the new data directory. Also, modify any other options that must be unique per instance, such as the TCP/IP port number and the log files. For a list of parameters that must be unique per instance, see [Section 6.6, “Running Multiple MySQL Instances on One Machine”](#).
5. Start the new instance, telling it to use the new option file.

## 6.6.2 Running Multiple MySQL Instances on Windows

You can run multiple servers on Windows by starting them manually from the command line, each with appropriate operating parameters, or by installing several servers as Windows services and running them that way. General instructions for running MySQL from the command line or as a service are given in [Section 2.3, “Installing MySQL on Microsoft Windows”](#). The following sections describe how to start each server with different values for those options that must be unique per server, such as the data directory. These options are listed in [Section 6.6, “Running Multiple MySQL Instances on One Machine”](#).

### 6.6.2.1 Starting Multiple MySQL Instances at the Windows Command Line

The procedure for starting a single MySQL server manually from the command line is described in [Section 2.3.5.6, “Starting MySQL from the Windows Command Line”](#). To start multiple servers this way, you can specify the appropriate options on the command line or in an option file. It is more convenient to place the options in an option file, but it is necessary to make sure that each server gets its own set of options. To do this, create an option file for each server and tell the server the file name with a `--defaults-file` option when you run it.

Suppose that you want to run one instance of `mysqld` on port 3307 with a data directory of `C:\mydata1`, and another instance on port 3308 with a data directory of `C:\mydata2`. Use this procedure:

1. Make sure that each data directory exists, including its own copy of the `mysql` database that contains the grant tables.
2. Create two option files. For example, create one file named `C:\my-opts1.cnf` that looks like this:

```
[mysqld]
datadir = C:/mydata1
port = 3307
```

Create a second file named `C:\my-opts2.cnf` that looks like this:

```
[mysqld]
datadir = C:/mydata2
```

```
port = 3308
```

3. Use the `--defaults-file` option to start each server with its own option file:

```
C:\> C:\mysql\bin\mysqld --defaults-file=C:\my-opts1.cnf
C:\> C:\mysql\bin\mysqld --defaults-file=C:\my-opts2.cnf
```

Each server starts in the foreground (no new prompt appears until the server exits later), so you will need to issue those two commands in separate console windows.

To shut down the servers, connect to each using the appropriate port number:

```
C:\> C:\mysql\bin\mysqladmin --port=3307 --host=127.0.0.1 --user=root --password shutdown
C:\> C:\mysql\bin\mysqladmin --port=3308 --host=127.0.0.1 --user=root --password shutdown
```

Servers configured as just described permit clients to connect over TCP/IP. If your version of Windows supports named pipes and you also want to permit named-pipe connections, specify options that enable the named pipe and specify its name. Each server that supports named-pipe connections must use a unique pipe name. For example, the `C:\my-opts1.cnf` file might be written like this:

```
[mysqld]
datadir = C:/mydata1
port = 3307
enable-named-pipe
socket = mypipe1
```

Modify `C:\my-opts2.cnf` similarly for use by the second server. Then start the servers as described previously.

A similar procedure applies for servers that you want to permit shared-memory connections. Enable such connections with the `--shared-memory` option and specify a unique shared-memory name for each server with the `--shared-memory-base-name` option.

### 6.6.2.2 Starting Multiple MySQL Instances as Windows Services

On Windows, a MySQL server can run as a Windows service. The procedures for installing, controlling, and removing a single MySQL service are described in [Section 2.3.5.8, “Starting MySQL as a Windows Service”](#).

To set up multiple MySQL services, you must make sure that each instance uses a different service name in addition to the other parameters that must be unique per instance.

For the following instructions, suppose that you want to run the `mysqld` server from two different versions of MySQL that are installed at `C:\mysql-5.5.9` and `C:\mysql-5.7.18`, respectively. (This might be the case if you are running 5.5.9 as your production server, but also want to conduct tests using 5.7.18.)

To install MySQL as a Windows service, use the `--install` or `--install-manual` option. For information about these options, see [Section 2.3.5.8, “Starting MySQL as a Windows Service”](#).

Based on the preceding information, you have several ways to set up multiple services. The following instructions describe some examples. Before trying any of them, shut down and remove any existing MySQL services.

- **Approach 1:** Specify the options for all services in one of the standard option files. To do this, use a different service name for each server. Suppose that you want to run the 5.5.9 `mysqld` using the service name of `mysqld1` and the 5.7.18 `mysqld` using the service name `mysqld2`. In this case, you can use the `[mysqld1]` group for 5.5.9 and the `[mysqld2]` group for 5.7.18. For example, you can set up `C:\my.cnf` like this:

```
# options for mysqld1 service
[mysqld1]
```

```

basedir = C:/mysql-5.5.9
port = 3307
enable-named-pipe
socket = mypipe1

# options for mysqld2 service
[mysqld2]
basedir = C:/mysql-5.7.18
port = 3308
enable-named-pipe
socket = mypipe2

```

Install the services as follows, using the full server path names to ensure that Windows registers the correct executable program for each service:

```

C:\> C:\mysql-5.5.9\bin\mysqld --install mysqld1
C:\> C:\mysql-5.7.18\bin\mysqld --install mysqld2

```

To start the services, use the services manager, or use `NET START` with the appropriate service names:

```

C:\> NET START mysqld1
C:\> NET START mysqld2

```

To stop the services, use the services manager, or use `NET STOP` with the appropriate service names:

```

C:\> NET STOP mysqld1
C:\> NET STOP mysqld2

```

- **Approach 2:** Specify options for each server in separate files and use `--defaults-file` when you install the services to tell each server what file to use. In this case, each file should list options using a `[mysqld]` group.

With this approach, to specify options for the 5.5.9 `mysqld`, create a file `C:\my-opts1.cnf` that looks like this:

```

[mysqld]
basedir = C:/mysql-5.5.9
port = 3307
enable-named-pipe
socket = mypipe1

```

For the 5.7.18 `mysqld`, create a file `C:\my-opts2.cnf` that looks like this:

```

[mysqld]
basedir = C:/mysql-5.7.18
port = 3308
enable-named-pipe
socket = mypipe2

```

Install the services as follows (enter each command on a single line):

```

C:\> C:\mysql-5.5.9\bin\mysqld --install mysqld1
      --defaults-file=C:\my-opts1.cnf
C:\> C:\mysql-5.7.18\bin\mysqld --install mysqld2
      --defaults-file=C:\my-opts2.cnf

```

When you install a MySQL server as a service and use a `--defaults-file` option, the service name must precede the option.

After installing the services, start and stop them the same way as in the preceding example.

To remove multiple services, use `mysqld --remove` for each one, specifying a service name following the `--remove` option. If the service name is the default (MySQL), you can omit it.

### 6.6.3 Running Multiple MySQL Instances on Unix

#### Note

The discussion here uses `mysqld_safe` to launch multiple instances of MySQL. For MySQL installation using an RPM distribution, server startup and shutdown is managed by `systemd` on several Linux platforms. On these platforms, `mysqld_safe` is no longer installed because it is unnecessary. For information about using `systemd` to handle multiple MySQL instances, see [Section 2.5.10, “Managing MySQL Server with systemd”](#).

One way to run multiple MySQL instances on Unix is to compile different servers with different default TCP/IP ports and Unix socket files so that each one listens on different network interfaces. Compiling in different base directories for each installation also results automatically in a separate, compiled-in data directory, log file, and PID file location for each server.

Assume that an existing 5.6 server is configured for the default TCP/IP port number (3306) and Unix socket file (`/tmp/mysql.sock`). To configure a new 5.7.18 server to have different operating parameters, use a `CMake` command something like this:

```
shell> cmake . -DMYSQL_TCP_PORT=port_number \
             -DMYSQL_UNIX_ADDR=file_name \
             -DCMAKE_INSTALL_PREFIX=/usr/local/mysql-5.7.18
```

Here, `port_number` and `file_name` must be different from the default TCP/IP port number and Unix socket file path name, and the `CMAKE_INSTALL_PREFIX` value should specify an installation directory different from the one under which the existing MySQL installation is located.

If you have a MySQL server listening on a given port number, you can use the following command to find out what operating parameters it is using for several important configurable variables, including the base directory and Unix socket file name:

```
shell> mysqladmin --host=host_name --port=port_number variables
```

With the information displayed by that command, you can tell what option values *not* to use when configuring an additional server.

If you specify `localhost` as the host name, `mysqladmin` defaults to using a Unix socket file connection rather than TCP/IP. To explicitly specify the connection protocol, use the `--protocol={TCP|SOCKET|PIPE|MEMORY}` option.

You need not compile a new MySQL server just to start with a different Unix socket file and TCP/IP port number. It is also possible to use the same server binary and start each invocation of it with different parameter values at runtime. One way to do so is by using command-line options:

```
shell> mysqld_safe --socket=file_name --port=port_number
```

To start a second server, provide different `--socket` and `--port` option values, and pass a `--datadir=dir_name` option to `mysqld_safe` so that the server uses a different data directory.

Alternatively, put the options for each server in a different option file, then start each server using a `--defaults-file` option that specifies the path to the appropriate option file. For example, if the option files for two server instances are named `/usr/local/mysql/my.cnf` and `/usr/local/mysql/my.cnf2`, start the servers like this: command:

```
shell> mysqld_safe --defaults-file=/usr/local/mysql/my.cnf
```

```
shell> mysqld_safe --defaults-file=/usr/local/mysql/my.cnf2
```

Another way to achieve a similar effect is to use environment variables to set the Unix socket file name and TCP/IP port number:

```
shell> MYSQL_UNIX_PORT=/tmp/mysqld-new.sock
shell> MYSQL_TCP_PORT=3307
shell> export MYSQL_UNIX_PORT MYSQL_TCP_PORT
shell> mysql_install_db --user=mysql
shell> mysqld_safe --datadir=/path/to/datadir &
```

This is a quick way of starting a second server to use for testing. The nice thing about this method is that the environment variable settings apply to any client programs that you invoke from the same shell. Thus, connections for those clients are automatically directed to the second server.

Section 5.9, “MySQL Program Environment Variables”, includes a list of other environment variables you can use to affect MySQL programs.

On Unix, the `mysqld_multi` script provides another way to start multiple servers. See Section 5.3.4, “`mysqld_multi` — Manage Multiple MySQL Servers”.

## 6.6.4 Using Client Programs in a Multiple-Server Environment

To connect with a client program to a MySQL server that is listening to different network interfaces from those compiled into your client, you can use one of the following methods:

- Start the client with `--host=host_name` `--port=port_number` to connect using TCP/IP to a remote server, with `--host=127.0.0.1` `--port=port_number` to connect using TCP/IP to a local server, or with `--host=localhost` `--socket=file_name` to connect to a local server using a Unix socket file or a Windows named pipe.
- Start the client with `--protocol=TCP` to connect using TCP/IP, `--protocol=SOCKET` to connect using a Unix socket file, `--protocol=PIPE` to connect using a named pipe, or `--protocol=MEMORY` to connect using shared memory. For TCP/IP connections, you may also need to specify `--host` and `--port` options. For the other types of connections, you may need to specify a `--socket` option to specify a Unix socket file or Windows named-pipe name, or a `--shared-memory-base-name` option to specify the shared-memory name. Shared-memory connections are supported only on Windows.
- On Unix, set the `MYSQL_UNIX_PORT` and `MYSQL_TCP_PORT` environment variables to point to the Unix socket file and TCP/IP port number before you start your clients. If you normally use a specific socket file or port number, you can place commands to set these environment variables in your `.login` file so that they apply each time you log in. See Section 5.9, “MySQL Program Environment Variables”.
- Specify the default Unix socket file and TCP/IP port number in the `[client]` group of an option file. For example, you can use `C:\my.cnf` on Windows, or the `.my.cnf` file in your home directory on Unix. See Section 5.2.6, “Using Option Files”.
- In a C program, you can specify the socket file or port number arguments in the `mysql_real_connect()` call. You can also have the program read option files by calling `mysql_options()`. See Section 26.8.7, “C API Function Descriptions”.
- If you are using the Perl `DBD: :mysql` module, you can read options from MySQL option files. For example:

```
$dsn = "DBI:mysql:test;mysql_read_default_group=client;"
      . "mysql_read_default_file=/usr/local/mysql/data/my.cnf";
$dbh = DBI->connect($dsn, $user, $password);
```

See Section 26.10, “MySQL Perl API”.

Other programming interfaces may provide similar capabilities for reading option files.

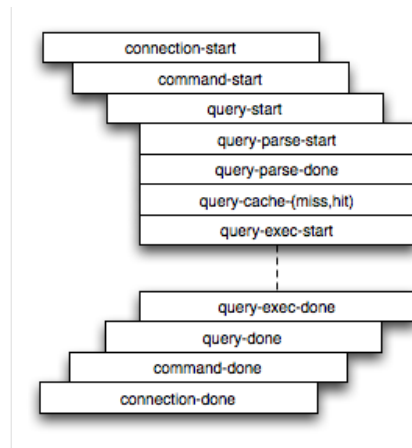

## 6.7 Tracing mysqld Using DTrace

Support for DTrace is deprecated in MySQL 5.7 and is removed in MySQL 8.0.

The DTrace probes in the MySQL server are designed to provide information about the execution of queries within MySQL and the different areas of the system being utilized during that process. The organization and triggering of the probes means that the execution of an entire query can be monitored with one level of probes ([query-start](#) and [query-done](#)) but by monitoring other probes you can get successively more detailed information about the execution of the query in terms of the locks used, sort methods and even row-by-row and storage-engine level execution information.

The DTrace probes are organized so that you can follow the entire query process, from the point of connection from a client, through the query execution, row-level operations, and back out again. You can think of the probes as being fired within a specific sequence during a typical client connect/execute/disconnect sequence, as shown in the following figure.

**Figure 6.1 The MySQL Architecture Using Pluggable Storage Engines**

Global information is provided in the arguments to the DTrace probes at various levels. Global information, that is, the connection ID and user/host and where relevant the query string, is provided at key levels ([connection-start](#), [command-start](#), [query-start](#), and [query-exec-start](#)). As you go deeper into the probes, it is assumed either you are only interested in the individual executions (row-level probes provide information on the database and table name only), or that you will combine the row-level probes with the notional parent probes to provide the information about a specific query. Examples of this will be given as the format and arguments of each probe are provided.

MySQL includes support for DTrace probes on these platforms:

- Solaris 10 Update 5 (Solaris 5/08) on SPARC, x86 and x86\_64 platforms
- OS X 10.4 and higher
- Oracle Linux 6 and higher with UEK kernel (as of MySQL 5.7.5)

Enabling the probes should be automatic on these platforms. To explicitly enable or disable the probes during building, use the `-DENABLE_DTRACE=1` or `-DENABLE_DTRACE=0` option to `CMake`.

If a non-Solaris platform includes DTrace support, building `mysqld` on that platform will include DTrace support.

## Additional Resources

- For more information on DTrace and writing DTrace scripts, read the [DTrace User Guide](#).

- For an introduction to DTrace, see the MySQL Dev Zone article [Getting started with DTracing MySQL](#).

## 6.7.1 mysql\_d DTrace Probe Reference

MySQL supports the following static probes, organized into groups of functionality.

**Table 6.5 MySQL DTrace Probes**

| Group           | Probes  |
|-----------------|---|
| Connection      | <code>connection-start</code> , <code>connection-done</code>  |
| Command         | <code>command-start</code> , <code>command-done</code>  |
| Query           | <code>query-start</code> , <code>query-done</code>  |
| Query Parsing   | <code>query-parse-start</code> , <code>query-parse-done</code>  |
| Query Cache     | <code>query-cache-hit</code> , <code>query-cache-miss</code>  |
| Query Execution | <code>query-exec-start</code> , <code>query-exec-done</code>  |
| Row Level       | <code>insert-row-start</code> , <code>insert-row-done</code>  |
|                 | <code>update-row-start</code> , <code>update-row-done</code>  |
|                 | <code>delete-row-start</code> , <code>delete-row-done</code>  |
| Row Reads       | <code>read-row-start</code> , <code>read-row-done</code>  |
| Index Reads     | <code>index-read-row-start</code> , <code>index-read-row-done</code>  |
| Lock            | <code>handler-rdlock-start</code> , <code>handler-rdlock-done</code>  |
|                 | <code>handler-wrlock-start</code> , <code>handler-wrlock-done</code>  |
|                 | <code>handler-unlock-start</code> , <code>handler-unlock-done</code>  |
| Filesort        | <code>filesort-start</code> , <code>filesort-done</code>  |
| Statement       | <code>select-start</code> , <code>select-done</code>  |
|                 | <code>insert-start</code> , <code>insert-done</code>  |
|                 | <code>insert-select-start</code> , <code>insert-select-done</code>  |
|                 | <code>update-start</code> , <code>update-done</code>  |
|                 | <code>multi-update-start</code> , <code>multi-update-done</code>  |
|                 | <code>delete-start</code> , <code>delete-done</code>  |
|                 | <code>multi-delete-start</code> , <code>multi-delete-done</code>  |
| Network         | <code>net-read-start</code> , <code>net-read-done</code> , <code>net-write-start</code> , <code>net-write-done</code>   |
| Keycache        | <code>keycache-read-start</code> , <code>keycache-read-block</code> , <code>keycache-read-done</code> , <code>keycache-read-hit</code> , <code>keycache-read-miss</code> , <code>keycache-write-start</code> , <code>keycache-write-block</code> , <code>keycache-write-done</code> |

### Note

When extracting the argument data from the probes, each argument is available as `argN`, starting with `arg0`. To identify each argument within the definitions they are provided with a descriptive name, but you must access the information using the corresponding `argN` parameter.

### 6.7.1.1 Connection Probes

The `connection-start` and `connection-done` probes enclose a connection from a client, regardless of whether the connection is through a socket or network connection.

```
connection-start(connectionid, user, host)
```

```
connection-done(status, connectionid)
```

- **connection-start**: Triggered after a connection and successful login/authentication have been completed by a client. The arguments contain the connection information:
  - **connectionid**: An `unsigned long` containing the connection ID. This is the same as the process ID shown as the `Id` value in the output from `SHOW PROCESSLIST`.
  - **user**: The username used when authenticating. The value will be blank for the anonymous user.
  - **host**: The host of the client connection. For a connection made using Unix sockets, the value will be blank.
- **connection-done**: Triggered just as the connection to the client has been closed. The arguments are:
  - **status**: The status of the connection when it was closed. A logout operation will have a value of 0; any other termination of the connection has a nonzero value.
  - **connectionid**: The connection ID of the connection that was closed.

The following D script will quantify and summarize the average duration of individual connections, and provide a count, dumping the information every 60 seconds:

```
#!/usr/sbin/dtrace -s

mysql*:::connection-start
{
    self->start = timestamp;
}

mysql*:::connection-done
/self->start/
{
    @ = quantize(((timestamp - self->start)/1000000));
    self->start = 0;
}

tick-60s
{
    printa(@);
}
```

When executed on a server with a large number of clients you might see output similar to this:

```
1 57413                               :tick-60s

value  ----- Distribution ----- count
-1 | 0
0 | @@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@@ 30011
1 | 59
2 | 5
4 | 20
8 | 29
16 | 18
32 | 27
64 | 30
128 | 11
256 | 10
512 | 1
1024 | 6
2048 | 8
4096 | 9
8192 | 8
16384 | 2
32768 | 1
65536 | 1
```

|        |  |   |
|--------|--|---|
| 131072 |  | 0 |
| 262144 |  | 1 |
| 524288 |  | 0 |

### 6.7.1.2 Command Probes

The command probes are executed before and after a client command is executed, including any SQL statement that might be executed during that period. Commands include operations such as the initialization of the DB, use of the `COM_CHANGE_USER` operation (supported by the MySQL protocol), and manipulation of prepared statements. Many of these commands are used only by the MySQL client API from various connectors such as PHP and Java.

```
command-start(connectionid, command, user, host)
command-done(status)
```

- `command-start`: Triggered when a command is submitted to the server.
- `connectionid`: The connection ID of the client executing the command.
- `command`: An integer representing the command that was executed. Possible values are shown in the following table.

| Value | Name                    | Description   |
|-------|-------------------------|---|
| 00    | COM_SLEEP               | Internal thread state   |
| 01    | COM_QUIT                | Close connection  |
| 02    | COM_INIT_DB             | Select database ( <code>USE ...</code> )  |
| 03    | COM_QUERY               | Execute a query   |
| 04    | COM_FIELD_LIST          | Get a list of fields  |
| 05    | COM_CREATE_DB           | Create a database (deprecated)  |
| 06    | COM_DROP_DB             | Drop a database (deprecated)  |
| 07    | COM_REFRESH             | Refresh connection  |
| 08    | COM_SHUTDOWN            | Shutdown server   |
| 09    | COM_STATISTICS          | Get statistics  |
| 10    | COM_PROCESS_INFO        | Get processes ( <code>SHOW PROCESSLIST</code> )                                       |
| 11    | COM_CONNECT             | Initialize connection   |
| 12    | COM_PROCESS_KILL        | Kill process  |
| 13    | COM_DEBUG               | Get debug information   |
| 14    | COM_PING                | Ping  |
| 15    | COM_TIME                | Internal thread state   |
| 16    | COM_DELAYED_INSERT      | Internal thread state   |
| 17    | COM_CHANGE_USER         | Change user   |
| 18    | COM_BINLOG_DUMP         | Used by a replication slave or <code>mysqlbinlog</code> to initiate a binary log read |
| 19    | COM_TABLE_DUMP          | Used by a replication slave to get the master table information                       |
| 20    | COM_CONNECT_OUT         | Used by a replication slave to log a connection to the server                         |
| 21    | COM_REGISTER_SLAVE      | Used by a replication slave during registration                                       |
| 22    | COM_STMT_PREPARE        | Prepare a statement   |
| 23    | COM_STMT_EXECUTE        | Execute a statement   |
| 24    | COM_STMT_SEND_LONG_DATA | Used by a replication slave when requesting extended data                             |
| 25    | COM_STMT_CLOSE          | Close a prepared statement  |

| Value | Name            | Description                |
|-------|-----------------|----------------------------|
| 26    | COM_STMT_RESET  | Reset a prepared statement |
| 27    | COM_SET_OPTIONS | Set a server option        |
| 28    | COM_STMT_FETCH  | Fetch a prepared statement |

- `user`: The user executing the command.
- `host`: The client host.
- `command-done`: Triggered when the command execution completes. The `status` argument contains 0 if the command executed successfully, or 1 if the statement was terminated before normal completion.

The `command-start` and `command-done` probes are best used when combined with the statement probes to get an idea of overall execution time.

### 6.7.1.3 Query Probes

The `query-start` and `query-done` probes are triggered when a specific query is received by the server and when the query has been completed and the information has been successfully sent to the client.

```
query-start(query, connectionid, database, user, host)
query-done(status)
```

- `query-start`: Triggered after the query string has been received from the client. The arguments are:
  - `query`: The full text of the submitted query.
  - `connectionid`: The connection ID of the client that submitted the query. The connection ID equals the connection ID returned when the client first connects and the `Id` value in the output from `SHOW PROCESSLIST`.
  - `database`: The database name on which the query is being executed.
  - `user`: The username used to connect to the server.
  - `host`: The hostname of the client.
- `query-done`: Triggered once the query has been executed and the information has been returned to the client. The probe includes a single argument, `status`, which returns 0 when the query is successfully executed and 1 if there was an error.

You can get a simple report of the execution time for each query using the following D script:

```
#!/usr/sbin/dtrace -s

#pragma D option quiet

dtrace:::BEGIN
{
    printf("%-20s %-20s %-40s %-9s\n", "Who", "Database", "Query", "Time(ms)");
}

mysql*:::query-start
{
    self->query = copyinstr(arg0);
    self->connid = arg1;
    self->db = copyinstr(arg2);
    self->who = strjoin(copyinstr(arg3), strjoin("@", copyinstr(arg4)));
    self->querystart = timestamp;
```

```

}

mysql*:::query-done
{
    printf("%-20s %-20s %-40s %-9d\n", self->who, self->db, self->query,
        (timestamp - self->querystart) / 1000000);
}

```

When executing the above script you should get a basic idea of the execution time of your queries:

```

shell> ./query.d
Who           Database      Query                                     Time (ms)
root@localhost test        select * from t1 order by i limit 10      0
root@localhost test        set global query_cache_size=0            0
root@localhost test        select * from t1 order by i limit 10      776
root@localhost test        select * from t1 order by i limit 10      773
root@localhost test        select * from t1 order by i desc limit 10 795

```

#### 6.7.1.4 Query Parsing Probes

The query parsing probes are triggered before the original SQL statement is parsed and when the parsing of the statement and determination of the execution model required to process the statement has been completed:

```

query-parse-start(query)
query-parse-done(status)

```

- **query-parse-start**: Triggered just before the statement is parsed by the MySQL query parser. The single argument, **query**, is a string containing the full text of the original query.
- **query-parse-done**: Triggered when the parsing of the original statement has been completed. The **status** is an integer describing the status of the operation. A **0** indicates that the query was successfully parsed. A **1** indicates that the parsing of the query failed.

For example, you could monitor the execution time for parsing a given query using the following D script:

```

#!/usr/sbin/dtrace -s

#pragma D option quiet

mysql*:::query-parse-start
{
    self->parsestart = timestamp;
    self->parsequery = copyinstr(arg0);
}

mysql*:::query-parse-done
/arg0 == 0/
{
    printf("Parsing %s: %d microseconds\n", self->parsequery, ((timestamp - self->parsestart)/1000));
}

mysql*:::query-parse-done
/arg0 != 0/
{
    printf("Error parsing %s: %d microseconds\n", self->parsequery, ((timestamp - self->parsestart)/1000));
}

```

In the above script a predicate is used on **query-parse-done** so that different output is generated based on the status value of the probe.

When running the script and monitoring the execution:

```

shell> ./query-parsing.d
Error parsing select from t1 join (t2) on (t1.i = t2.i) order by t1.s,t1.i limit 10: 36 ms
Parsing select * from t1 join (t2) on (t1.i = t2.i) order by t1.s,t1.i limit 10: 176 ms

```

### 6.7.1.5 Query Cache Probes

The query cache probes are fired when executing any query. The `query-cache-hit` query is triggered when a query exists in the query cache and can be used to return the query cache information. The arguments contain the original query text and the number of rows returned from the query cache for the query. If the query is not within the query cache, or the query cache is not enabled, then the `query-cache-miss` probe is triggered instead.

```
query-cache-hit(query, rows)
query-cache-miss(query)
```

- `query-cache-hit`: Triggered when the query has been found within the query cache. The first argument, `query`, contains the original text of the query. The second argument, `rows`, is an integer containing the number of rows in the cached query.
- `query-cache-miss`: Triggered when the query is not found within the query cache. The first argument, `query`, contains the original text of the query.

The query cache probes are best combined with a probe on the main query so that you can determine the differences in times between using or not using the query cache for specified queries. For example, in the following D script, the query and query cache information are combined into the information output during monitoring:

```
#!/usr/sbin/dtrace -s

#pragma D option quiet

dtrace:::BEGIN
{
    printf("%-20s %-20s %-40s %2s %-9s\n", "Who", "Database", "Query", "QC", "Time(ms)");
}

mysql*:::query-start
{
    self->query = copyinstr(arg0);
    self->connid = arg1;
    self->db = copyinstr(arg2);
    self->who = strjoin(copyinstr(arg3), strjoin("@", copyinstr(arg4)));
    self->querystart = timestamp;
    self->qc = 0;
}

mysql*:::query-cache-hit
{
    self->qc = 1;
}

mysql*:::query-cache-miss
{
    self->qc = 0;
}

mysql*:::query-done
{
    printf("%-20s %-20s %-40s %2s %-9d\n", self->who, self->db, self->query, (self->qc ? "Y" : "N"),
        (timestamp - self->querystart) / 1000000);
}
```

When executing the script you can see the effects of the query cache. Initially the query cache is disabled. If you set the query cache size and then execute the query multiple times you should see that the query cache is being used to return the query data:

```
shell> ./query-cache.d
root@localhost      test      select * from t1 order by i limit 10      N      1072
root@localhost      test      set global query_cache_size=262144      N      0
root@localhost      test      select * from t1 order by i limit 10      N      781
root@localhost      test      select * from t1 order by i limit 10      Y      0
```

### 6.7.1.6 Query Execution Probes

The query execution probe is triggered when the actual execution of the query starts, after the parsing and checking the query cache but before any privilege checks or optimization. By comparing the difference between the start and done probes you can monitor the time actually spent servicing the query (instead of just handling the parsing and other elements of the query).

```
query-exec-start(query, connectionid, database, user, host, exec_type)
query-exec-done(status)
```

#### Note

The information provided in the arguments for `query-start` and `query-exec-start` are almost identical and designed so that you can choose to monitor either the entire query process (using `query-start`) or only the execution (using `query-exec-start`) while exposing the core information about the user, client, and query being executed.

- `query-exec-start`: Triggered when the execution of a individual query is started. The arguments are:
  - `query`: The full text of the submitted query.
  - `connectionid`: The connection ID of the client that submitted the query. The connection ID equals the connection ID returned when the client first connects and the `Id` value in the output from `SHOW PROCESSLIST`.
  - `database`: The database name on which the query is being executed.
  - `user`: The username used to connect to the server.
  - `host`: The hostname of the client.
  - `exec_type`: The type of execution. Execution types are determined based on the contents of the query and where it was submitted. The values for each type are shown in the following table.

| Value | Description                                     |
|-------|---|
| 0     | Executed query from sql_parse, top-level query. |
| 1     | Executed prepared statement                     |
| 2     | Executed cursor statement                       |
| 3     | Executed query in stored procedure              |

- `query-exec-done`: Triggered when the execution of the query has completed. The probe includes a single argument, `status`, which returns 0 when the query is successfully executed and 1 if there was an error.

### 6.7.1.7 Row-Level Probes

The `*row-{start,done}` probes are triggered each time a row operation is pushed down to a storage engine. For example, if you execute an `INSERT` statement with 100 rows of data, then the `insert-row-start` and `insert-row-done` probes will be triggered 100 times each, for each row insert.

```
insert-row-start(database, table)
insert-row-done(status)

update-row-start(database, table)
update-row-done(status)

delete-row-start(database, table)
```

```
delete-row-done(status)
```

- `insert-row-start`: Triggered before a row is inserted into a table.
- `insert-row-done`: Triggered after a row is inserted into a table.
- `update-row-start`: Triggered before a row is updated in a table.
- `update-row-done`: Triggered before a row is updated in a table.
- `delete-row-start`: Triggered before a row is deleted from a table.
- `delete-row-done`: Triggered before a row is deleted from a table.

The arguments supported by the probes are consistent for the corresponding `start` and `done` probes in each case:

- `database`: The database name.
- `table`: The table name.
- `status`: The status; 0 for success or 1 for failure.

Because the row-level probes are triggered for each individual row access, these probes can be triggered many thousands of times each second, which may have a detrimental effect on both the monitoring script and MySQL. The DTrace environment should limit the triggering on these probes to prevent the performance being adversely affected. Either use the probes sparingly, or use counter or aggregation functions to report on these probes and then provide a summary when the script terminates or as part of a `query-done` or `query-exec-done` probes.

The following example script summarizes the duration of each row operation within a larger query:

```
#!/usr/sbin/dtrace -s

#pragma D option quiet

dtrace:::BEGIN
{
    printf("%-2s %-10s %-10s %9s %9s %-s \n",
        "St", "Who", "DB", "ConnID", "Dur ms", "Query");
}

mysql*:::query-start
{
    self->query = copyinstr(arg0);
    self->who   = strjoin(copyinstr(arg3), strjoin("@", copyinstr(arg4)));
    self->db    = copyinstr(arg2);
    self->connid = arg1;
    self->querystart = timestamp;
    self->rowdur = 0;
}

mysql*:::query-done
{
    this->elapsed = (timestamp - self->querystart) / 1000000;
    printf("%2d %-10s %-10s %9d %9d %s\n",
        arg0, self->who, self->db,
        self->connid, this->elapsed, self->query);
}

mysql*:::query-done
/ self->rowdur /
{
    printf("%34s %9d %s\n", "", (self->rowdur/1000000), "-> Row ops");
}

mysql*:::insert-row-start
{

```

```

    self->rowstart = timestamp;
}

mysql*:::delete-row-start
{
    self->rowstart = timestamp;
}

mysql*:::update-row-start
{
    self->rowstart = timestamp;
}

mysql*:::insert-row-done
{
    self->rowdur += (timestamp-self->rowstart);
}

mysql*:::delete-row-done
{
    self->rowdur += (timestamp-self->rowstart);
}

mysql*:::update-row-done
{
    self->rowdur += (timestamp-self->rowstart);
}

```

Running the above script with a query that inserts data into a table, you can monitor the exact time spent performing the raw row insertion:

| St | Who        | DB   | ConnID | Dur ms | Query                            |
|----|------------|------|--------|--------|----------------------------------|
| 0  | @localhost | test | 13     | 20767  | insert into t1(select * from t2) |
|    |            |      |        | 4827   | -> Row ops                       |

### 6.7.1.8 Read Row Probes

The read row probes are triggered at a storage engine level each time a row read operation occurs. These probes are specified within each storage engine (as opposed to the `*row-start` probes which are in the storage engine interface). These probes can therefore be used to monitor individual storage engine row-level operations and performance. Because these probes are triggered around the storage engine row read interface, they may be hit a significant number of times during a basic query.

```

read-row-start(database, table, scan_flag)
read-row-done(status)

```

- `read-row-start`: Triggered when a row is read by the storage engine from the specified `database` and `table`. The `scan_flag` is set to 1 (true) when the read is part of a table scan (that is, a sequential read), or 0 (false) when the read is of a specific record.
- `read-row-done`: Triggered when a row read operation within a storage engine completes. The `status` returns 0 on success, or a positive value on failure.

### 6.7.1.9 Index Probes

The index probes are triggered each time a row is read using one of the indexes for the specified table. The probe is triggered within the corresponding storage engine for the table.

```

index-read-row-start(database, table)
index-read-row-done(status)

```

- `index-read-row-start`: Triggered when a row is read by the storage engine from the specified `database` and `table`.
- `index-read-row-done`: Triggered when an indexed row read operation within a storage engine completes. The `status` returns 0 on success, or a positive value on failure.

### 6.7.1.10 Lock Probes

The lock probes are called whenever an external lock is requested by MySQL for a table using the corresponding lock mechanism on the table as defined by the table's engine type. There are three different types of lock, the read lock, write lock, and unlock operations. Using the probes you can determine the duration of the external locking routine (that is, the time taken by the storage engine to implement the lock, including any time waiting for another lock to become free) and the total duration of the lock/unlock process.

```
handler-rdlock-start(database, table)
handler-rdlock-done(status)

handler-wrlock-start(database, table)
handler-wrlock-done(status)

handler-unlock-start(database, table)
handler-unlock-done(status)
```

- **handler-rdlock-start**: Triggered when a read lock is requested on the specified `database` and `table`.
- **handler-wrlock-start**: Triggered when a write lock is requested on the specified `database` and `table`.
- **handler-unlock-start**: Triggered when an unlock request is made on the specified `database` and `table`.
- **handler-rdlock-done**: Triggered when a read lock request completes. The `status` is 0 if the lock operation succeeded, or `>0` on failure.
- **handler-wrlock-done**: Triggered when a write lock request completes. The `status` is 0 if the lock operation succeeded, or `>0` on failure.
- **handler-unlock-done**: Triggered when an unlock request completes. The `status` is 0 if the unlock operation succeeded, or `>0` on failure.

You can use arrays to monitor the locking and unlocking of individual tables and then calculate the duration of the entire table lock using the following script:

```
#!/usr/sbin/dtrace -s

#pragma D option quiet

mysql*:::handler-rdlock-start
{
    self->rdlockstart = timestamp;
    this->lockref = strjoin(copyinstr(arg0),strjoin("@",copyinstr(arg1)));
    self->lockmap[this->lockref] = self->rdlockstart;
    printf("Start: Lock->Read   %s.%s\n",copyinstr(arg0),copyinstr(arg1));
}

mysql*:::handler-wrlock-start
{
    self->wrlockstart = timestamp;
    this->lockref = strjoin(copyinstr(arg0),strjoin("@",copyinstr(arg1)));
    self->lockmap[this->lockref] = self->rdlockstart;
    printf("Start: Lock->Write  %s.%s\n",copyinstr(arg0),copyinstr(arg1));
}

mysql*:::handler-unlock-start
{
    self->unlockstart = timestamp;
    this->lockref = strjoin(copyinstr(arg0),strjoin("@",copyinstr(arg1)));
    printf("Start: Lock->Unlock %s.%s (%d ms lock duration)\n",
        copyinstr(arg0),copyinstr(arg1),
        (timestamp - self->lockmap[this->lockref])/1000000);
}
```

```
mysql*:::handler-rdlock-done
{
    printf("End:   Lock->Read   %d ms\n",
           (timestamp - self->rdlockstart)/1000000);
}

mysql*:::handler-wrlock-done
{
    printf("End:   Lock->Write  %d ms\n",
           (timestamp - self->wrlockstart)/1000000);
}

mysql*:::handler-unlock-done
{
    printf("End:   Lock->Unlock %d ms\n",
           (timestamp - self->unlockstart)/1000000);
}
```

When executed, you should get information both about the duration of the locking process itself, and of the locks on a specific table:

```
Start: Lock->Read   test.t2
End:   Lock->Read   0 ms
Start: Lock->Unlock test.t2 (25743 ms lock duration)
End:   Lock->Unlock 0 ms
Start: Lock->Read   test.t2
End:   Lock->Read   0 ms
Start: Lock->Unlock test.t2 (1 ms lock duration)
End:   Lock->Unlock 0 ms
Start: Lock->Read   test.t2
End:   Lock->Read   0 ms
Start: Lock->Unlock test.t2 (1 ms lock duration)
End:   Lock->Unlock 0 ms
Start: Lock->Read   test.t2
End:   Lock->Read   0 ms
```

### 6.7.1.11 Filesort Probes

The filesort probes are triggered whenever a filesort operation is applied to a table. For more information on filesort and the conditions under which it occurs, see [Section 9.2.1.15, “ORDER BY Optimization”](#).

```
filesort-start(database, table)
filesort-done(status, rows)
```

- **filesort-start**: Triggered when the filesort operation starts on a table. The two arguments to the probe, **database** and **table**, will identify the table being sorted.
- **filesort-done**: Triggered when the filesort operation completes. Two arguments are supplied, the **status** (0 for success, 1 for failure), and the number of rows sorted during the filesort process.

An example of this is in the following script, which tracks the duration of the filesort process in addition to the duration of the main query:

```
#!/usr/sbin/dtrace -s

#pragma D option quiet

dtrace:::BEGIN
{
    printf("%-2s %-10s %-10s %9s %18s %-s \n",
           "St", "Who", "DB", "ConnID", "Dur microsec", "Query");
}

mysql*:::query-start
{
    self->query = copyinstr(arg0);
    self->who   = strjoin(copyinstr(arg3), strjoin("@", copyinstr(arg4)));
}
```

```

    self->db      = copyinstr(arg2);
    self->connid = arg1;
    self->querystart = timestamp;
    self->filesort = 0;
    self->fsdb = "";
    self->fstable = "";
}

mysql*:::filesort-start
{
    self->filesort = timestamp;
    self->fsdb = copyinstr(arg0);
    self->fstable = copyinstr(arg1);
}

mysql*:::filesort-done
{
    this->elapsed = (timestamp - self->filesort) / 1000;
    printf("%2d %-10s %-10s %9d %18d Filesort on %s\n",
        arg0, self->who, self->fsdb,
        self->connid, this->elapsed, self->fstable);
}

mysql*:::query-done
{
    this->elapsed = (timestamp - self->querystart) / 1000;
    printf("%2d %-10s %-10s %9d %18d %s\n",
        arg0, self->who, self->db,
        self->connid, this->elapsed, self->query);
}

```

Executing a query on a large table with an `ORDER BY` clause that triggers a filesort, and then creating an index on the table and then repeating the same query, you can see the difference in execution speed:

| St | Who        | DB   | ConnID | Dur       | microsec                              | Query |
|----|------------|------|--------|-----------|---------------------------------------|-------|
| 0  | @localhost | test | 14     | 11335469  | Filesort on t1                        |       |
| 0  | @localhost | test | 14     | 11335787  | select * from t1 order by i limit 100 |       |
| 0  | @localhost | test | 14     | 466734378 | create index t1a on t1 (i)            |       |
| 0  | @localhost | test | 14     | 26472     | select * from t1 order by i limit 100 |       |

### 6.7.1.12 Statement Probes

The individual statement probes are provided to give specific information about different statement types. For the start probes the string of the query is provided as the only argument. Depending on the statement type, the information provided by the corresponding done probe will differ. For all done probes the status of the operation (0 for success, >0 for failure) is provided. For `SELECT`, `INSERT`, `INSERT ... (SELECT FROM ...)`, `DELETE`, and `DELETE FROM t1,t2` operations the number of rows affected is returned.

For `UPDATE` and `UPDATE t1,t2 ...` statements the number of rows matched and the number of rows actually changed is provided. This is because the number of rows actually matched by the corresponding `WHERE` clause, and the number of rows changed can differ. MySQL does not update the value of a row if the value already matches the new setting.

```

select-start(query)
select-done(status,rows)

insert-start(query)
insert-done(status,rows)

insert-select-start(query)
insert-select-done(status,rows)

update-start(query)
update-done(status,rowsmatched,rowschanged)

multi-update-start(query)
multi-update-done(status,rowsmatched,rowschanged)

```

```
delete-start(query)
delete-done(status,rows)

multi-delete-start(query)
multi-delete-done(status,rows)
```

- `select-start`: Triggered before a `SELECT` statement.
- `select-done`: Triggered at the end of a `SELECT` statement.
- `insert-start`: Triggered before a `INSERT` statement.
- `insert-done`: Triggered at the end of an `INSERT` statement.
- `insert-select-start`: Triggered before an `INSERT ... SELECT` statement.
- `insert-select-done`: Triggered at the end of an `INSERT ... SELECT` statement.
- `update-start`: Triggered before an `UPDATE` statement.
- `update-done`: Triggered at the end of an `UPDATE` statement.
- `multi-update-start`: Triggered before an `UPDATE` statement involving multiple tables.
- `multi-update-done`: Triggered at the end of an `UPDATE` statement involving multiple tables.
- `delete-start`: Triggered before a `DELETE` statement.
- `delete-done`: Triggered at the end of a `DELETE` statement.
- `multi-delete-start`: Triggered before a `DELETE` statement involving multiple tables.
- `multi-delete-done`: Triggered at the end of a `DELETE` statement involving multiple tables.

The arguments for the statement probes are:

- `query`: The query string.
- `status`: The status of the query. 0 for success, and >0 for failure.
- `rows`: The number of rows affected by the statement. This returns the number rows found for `SELECT`, the number of rows deleted for `DELETE`, and the number of rows successfully inserted for `INSERT`.
- `rowsmatched`: The number of rows matched by the `WHERE` clause of an `UPDATE` operation.
- `rowschanged`: The number of rows actually changed during an `UPDATE` operation.

You use these probes to monitor the execution of these statement types without having to monitor the user or client executing the statements. A simple example of this is to track the execution times:

```
#!/usr/sbin/dtrace -s

#pragma D option quiet

dtrace:::BEGIN
{
    printf("%-60s %-8s %-8s %-8s\n", "Query", "RowsU", "RowsM", "Dur (ms)");
}

mysql*:::update-start, mysql*:::insert-start,
mysql*:::delete-start, mysql*:::multi-delete-start,
mysql*:::multi-delete-done, mysql*:::select-start,
mysql*:::insert-select-start, mysql*:::multi-update-start
{
```

```

    self->query = copyinstr(arg0);
    self->querystart = timestamp;
}

mysql*:::insert-done, mysql*:::select-done,
mysql*:::delete-done, mysql*:::multi-delete-done, mysql*:::insert-select-done
/ self->querystart /
{
    this->elapsed = ((timestamp - self->querystart)/1000000);
    printf("%-60s %-8d %-8d %d\n",
        self->query,
        0,
        arg1,
        this->elapsed);
    self->querystart = 0;
}

mysql*:::update-done, mysql*:::multi-update-done
/ self->querystart /
{
    this->elapsed = ((timestamp - self->querystart)/1000000);
    printf("%-60s %-8d %-8d %d\n",
        self->query,
        arg1,
        arg2,
        this->elapsed);
    self->querystart = 0;
}

```

When executed you can see the basic execution times and rows matches:

| Query                             | RowsU | RowsM | Dur (ms) |
|-----------------------------------|-------|-------|----------|
| select * from t2                  | 0     | 275   | 0        |
| insert into t2 (select * from t2) | 0     | 275   | 9        |
| update t2 set i=5 where i > 75    | 110   | 110   | 8        |
| update t2 set i=5 where i < 25    | 254   | 134   | 12       |
| delete from t2 where i < 5        | 0     | 0     | 0        |

Another alternative is to use the aggregation functions in DTrace to aggregate the execution time of individual statements together:

```

#!/usr/sbin/dtrace -s

#pragma D option quiet

mysql*:::update-start, mysql*:::insert-start,
mysql*:::delete-start, mysql*:::multi-delete-start,
mysql*:::multi-delete-done, mysql*:::select-start,
mysql*:::insert-select-start, mysql*:::multi-update-start
{
    self->querystart = timestamp;
}

mysql*:::select-done
{
    @statements["select"] = sum(((timestamp - self->querystart)/1000000));
}

mysql*:::insert-done, mysql*:::insert-select-done
{
    @statements["insert"] = sum(((timestamp - self->querystart)/1000000));
}

mysql*:::update-done, mysql*:::multi-update-done
{
    @statements["update"] = sum(((timestamp - self->querystart)/1000000));
}

mysql*:::delete-done, mysql*:::multi-delete-done
{
    @statements["delete"] = sum(((timestamp - self->querystart)/1000000));
}

```

```

}

tick-30s
{
    printa(@statements);
}

```

The script just shown aggregates the times spent doing each operation, which could be used to help benchmark a standard suite of tests.

|        |       |
|--------|-------|
| delete | 0     |
| update | 0     |
| insert | 23    |
| select | 2484  |
|        |       |
| delete | 0     |
| update | 0     |
| insert | 39    |
| select | 10744 |
|        |       |
| delete | 0     |
| update | 26    |
| insert | 56    |
| select | 10944 |
|        |       |
| delete | 0     |
| update | 26    |
| insert | 2287  |
| select | 15985 |

### 6.7.1.13 Network Probes

The network probes monitor the transfer of information from the MySQL server and clients of all types over the network. The probes are defined as follows:

```

net-read-start()
net-read-done(status, bytes)
net-write-start(bytes)
net-write-done(status)

```

- **net-read-start**: Triggered when a network read operation is started.
- **net-read-done**: Triggered when the network read operation completes. The `status` is an integer representing the return status for the operation, `0` for success and `1` for failure. The `bytes` argument is an integer specifying the number of bytes read during the process.
- **net-start-bytes**: Triggered when data is written to a network socket. The single argument, `bytes`, specifies the number of bytes written to the network socket.
- **net-write-done**: Triggered when the network write operation has completed. The single argument, `status`, is an integer representing the return status for the operation, `0` for success and `1` for failure.

You can use the network probes to monitor the time spent reading from and writing to network clients during execution. The following D script provides an example of this. Both the cumulative time for the read or write is calculated, and the number of bytes. Note that the dynamic variable size has been increased (using the `dynvarsize` option) to cope with the rapid firing of the individual probes for the network reads/writes.

```

#!/usr/sbin/dtrace -s

#pragma D option quiet
#pragma D option dynvarsize=4m

dtrace::BEGIN
{
    printf("%-2s %-30s %-10s %9s %18s %-s \n",

```

```

        "St", "Who", "DB", "ConnID", "Dur microsec", "Query");
    }

mysql*:::query-start
{
    self->query = copyinstr(arg0);
    self->who   = strjoin(copyinstr(arg3), strjoin("@", copyinstr(arg4)));
    self->db    = copyinstr(arg2);
    self->connid = arg1;
    self->querystart = timestamp;
    self->netwrite = 0;
    self->netwritecum = 0;
    self->netwritebase = 0;
    self->netread = 0;
    self->netreadcum = 0;
    self->netreadbase = 0;
}

mysql*:::net-write-start
{
    self->netwrite += arg0;
    self->netwritebase = timestamp;
}

mysql*:::net-write-done
{
    self->netwritecum += (timestamp - self->netwritebase);
    self->netwritebase = 0;
}

mysql*:::net-read-start
{
    self->netreadbase = timestamp;
}

mysql*:::net-read-done
{
    self->netread += arg1;
    self->netreadcum += (timestamp - self->netreadbase);
    self->netreadbase = 0;
}

mysql*:::query-done
{
    this->elapsed = (timestamp - self->querystart) / 1000000;
    printf("%2d %-30s %-10s %9d %18d %s\n",
           arg0, self->who, self->db,
           self->connid, this->elapsed, self->query);
    printf("Net read: %d bytes (%d ms) write: %d bytes (%d ms)\n",
           self->netread, (self->netreadcum/1000000),
           self->netwrite, (self->netwritecum/1000000));
}

```

When executing the above script on a machine with a remote client, you can see that approximately a third of the time spent executing the query is related to writing the query results back to the client.

| St   | Who                       | DB   | ConnID | Dur microsec | Query                         |
|--|---------------------------|------|--------|--------------|-------------------------------|
| 0  | root@::ffff:192.168.0.108 | test | 31     | 3495         | select * from t1 limit 100000 |
| Net read: 0 bytes (0 ms) write: 10000075 bytes (1220 ms) |                           |      |        |              |                               |

### 6.7.1.14 Keycache Probes

The keycache probes are triggered when using the index key cache used with the MyISAM storage engine. Probes exist to monitor when data is read into the keycache, cached key data is written from the cache into a cached file, or when accessing the keycache.

Keycache usage indicates when data is read or written from the index files into the cache, and can be used to monitor how efficient the memory allocated to the keycache is being used. A high number of keycache reads across a range of queries may indicate that the keycache is too small for size of data being accessed.

```
keycache-read-start(filepath, bytes, mem_used, mem_free)
keycache-read-block(bytes)
keycache-read-hit()
keycache-read-miss()
keycache-read-done(mem_used, mem_free)
keycache-write-start(filepath, bytes, mem_used, mem_free)
keycache-write-block(bytes)
keycache-write-done(mem_used, mem_free)
```

When reading data from the index files into the keycache, the process first initializes the read operation (indicated by `keycache-read-start`), then loads blocks of data (`keycache-read-block`), and then the read block is either matches the data being identified (`keycache-read-hit`) or more data needs to be read (`keycache-read-miss`). Once the read operation has completed, reading stops with the `keycache-read-done`.

Data will be read from the index file into the keycache only when the specified key is not already within the keycache.

- `keycache-read-start`: Triggered when the keycache read operation is started. Data is read from the specified `filepath`, reading the specified number of `bytes`. The `mem_used` and `mem_avail` indicate memory currently used by the keycache and the amount of memory available within the keycache.
- `keycache-read-block`: Triggered when the keycache reads a block of data, of the specified number of `bytes`, from the index file into the keycache.
- `keycache-read-hit`: Triggered when the block of data read from the index file matches the key data requested.
- `keycache-read-miss`: Triggered when the block of data read from the index file does not match the key data needed.
- `keycache-read-done`: Triggered when the keycache read operation has completed. The `mem_used` and `mem_avail` indicate memory currently used by the keycache and the amount of memory available within the keycache.

Keycache writes occur when the index information is updated during an `INSERT`, `UPDATE`, or `DELETE` operation, and the cached key information is flushed back to the index file.

- `keycache-write-start`: Triggered when the keycache write operation is started. Data is written to the specified `filepath`, reading the specified number of `bytes`. The `mem_used` and `mem_avail` indicate memory currently used by the keycache and the amount of memory available within the keycache.
- `keycache-write-block`: Triggered when the keycache writes a block of data, of the specified number of `bytes`, to the index file from the keycache.
- `keycache-write-done`: Triggered when the keycache write operation has completed. The `mem_used` and `mem_avail` indicate memory currently used by the keycache and the amount of memory available within the keycache.

When thinking about security within a MySQL installation, you should consider a wide range of possible topics and how they affect the security of your MySQL server and related applications:

- General factors that affect security. These include choosing good passwords, not granting unnecessary privileges to users, ensuring application security by preventing SQL injections and data corruption, and others. See [Section 7.1, “General Security Issues”](#).

- Security of the installation itself. The data files, log files, and the all the application files of your installation should be protected to ensure that they are not readable or writable by unauthorized parties. For more information, see [Section 2.10, “Postinstallation Setup and Testing”](#).
- Access control and security within the database system itself, including the users and databases granted with access to the databases, views and stored programs in use within the database. For more information, see [Section 7.2, “The MySQL Access Privilege System”](#), and [Section 7.3, “MySQL User Account Management”](#).
- The features offered by security-related plugins. See [Section 7.5, “Security Plugins”](#).
- Network security of MySQL and your system. The security is related to the grants for individual users, but you may also wish to restrict MySQL so that it is available only locally on the MySQL server host, or to a limited set of other hosts.
- Ensure that you have adequate and appropriate backups of your database files, configuration and log files. Also be sure that you have a recovery solution in place and test that you are able to successfully recover the information from your backups. See [Chapter 8, Backup and Recovery](#).

## 7.1 General Security Issues

This section describes general security issues to be aware of and what you can do to make your MySQL installation more secure against attack or misuse. For information specifically about the access control system that MySQL uses for setting up user accounts and checking database access, see [Section 2.10, “Postinstallation Setup and Testing”](#).

For answers to some questions that are often asked about MySQL Server security issues, see [Section A.9, “MySQL 5.7 FAQ: Security”](#).

### 7.1.1 Security Guidelines

Anyone using MySQL on a computer connected to the Internet should read this section to avoid the most common security mistakes.

In discussing security, it is necessary to consider fully protecting the entire server host (not just the MySQL server) against all types of applicable attacks: eavesdropping, altering, playback, and denial of service. We do not cover all aspects of availability and fault tolerance here.

MySQL uses security based on Access Control Lists (ACLs) for all connections, queries, and other operations that users can attempt to perform. There is also support for SSL-encrypted connections between MySQL clients and servers. Many of the concepts discussed here are not specific to MySQL at all; the same general ideas apply to almost all applications.

When running MySQL, follow these guidelines:

- **Do not ever give anyone (except MySQL `root` accounts) access to the `user` table in the `mysql` database!** This is critical.
- Learn how the MySQL access privilege system works (see [Section 7.2, “The MySQL Access Privilege System”](#)). Use the `GRANT` and `REVOKE` statements to control access to MySQL. Do not grant more privileges than necessary. Never grant privileges to all hosts.

Checklist:

- Try `mysql -u root`. If you are able to connect successfully to the server without being asked for a password, anyone can connect to your MySQL server as the MySQL `root` user with full privileges! Review the MySQL installation instructions, paying particular attention to the information about setting a `root` password. See [Section 2.10.4, “Securing the Initial MySQL Accounts”](#).
- Use the `SHOW GRANTS` statement to check which accounts have access to what. Then use the `REVOKE` statement to remove those privileges that are not necessary.

- Do not store cleartext passwords in your database. If your computer becomes compromised, the intruder can take the full list of passwords and use them. Instead, use `SHA2()`, `SHA1()`, `MD5()`, or some other one-way hashing function and store the hash value.

To prevent password recovery using rainbow tables, do not use these functions on a plain password; instead, choose some string to be used as a salt, and use `hash(hash(password)+salt)` values.

- Do not choose passwords from dictionaries. Special programs exist to break passwords. Even passwords like “xfish98” are very bad. Much better is “duag98” which contains the same word “fish” but typed one key to the left on a standard QWERTY keyboard. Another method is to use a password that is taken from the first characters of each word in a sentence (for example, “Four score and seven years ago” results in a password of “Fsasya”). The password is easy to remember and type, but difficult to guess for someone who does not know the sentence. In this case, you can additionally substitute digits for the number words to obtain the phrase “4 score and 7 years ago”, yielding the password “4sa7ya” which is even more difficult to guess.
- Invest in a firewall. This protects you from at least 50% of all types of exploits in any software. Put MySQL behind the firewall or in a demilitarized zone (DMZ).

Checklist:

- Try to scan your ports from the Internet using a tool such as `nmap`. MySQL uses port 3306 by default. This port should not be accessible from untrusted hosts. As a simple way to check whether your MySQL port is open, try the following command from some remote machine, where `server_host` is the host name or IP address of the host on which your MySQL server runs:

```
shell> telnet server_host 3306
```

If `telnet` hangs or the connection is refused, the port is blocked, which is how you want it to be. If you get a connection and some garbage characters, the port is open, and should be closed on your firewall or router, unless you really have a good reason to keep it open.

- Applications that access MySQL should not trust any data entered by users, and should be written using proper defensive programming techniques. See [Section 7.1.7, “Client Programming Security Guidelines”](#).
- Do not transmit plain (unencrypted) data over the Internet. This information is accessible to everyone who has the time and ability to intercept it and use it for their own purposes. Instead, use an encrypted protocol such as SSL or SSH. MySQL supports internal SSL connections. Another technique is to use SSH port-forwarding to create an encrypted (and compressed) tunnel for the communication.
- Learn to use the `tcpdump` and `strings` utilities. In most cases, you can check whether MySQL data streams are unencrypted by issuing a command like the following:

```
shell> tcpdump -l -i eth0 -w - src or dst port 3306 | strings
```

This works under Linux and should work with small modifications under other systems.

### Warning

If you do not see cleartext data, this does not always mean that the information actually is encrypted. If you need high security, consult with a security expert.

## 7.1.2 Keeping Passwords Secure

Passwords occur in several contexts within MySQL. The following sections provide guidelines that enable end users and administrators to keep these passwords secure and avoid exposing them. There

is also a discussion of how MySQL uses password hashing internally and of a plugin that you can use to enforce stricter passwords.

### 7.1.2.1 End-User Guidelines for Password Security

MySQL users should use the following guidelines to keep passwords secure.

When you run a client program to connect to the MySQL server, it is inadvisable to specify your password in a way that exposes it to discovery by other users. The methods you can use to specify your password when you run client programs are listed here, along with an assessment of the risks of each method. In short, the safest methods are to have the client program prompt for the password or to specify the password in a properly protected option file.

- Use the `mysql_config_editor` utility, which enables you to store authentication credentials in an encrypted login path file named `.mylogin.cnf`. The file can be read later by MySQL client programs to obtain authentication credentials for connecting to MySQL Server. See [Section 5.6.6, “mysql\\_config\\_editor — MySQL Configuration Utility”](#).
- Use a `-p` or `--password=your_pass` option on the command line. For example:

```
shell> mysql -u francis -pfrank db_name
```

This is convenient *but insecure*. On some systems, your password becomes visible to system status programs such as `ps` that may be invoked by other users to display command lines. MySQL clients typically overwrite the command-line password argument with zeros during their initialization sequence. However, there is still a brief interval during which the value is visible. Also, on some systems this overwriting strategy is ineffective and the password remains visible to `ps`. (SystemV Unix systems and perhaps others are subject to this problem.)

If your operating environment is set up to display your current command in the title bar of your terminal window, the password remains visible as long as the command is running, even if the command has scrolled out of view in the window content area.

- Use the `-p` or `--password` option on the command line with no password value specified. In this case, the client program solicits the password interactively:

```
shell> mysql -u francis -p db_name
Enter password: *****
```

The `*` characters indicate where you enter your password. The password is not displayed as you enter it.

It is more secure to enter your password this way than to specify it on the command line because it is not visible to other users. However, this method of entering a password is suitable only for programs that you run interactively. If you want to invoke a client from a script that runs noninteractively, there is no opportunity to enter the password from the keyboard. On some systems, you may even find that the first line of your script is read and interpreted (incorrectly) as your password.

- Store your password in an option file. For example, on Unix, you can list your password in the `[client]` section of the `.my.cnf` file in your home directory:

```
[client]
password=your_pass
```

To keep the password safe, the file should not be accessible to anyone but yourself. To ensure this, set the file access mode to `400` or `600`. For example:

```
shell> chmod 600 .my.cnf
```

To name from the command line a specific option file containing the password, use the `--defaults-file=file_name` option, where `file_name` is the full path name to the file. For example:

```
shell> mysql --defaults-file=/home/francis/mysql-opts
```

Section 5.2.6, “Using Option Files”, discusses option files in more detail.

- Store your password in the `MYSQL_PWD` environment variable. See Section 5.9, “MySQL Program Environment Variables”.

This method of specifying your MySQL password must be considered *extremely insecure* and should not be used. Some versions of `ps` include an option to display the environment of running processes. On some systems, if you set `MYSQL_PWD`, your password is exposed to any other user who runs `ps`. Even on systems without such a version of `ps`, it is unwise to assume that there are no other methods by which users can examine process environments.

On Unix, the `mysql` client writes a record of executed statements to a history file (see Section 5.5.1.3, “mysql Logging”). By default, this file is named `.mysql_history` and is created in your home directory. Passwords can be written as plain text in SQL statements such as `CREATE USER` and `ALTER USER`, so if you use these statements, they are logged in the history file. To keep this file safe, use a restrictive access mode, the same way as described earlier for the `.my.cnf` file.

If your command interpreter is configured to maintain a history, any file in which the commands are saved will contain MySQL passwords entered on the command line. For example, `bash` uses `~/.bash_history`. Any such file should have a restrictive access mode.

### 7.1.2.2 Administrator Guidelines for Password Security

Database administrators should use the following guidelines to keep passwords secure.

MySQL stores passwords for user accounts in the `mysql.user` table. Access to this table should never be granted to any nonadministrative accounts.

Account passwords can be expired so that users must reset them. See Section 7.3.6, “Password Expiration Policy”, and Section 7.3.7, “Password Expiration and Sandbox Mode”.

The `validate_password` plugin can be used to enforce a policy on acceptable password. See Section 7.5.3, “The Password Validation Plugin”.

A user who has access to modify the plugin directory (the value of the `plugin_dir` system variable) or the `my.cnf` file that specifies the plugin directory location can replace plugins and modify the capabilities provided by plugins, including authentication plugins.

Files such as log files to which passwords might be written should be protected. See Section 7.1.2.3, “Passwords and Logging”.

### 7.1.2.3 Passwords and Logging

Passwords can be written as plain text in SQL statements such as `CREATE USER`, `GRANT`, `SET PASSWORD`, and statements that invoke the `PASSWORD()` function. If such statements are logged by the MySQL server as written, passwords in them become visible to anyone with access to the logs.

In MySQL 5.7, statement logging avoids writing passwords in cleartext for the following statements:

```
CREATE USER ... IDENTIFIED BY ...
ALTER USER ... IDENTIFIED BY ...
GRANT ... IDENTIFIED BY ...
```

```
SET PASSWORD ...
SLAVE START ... PASSWORD = ...
CREATE SERVER ... OPTIONS(... PASSWORD ...)
ALTER SERVER ... OPTIONS(... PASSWORD ...)
```

Passwords in those statements are rewritten to not appear literally in statement text written to the general query log, slow query log, and binary log. Rewriting does not apply to other statements. In particular, `INSERT` or `UPDATE` statements for the `mysql.user` table that refer to literal passwords are logged as is, so you should avoid such statements. (Direct manipulation of grant tables is discouraged, anyway.)

For the general query log, password rewriting can be suppressed by starting the server with the `--log-raw` option. For security reasons, this option is not recommended for production use. For diagnostic purposes, it may be useful to see the exact text of statements as received by the server.

Contents of the audit log file produced by the audit log plugin are not encrypted. For security reasons, this file should be written to a directory accessible only to the MySQL server and users with a legitimate reason to view the log. See [Section 7.5.5.3, “MySQL Enterprise Audit Security Considerations”](#).

Statements received by the server may be rewritten if a query rewrite plugin is installed (see [Query Rewrite Plugins](#)). In this case, the `--log-raw` option affects statement logging as follows:

- Without `--log-raw`, the server logs the statement returned by the query rewrite plugin. This may differ from the statement as received.
- With `--log-raw`, the server logs the original statement as received.

An implication of password rewriting is that statements that cannot be parsed (due, for example, to syntax errors) are not written to the general query log because they cannot be known to be password free. Use cases that require logging of all statements including those with errors should use the `--log-raw` option, bearing in mind that this also bypasses password rewriting.

Password rewriting occurs only when plain text passwords are expected. For statements with syntax that expect a password hash value, no rewriting occurs. If a plain text password is supplied erroneously for such syntax, the password is logged as given, without rewriting. For example, the following statement is logged as shown because a password hash value is expected:

```
CREATE USER 'user1'@'localhost' IDENTIFIED BY PASSWORD 'not-so-secret';
```

To guard log files against unwarranted exposure, locate them in a directory that restricts access to the server and the database administrator. If the server logs to tables in the `mysql` database, grant access to those tables only to the database administrator.

Replication slaves store the password for the replication master in the master info repository, which can be either a file or a table (see [Section 18.2.4, “Replication Relay and Status Logs”](#)). Ensure that the repository can be accessed only by the database administrator. An alternative to storing the password in a file is to use the `START SLAVE` statement to specify credentials for connecting to the master.

Use a restricted access mode to protect database backups that include log tables or log files containing passwords.

#### 7.1.2.4 Password Hashing in MySQL

##### Note

The information in this section applies fully only before MySQL 5.7.5, and only for accounts that use the `mysql_native_password` or `mysql_old_password` authentication plugins. Support for pre-4.1 password hashes is removed in MySQL 5.7.5. This includes removal of the `mysql_old_password` authentication plugin and the `OLD_PASSWORD()`

function. Also, `secure_auth` cannot be disabled, and `old_passwords` cannot be set to 1.

As of MySQL 5.7.5, only the information about 4.1 password hashes and the `mysql_native_password` authentication plugin remains relevant.

MySQL lists user accounts in the `user` table of the `mysql` database. Each MySQL account can be assigned a password, although the `user` table does not store the cleartext version of the password, but a hash value computed from it.

MySQL uses passwords in two phases of client/server communication:

- When a client attempts to connect to the server, there is an initial authentication step in which the client must present a password that has a hash value matching the hash value stored in the `user` table for the account the client wants to use.
- After the client connects, it can (if it has sufficient privileges) set or change the password hash for accounts listed in the `user` table. The client can do this by using the `PASSWORD()` function to generate a password hash, or by using a password-generating statement (`CREATE USER`, `GRANT`, or `SET PASSWORD`).

In other words, the server *checks* hash values during authentication when a client first attempts to connect. The server *generates* hash values if a connected client invokes the `PASSWORD()` function or uses a password-generating statement to set or change a password.

Password hashing methods in MySQL have the history described following. These changes are illustrated by changes in the result from the `PASSWORD()` function that computes password hash values and in the structure of the `user` table where passwords are stored.

## The Original (Pre-4.1) Hashing Method

The original hashing method produced a 16-byte string. Such hashes look like this:

```
mysql> SELECT PASSWORD('mypass');
+-----+
| PASSWORD('mypass') |
+-----+
| 6f8c114b58f2ce9e   |
+-----+
```

To store account passwords, the `Password` column of the `user` table was at this point 16 bytes long.

## The 4.1 Hashing Method

MySQL 4.1 introduced password hashing that provided better security and reduced the risk of passwords being intercepted. There were several aspects to this change:

- Different format of password values produced by the `PASSWORD()` function
- Widening of the `Password` column
- Control over the default hashing method
- Control over the permitted hashing methods for clients attempting to connect to the server

The changes in MySQL 4.1 took place in two stages:

- MySQL 4.1.0 used a preliminary version of the 4.1 hashing method. This method was short lived and the following discussion says nothing more about it.
- In MySQL 4.1.1, the hashing method was modified to produce a longer 41-byte hash value:

```
mysql> SELECT PASSWORD('mypass');
+-----+
| PASSWORD('mypass') |
+-----+
| *6C8989366EAF75BB670AD8EA7A7FC1176A95CEF4 |
+-----+
```

The longer password hash format has better cryptographic properties, and client authentication based on long hashes is more secure than that based on the older short hashes.

To accommodate longer password hashes, the `Password` column in the `user` table was changed at this point to be 41 bytes, its current length.

A widened `Password` column can store password hashes in both the pre-4.1 and 4.1 formats. The format of any given hash value can be determined two ways:

- The length: 4.1 and pre-4.1 hashes are 41 and 16 bytes, respectively.
- Password hashes in the 4.1 format always begin with a `*` character, whereas passwords in the pre-4.1 format never do.

To permit explicit generation of pre-4.1 password hashes, two additional changes were made:

- The `OLD_PASSWORD()` function was added, which returns hash values in the 16-byte format.
- For compatibility purposes, the `old_passwords` system variable was added, to enable DBAs and applications control over the hashing method. The default `old_passwords` value of 0 causes hashing to use the 4.1 method (41-byte hash values), but setting `old_passwords=1` causes hashing to use the pre-4.1 method. In this case, `PASSWORD()` produces 16-byte values and is equivalent to `OLD_PASSWORD()`.

To permit DBAs control over how clients are permitted to connect, the `secure_auth` system variable was added. Starting the server with this variable disabled or enabled permits or prohibits clients to connect using the older pre-4.1 password hashing method. Before MySQL 5.6.5, `secure_auth` is disabled by default. As of 5.6.5, `secure_auth` is enabled by default to promote a more secure default configuration DBAs can disable it at their discretion, but this is not recommended, and pre-4.1 password hashes are deprecated and should be avoided. (For account upgrade instructions, see [Section 7.5.1.3, “Migrating Away from Pre-4.1 Password Hashing and the mysql\\_old\\_password Plugin”](#).)

In addition, the `mysql` client supports a `--secure-auth` option that is analogous to `secure_auth`, but from the client side. It can be used to prevent connections to less secure accounts that use pre-4.1 password hashing. This option is disabled by default before MySQL 5.6.7, enabled thereafter.

## Compatibility Issues Related to Hashing Methods

The widening of the `Password` column in MySQL 4.1 from 16 bytes to 41 bytes affects installation or upgrade operations as follows:

- If you perform a new installation of MySQL, the `Password` column is made 41 bytes long automatically.
- Upgrades from MySQL 4.1 or later to current versions of MySQL should not give rise to any issues in regard to the `Password` column because both versions use the same column length and password hashing method.
- For upgrades from a pre-4.1 release to 4.1 or later, you must upgrade the system tables after upgrading. (See [Section 5.4.7, “mysql\\_upgrade — Check and Upgrade MySQL Tables”](#).)

The 4.1 hashing method is understood only by MySQL 4.1 (and higher) servers and clients, which can result in some compatibility problems. A 4.1 or higher client can connect to a pre-4.1 server, because

the client understands both the pre-4.1 and 4.1 password hashing methods. However, a pre-4.1 client that attempts to connect to a 4.1 or higher server may run into difficulties. For example, a 4.0 `mysql` client may fail with the following error message:

```
shell> mysql -h localhost -u root
Client does not support authentication protocol requested
by server; consider upgrading MySQL client
```

This phenomenon also occurs for attempts to use the older PHP `mysql` extension after upgrading to MySQL 4.1 or higher. (See [Common Problems with MySQL and PHP](#).)

The following discussion describes the differences between the pre-4.1 and 4.1 hashing methods, and what you should do if you upgrade your server but need to maintain backward compatibility with pre-4.1 clients. (However, permitting connections by old clients is not recommended and should be avoided if possible.) Additional information can be found in [Section B.5.2.4](#), “Client does not support authentication protocol”. This information is of particular importance to PHP programmers migrating MySQL databases from versions older than 4.1 to 4.1 or higher.

The differences between short and long password hashes are relevant both for how the server uses passwords during authentication and for how it generates password hashes for connected clients that perform password-changing operations.

The way in which the server uses password hashes during authentication is affected by the width of the `Password` column:

- If the column is short, only short-hash authentication is used.
- If the column is long, it can hold either short or long hashes, and the server can use either format:
  - Pre-4.1 clients can connect, but because they know only about the pre-4.1 hashing method, they can authenticate only using accounts that have short hashes.
  - 4.1 and later clients can authenticate using accounts that have short or long hashes.

Even for short-hash accounts, the authentication process is actually a bit more secure for 4.1 and later clients than for older clients. In terms of security, the gradient from least to most secure is:

- Pre-4.1 client authenticating with short password hash
- 4.1 or later client authenticating with short password hash
- 4.1 or later client authenticating with long password hash

The way in which the server generates password hashes for connected clients is affected by the width of the `Password` column and by the `old_passwords` system variable. A 4.1 or later server generates long hashes only if certain conditions are met: The `Password` column must be wide enough to hold long values and `old_passwords` must not be set to 1.

Those conditions apply as follows:

- The `Password` column must be wide enough to hold long hashes (41 bytes). If the column has not been updated and still has the pre-4.1 width of 16 bytes, the server notices that long hashes cannot fit into it and generates only short hashes when a client performs password-changing operations using the `PASSWORD()` function or a password-generating statement. This is the behavior that occurs if you have upgraded from a version of MySQL older than 4.1 to 4.1 or later but have not yet run the `mysql_upgrade` program to widen the `Password` column.
- If the `Password` column is wide, it can store either short or long password hashes. In this case, the `PASSWORD()` function and password-generating statements generate long hashes unless the server was started with the `old_passwords` system variable set to 1 to force the server to generate short password hashes instead.

The purpose of the `old_passwords` system variable is to permit backward compatibility with pre-4.1 clients under circumstances where the server would otherwise generate long password hashes. The option does not affect authentication (4.1 and later clients can still use accounts that have long password hashes), but it does prevent creation of a long password hash in the `user` table as the result of a password-changing operation. Were that permitted to occur, the account could no longer be used by pre-4.1 clients. With `old_passwords` disabled, the following undesirable scenario is possible:

- An old pre-4.1 client connects to an account that has a short password hash.
- The client changes its own password. With `old_passwords` disabled, this results in the account having a long password hash.
- The next time the old client attempts to connect to the account, it cannot, because the account has a long password hash that requires the 4.1 hashing method during authentication. (Once an account has a long password hash in the user table, only 4.1 and later clients can authenticate for it because pre-4.1 clients do not understand long hashes.)

This scenario illustrates that, if you must support older pre-4.1 clients, it is problematic to run a 4.1 or higher server without `old_passwords` set to 1. By running the server with `old_passwords=1`, password-changing operations do not generate long password hashes and thus do not cause accounts to become inaccessible to older clients. (Those clients cannot inadvertently lock themselves out by changing their password and ending up with a long password hash.)

The downside of `old_passwords=1` is that any passwords created or changed use short hashes, even for 4.1 or later clients. Thus, you lose the additional security provided by long password hashes. To create an account that has a long hash (for example, for use by 4.1 clients) or to change an existing account to use a long password hash, an administrator can set the session value of `old_passwords` set to 0 while leaving the global value set to 1:

```
mysql> SET @@session.old_passwords = 0;
Query OK, 0 rows affected (0.00 sec)

mysql> SELECT @@session.old_passwords, @@global.old_passwords;
+-----+-----+
| @@session.old_passwords | @@global.old_passwords |
+-----+-----+
| 0 | 1 |
+-----+-----+
1 row in set (0.00 sec)

mysql> CREATE USER 'newuser'@'localhost' IDENTIFIED BY 'newpass';
Query OK, 0 rows affected (0.03 sec)

mysql> SET PASSWORD FOR 'existinguser'@'localhost' = PASSWORD('existingpass');
Query OK, 0 rows affected (0.00 sec)
```

The following scenarios are possible in MySQL 4.1 or later. The factors are whether the `Password` column is short or long, and, if long, whether the server is started with `old_passwords` enabled or disabled.

#### Scenario 1: Short `Password` column in user table:

- Only short hashes can be stored in the `Password` column.
- The server uses only short hashes during client authentication.
- For connected clients, password hash-generating operations involving the `PASSWORD( )` function or password-generating statements use short hashes exclusively. Any change to an account's password results in that account having a short password hash.
- The value of `old_passwords` is irrelevant because with a short `Password` column, the server generates only short password hashes anyway.

This scenario occurs when a pre-4.1 MySQL installation has been upgraded to 4.1 or later but `mysql_upgrade` has not been run to upgrade the system tables in the `mysql` database. (This is not a recommended configuration because it does not permit use of more secure 4.1 password hashing.)

**Scenario 2:** Long `Password` column; server started with `old_passwords=1`:

- Short or long hashes can be stored in the `Password` column.
- 4.1 and later clients can authenticate for accounts that have short or long hashes.
- Pre-4.1 clients can authenticate only for accounts that have short hashes.
- For connected clients, password hash-generating operations involving the `PASSWORD()` function or password-generating statements use short hashes exclusively. Any change to an account's password results in that account having a short password hash.

In this scenario, newly created accounts have short password hashes because `old_passwords=1` prevents generation of long hashes. Also, if you create an account with a long hash before setting `old_passwords` to 1, changing the account's password while `old_passwords=1` results in the account being given a short password, causing it to lose the security benefits of a longer hash.

To create a new account that has a long password hash, or to change the password of any existing account to use a long hash, first set the session value of `old_passwords` set to 0 while leaving the global value set to 1, as described previously.

In this scenario, the server has an up to date `Password` column, but is running with the default password hashing method set to generate pre-4.1 hash values. This is not a recommended configuration but may be useful during a transitional period in which pre-4.1 clients and passwords are upgraded to 4.1 or later. When that has been done, it is preferable to run the server with `old_passwords=0` and `secure_auth=1`.

**Scenario 3:** Long `Password` column; server started with `old_passwords=0`:

- Short or long hashes can be stored in the `Password` column.
- 4.1 and later clients can authenticate using accounts that have short or long hashes.
- Pre-4.1 clients can authenticate only using accounts that have short hashes.
- For connected clients, password hash-generating operations involving the `PASSWORD()` function or password-generating statements use long hashes exclusively. A change to an account's password results in that account having a long password hash.

As indicated earlier, a danger in this scenario is that it is possible for accounts that have a short password hash to become inaccessible to pre-4.1 clients. A change to such an account's password made using the `PASSWORD()` function or a password-generating statement results in the account being given a long password hash. From that point on, no pre-4.1 client can connect to the server using that account. The client must upgrade to 4.1 or later.

If this is a problem, you can change a password in a special way. For example, normally you use `SET PASSWORD` as follows to change an account password:

```
SET PASSWORD FOR 'some_user'@'some_host' = PASSWORD('mypass');
```

To change the password but create a short hash, use the `OLD_PASSWORD()` function instead:

```
SET PASSWORD FOR 'some_user'@'some_host' = OLD_PASSWORD('mypass');
```

`OLD_PASSWORD()` is useful for situations in which you explicitly want to generate a short hash.

The disadvantages for each of the preceding scenarios may be summarized as follows:

In scenario 1, you cannot take advantage of longer hashes that provide more secure authentication.

In scenario 2, `old_passwords=1` prevents accounts with short hashes from becoming inaccessible, but password-changing operations cause accounts with long hashes to revert to short hashes unless you take care to change the session value of `old_passwords` to 0 first.

In scenario 3, accounts with short hashes become inaccessible to pre-4.1 clients if you change their passwords without explicitly using `OLD_PASSWORD()`.

The best way to avoid compatibility problems related to short password hashes is to not use them:

- Upgrade all client programs to MySQL 4.1 or later.
- Run the server with `old_passwords=0`.
- Reset the password for any account with a short password hash to use a long password hash.
- For additional security, run the server with `secure_auth=1`.

### 7.1.3 Making MySQL Secure Against Attackers

When you connect to a MySQL server, you should use a password. The password is not transmitted in clear text over the connection. Password handling during the client connection sequence was upgraded in MySQL 4.1.1 to be very secure. If you are still using pre-4.1.1-style passwords, the encryption algorithm is not as strong as the newer algorithm. With some effort, a clever attacker who can sniff the traffic between the client and the server can crack the password. (See [Section 7.1.2.4, “Password Hashing in MySQL”](#), for a discussion of the different password handling methods.)

All other information is transferred as text, and can be read by anyone who is able to watch the connection. If the connection between the client and the server goes through an untrusted network, and you are concerned about this, you can use the compressed protocol to make traffic much more difficult to decipher. You can also use MySQL's internal SSL support to make the connection even more secure. See [Section 7.4, “Using Secure Connections”](#). Alternatively, use SSH to get an encrypted TCP/IP connection between a MySQL server and a MySQL client. You can find an Open Source SSH client at <http://www.openssh.org/>, and a comparison of both Open Source and Commercial SSH clients at [http://en.wikipedia.org/wiki/Comparison\\_of\\_SSH\\_clients](http://en.wikipedia.org/wiki/Comparison_of_SSH_clients).

To make a MySQL system secure, you should strongly consider the following suggestions:

- Require all MySQL accounts to have a password. A client program does not necessarily know the identity of the person running it. It is common for client/server applications that the user can specify any user name to the client program. For example, anyone can use the `mysql` program to connect as any other person simply by invoking it as `mysql -u other_user db_name` if `other_user` has no password. If all accounts have a password, connecting using another user's account becomes much more difficult.

For a discussion of methods for setting passwords, see [Section 7.3.5, “Assigning Account Passwords”](#).

- Make sure that the only Unix user account with read or write privileges in the database directories is the account that is used for running `mysqld`.
- Never run the MySQL server as the Unix `root` user. This is extremely dangerous, because any user with the `FILE` privilege is able to cause the server to create files as `root` (for example, `~root/.bashrc`). To prevent this, `mysqld` refuses to run as `root` unless that is specified explicitly using the `--user=root` option.

`mysqld` can (and should) be run as an ordinary, unprivileged user instead. You can create a separate Unix account named `mysql` to make everything even more secure. Use this account only for administering MySQL. To start `mysqld` as a different Unix user, add a `user` option that specifies

the user name in the `[mysqld]` group of the `my.cnf` option file where you specify server options. For example:

```
[mysqld]
user=mysql
```

This causes the server to start as the designated user whether you start it manually or by using `mysqld_safe` or `mysql.server`. For more details, see [Section 7.1.5, “How to Run MySQL as a Normal User”](#).

Running `mysqld` as a Unix user other than `root` does not mean that you need to change the `root` user name in the `user` table. *User names for MySQL accounts have nothing to do with user names for Unix accounts.*

- Do not grant the `FILE` privilege to nonadministrative users. Any user that has this privilege can write a file anywhere in the file system with the privileges of the `mysqld` daemon. This includes the server's data directory containing the files that implement the privilege tables. To make `FILE`-privilege operations a bit safer, files generated with `SELECT ... INTO OUTFILE` do not overwrite existing files and are writable by everyone.

The `FILE` privilege may also be used to read any file that is world-readable or accessible to the Unix user that the server runs as. With this privilege, you can read any file into a database table. This could be abused, for example, by using `LOAD DATA` to load `/etc/passwd` into a table, which then can be displayed with `SELECT`.

To limit the location in which files can be read and written, set the `secure_file_priv` system to a specific directory. See [Section 6.1.5, “Server System Variables”](#).

- Do not grant the `PROCESS` or `SUPER` privilege to nonadministrative users. The output of `mysqladmin processlist` and `SHOW PROCESSLIST` shows the text of any statements currently being executed, so any user who is permitted to see the server process list might be able to see statements issued by other users such as `UPDATE user SET password=PASSWORD('not_secure')`.

`mysqld` reserves an extra connection for users who have the `SUPER` privilege, so that a MySQL `root` user can log in and check server activity even if all normal connections are in use.

The `SUPER` privilege can be used to terminate client connections, change server operation by changing the value of system variables, and control replication servers.

- Do not permit the use of symlinks to tables. (This capability can be disabled with the `--skip-symbolic-links` option.) This is especially important if you run `mysqld` as `root`, because anyone that has write access to the server's data directory then could delete any file in the system! See [Section 9.12.3.2, “Using Symbolic Links for MyISAM Tables on Unix”](#).
- Stored programs and views should be written using the security guidelines discussed in [Section 22.6, “Access Control for Stored Programs and Views”](#).
- If you do not trust your DNS, you should use IP addresses rather than host names in the grant tables. In any case, you should be very careful about creating grant table entries using host name values that contain wildcards.
- If you want to restrict the number of connections permitted to a single account, you can do so by setting the `max_user_connections` variable in `mysqld`. The `GRANT` statement also supports resource control options for limiting the extent of server use permitted to an account. See [Section 14.7.1.4, “GRANT Syntax”](#).
- If the plugin directory is writable by the server, it may be possible for a user to write executable code to a file in the directory using `SELECT ... INTO DUMPFILE`. This can be prevented by making `plugin_dir` read only to the server or by setting `--secure-file-priv` to a directory where `SELECT` writes can be made safely.

## 7.1.4 Security-Related mysqld Options and Variables

The following table shows `mysqld` options and system variables that affect security. For descriptions of each of these, see [Section 6.1.4, “Server Command Options”](#), and [Section 6.1.5, “Server System Variables”](#).

**Table 7.1 Security Option/Variable Summary**

| Name  | Cmd-Line | Option File | System Var | Status Var | Var Scope | Dynamic |
|---|----------|-------------|------------|------------|-----------|---------|
| <a href="#">allow-suspicious-udfs</a>             | Yes      | Yes         |            |            |           |         |
| <a href="#">automatic_sp_privileges</a>           |          |             | Yes        |            | Global    | Yes     |
| <a href="#">chroot</a>                            | Yes      | Yes         |            |            |           |         |
| <a href="#">des-key-file</a>                      | Yes      | Yes         |            |            |           |         |
| <a href="#">local_infile</a>                      |          |             | Yes        |            | Global    | Yes     |
| <a href="#">old_passwords</a>                     |          |             | Yes        |            | Both      | Yes     |
| <a href="#">safe-user-create</a>                  | Yes      | Yes         |            |            |           |         |
| <a href="#">secure-auth</a>                       | Yes      | Yes         |            |            | Global    | Yes     |
| - Variable:<br><a href="#">secure_auth</a>        |          |             | Yes        |            | Global    | Yes     |
| <a href="#">secure-file-priv</a>                  | Yes      | Yes         |            |            | Global    | No      |
| - Variable:<br><a href="#">secure_file_priv</a>   |          |             | Yes        |            | Global    | No      |
| <a href="#">skip-grant-tables</a>                 | Yes      | Yes         |            |            |           |         |
| <a href="#">skip-name-resolve</a>                 | Yes      | Yes         |            |            | Global    | No      |
| - Variable:<br><a href="#">skip_name_resolve</a>  |          |             | Yes        |            | Global    | No      |
| <a href="#">skip-networking</a>                   | Yes      | Yes         |            |            | Global    | No      |
| - Variable:<br><a href="#">skip_networking</a>    |          |             | Yes        |            | Global    | No      |
| <a href="#">skip-show-database</a>                | Yes      | Yes         |            |            | Global    | No      |
| - Variable:<br><a href="#">skip_show_database</a> |          |             | Yes        |            | Global    | No      |

## 7.1.5 How to Run MySQL as a Normal User

On Windows, you can run the server as a Windows service using a normal user account.

On Linux, for installations performed using a MySQL repository, RPM packages, or Debian packages, the MySQL server `mysqld` should be started by the local `mysql` operating system user. Starting by another operating system user is not supported by the init scripts that are included as part of the installation.

On Unix (or Linux for installations performed using `tar` or `tar.gz` packages), the MySQL server `mysqld` can be started and run by any user. However, you should avoid running the server as the Unix `root` user for security reasons. To change `mysqld` to run as a normal unprivileged Unix user `user_name`, you must do the following:

1. Stop the server if it is running (use `mysqladmin shutdown`).

2. Change the database directories and files so that `user_name` has privileges to read and write files in them (you might need to do this as the Unix `root` user):

```
shell> chown -R user_name /path/to/mysql/datadir
```

If you do not do this, the server will not be able to access databases or tables when it runs as `user_name`.

If directories or files within the MySQL data directory are symbolic links, `chown -R` might not follow symbolic links for you. If it does not, you will also need to follow those links and change the directories and files they point to.

3. Start the server as user `user_name`. Another alternative is to start `mysqld` as the Unix `root` user and use the `--user=user_name` option. `mysqld` starts up, then switches to run as the Unix user `user_name` before accepting any connections.
4. To start the server as the given user automatically at system startup time, specify the user name by adding a `user` option to the `[mysqld]` group of the `/etc/my.cnf` option file or the `my.cnf` option file in the server's data directory. For example:

```
[mysqld]
user=user_name
```

If your Unix machine itself is not secured, you should assign passwords to the MySQL `root` account in the grant tables. Otherwise, any user with a login account on that machine can run the `mysql` client with a `--user=root` option and perform any operation. (It is a good idea to assign passwords to MySQL accounts in any case, but especially so when other login accounts exist on the server host.) See [Section 2.10.4, “Securing the Initial MySQL Accounts”](#).

## 7.1.6 Security Issues with LOAD DATA LOCAL

The `LOAD DATA` statement can load a file that is located on the server host, or it can load a file that is located on the client host when the `LOCAL` keyword is specified.

There are two potential security issues with supporting the `LOCAL` version of `LOAD DATA` statements:

- The transfer of the file from the client host to the server host is initiated by the MySQL server. In theory, a patched server could be built that would tell the client program to transfer a file of the server's choosing rather than the file named by the client in the `LOAD DATA` statement. Such a server could access any file on the client host to which the client user has read access.
- In a Web environment where the clients are connecting from a Web server, a user could use `LOAD DATA LOCAL` to read any files that the Web server process has read access to (assuming that a user could run any command against the SQL server). In this environment, the client with respect to the MySQL server actually is the Web server, not the remote program being run by the user who connects to the Web server.

To deal with these problems, `LOAD DATA LOCAL` works like this:

- By default, all MySQL clients and libraries in binary distributions are compiled with the `-DENABLED_LOCAL_INFILE=1` option.
- If you build MySQL from source but do not invoke `CMake` with the `-DENABLED_LOCAL_INFILE=1` option, `LOAD DATA LOCAL` cannot be used by any client unless it is written explicitly to invoke `mysql_options(... MYSQL_OPT_LOCAL_INFILE, 0)`. See [Section 26.8.7.50, “mysql\\_options\(\)”](#).
- You can disable all `LOAD DATA LOCAL` statements from the server side by starting `mysqld` with the `--local-infile=0` option.

- For the `mysql` command-line client, enable `LOAD DATA LOCAL` by specifying the `--local-infile[=1]` option, or disable it with the `--local-infile=0` option. For `mysqlimport`, local data file loading is off by default; enable it with the `--local` or `-L` option. In any case, successful use of a local load operation requires that the server permits it.
- If you use `LOAD DATA LOCAL` in Perl scripts or other programs that read the `[client]` group from option files, you can add the `local-infile=1` option to that group. However, to keep this from causing problems for programs that do not understand `local-infile`, specify it using the `loose-` prefix:

```
[client]
loose-local-infile=1
```

- If `LOAD DATA LOCAL` is disabled, either in the server or the client, a client that attempts to issue such a statement receives the following error message:

```
ERROR 1148: The used command is not allowed with this MySQL version
```

## 7.1.7 Client Programming Security Guidelines

Applications that access MySQL should not trust any data entered by users, who can try to trick your code by entering special or escaped character sequences in Web forms, URLs, or whatever application you have built. Be sure that your application remains secure if a user enters something like `; DROP DATABASE mysql;`. This is an extreme example, but large security leaks and data loss might occur as a result of hackers using similar techniques, if you do not prepare for them.

A common mistake is to protect only string data values. Remember to check numeric data as well. If an application generates a query such as `SELECT * FROM table WHERE ID=234` when a user enters the value `234`, the user can enter the value `234 OR 1=1` to cause the application to generate the query `SELECT * FROM table WHERE ID=234 OR 1=1`. As a result, the server retrieves every row in the table. This exposes every row and causes excessive server load. The simplest way to protect from this type of attack is to use single quotation marks around the numeric constants: `SELECT * FROM table WHERE ID='234'`. If the user enters extra information, it all becomes part of the string. In a numeric context, MySQL automatically converts this string to a number and strips any trailing nonnumeric characters from it.

Sometimes people think that if a database contains only publicly available data, it need not be protected. This is incorrect. Even if it is permissible to display any row in the database, you should still protect against denial of service attacks (for example, those that are based on the technique in the preceding paragraph that causes the server to waste resources). Otherwise, your server becomes unresponsive to legitimate users.

Checklist:

- Enable strict SQL mode to tell the server to be more restrictive of what data values it accepts. See [Section 6.1.8, “Server SQL Modes”](#).
- Try to enter single and double quotation marks ( `'` and `"` ) in all of your Web forms. If you get any kind of MySQL error, investigate the problem right away.
- Try to modify dynamic URLs by adding `%22 (")`, `%23 (#)`, and `%27 (')` to them.
- Try to modify data types in dynamic URLs from numeric to character types using the characters shown in the previous examples. Your application should be safe against these and similar attacks.
- Try to enter characters, spaces, and special symbols rather than numbers in numeric fields. Your application should remove them before passing them to MySQL or else generate an error. Passing unchecked values to MySQL is very dangerous!
- Check the size of data before passing it to MySQL.

- Have your application connect to the database using a user name different from the one you use for administrative purposes. Do not give your applications any access privileges they do not need.

Many application programming interfaces provide a means of escaping special characters in data values. Properly used, this prevents application users from entering values that cause the application to generate statements that have a different effect than you intend:

- MySQL C API: Use the `mysql_real_escape_string_quote()` API call.
- MySQL++: Use the `escape` and `quote` modifiers for query streams.
- PHP: Use either the `mysqli` or `pdo_mysql` extensions, and not the older `ext/mysql` extension. The preferred API's support the improved MySQL authentication protocol and passwords, as well as prepared statements with placeholders. See also [Choosing an API](#).

If the older `ext/mysql` extension must be used, then for escaping use the `mysql_real_escape_string_quote()` function and not `mysql_escape_string()` or `addslashes()` because only `mysql_real_escape_string_quote()` is character set-aware; the other functions can be “bypassed” when using (invalid) multibyte character sets.

- Perl DBI: Use placeholders or the `quote()` method.
- Ruby DBI: Use placeholders or the `quote()` method.
- Java JDBC: Use a `PreparedStatement` object and placeholders.

Other programming interfaces might have similar capabilities.

## 7.2 The MySQL Access Privilege System

The primary function of the MySQL privilege system is to authenticate a user who connects from a given host and to associate that user with privileges on a database such as `SELECT`, `INSERT`, `UPDATE`, and `DELETE`. Additional functionality includes the ability to have anonymous users and to grant privileges for MySQL-specific functions such as `LOAD DATA INFILE` and administrative operations.

There are some things that you cannot do with the MySQL privilege system:

- You cannot explicitly specify that a given user should be denied access. That is, you cannot explicitly match a user and then refuse the connection.
- You cannot specify that a user has privileges to create or drop tables in a database but not to create or drop the database itself.
- A password applies globally to an account. You cannot associate a password with a specific object such as a database, table, or routine.

The user interface to the MySQL privilege system consists of SQL statements such as `CREATE USER`, `GRANT`, and `REVOKE`. See [Section 14.7.1, “Account Management Statements”](#).

Internally, the server stores privilege information in the grant tables of the `mysql` database (that is, in the database named `mysql`). The MySQL server reads the contents of these tables into memory when it starts and bases access-control decisions on the in-memory copies of the grant tables.

The MySQL privilege system ensures that all users may perform only the operations permitted to them. As a user, when you connect to a MySQL server, your identity is determined by *the host from which you connect* and *the user name you specify*. When you issue requests after connecting, the system grants privileges according to your identity and *what you want to do*.

MySQL considers both your host name and user name in identifying you because there is no reason to assume that a given user name belongs to the same person on all hosts. For example, the user `joe` who connects from `office.example.com` need not be the same person as the user `joe` who connects from `home.example.com`. MySQL handles this by enabling you to distinguish users on different hosts that happen to have the same name: You can grant one set of privileges for connections

by `joe` from `office.example.com`, and a different set of privileges for connections by `joe` from `home.example.com`. To see what privileges a given account has, use the `SHOW GRANTS` statement. For example:

```
SHOW GRANTS FOR 'joe'@'office.example.com';
SHOW GRANTS FOR 'joe'@'home.example.com';
```

MySQL access control involves two stages when you run a client program that connects to the server:

**Stage 1:** The server accepts or rejects the connection based on your identity and whether you can verify your identity by supplying the correct password.

**Stage 2:** Assuming that you can connect, the server checks each statement you issue to determine whether you have sufficient privileges to perform it. For example, if you try to select rows from a table in a database or drop a table from the database, the server verifies that you have the `SELECT` privilege for the table or the `DROP` privilege for the database.

For a more detailed description of what happens during each stage, see [Section 7.2.4, “Access Control, Stage 1: Connection Verification”](#), and [Section 7.2.5, “Access Control, Stage 2: Request Verification”](#).

If your privileges are changed (either by yourself or someone else) while you are connected, those changes do not necessarily take effect immediately for the next statement that you issue. For details about the conditions under which the server reloads the grant tables, see [Section 7.2.6, “When Privilege Changes Take Effect”](#).

For general security-related advice, see [Section 7.1, “General Security Issues”](#). For help in diagnosing privilege-related problems, see [Section 7.2.7, “Troubleshooting Problems Connecting to MySQL”](#).

## 7.2.1 Privileges Provided by MySQL

MySQL provides privileges that apply in different contexts and at different levels of operation:

- Administrative privileges enable users to manage operation of the MySQL server. These privileges are global because they are not specific to a particular database.
- Database privileges apply to a database and to all objects within it. These privileges can be granted for specific databases, or globally so that they apply to all databases.
- Privileges for database objects such as tables, indexes, views, and stored routines can be granted for specific objects within a database, for all objects of a given type within a database (for example, all tables in a database), or globally for all objects of a given type in all databases).

Information about account privileges is stored in the `user`, `db`, `tables_priv`, `columns_priv`, and `procs_priv` tables in the `mysql` database (see [Section 7.2.2, “Grant Tables”](#)). The MySQL server reads the contents of these tables into memory when it starts and reloads them under the circumstances indicated in [Section 7.2.6, “When Privilege Changes Take Effect”](#). Access-control decisions are based on the in-memory copies of the grant tables.

Some releases of MySQL introduce changes to the structure of the grant tables to add new privileges or features. To make sure that you can take advantage of any new capabilities, update your grant tables to have the current structure whenever you update to a new version of MySQL. See [Section 5.4.7, “mysql\\_upgrade — Check and Upgrade MySQL Tables”](#).

The following table shows the privilege names used at the SQL level in the `GRANT` and `REVOKE` statements, along with the column name associated with each privilege in the grant tables and the context in which the privilege applies.

**Table 7.2 Permissible Privileges for GRANT and REVOKE**

| Privilege           | Column                   | Context                       |
|---------------------|--------------------------|-------------------------------|
| <code>CREATE</code> | <code>Create_priv</code> | databases, tables, or indexes |

| Privilege               | Column                 | Context                               |
|-------------------------|------------------------|---------------------------------------|
| DROP                    | Drop_priv              | databases, tables, or views           |
| GRANT OPTION            | Grant_priv             | databases, tables, or stored routines |
| LOCK TABLES             | Lock_tables_priv       | databases                             |
| REFERENCES              | References_priv        | databases or tables                   |
| EVENT                   | Event_priv             | databases                             |
| ALTER                   | Alter_priv             | tables                                |
| DELETE                  | Delete_priv            | tables                                |
| INDEX                   | Index_priv             | tables                                |
| INSERT                  | Insert_priv            | tables or columns                     |
| SELECT                  | Select_priv            | tables or columns                     |
| UPDATE                  | Update_priv            | tables or columns                     |
| CREATE TEMPORARY TABLES | Create_tmp_table_priv  | tables                                |
| TRIGGER                 | Trigger_priv           | tables                                |
| CREATE VIEW             | Create_view_priv       | views                                 |
| SHOW VIEW               | Show_view_priv         | views                                 |
| ALTER ROUTINE           | Alter_routine_priv     | stored routines                       |
| CREATE ROUTINE          | Create_routine_priv    | stored routines                       |
| EXECUTE                 | Execute_priv           | stored routines                       |
| FILE                    | File_priv              | file access on server host            |
| CREATE TABLESPACE       | Create_tablespace_priv | server administration                 |
| CREATE USER             | Create_user_priv       | server administration                 |
| PROCESS                 | Process_priv           | server administration                 |
| PROXY                   | see proxies_priv table | server administration                 |
| RELOAD                  | Reload_priv            | server administration                 |
| REPLICATION CLIENT      | Repl_client_priv       | server administration                 |
| REPLICATION SLAVE       | Repl_slave_priv        | server administration                 |
| SHOW DATABASES          | Show_db_priv           | server administration                 |
| SHUTDOWN                | Shutdown_priv          | server administration                 |
| SUPER                   | Super_priv             | server administration                 |
| ALL [PRIVILEGES]        |                        | server administration                 |
| USAGE                   |                        | server administration                 |

The following list provides a general description of each privilege available in MySQL. Particular SQL statements might have more specific privilege requirements than indicated here. If so, the description for the statement in question provides the details.

- The [ALL](#) or [ALL PRIVILEGES](#) privilege specifier is shorthand. It stands for “all privileges available at a given privilege level” (except [GRANT OPTION](#)). For example, granting [ALL](#) at the global or table level grants all global privileges or all table-level privileges.
- The [ALTER](#) privilege enables use of [ALTER TABLE](#) to change the structure of tables. [ALTER TABLE](#) also requires the [CREATE](#) and [INSERT](#) privileges. Renaming a table requires [ALTER](#) and [DROP](#) on the old table, [CREATE](#), and [INSERT](#) on the new table.
- The [ALTER ROUTINE](#) privilege is needed to alter or drop stored routines (procedures and functions).

- The `CREATE` privilege enables creation of new databases and tables.
- The `CREATE ROUTINE` privilege is needed to create stored routines (procedures and functions).
- The `CREATE TABLESPACE` privilege is needed to create, alter, or drop tablespaces and log file groups.
- The `CREATE TEMPORARY TABLES` privilege enables the creation of temporary tables using the `CREATE TEMPORARY TABLE` statement.

After a session has created a temporary table, the server performs no further privilege checks on the table. The creating session can perform any operation on the table, such as `DROP TABLE`, `INSERT`, `UPDATE`, or `SELECT`.

One implication of this behavior is that a session can manipulate its temporary tables even if the current user has no privilege to create them. Suppose that the current user does not have the `CREATE TEMPORARY TABLES` privilege but is able to execute a `DEFINER`-context stored procedure that executes with the privileges of a user who does have `CREATE TEMPORARY TABLES` and that creates a temporary table. While the procedure executes, the session uses the privileges of the defining user. After the procedure returns, the effective privileges revert to those of the current user, which can still see the temporary table and perform any operation on it.

To keep privileges for temporary and nontemporary tables separate, a common workaround for this situation is to create a database dedicated to the use of temporary tables. Then for that database, a user can be granted the `CREATE TEMPORARY TABLES` privilege, along with any other privileges required for temporary table operations done by that user.

- The `CREATE USER` privilege enables use of `ALTER USER`, `CREATE USER`, `DROP USER`, `RENAME USER`, and `REVOKE ALL PRIVILEGES`.
- The `CREATE VIEW` privilege enables use of `CREATE VIEW`.
- The `DELETE` privilege enables rows to be deleted from tables in a database.
- The `DROP` privilege enables you to drop (remove) existing databases, tables, and views. The `DROP` privilege is required in order to use the statement `ALTER TABLE ... DROP PARTITION` on a partitioned table. The `DROP` privilege is also required for `TRUNCATE TABLE`. *If you grant the `DROP` privilege for the `mysql` database to a user, that user can drop the database in which the MySQL access privileges are stored.*
- The `EVENT` privilege is required to create, alter, drop, or see events for the Event Scheduler.
- The `EXECUTE` privilege is required to execute stored routines (procedures and functions).
- The `FILE` privilege gives you permission to read and write files on the server host using the `LOAD DATA INFILE` and `SELECT ... INTO OUTFILE` statements and the `LOAD_FILE()` function. A user who has the `FILE` privilege can read any file on the server host that is either world-readable or readable by the MySQL server. (This implies the user can read any file in any database directory, because the server can access any of those files.) The `FILE` privilege also enables the user to create new files in any directory where the MySQL server has write access. This includes the server's data directory containing the files that implement the privilege tables. As a security measure, the server will not overwrite existing files.

To limit the location in which files can be read and written, set the `secure_file_priv` system to a specific directory. See [Section 6.1.5, “Server System Variables”](#).

- The `GRANT OPTION` privilege enables you to give to other users or remove from other users those privileges that you yourself possess.
- The `INDEX` privilege enables you to create or drop (remove) indexes. `INDEX` applies to existing tables. If you have the `CREATE` privilege for a table, you can include index definitions in the `CREATE TABLE` statement.

- The `INSERT` privilege enables rows to be inserted into tables in a database. `INSERT` is also required for the `ANALYZE TABLE`, `OPTIMIZE TABLE`, and `REPAIR TABLE` table-maintenance statements.
- The `LOCK TABLES` privilege enables the use of explicit `LOCK TABLES` statements to lock tables for which you have the `SELECT` privilege. This includes the use of write locks, which prevents other sessions from reading the locked table.
- The `PROCESS` privilege pertains to display of information about the threads executing within the server (that is, information about the statements being executed by sessions). The privilege enables use of `SHOW PROCESSLIST` or `mysqladmin processlist` to see threads belonging to other accounts; you can always see your own threads. The `PROCESS` privilege also enables use of `SHOW ENGINE`.
- The `PROXY` privilege enables a user to impersonate or become known as another user. See [Section 7.3.9, “Proxy Users”](#).
- The `REFERENCES` privilege is unused before MySQL 5.7.6. As of 5.7.6, creation of a foreign key constraint requires the `REFERENCES` privilege for the parent table.
- The `RELOAD` privilege enables use of the `FLUSH` statement. It also enables `mysqladmin` commands that are equivalent to `FLUSH` operations: `flush-hosts`, `flush-logs`, `flush-privileges`, `flush-status`, `flush-tables`, `flush-threads`, `refresh`, and `reload`.

The `reload` command tells the server to reload the grant tables into memory. `flush-privileges` is a synonym for `reload`. The `refresh` command closes and reopens the log files and flushes all tables. The other `flush-xxx` commands perform functions similar to `refresh`, but are more specific and may be preferable in some instances. For example, if you want to flush just the log files, `flush-logs` is a better choice than `refresh`.

- The `REPLICATION CLIENT` privilege enables the use of `SHOW MASTER STATUS`, `SHOW SLAVE STATUS`, and `SHOW BINARY LOGS`.
- The `REPLICATION SLAVE` privilege should be granted to accounts that are used by slave servers to connect to the current server as their master. Without this privilege, the slave cannot request updates that have been made to databases on the master server.
- The `SELECT` privilege enables you to select rows from tables in a database. `SELECT` statements require the `SELECT` privilege only if they actually retrieve rows from a table. Some `SELECT` statements do not access tables and can be executed without permission for any database. For example, you can use `SELECT` as a simple calculator to evaluate expressions that make no reference to tables:

```
SELECT 1+1;
SELECT PI()*2;
```

The `SELECT` privilege is also needed for other statements that read column values. For example, `SELECT` is needed for columns referenced on the right hand side of `col_name=expr` assignment in `UPDATE` statements or for columns named in the `WHERE` clause of `DELETE` or `UPDATE` statements.

- The `SHOW DATABASES` privilege enables the account to see database names by issuing the `SHOW DATABASE` statement. Accounts that do not have this privilege see only databases for which they have some privileges, and cannot use the statement at all if the server was started with the `--skip-show-database` option. Note that *any* global privilege is a privilege for the database.
- The `SHOW VIEW` privilege enables use of `SHOW CREATE VIEW`.
- The `SHUTDOWN` privilege enables use of the `SHUTDOWN` statement, the `mysqladmin shutdown` command, and the `mysql_shutdown()` C API function.
- The `SUPER` privilege enables an account to use `CHANGE MASTER TO`, `KILL` or `mysqladmin kill` to kill threads belonging to other accounts (you can always kill your own threads), `PURGE BINARY LOGS`, the `mysqladmin debug` command, enabling or disabling logging, performing updates even

if the `read_only` system variable is enabled, starting and stopping replication on slave servers, specification of any account in the `DEFINER` attribute of stored programs and views, and enables you to connect (once) even if the connection limit controlled by the `max_connections` system variable is reached.

The `SUPER` privilege is required to make configuration changes by modifying the global value of system variables. For some system variables, setting the session value also requires the `SUPER` privilege; if so, it is indicated in the variable description.

To create or alter stored functions if binary logging is enabled, you may also need the `SUPER` privilege, as described in [Section 22.7, “Binary Logging of Stored Programs”](#).

- The `TRIGGER` privilege enables trigger operations. You must have this privilege for a table to create, drop, execute, or display triggers for that table.

When a trigger is activated (by a user who has privileges to execute `INSERT`, `UPDATE`, or `DELETE` statements for the table associated with the trigger), trigger execution requires that the user who defined the trigger still have the `TRIGGER` privilege.

- The `UPDATE` privilege enables rows to be updated in tables in a database.
- The `USAGE` privilege specifier stands for “no privileges.” It is used at the global level with `GRANT` to modify account attributes such as resource limits or SSL characteristics without affecting existing account privileges.

It is a good idea to grant to an account only those privileges that it needs. You should exercise particular caution in granting the `FILE` and administrative privileges:

- The `FILE` privilege can be abused to read into a database table any files that the MySQL server can read on the server host. This includes all world-readable files and files in the server's data directory. The table can then be accessed using `SELECT` to transfer its contents to the client host.
- The `GRANT OPTION` privilege enables users to give their privileges to other users. Two users that have different privileges and with the `GRANT OPTION` privilege are able to combine privileges.
- The `ALTER` privilege may be used to subvert the privilege system by renaming tables.
- The `SHUTDOWN` privilege can be abused to deny service to other users entirely by terminating the server.
- The `PROCESS` privilege can be used to view the plain text of currently executing statements, including statements that set or change passwords.
- The `SUPER` privilege can be used to terminate other sessions or change how the server operates.
- Privileges granted for the `mysql` database itself can be used to change passwords and other access privilege information. Passwords are stored encrypted, so a malicious user cannot simply read them to know the plain text password. However, a user with write access to the `user` table `authentication_string` column can change an account's password, and then connect to the MySQL server using that account.

## 7.2.2 Grant Tables

The `mysql` system database includes several grant tables that contain information about user accounts and the privileges held by them. This section describes those tables. For information about other tables in the system database, see [Section 6.3, “The mysql System Database”](#).

Normally, to manipulate the contents of grant tables, you modify them indirectly by using account-management statements such as `CREATE USER`, `GRANT`, and `REVOKE` to set up accounts and control the privileges available to each one. See [Section 14.7.1, “Account Management Statements”](#). The discussion here describes the underlying structure of the grant tables and how the server uses their contents when interacting with clients.

**Note**

Direct modification of grant tables using statements such as [INSERT](#), [UPDATE](#), or [DELETE](#) is discouraged and done at your own risk. The server is free to ignore rows that become malformed as a result of such modifications.

As of MySQL 5.7.18, for any operation that modifies a grant table, the server checks whether the table has the expected structure and produces an error if not. [mysql\\_upgrade](#) must be run to update the tables to the expected structure.

These [mysql](#) database tables contain grant information:

- [user](#): User accounts, global privileges, and other non-privilege columns
- [db](#): Database-level privileges
- [tables\\_priv](#): Table-level privileges
- [columns\\_priv](#): Column-level privileges
- [procs\\_priv](#): Stored procedure and function privileges
- [proxies\\_priv](#): Proxy-user privileges

Each grant table contains scope columns and privilege columns:

- Scope columns determine the scope of each row in the tables; that is, the context in which the row applies. For example, a [user](#) table row with [Host](#) and [User](#) values of '[thomas.loc.gov](#)' and '[bob](#)' applies to authenticating connections made to the server from the host [thomas.loc.gov](#) by a client that specifies a user name of [bob](#). Similarly, a [db](#) table row with [Host](#), [User](#), and [Db](#) column values of '[thomas.loc.gov](#)', '[bob](#)' and '[reports](#)' applies when [bob](#) connects from the host [thomas.loc.gov](#) to access the [reports](#) database. The [tables\\_priv](#) and [columns\\_priv](#) tables contain scope columns indicating tables or table/column combinations to which each row applies. The [procs\\_priv](#) scope columns indicate the stored routine to which each row applies.
- Privilege columns indicate which privileges a table row grants; that is, which operations it permits to be performed. The server combines the information in the various grant tables to form a complete description of a user's privileges. [Section 7.2.5, “Access Control, Stage 2: Request Verification”](#), describes the rules for this.

The server uses the grant tables in the following manner:

- The [user](#) table scope columns determine whether to reject or permit incoming connections. For permitted connections, any privileges granted in the [user](#) table indicate the user's global privileges. Any privileges granted in this table apply to *all* databases on the server.

**Caution**

Because any global privilege is considered a privilege for all databases, any global privilege enables a user to see all database names with [SHOW DATABASES](#) or by examining the [SCHEMATA](#) table of [INFORMATION\\_SCHEMA](#).

- The [db](#) table scope columns determine which users can access which databases from which hosts. The privilege columns determine the permitted operations. A privilege granted at the database level applies to the database and to all objects in the database, such as tables and stored programs.
- The [tables\\_priv](#) and [columns\\_priv](#) tables are similar to the [db](#) table, but are more fine-grained: They apply at the table and column levels rather than at the database level. A privilege granted at the table level applies to the table and to all its columns. A privilege granted at the column level applies only to a specific column.

- The `procs_priv` table applies to stored routines (procedures and functions). A privilege granted at the routine level applies only to a single procedure or function.
- The `proxies_priv` table indicates which users can act as proxies for other users and whether a user can grant the `PROXY` privilege to other users.

The server uses the `user` and `db` tables in the `mysql` database at both the first and second stages of access control (see [Section 7.2, “The MySQL Access Privilege System”](#)). The columns in the `user` and `db` tables are shown here.

**Table 7.3 user and db Table Columns**

| Table Name               | <code>user</code>                   | <code>db</code>                    |
|--------------------------|-------------------------------------|------------------------------------|
| <b>Scope columns</b>     | <code>Host</code>                   | <code>Host</code>                  |
|                          | <code>User</code>                   | <code>Db</code>                    |
|                          | <code>Password</code>               | <code>User</code>                  |
| <b>Privilege columns</b> | <code>Select_priv</code>            | <code>Select_priv</code>           |
|                          | <code>Insert_priv</code>            | <code>Insert_priv</code>           |
|                          | <code>Update_priv</code>            | <code>Update_priv</code>           |
|                          | <code>Delete_priv</code>            | <code>Delete_priv</code>           |
|                          | <code>Index_priv</code>             | <code>Index_priv</code>            |
|                          | <code>Alter_priv</code>             | <code>Alter_priv</code>            |
|                          | <code>Create_priv</code>            | <code>Create_priv</code>           |
|                          | <code>Drop_priv</code>              | <code>Drop_priv</code>             |
|                          | <code>Grant_priv</code>             | <code>Grant_priv</code>            |
|                          | <code>Create_view_priv</code>       | <code>Create_view_priv</code>      |
|                          | <code>Show_view_priv</code>         | <code>Show_view_priv</code>        |
|                          | <code>Create_routine_priv</code>    | <code>Create_routine_priv</code>   |
|                          | <code>Alter_routine_priv</code>     | <code>Alter_routine_priv</code>    |
|                          | <code>Execute_priv</code>           | <code>Execute_priv</code>          |
|                          | <code>Trigger_priv</code>           | <code>Trigger_priv</code>          |
|                          | <code>Event_priv</code>             | <code>Event_priv</code>            |
|                          | <code>Create_tmp_table_priv</code>  | <code>Create_tmp_table_priv</code> |
|                          | <code>Lock_tables_priv</code>       | <code>Lock_tables_priv</code>      |
|                          | <code>References_priv</code>        | <code>References_priv</code>       |
|                          | <code>Reload_priv</code>            |                                    |
|                          | <code>Shutdown_priv</code>          |                                    |
|                          | <code>Process_priv</code>           |                                    |
|                          | <code>File_priv</code>              |                                    |
|                          | <code>Show_db_priv</code>           |                                    |
|                          | <code>Super_priv</code>             |                                    |
|                          | <code>Repl_slave_priv</code>        |                                    |
|                          | <code>Repl_client_priv</code>       |                                    |
|                          | <code>Create_user_priv</code>       |                                    |
|                          | <code>Create_tablespace_priv</code> |                                    |
| <b>Security columns</b>  | <code>ssl_type</code>               |                                    |

| Table Name                      | user                  | db |
|---------------------------------|-----------------------|----|
|                                 | ssl_cipher            |    |
|                                 | x509_issuer           |    |
|                                 | x509_subject          |    |
|                                 | plugin                |    |
|                                 | authentication_string |    |
|                                 | password_expired      |    |
|                                 | password_last_changed |    |
|                                 | password_lifetime     |    |
|                                 | account_locked        |    |
| <b>Resource control columns</b> | max_questions         |    |
|                                 | max_updates           |    |
|                                 | max_connections       |    |
|                                 | max_user_connections  |    |

The `user` table `plugin`, `Password`, and `authentication_string` columns store authentication plugin and credential information. In MySQL 5.7.6, the `Password` column was removed and all credentials are stored in the `authentication_string` column.

If an account row names a plugin in the `plugin` column, the server uses it to authenticate connection attempts for the account. It is up to the plugin whether it uses the `Password` and `authentication_string` column values.

As of MySQL 5.7.2, the `plugin` column must be nonempty.

Before MySQL 5.7.2, the `plugin` column for an account row is permitted to be empty. In this case, the server authenticates the account using the `mysql_native_password` or `mysql_old_password` plugin implicitly, depending on the format of the password hash in the `Password` column.

If the `Password` value is empty or a 4.1 password hash (41 characters), the server uses `mysql_native_password`. If the password value is a pre-4.1 password hash (16 characters), the server uses `mysql_old_password`. (For additional information about these hash formats, see [Section 7.1.2.4, “Password Hashing in MySQL”](#).) Clients must match the password in the `Password` column of the account row.

At startup, and at runtime when `FLUSH PRIVILEGES` is executed, the server checks `user` table rows. As of MySQL 5.7.2, for any row with an empty `plugin` column, the server writes a warning to the error log of this form:

```
[Warning] User entry 'user_name'@'host_name' has an empty plugin
value. The user will be ignored and no one can login with this user
anymore.
```

To address this problem, see [Section 7.5.1.3, “Migrating Away from Pre-4.1 Password Hashing and the mysql\\_old\\_password Plugin”](#).

The `password_expired` column permits DBAs to expire account passwords and require users to reset their password. The default `password_expired` value is `'N'`, but can be set to `'Y'` with the `ALTER USER` statement. After an account's password has been expired, all operations performed by the account in subsequent connections to the server result in an error until the user issues an `ALTER USER` statement (for MySQL 5.7.6 and up) or `SET PASSWORD` statement (before MySQL 5.7.6) to establish a new account password.

It is possible after password expiration to “reset” a password by setting it to its current value. As a matter of good policy, it is preferable to choose a different password.

`password_last_changed` (added in MySQL 5.7.4) is a `TIMESTAMP` column indicating when the password was last changed. The value is non-`NULL` only for accounts that use MySQL built-in authentication methods (accounts that use an authentication plugin of `mysql_native_password`, `mysql_old_password`, or `sha256_password`). The value is `NULL` for other accounts, such as those authenticated using an external authentication system.

`password_last_changed` is updated by the `CREATE USER`, `ALTER USER`, and `SET PASSWORD` statements, and by `GRANT` statements that create an account or change an account password.

`password_lifetime` (added in MySQL 5.7.4) indicates the account password lifetime, in days. If the password is past its lifetime (assessed using the `password_last_changed` column), the server considers the password expired when clients connect using the account. A value of `N` greater than zero means that the password must be changed every `N` days. A value of 0 disables automatic password expiration. If the value is `NULL` (the default), the global expiration policy applies, as defined by the `default_password_lifetime` system variable.

`account_locked` (added in MySQL 5.7.6) indicates whether the account is locked (see [Section 7.3.10, “User Account Locking”](#)).

During the second stage of access control, the server performs request verification to ensure that each client has sufficient privileges for each request that it issues. In addition to the `user` and `db` grant tables, the server may also consult the `tables_priv` and `columns_priv` tables for requests that involve tables. The latter tables provide finer privilege control at the table and column levels. They have the columns shown in the following table.

**Table 7.4 `tables_priv` and `columns_priv` Table Columns**

| Table Name               | <code>tables_priv</code> | <code>columns_priv</code> |
|--------------------------|--------------------------|---------------------------|
| <b>Scope columns</b>     | Host                     | Host                      |
|                          | Db                       | Db                        |
|                          | User                     | User                      |
|                          | Table_name               | Table_name                |
|                          |                          | Column_name               |
| <b>Privilege columns</b> | Table_priv               | Column_priv               |
|                          | Column_priv              |                           |
| <b>Other columns</b>     | Timestamp                | Timestamp                 |
|                          | Grantor                  |                           |

The `Timestamp` and `Grantor` columns are set to the current timestamp and the `CURRENT_USER` value, respectively, but are otherwise unused.

For verification of requests that involve stored routines, the server may consult the `procs_priv` table, which has the columns shown in the following table.

**Table 7.5 `procs_priv` Table Columns**

| Table Name               | <code>procs_priv</code> |
|--------------------------|-------------------------|
| <b>Scope columns</b>     | Host                    |
|                          | Db                      |
|                          | User                    |
|                          | Routine_name            |
|                          | Routine_type            |
| <b>Privilege columns</b> | Proc_priv               |
| <b>Other columns</b>     | Timestamp               |
|                          | Grantor                 |

The `Routine_type` column is an `ENUM` column with values of `'FUNCTION'` or `'PROCEDURE'` to indicate the type of routine the row refers to. This column enables privileges to be granted separately for a function and a procedure with the same name.

The `Timestamp` and `Grantor` columns are unused.

The `proxies_priv` table records information about proxy accounts. It has these columns:

- `Host`, `User`: The proxy account; that is, the account that has the `PROXY` privilege for the proxied account.
- `Proxied_host`, `Proxied_user`: The proxied account.
- `Grantor`, `Timestamp`: Unused.
- `With_grant`: Whether the proxy account can grant the `PROXY` privilege to other accounts.

For an account to be able to grant the `PROXY` privilege to other accounts, it must have a row in the `proxies_priv` table with `With_grant` set to 1 and `Proxied_host` and `Proxied_user` set to indicate the account or accounts for which the privilege can be granted. For example, the `'root'@'localhost'` account created during MySQL installation has a row in the `proxies_priv` table that enables granting the `PROXY` privilege for `'@'`, that is, for all users and all hosts. This enables `root` to set up proxy users, as well as to delegate to other accounts the authority to set up proxy users. See [Section 7.3.9, “Proxy Users”](#).

Scope columns in the grant tables contain strings. The default value for each is the empty string. The following table shows the number of characters permitted in each column.

**Table 7.6 Grant Table Scope Column Lengths**

| Column Name                                   | Maximum Permitted Characters |
|---|------------------------------|
| <code>Host</code> , <code>Proxied_host</code> | 60                           |
| <code>User</code> , <code>Proxied_user</code> | 32 (16 before MySQL 5.7.8)   |
| <code>Password</code>                         | 41                           |
| <code>Db</code>                               | 64                           |
| <code>Table_name</code>                       | 64                           |
| <code>Column_name</code>                      | 64                           |
| <code>Routine_name</code>                     | 64                           |

For access-checking purposes, comparisons of `User`, `Proxied_user`, `Password`, `authentication_string`, `Db`, and `Table_name` values are case sensitive. Comparisons of `Host`, `Proxied_host`, `Column_name`, and `Routine_name` values are not case sensitive.

The `user` and `db` tables list each privilege in a separate column that is declared as `ENUM('N','Y') DEFAULT 'N'`. In other words, each privilege can be disabled or enabled, with the default being disabled.

The `tables_priv`, `columns_priv`, and `procs_priv` tables declare the privilege columns as `SET` columns. Values in these columns can contain any combination of the privileges controlled by the table. Only those privileges listed in the column value are enabled.

**Table 7.7 Set-Type Privilege Column Values**

| Table Name               | Column Name             | Possible Set Elements   |
|--------------------------|-------------------------|---|
| <code>tables_priv</code> | <code>Table_priv</code> | <code>'Select'</code> , <code>'Insert'</code> , <code>'Update'</code> , <code>'Delete'</code> , <code>'Create'</code> , <code>'Drop'</code> , <code>'Grant'</code> , <code>'References'</code> , <code>'Index'</code> , <code>'Alter'</code> , <code>'Create View'</code> , <code>'Show view'</code> , <code>'Trigger'</code> |

| Table Name                | Column Name              | Possible Set Elements                      |
|---------------------------|--------------------------|--|
| <code>tables_priv</code>  | <code>Column_priv</code> | 'Select', 'Insert', 'Update', 'References' |
| <code>columns_priv</code> | <code>Column_priv</code> | 'Select', 'Insert', 'Update', 'References' |
| <code>procs_priv</code>   | <code>Proc_priv</code>   | 'Execute', 'Alter Routine', 'Grant'        |

Only the `user` table specifies administrative privileges, such as `RELOAD` and `SHUTDOWN`. Administrative operations are operations on the server itself and are not database-specific, so there is no reason to list these privileges in the other grant tables. Consequently, the server need consult only the `user` table to determine whether a user can perform an administrative operation.

The `FILE` privilege also is specified only in the `user` table. It is not an administrative privilege as such, but a user's ability to read or write files on the server host is independent of the database being accessed.

The server reads the contents of the grant tables into memory when it starts. You can tell it to reload the tables by issuing a `FLUSH PRIVILEGES` statement or executing a `mysqladmin flush-privileges` or `mysqladmin reload` command. Changes to the grant tables take effect as indicated in [Section 7.2.6, “When Privilege Changes Take Effect”](#).

When you modify an account, it is a good idea to verify that your changes have the intended effect. To check the privileges for a given account, use the `SHOW GRANTS` statement. For example, to determine the privileges that are granted to an account with user name and host name values of `bob` and `pc84.example.com`, use this statement:

```
SHOW GRANTS FOR 'bob'@'pc84.example.com';
```

To display nonprivilege properties of an account, use `SHOW CREATE USER`:

```
SHOW CREATE USER 'bob'@'pc84.example.com';
```

## 7.2.3 Specifying Account Names

MySQL account names consist of a user name and a host name. This enables creation of accounts for users with the same name who can connect from different hosts. This section describes how to write account names, including special values and wildcard rules.

In SQL statements such as `CREATE USER`, `GRANT`, and `SET PASSWORD`, account names follow these rules:

- Account name syntax is `'user_name'@'host_name'`.
- An account name consisting only of a user name is equivalent to `'user_name'@'%'`. For example, `'me'` is equivalent to `'me'@'%'`.
- The user name and host name need not be quoted if they are legal as unquoted identifiers. Quotes are necessary to specify a `user_name` string containing special characters (such as space or `-`), or a `host_name` string containing special characters or wildcard characters (such as `.` or `%`); for example, `'test-user'@'%.com'`.
- Quote user names and host names as identifiers or as strings, using either backticks (```), single quotation marks (`'`), or double quotation marks (`"`). For string-quoting and identifier-quoting guidelines, see [Section 10.1.1, “String Literals”](#), and [Section 10.2, “Schema Object Names”](#).
- The user name and host name parts, if quoted, must be quoted separately. That is, write `'me'@'localhost'`, not `'me@localhost'`; the latter is actually equivalent to `'me@localhost'@'%'`.

- A reference to the `CURRENT_USER` or `CURRENT_USER()` function is equivalent to specifying the current client's user name and host name literally.

MySQL stores account names in grant tables in the `mysql` system database using separate columns for the user name and host name parts:

- The `user` table contains one row for each account. The `User` and `Host` columns store the user name and host name. This table also indicates which global privileges the account has.
- Other grant tables indicate privileges an account has for databases and objects within databases. These tables have `User` and `Host` columns to store the account name. Each row in these tables associates with the account in the `user` table that has the same `User` and `Host` values.
- For access-checking purposes, comparisons of User values are case sensitive. Comparisons of Host values are not case sensitive.

For additional detail about grant table structure, see [Section 7.2.2, “Grant Tables”](#).

User names and host names have certain special values or wildcard conventions, as described following.

The user name part of an account name is either a nonblank value that literally matches the user name for incoming connection attempts, or a blank value (empty string) that matches any user name. An account with a blank user name is an anonymous user. To specify an anonymous user in SQL statements, use a quoted empty user name part, such as `'@'localhost`.

The host name part of an account name can take many forms, and wildcards are permitted:

- A host value can be a host name or an IP address (IPv4 or IPv6). The name `'localhost'` indicates the local host. The IP address `'127.0.0.1'` indicates the IPv4 loopback interface. The IP address `:::1` indicates the IPv6 loopback interface.
- The `%` and `_` wildcard characters are permitted in host name or IP address values. These have the same meaning as for pattern-matching operations performed with the `LIKE` operator. For example, a host value of `'%'` matches any host name, whereas a value of `'%.mysql.com'` matches any host in the `mysql.com` domain. `'192.168.1.%'` matches any host in the 192.168.1 class C network.

Because IP wildcard values are permitted in host values (for example, `'192.168.1.%'` to match every host on a subnet), someone could try to exploit this capability by naming a host `192.168.1.somewhere.com`. To foil such attempts, MySQL does not perform matching on host names that start with digits and a dot. For example, if a host is named `1.2.example.com`, its name never matches the host part of account names. An IP wildcard value can match only IP addresses, not host names.

- For a host value specified as an IPv4 address, a netmask can be given to indicate how many address bits to use for the network number. Netmask notation cannot be used for IPv6 addresses.

The syntax is `host_ip/netmask`. For example:

```
CREATE USER 'david'@'192.58.197.0/255.255.255.0';
```

This enables `david` to connect from any client host having an IP address `client_ip` for which the following condition is true:

```
client_ip & netmask = host_ip
```

That is, for the `CREATE USER` statement just shown:

```
client_ip & 255.255.255.0 = 192.58.197.0
```

IP addresses that satisfy this condition range from `192.58.197.0` to `192.58.197.255`.

A netmask typically begins with bits set to 1, followed by bits set to 0. Examples:

- `192.0.0.0/255.0.0.0`: Any host on the 192 class A network
- `192.168.0.0/255.255.0.0`: Any host on the 192.168 class B network
- `192.168.1.0/255.255.255.0`: Any host on the 192.168.1 class C network
- `192.168.1.1`: Only the host with this specific IP address

The server performs matching of host values in account names against the client host using the value returned by the system DNS resolver for the client host name or IP address. Except in the case that the account host value is specified using netmask notation, the server performs this comparison as a string match, even for an account host value given as an IP address. This means that you should specify account host values in the same format used by DNS. Here are examples of problems to watch out for:

- Suppose that a host on the local network has a fully qualified name of `host1.example.com`. If DNS returns name lookups for this host as `host1.example.com`, use that name in account host values. If DNS returns just `host1`, use `host1` instead.
- If DNS returns the IP address for a given host as `192.168.1.2`, that will match an account host value of `192.168.1.2` but not `192.168.01.2`. Similarly, it will match an account host pattern like `192.168.1.%` but not `192.168.01.%`.

To avoid problems like these, it is advisable to check the format in which your DNS returns host names and addresses. Use values in the same format in MySQL account names.

## 7.2.4 Access Control, Stage 1: Connection Verification

When you attempt to connect to a MySQL server, the server accepts or rejects the connection based on these conditions:

- Your identity and whether you can verify your identity by supplying the correct password
- Whether your account is locked or unlocked

The server checks credentials first, then account locking state. A failure for either step causes the server to deny access to you completely. Otherwise, the server accepts the connection, and then enters Stage 2 and waits for requests.

Credential checking is performed using the three `user` table scope columns (`Host`, `User`, and `authentication_string`). Locking state is recorded in the `user` table `account_locked` column. The server accepts the connection only if the `Host` and `User` columns in some `user` table row match the client host name and user name, the client supplies the password specified in that row, and the `account_locked` value is `'N'`. The rules for permissible `Host` and `User` values are given in [Section 7.2.3, “Specifying Account Names”](#). Account locking can be changed with the `ALTER USER` statement.

Your identity is based on two pieces of information:

- The client host from which you connect
- Your MySQL user name

If the `User` column value is nonblank, the user name in an incoming connection must match exactly. If the `User` value is blank, it matches any user name. If the `user` table row that matches an incoming connection has a blank user name, the user is considered to be an anonymous user with no name, not a user with the name that the client actually specified. This means that a blank user name is used for all further access checking for the duration of the connection (that is, during Stage 2).

The `authentication_string` column can be blank. This is not a wildcard and does not mean that any password matches. It means that the user must connect without specifying a password. If the server authenticates a client using a plugin, the authentication method that the plugin implements may or may not use the password in the `authentication_string` column. In this case, it is possible that an external password is also used to authenticate to the MySQL server.

Nonblank `authentication_string` values in the `user` table represent encrypted passwords. MySQL does not store passwords in cleartext form for anyone to see. Rather, the password supplied by a user who is attempting to connect is encrypted (using the password hashing method implemented by the account authentication plugin). The encrypted password then is used during the connection process when checking whether the password is correct. This is done without the encrypted password ever traveling over the connection. See [Section 7.3.1, “User Names and Passwords”](#).

From MySQL's point of view, the encrypted password is the *real* password, so you should never give anyone access to it. In particular, *do not give nonadministrative users read access to tables in the `mysql` database*.

The following table shows how various combinations of `User` and `Host` values in the `user` table apply to incoming connections.

| User Value | Host Value                   | Permissible Connections   |
|------------|------------------------------|---|
| 'fred'     | 'thomas.loc.gov'             | fred, connecting from thomas.loc.gov  |
| ' '        | 'thomas.loc.gov'             | Any user, connecting from thomas.loc.gov  |
| 'fred'     | '%'                          | fred, connecting from any host  |
| ' '        | '%'                          | Any user, connecting from any host  |
| 'fred'     | '%.loc.gov'                  | fred, connecting from any host in the loc.gov domain                                    |
| 'fred'     | 'x.y.%'                      | fred, connecting from x.y.net, x.y.com, x.y.edu, and so on; this is probably not useful |
| 'fred'     | '192.168.10.177'             | fred, connecting from the host with IP address 192.168.10.177                           |
| 'fred'     | '192.168.10.%'               | fred, connecting from any host in the 192.168.10 class C subnet                         |
| 'fred'     | '192.168.10.0/255.255.255.0' | Same as previous example  |

It is possible for the client host name and user name of an incoming connection to match more than one row in the `user` table. The preceding set of examples demonstrates this: Several of the entries shown match a connection from `thomas.loc.gov` by `fred`.

When multiple matches are possible, the server must determine which of them to use. It resolves this issue as follows:

- Whenever the server reads the `user` table into memory, it sorts the rows.
- When a client attempts to connect, the server looks through the rows in sorted order.
- The server uses the first row that matches the client host name and user name.

The server uses sorting rules that order rows with the most-specific `Host` values first. Literal host names and IP addresses are the most specific. (The specificity of a literal IP address is not affected by whether it has a netmask, so `192.168.1.13` and `192.168.1.0/255.255.255.0` are considered equally specific.) The pattern `'%'` means “any host” and is least specific. The empty string `' '` also means “any host” but sorts after `'%'`. Rows with the same `Host` value are ordered with the most-specific `User` values first (a blank `User` value means “any user” and is least specific). For rows with equally-specific `Host` and `User` values, the order is indeterminate.

To see how this works, suppose that the `user` table looks like this:

| Host      | User    | ... |
|-----------|---------|-----|
| %         | root    | ... |
| %         | jeffrey | ... |
| localhost | root    | ... |
| localhost |         | ... |

When the server reads the table into memory, it sorts the rows using the rules just described. The result after sorting looks like this:

| Host      | User    | ... |
|-----------|---------|-----|
| localhost | root    | ... |
| localhost |         | ... |
| %         | jeffrey | ... |
| %         | root    | ... |

When a client attempts to connect, the server looks through the sorted rows and uses the first match found. For a connection from `localhost` by `jeffrey`, two of the rows from the table match: the one with `Host` and `User` values of '`localhost`' and '', and the one with values of '%' and '`jeffrey`'. The '`localhost`' row appears first in sorted order, so that is the one the server uses.

Here is another example. Suppose that the `user` table looks like this:

| Host           | User    | ... |
|----------------|---------|-----|
| %              | jeffrey | ... |
| thomas.loc.gov |         | ... |

The sorted table looks like this:

| Host           | User    | ... |
|----------------|---------|-----|
| thomas.loc.gov |         | ... |
| %              | jeffrey | ... |

A connection by `jeffrey` from `thomas.loc.gov` is matched by the first row, whereas a connection by `jeffrey` from any host is matched by the second.

#### Note

It is a common misconception to think that, for a given user name, all rows that explicitly name that user are used first when the server attempts to find a match for the connection. This is not true. The preceding example illustrates this, where a connection from `thomas.loc.gov` by `jeffrey` is first matched not by the row containing '`jeffrey`' as the `User` column value, but by the row with no user name. As a result, `jeffrey` is authenticated as an anonymous user, even though he specified a user name when connecting.

If you are able to connect to the server, but your privileges are not what you expect, you probably are being authenticated as some other account. To find out what account the server used to authenticate you, use the `CURRENT_USER( )` function. (See [Section 13.14, "Information Functions"](#).) It returns a value in `user_name@host_name` format that indicates the `User` and `Host` values from the matching `user` table row. Suppose that `jeffrey` connects and issues the following query:

```
mysql> SELECT CURRENT_USER();
+-----+
| CURRENT_USER() |
+-----+
| @localhost      |
+-----+
```

The result shown here indicates that the matching `user` table row had a blank `User` column value. In other words, the server is treating `jeffrey` as an anonymous user.

Another way to diagnose authentication problems is to print out the `user` table and sort it by hand to see where the first match is being made.

## 7.2.5 Access Control, Stage 2: Request Verification

After you establish a connection, the server enters Stage 2 of access control. For each request that you issue through that connection, the server determines what operation you want to perform, then checks whether you have sufficient privileges to do so. This is where the privilege columns in the grant tables come into play. These privileges can come from any of the `user`, `db`, `tables_priv`, `columns_priv`, or `procs_priv` tables. (You may find it helpful to refer to [Section 7.2.2, “Grant Tables”](#), which lists the columns present in each of the grant tables.)

The `user` table grants privileges that are assigned to you on a global basis and that apply no matter what the default database is. For example, if the `user` table grants you the `DELETE` privilege, you can delete rows from any table in any database on the server host! It is wise to grant privileges in the `user` table only to people who need them, such as database administrators. For other users, you should leave all privileges in the `user` table set to `'N'` and grant privileges at more specific levels only. You can grant privileges for particular databases, tables, columns, or routines.

The `db` table grants database-specific privileges. Values in the scope columns of this table can take the following forms:

- A blank `User` value matches the anonymous user. A nonblank value matches literally; there are no wildcards in user names.
- The wildcard characters `%` and `_` can be used in the `Host` and `Db` columns. These have the same meaning as for pattern-matching operations performed with the `LIKE` operator. If you want to use either character literally when granting privileges, you must escape it with a backslash. For example, to include the underscore character (`_`) as part of a database name, specify it as `\_` in the `GRANT` statement.
- A `'%'` or blank `Host` value means “any host.”
- A `'%'` or blank `Db` value means “any database.”

The server reads the `db` table into memory and sorts it at the same time that it reads the `user` table. The server sorts the `db` table based on the `Host`, `Db`, and `User` scope columns. As with the `user` table, sorting puts the most-specific values first and least-specific values last, and when the server looks for matching rows, it uses the first match that it finds.

The `tables_priv`, `columns_priv`, and `procs_priv` tables grant table-specific, column-specific, and routine-specific privileges. Values in the scope columns of these tables can take the following forms:

- The wildcard characters `%` and `_` can be used in the `Host` column. These have the same meaning as for pattern-matching operations performed with the `LIKE` operator.
- A `'%'` or blank `Host` value means “any host.”
- The `Db`, `Table_name`, `Column_name`, and `Routine_name` columns cannot contain wildcards or be blank.

The server sorts the `tables_priv`, `columns_priv`, and `procs_priv` tables based on the `Host`, `Db`, and `User` columns. This is similar to `db` table sorting, but simpler because only the `Host` column can contain wildcards.

The server uses the sorted tables to verify each request that it receives. For requests that require administrative privileges such as `SHUTDOWN` or `RELOAD`, the server checks only the `user` table row because that is the only table that specifies administrative privileges. The server grants access if the row permits the requested operation and denies access otherwise. For example, if you want to execute `mysqladmin shutdown` but your `user` table row does not grant the `SHUTDOWN` privilege to you, the server denies access without even checking the `db` table. (It contains no `Shutdown_priv` column, so there is no need to do so.)

For database-related requests (`INSERT`, `UPDATE`, and so on), the server first checks the user's global privileges by looking in the `user` table row. If the row permits the requested operation, access is granted. If the global privileges in the `user` table are insufficient, the server determines the user's database-specific privileges by checking the `db` table:

The server looks in the `db` table for a match on the `Host`, `Db`, and `User` columns. The `Host` and `User` columns are matched to the connecting user's host name and MySQL user name. The `Db` column is matched to the database that the user wants to access. If there is no row for the `Host` and `User`, access is denied.

After determining the database-specific privileges granted by the `db` table rows, the server adds them to the global privileges granted by the `user` table. If the result permits the requested operation, access is granted. Otherwise, the server successively checks the user's table and column privileges in the `tables_priv` and `columns_priv` tables, adds those to the user's privileges, and permits or denies access based on the result. For stored-routine operations, the server uses the `procs_priv` table rather than `tables_priv` and `columns_priv`.

Expressed in boolean terms, the preceding description of how a user's privileges are calculated may be summarized like this:

```
global privileges
OR (database privileges AND host privileges)
OR table privileges
OR column privileges
OR routine privileges
```

It may not be apparent why, if the global `user` row privileges are initially found to be insufficient for the requested operation, the server adds those privileges to the database, table, and column privileges later. The reason is that a request might require more than one type of privilege. For example, if you execute an `INSERT INTO ... SELECT` statement, you need both the `INSERT` and the `SELECT` privileges. Your privileges might be such that the `user` table row grants one privilege and the `db` table row grants the other. In this case, you have the necessary privileges to perform the request, but the server cannot tell that from either table by itself; the privileges granted by the rows in both tables must be combined.

## 7.2.6 When Privilege Changes Take Effect

When `mysqld` starts, it reads all grant table contents into memory. The in-memory tables become effective for access control at that point.

If you modify the grant tables indirectly using account-management statements such as `GRANT`, `REVOKE`, `SET PASSWORD`, or `RENAME USER`, the server notices these changes and loads the grant tables into memory again immediately.

If you modify the grant tables directly using statements such as `INSERT`, `UPDATE`, or `DELETE`, your changes have no effect on privilege checking until you either restart the server or tell it to reload the tables. If you change the grant tables directly but forget to reload them, your changes have *no effect* until you restart the server. This may leave you wondering why your changes seem to make no difference!

To tell the server to reload the grant tables, perform a flush-privileges operation. This can be done by issuing a `FLUSH PRIVILEGES` statement or by executing a `mysqladmin flush-privileges` or `mysqladmin reload` command.

A grant table reload affects privileges for each existing client connection as follows:

- Table and column privilege changes take effect with the client's next request.
- Database privilege changes take effect the next time the client executes a `USE db_name` statement.

#### Note

Client applications may cache the database name; thus, this effect may not be visible to them without actually changing to a different database or flushing the privileges.

- Global privileges and passwords are unaffected for a connected client. These changes take effect only for subsequent connections.

If the server is started with the `--skip-grant-tables` option, it does not read the grant tables or implement any access control. Anyone can connect and do anything, *which is insecure*. To cause a server thus started to read the tables and enable access checking, flush the privileges.

## 7.2.7 Troubleshooting Problems Connecting to MySQL

If you encounter problems when you try to connect to the MySQL server, the following items describe some courses of action you can take to correct the problem.

- Make sure that the server is running. If it is not, clients cannot connect to it. For example, if an attempt to connect to the server fails with a message such as one of those following, one cause might be that the server is not running:

```
shell> mysql
ERROR 2003: Can't connect to MySQL server on 'host_name' (111)
shell> mysql
ERROR 2002: Can't connect to local MySQL server through socket
'/tmp/mysql.sock' (111)
```

- It might be that the server is running, but you are trying to connect using a TCP/IP port, named pipe, or Unix socket file different from the one on which the server is listening. To correct this when you invoke a client program, specify a `--port` option to indicate the proper port number, or a `--socket` option to indicate the proper named pipe or Unix socket file. To find out where the socket file is, you can use this command:

```
shell> netstat -ln | grep mysql
```

- Make sure that the server has not been configured to ignore network connections or (if you are attempting to connect remotely) that it has not been configured to listen only locally on its network interfaces. If the server was started with `--skip-networking`, it will not accept TCP/IP connections at all. If the server was started with `--bind-address=127.0.0.1`, it will listen for TCP/IP connections only locally on the loopback interface and will not accept remote connections.
- Check to make sure that there is no firewall blocking access to MySQL. Your firewall may be configured on the basis of the application being executed, or the port number used by MySQL for communication (3306 by default). Under Linux or Unix, check your IP tables (or similar) configuration to ensure that the port has not been blocked. Under Windows, applications such as ZoneAlarm or Windows Firewall may need to be configured not to block the MySQL port.
- The grant tables must be properly set up so that the server can use them for access control. For some distribution types (such as binary distributions on Windows, or RPM distributions on Linux), the

installation process initializes the MySQL data directory, including the `mysql` database containing the grant tables. For distributions that do not do this, you must initialize the data directory manually. For details, see [Section 2.10, “Postinstallation Setup and Testing”](#).

To determine whether you need to initialize the grant tables, look for a `mysql` directory under the data directory. (The data directory normally is named `data` or `var` and is located under your MySQL installation directory.) Make sure that you have a file named `user.MYD` in the `mysql` database directory. If not, initialize the data directory. After doing so and starting the server, test the initial privileges by executing this command:

```
shell> mysql -u root
```

The server should let you connect without error.

- After a fresh installation, you should connect to the server and set up your users and their access permissions:

```
shell> mysql -u root mysql
```

The server should let you connect with no password if you initialized MySQL using `mysqld --initialize-secure` to not create a password for the initial `root` account (see [Section 2.10.1.1, “Initializing the Data Directory Manually Using mysqld”](#)). That is a security risk, so setting the password for the `root` account is something you should do while you're setting up your other MySQL accounts. For instructions on setting the initial password, see [Section 2.10.4, “Securing the Initial MySQL Accounts”](#).

- If you have updated an existing MySQL installation to a newer version, did you run the `mysql_upgrade` script? If not, do so. The structure of the grant tables changes occasionally when new capabilities are added, so after an upgrade you should always make sure that your tables have the current structure. For instructions, see [Section 5.4.7, “mysql\\_upgrade — Check and Upgrade MySQL Tables”](#).
- If a client program receives the following error message when it tries to connect, it means that the server expects passwords in a newer format than the client is capable of generating:

```
shell> mysql
Client does not support authentication protocol requested
by server; consider upgrading MySQL client
```

For information on how to deal with this, see [Section 7.1.2.4, “Password Hashing in MySQL”](#), and [Section B.5.2.4, “Client does not support authentication protocol”](#).

- Remember that client programs use connection parameters specified in option files or environment variables. If a client program seems to be sending incorrect default connection parameters when you have not specified them on the command line, check any applicable option files and your environment. For example, if you get `Access denied` when you run a client without any options, make sure that you have not specified an old password in any of your option files!

You can suppress the use of option files by a client program by invoking it with the `--no-defaults` option. For example:

```
shell> mysqladmin --no-defaults -u root version
```

The option files that clients use are listed in [Section 5.2.6, “Using Option Files”](#). Environment variables are listed in [Section 5.9, “MySQL Program Environment Variables”](#).

- If you get the following error, it means that you are using an incorrect `root` password:

```
shell> mysqladmin -u root -pxxxx ver
```

```
Access denied for user 'root'@'localhost' (using password: YES)
```

If the preceding error occurs even when you have not specified a password, it means that you have an incorrect password listed in some option file. Try the `--no-defaults` option as described in the previous item.

For information on changing passwords, see [Section 7.3.5, “Assigning Account Passwords”](#).

If you have lost or forgotten the `root` password, see [Section B.5.3.2, “How to Reset the Root Password”](#).

- If you change a password by using `SET PASSWORD`, `INSERT`, or `UPDATE`, you must encrypt the password using the `PASSWORD()` function. If you do not use `PASSWORD()` for these statements, the password will not work. For example, the following statement assigns a password, but fails to encrypt it, so the user is not able to connect afterward:

```
SET PASSWORD FOR 'abe'@'host_name' = 'eagle';
```

Instead, set the password like this:

```
SET PASSWORD FOR 'abe'@'host_name' = PASSWORD('eagle');
```

The `PASSWORD()` function is unnecessary when you specify a password using the `CREATE USER` or `GRANT` statements or the `mysqladmin password` command. Each of those automatically uses `PASSWORD()` to encrypt the password. See [Section 7.3.5, “Assigning Account Passwords”](#), and [Section 14.7.1.2, “CREATE USER Syntax”](#).

- `localhost` is a synonym for your local host name, and is also the default host to which clients try to connect if you specify no host explicitly.

You can use a `--host=127.0.0.1` option to name the server host explicitly. This will make a TCP/IP connection to the local `mysqld` server. You can also use TCP/IP by specifying a `--host` option that uses the actual host name of the local host. In this case, the host name must be specified in a `user` table row on the server host, even though you are running the client program on the same host as the server.

- The `Access denied` error message tells you who you are trying to log in as, the client host from which you are trying to connect, and whether you were using a password. Normally, you should have one row in the `user` table that exactly matches the host name and user name that were given in the error message. For example, if you get an error message that contains `using password: NO`, it means that you tried to log in without a password.
- If you get an `Access denied` error when trying to connect to the database with `mysql -u user_name`, you may have a problem with the `user` table. Check this by executing `mysql -u root mysql` and issuing this SQL statement:

```
SELECT * FROM user;
```

The result should include a row with the `Host` and `User` columns matching your client's host name and your MySQL user name.

- If the following error occurs when you try to connect from a host other than the one on which the MySQL server is running, it means that there is no row in the `user` table with a `Host` value that matches the client host:

```
Host ... is not allowed to connect to this MySQL server
```

You can fix this by setting up an account for the combination of client host name and user name that you are using when trying to connect.

If you do not know the IP address or host name of the machine from which you are connecting, you should put a row with `'%'` as the `Host` column value in the `user` table. After trying to connect from the client machine, use a `SELECT USER()` query to see how you really did connect. Then change the `'%'` in the `user` table row to the actual host name that shows up in the log. Otherwise, your system is left insecure because it permits connections from any host for the given user name.

On Linux, another reason that this error might occur is that you are using a binary MySQL version that is compiled with a different version of the `glibc` library than the one you are using. In this case, you should either upgrade your operating system or `glibc`, or download a source distribution of MySQL version and compile it yourself. A source RPM is normally trivial to compile and install, so this is not a big problem.

- If you specify a host name when trying to connect, but get an error message where the host name is not shown or is an IP address, it means that the MySQL server got an error when trying to resolve the IP address of the client host to a name:

```
shell> mysqladmin -u root -pxxxx -h some_hostname ver
Access denied for user 'root'@'' (using password: YES)
```

If you try to connect as `root` and get the following error, it means that you do not have a row in the `user` table with a `User` column value of `'root'` and that `mysqld` cannot resolve the host name for your client:

```
Access denied for user ''@'unknown'
```

These errors indicate a DNS problem. To fix it, execute `mysqladmin flush-hosts` to reset the internal DNS host cache. See [Section 9.12.5.2, “DNS Lookup Optimization and the Host Cache”](#).

Some permanent solutions are:

- Determine what is wrong with your DNS server and fix it.
- Specify IP addresses rather than host names in the MySQL grant tables.
- Put an entry for the client machine name in `/etc/hosts` on Unix or `\windows\hosts` on Windows.
- Start `mysqld` with the `--skip-name-resolve` option.
- Start `mysqld` with the `--skip-host-cache` option.
- On Unix, if you are running the server and the client on the same machine, connect to `localhost`. For connections to `localhost`, MySQL programs attempt to connect to the local server by using a Unix socket file, unless there are connection parameters specified to ensure that the client makes a TCP/IP connection. For more information, see [Section 5.2.2, “Connecting to the MySQL Server”](#).
- On Windows, if you are running the server and the client on the same machine and the server supports named pipe connections, connect to the host name `.` (period). Connections to `.` use a named pipe rather than TCP/IP.
- If `mysql -u root` works but `mysql -h your_hostname -u root` results in `Access denied` (where `your_hostname` is the actual host name of the local host), you may not have the correct name for your host in the `user` table. A common problem here is that the `Host` value in the `user` table row specifies an unqualified host name, but your system's name resolution routines return a fully qualified domain name (or vice versa). For example, if you have a row with host `'pluto'` in the `user` table, but your DNS tells MySQL that your host name is `'pluto.example.com'`, the row does not work. Try adding a row to the `user` table that contains the IP address of your host as the `Host` column value. (Alternatively, you could add a row to the `user` table with a `Host` value

that contains a wildcard; for example, 'pluto.%'. However, use of `Host` values ending with % is *insecure* and is *not* recommended!)

- If `mysql -u user_name` works but `mysql -u user_name some_db` does not, you have not granted access to the given user for the database named `some_db`.
- If `mysql -u user_name` works when executed on the server host, but `mysql -h host_name -u user_name` does not work when executed on a remote client host, you have not enabled access to the server for the given user name from the remote host.
- If you cannot figure out why you get `Access denied`, remove from the `user` table all rows that have `Host` values containing wildcards (rows that contain '%' or '\_' characters). A very common error is to insert a new row with `Host='%'` and `User='some_user'`, thinking that this enables you to specify `localhost` to connect from the same machine. The reason that this does not work is that the default privileges include a row with `Host='localhost'` and `User=''`. Because that row has a `Host` value 'localhost' that is more specific than '%', it is used in preference to the new row when connecting from `localhost`! The correct procedure is to insert a second row with `Host='localhost'` and `User='some_user'`, or to delete the row with `Host='localhost'` and `User=''`. After deleting the row, remember to issue a `FLUSH PRIVILEGES` statement to reload the grant tables. See also [Section 7.2.4, “Access Control, Stage 1: Connection Verification”](#).
- If you are able to connect to the MySQL server, but get an `Access denied` message whenever you issue a `SELECT ... INTO OUTFILE` or `LOAD DATA INFILE` statement, your row in the `user` table does not have the `FILE` privilege enabled.
- If you change the grant tables directly (for example, by using `INSERT`, `UPDATE`, or `DELETE` statements) and your changes seem to be ignored, remember that you must execute a `FLUSH PRIVILEGES` statement or a `mysqladmin flush-privileges` command to cause the server to reload the privilege tables. Otherwise, your changes have no effect until the next time the server is restarted. Remember that after you change the `root` password with an `UPDATE` statement, you will not need to specify the new password until after you flush the privileges, because the server will not know you've changed the password yet!
- If your privileges seem to have changed in the middle of a session, it may be that a MySQL administrator has changed them. Reloading the grant tables affects new client connections, but it also affects existing connections as indicated in [Section 7.2.6, “When Privilege Changes Take Effect”](#).
- If you have access problems with a Perl, PHP, Python, or ODBC program, try to connect to the server with `mysql -u user_name db_name` or `mysql -u user_name -pyour_pass db_name`. If you are able to connect using the `mysql` client, the problem lies with your program, not with the access privileges. (There is no space between `-p` and the password; you can also use the `--password=your_pass` syntax to specify the password. If you use the `-p` or `--password` option with no password value, MySQL prompts you for the password.)
- For testing purposes, start the `mysqld` server with the `--skip-grant-tables` option. Then you can change the MySQL grant tables and use the `SHOW GRANTS` statement to check whether your modifications have the desired effect. When you are satisfied with your changes, execute `mysqladmin flush-privileges` to tell the `mysqld` server to reload the privileges. This enables you to begin using the new grant table contents without stopping and restarting the server.
- If everything else fails, start the `mysqld` server with a debugging option (for example, `--debug=d,general,query`). This prints host and user information about attempted connections, as well as information about each command issued. See [Section 27.5.3, “The DEBUG Package”](#).
- If you have any other problems with the MySQL grant tables and feel you must post the problem to the mailing list, always provide a dump of the MySQL grant tables. You can dump the tables with the `mysqldump mysql` command. To file a bug report, see the instructions at [Section 1.7, “How to Report Bugs or Problems”](#). In some cases, you may need to restart `mysqld` with `--skip-grant-tables` to run `mysqldump`.

## 7.3 MySQL User Account Management

This section describes how to set up accounts for clients of your MySQL server. It discusses the following topics:

- The meaning of account names and passwords as used in MySQL and how that compares to names and passwords used by your operating system
- How to set up new accounts and remove existing accounts
- How to change passwords
- Guidelines for using passwords securely

See also [Section 14.7.1, “Account Management Statements”](#), which describes the syntax and use for all user-management SQL statements.

### 7.3.1 User Names and Passwords

MySQL stores accounts in the `user` table of the `mysql` system database. An account is defined in terms of a user name and the client host or hosts from which the user can connect to the server. For information about account representation in the `user` table, see [Section 7.2.2, “Grant Tables”](#).

The account may also have a password. MySQL supports authentication plugins, so it is possible that an account authenticates using some external authentication method. See [Section 7.3.8, “Pluggable Authentication”](#).

There are several distinctions between the way user names and passwords are used by MySQL and your operating system:

- User names, as used by MySQL for authentication purposes, have nothing to do with user names (login names) as used by Windows or Unix. On Unix, most MySQL clients by default try to log in using the current Unix user name as the MySQL user name, but that is for convenience only. The default can be overridden easily, because client programs permit any user name to be specified with a `-u` or `--user` option. This means that anyone can attempt to connect to the server using any user name, so you cannot make a database secure in any way unless all MySQL accounts have passwords. Anyone who specifies a user name for an account that has no password is able to connect successfully to the server.
- MySQL user names can be up to 32 characters long (16 characters before MySQL 5.7.8). Operating system user names may be of a different maximum length. For example, Unix user names typically are limited to eight characters.

#### Warning

The limit on MySQL user name length is hardcoded in MySQL servers and clients, and trying to circumvent it by modifying the definitions of the tables in the `mysql` database *does not work*.

You should never alter the structure of tables in the `mysql` database in any manner whatsoever except by means of the procedure that is described in [Section 5.4.7, “mysql\\_upgrade — Check and Upgrade MySQL Tables”](#). Attempting to redefine MySQL's system tables in any other fashion results in undefined (and unsupported!) behavior. The server is free to ignore rows that become malformed as a result of such modifications.

- To authenticate client connections for accounts that use MySQL native authentication (implemented by the `mysql_native_password` authentication plugin), the server uses passwords stored in the `user` table. These passwords are distinct from passwords for logging in to your operating system. There is no necessary connection between the “external” password you use to log in to a Windows or Unix machine and the password you use to access the MySQL server on that machine.

If the server authenticates a client using some other plugin, the authentication method that the plugin implements may or may not use a password stored in the `user` table. In this case, it is possible that an external password is also used to authenticate to the MySQL server.

- Passwords stored in the `user` table are encrypted using plugin-specific algorithms. For information about MySQL native password hashing, see [Section 7.1.2.4, “Password Hashing in MySQL”](#).
- If the user name and password contain only ASCII characters, it is possible to connect to the server regardless of character set settings. To connect when the user name or password contain non-ASCII characters, the client should call the `mysql_options()` C API function with the `MYSQL_SET_CHARSET_NAME` option and appropriate character set name as arguments. This causes authentication to take place using the specified character set. Otherwise, authentication will fail unless the server default character set is the same as the encoding in the authentication defaults.

Standard MySQL client programs support a `--default-character-set` option that causes `mysql_options()` to be called as just described. In addition, character set autodetection is supported as described in [Section 11.1.4, “Connection Character Sets and Collations”](#). For programs that use a connector that is not based on the C API, the connector may provide an equivalent to `mysql_options()` that can be used instead. Check the connector documentation.

The preceding notes do not apply for `ucs2`, `utf16`, and `utf32`, which are not permitted as client character sets.

The MySQL installation process populates the grant tables with an initial `root` account, as described in [Section 2.10.4, “Securing the Initial MySQL Accounts”](#), which also discusses how to assign passwords to it. Thereafter, you normally set up, modify, and remove MySQL accounts using statements such as `CREATE USER`, `DROP USER`, `GRANT`, and `REVOKE`. See [Section 14.7.1, “Account Management Statements”](#).

To connect to a MySQL server with a command-line client, specify user name and password options as necessary for the account that you want to use:

```
shell> mysql --user=finley --password db_name
```

If you prefer short options, the command looks like this:

```
shell> mysql -u finley -p db_name
```

If you omit the password value following the `--password` or `-p` option on the command line (as just shown), the client prompts for one. Alternatively, the password can be specified on the command line:

```
shell> mysql --user=finley --password=password db_name
shell> mysql -u finley -ppassword db_name
```

If you use the `-p` option, there must be *no space* between `-p` and the following password value.

Specifying a password on the command line should be considered insecure. See [Section 7.1.2.1, “End-User Guidelines for Password Security”](#). You can use an option file or a login path file to avoid giving the password on the command line. See [Section 5.2.6, “Using Option Files”](#), and [Section 5.6.6, “mysql\\_config\\_editor — MySQL Configuration Utility”](#).

For additional information about specifying user names, passwords, and other connection parameters, see [Section 5.2.2, “Connecting to the MySQL Server”](#).

## 7.3.2 Adding User Accounts

You can create MySQL accounts two ways:

- By using account-management statements intended for creating accounts and establishing their privileges, such as `CREATE USER` and `GRANT`. These statements cause the server to make appropriate modifications to the underlying grant tables.
- By manipulating the MySQL grant tables directly with statements such as `INSERT`, `UPDATE`, or `DELETE`.

The preferred method is to use account-management statements because they are more concise and less error-prone than manipulating the grant tables directly. All such statements are described in [Section 14.7.1, “Account Management Statements”](#). Direct grant table manipulation is discouraged, and is not described here. The server is free to ignore rows that become malformed as a result of such modifications.

Another option for creating accounts is to use the GUI tool MySQL Workbench. Also, several third-party programs offer capabilities for MySQL account administration. [phpMyAdmin](#) is one such program.

The following examples show how to use the `mysql` client program to set up new accounts. These examples assume that privileges have been set up according to the defaults described in [Section 2.10.4, “Securing the Initial MySQL Accounts”](#). This means that to make changes, you must connect to the MySQL server as the MySQL `root` user, which has the `CREATE USER` privilege.

First, use the `mysql` program to connect to the server as the MySQL `root` user:

```
shell> mysql --user=root mysql
```

If you have assigned a password to the `root` account, you must also supply a `--password` or `-p` option.

After connecting to the server as `root`, you can add new accounts. The following example uses `CREATE USER` and `GRANT` statements to set up four accounts:

```
mysql> CREATE USER 'finley'@'localhost' IDENTIFIED BY 'some_pass';
mysql> GRANT ALL PRIVILEGES ON *.* TO 'finley'@'localhost'
-> WITH GRANT OPTION;
mysql> CREATE USER 'finley'@'%' IDENTIFIED BY 'some_pass';
mysql> GRANT ALL PRIVILEGES ON *.* TO 'finley'@'%'
-> WITH GRANT OPTION;
mysql> CREATE USER 'admin'@'localhost' IDENTIFIED BY 'admin_pass';
mysql> GRANT RELOAD,PROCESS ON *.* TO 'admin'@'localhost';
mysql> CREATE USER 'dummy'@'localhost';
```

The accounts created by those statements have the following properties:

- Two accounts have a user name of `finley` and a password of `some_pass`. Both are superuser accounts with full privileges to do anything. The `'finley'@'localhost'` account can be used only when connecting from the local host. The `'finley'@'%'` account uses the `'%'` wildcard for the host part, so it can be used to connect from any host.

The `'finley'@'localhost'` account is necessary if there is an anonymous-user account for `localhost`. Without the `'finley'@'localhost'` account, that anonymous-user account takes precedence when `finley` connects from the local host and `finley` is treated as an anonymous user. The reason for this is that the anonymous-user account has a more specific `Host` column value than the `'finley'@'%'` account and thus comes earlier in the `user` table sort order. (`user` table sorting is discussed in [Section 7.2.4, “Access Control, Stage 1: Connection Verification”](#).)

- The `'admin'@'localhost'` account has a password of `admin_pass`. This account can be used only by `admin` to connect from the local host. It is granted the `RELOAD` and `PROCESS` administrative privileges. These privileges enable the `admin` user to execute the `mysqladmin reload`, `mysqladmin refresh`, and `mysqladmin flush-xxx` commands, as well as `mysqladmin processlist`. No privileges are granted for accessing any databases. You could add such privileges using `GRANT` statements.

- The 'dummy'@'localhost' account has no password (which is insecure and not recommended). This account can be used only to connect from the local host. No privileges are granted. It is assumed that you will grant specific privileges to the account using `GRANT` statements.

To see the privileges for an account, use `SHOW GRANTS`:

```
mysql> SHOW GRANTS FOR 'admin'@'localhost';
+-----+
| Grants for admin@localhost |
+-----+
| GRANT RELOAD, PROCESS ON *.* TO 'admin'@'localhost' |
+-----+
```

To see nonprivilege properties for an account, use `SHOW CREATE USER`:

```
mysql> SHOW CREATE USER 'admin'@'localhost'\G
***** 1. row *****
CREATE USER for admin@localhost: CREATE USER 'admin'@'localhost'
IDENTIFIED WITH 'mysql_native_password'
AS '*67ACDEBDAB923990001F0FFB017EB8ED41861105'
REQUIRE NONE PASSWORD EXPIRE DEFAULT ACCOUNT UNLOCK
```

The next examples create three accounts and grant them access to specific databases. Each of them has a user name of `custom` and password of `obscure`:

```
mysql> CREATE USER 'custom'@'localhost' IDENTIFIED BY 'obscure';
mysql> GRANT SELECT,INSERT,UPDATE,DELETE,CREATE,DROP
-> ON bankaccount.*
-> TO 'custom'@'localhost';
mysql> CREATE USER 'custom'@'host47.example.com' IDENTIFIED BY 'obscure';
mysql> GRANT SELECT,INSERT,UPDATE,DELETE,CREATE,DROP
-> ON expenses.*
-> TO 'custom'@'host47.example.com';
mysql> CREATE USER 'custom'@'%.example.com' IDENTIFIED BY 'obscure';
mysql> GRANT SELECT,INSERT,UPDATE,DELETE,CREATE,DROP
-> ON customer.*
-> TO 'custom'@'%.example.com';
```

The three accounts can be used as follows:

- The first account can access the `bankaccount` database, but only from the local host.
- The second account can access the `expenses` database, but only from the host `host47.example.com`.
- The third account can access the `customer` database, from any host in the `example.com` domain. This account has access from all machines in the domain due to use of the `%` wildcard character in the host part of the account name.

### 7.3.3 Removing User Accounts

To remove an account, use the `DROP USER` statement, which is described in [Section 14.7.1.3, “DROP USER Syntax”](#). For example:

```
mysql> DROP USER 'jeffrey'@'localhost';
```

### 7.3.4 Setting Account Resource Limits

One means of restricting client use of MySQL server resources is to set the global `max_user_connections` system variable to a nonzero value. This limits the number of simultaneous connections that can be made by any given account, but places no limits on what a client can do once connected. In addition, setting `max_user_connections` does not enable management of individual accounts. Both types of control are of interest to MySQL administrators.

To address such concerns, MySQL permits limits for individual accounts on use of these server resources:

- The number of queries an account can issue per hour
- The number of updates an account can issue per hour
- The number of times an account can connect to the server per hour
- The number of simultaneous connections to the server by an account

Any statement that a client can issue counts against the query limit, unless its results are served from the query cache. Only statements that modify databases or tables count against the update limit.

An “account” in this context corresponds to a row in the `mysql.user` table. That is, a connection is assessed against the `User` and `Host` values in the `user` table row that applies to the connection. For example, an account `'usera'@'%.example.com'` corresponds to a row in the `user` table that has `User` and `Host` values of `usera` and `%.example.com`, to permit `usera` to connect from any host in the `example.com` domain. In this case, the server applies resource limits in this row collectively to all connections by `usera` from any host in the `example.com` domain because all such connections use the same account.

Before MySQL 5.0.3, an “account” was assessed against the actual host from which a user connects. This older method of accounting may be selected by starting the server with the `--old-style-user-limits` option. In this case, if `usera` connects simultaneously from `host1.example.com` and `host2.example.com`, the server applies the account resource limits separately to each connection. If `usera` connects again from `host1.example.com`, the server applies the limits for that connection together with the existing connection from that host.

To establish resource limits for an account at account-creation time, use the `CREATE USER` statement. To modify the limits for an existing account, use `ALTER USER`. (Before MySQL 5.7.6, use `GRANT`, for new or existing accounts.) Provide a `WITH` clause that names each resource to be limited. The default value for each limit is zero (no limit). For example, to create a new account that can access the `customer` database, but only in a limited fashion, issue these statements:

```
mysql> CREATE USER 'francis'@'localhost' IDENTIFIED BY 'frank'
->     WITH MAX_QUERIES_PER_HOUR 20
->         MAX_UPDATES_PER_HOUR 10
->         MAX_CONNECTIONS_PER_HOUR 5
->         MAX_USER_CONNECTIONS 2;
```

The limit types need not all be named in the `WITH` clause, but those named can be present in any order. The value for each per-hour limit should be an integer representing a count per hour. For `MAX_USER_CONNECTIONS`, the limit is an integer representing the maximum number of simultaneous connections by the account. If this limit is set to zero, the global `max_user_connections` system variable value determines the number of simultaneous connections. If `max_user_connections` is also zero, there is no limit for the account.

To modify limits for an existing account, use an `ALTER USER` statement. The following statement changes the query limit for `francis` to 100:

```
mysql> ALTER USER 'francis'@'localhost' WITH MAX_QUERIES_PER_HOUR 100;
```

The statement modifies only the limit value specified and leaves the account otherwise unchanged.

To remove a limit, set its value to zero. For example, to remove the limit on how many times per hour `francis` can connect, use this statement:

```
mysql> ALTER USER 'francis'@'localhost' WITH MAX_CONNECTIONS_PER_HOUR 0;
```

As mentioned previously, the simultaneous-connection limit for an account is determined from the `MAX_USER_CONNECTIONS` limit and the `max_user_connections` system variable. Suppose that the global `max_user_connections` value is 10 and three accounts have individual resource limits specified as follows:

```
ALTER USER 'user1'@'localhost' WITH MAX_USER_CONNECTIONS 0;  
ALTER USER 'user2'@'localhost' WITH MAX_USER_CONNECTIONS 5;  
ALTER USER 'user3'@'localhost' WITH MAX_USER_CONNECTIONS 20;
```

`user1` has a connection limit of 10 (the global `max_user_connections` value) because it has a `MAX_USER_CONNECTIONS` limit of zero. `user2` and `user3` have connection limits of 5 and 20, respectively, because they have nonzero `MAX_USER_CONNECTIONS` limits.

The server stores resource limits for an account in the `user` table row corresponding to the account. The `max_questions`, `max_updates`, and `max_connections` columns store the per-hour limits, and the `max_user_connections` column stores the `MAX_USER_CONNECTIONS` limit. (See [Section 7.2.2, “Grant Tables”](#).)

Resource-use counting takes place when any account has a nonzero limit placed on its use of any of the resources.

As the server runs, it counts the number of times each account uses resources. If an account reaches its limit on number of connections within the last hour, the server rejects further connections for the account until that hour is up. Similarly, if the account reaches its limit on the number of queries or updates, the server rejects further queries or updates until the hour is up. In all such cases, the server issues appropriate error messages.

Resource counting occurs per account, not per client. For example, if your account has a query limit of 50, you cannot increase your limit to 100 by making two simultaneous client connections to the server. Queries issued on both connections are counted together.

The current per-hour resource-use counts can be reset globally for all accounts, or individually for a given account:

- To reset the current counts to zero for all accounts, issue a `FLUSH USER_RESOURCES` statement. The counts also can be reset by reloading the grant tables (for example, with a `FLUSH PRIVILEGES` statement or a `mysqladmin reload` command).
- The counts for an individual account can be reset to zero by setting any of its limits again. Specify a limit value equal to the value currently assigned to the account.

Per-hour counter resets do not affect the `MAX_USER_CONNECTIONS` limit.

All counts begin at zero when the server starts. Counts do not carry over through server restarts.

For the `MAX_USER_CONNECTIONS` limit, an edge case can occur if the account currently has open the maximum number of connections permitted to it: A disconnect followed quickly by a connect can result in an error (`ER_TOO_MANY_USER_CONNECTIONS` or `ER_USER_LIMIT_REACHED`) if the server has not fully processed the disconnect by the time the connect occurs. When the server finishes disconnect processing, another connection will once more be permitted.

## 7.3.5 Assigning Account Passwords

Required credentials for clients that connect to the MySQL server can include a password. This section describes how to assign passwords for MySQL accounts.

MySQL stores passwords in the `user` table in the `mysql` system database. Operations that assign or modify passwords are permitted only to users with the `CREATE USER` privilege, or, alternatively, privileges for the `mysql` database (`INSERT` privilege to create new accounts, `UPDATE` privilege to modify existing accounts). If the `read_only` system variable is enabled, use of account-modification statements such as `CREATE USER` or `SET PASSWORD` additionally requires the `SUPER` privilege.

The discussion here summarizes syntax only for the most common password-assignment statements. For complete details on other possibilities, see [Section 14.7.1.2, “CREATE USER Syntax”](#), [Section 14.7.1.1, “ALTER USER Syntax”](#), [Section 14.7.1.4, “GRANT Syntax”](#), and [Section 14.7.1.7, “SET PASSWORD Syntax”](#).

MySQL hashes passwords stored in the `mysql.user` table to obfuscate them. For most statements described here, MySQL automatically hashes the password specified. An exception is `SET PASSWORD ... = PASSWORD('auth_string')`, for which you use the `PASSWORD()` function explicitly to hash the password. There are also syntaxes for `CREATE USER`, `ALTER USER`, `GRANT`, and `SET PASSWORD` that permit hashed values to be specified literally; for details, see the descriptions of those statements.

MySQL uses plugins to perform client authentication; see [Section 7.3.8, “Pluggable Authentication”](#). The authentication plugin associated with an account determines the algorithm used to hash passwords for that account.

To assign a password when you create a new account, use `CREATE USER` and include an `IDENTIFIED BY` clause:

```
mysql> CREATE USER 'jeffrey'@'localhost'
      -> IDENTIFIED BY 'mypass';
```

For this `CREATE USER` syntax, MySQL automatically hashes the password before storing it in the `mysql.user` table.

`CREATE USER` also supports syntax for specifying the account authentication plugin. See [Section 14.7.1.2, “CREATE USER Syntax”](#).

To assign or change a password for an existing account, use one of the following methods:

- Use the `ALTER USER` statement with an `IDENTIFIED BY` clause:

```
mysql> ALTER USER 'jeffrey'@'localhost'
      -> IDENTIFIED BY 'mypass';
```

If you are not connected as an anonymous user, you can change your own password without naming your own account literally:

```
mysql> ALTER USER USER()
      -> IDENTIFIED BY 'mypass';
```

For these `ALTER USER` syntaxes, MySQL automatically hashes the password before storing it in the `mysql.user` table.

`ALTER USER` syntax for changing passwords is available as of MySQL 5.7.6.

- Use `SET PASSWORD` with the `PASSWORD()` function:

```
mysql> SET PASSWORD FOR
      -> 'jeffrey'@'localhost' = PASSWORD('mypass');
```

If you are not connected as an anonymous user, you can change your own password by omitting the `FOR` clause:

```
mysql> SET PASSWORD = PASSWORD('mypass');
```

The `PASSWORD()` function hashes the password using the hashing method determined by the value of the `old_passwords` system variable value. If `SET PASSWORD` rejects the hashed password value returned by `PASSWORD()` as not being in the correct format, it may be necessary to change `old_passwords` to change the hashing method. See [Section 14.7.1.7, “SET PASSWORD Syntax”](#).

**Note**

Use of `SET PASSWORD ... = PASSWORD('auth_string')` for password modification is deprecated as of MySQL 5.7.6. Use `ALTER USER` instead.

- Use `SET PASSWORD` without the `PASSWORD()` function:

For this syntax, the meaning *differs in MySQL 5.7.6 and higher from earlier versions*:

- As of MySQL 5.7.6, `SET PASSWORD` interprets the string as a cleartext string and hashes it appropriately for the account authentication plugin before storing it in the `mysql.user` account row.

```
mysql> SET PASSWORD FOR
-> 'jeffrey'@'localhost' = 'mypass';
```

- Before MySQL 5.7.6, `SET PASSWORD` interprets the string as a hashed password value to be stored directly.

```
mysql> SET PASSWORD FOR
-> 'jeffrey'@'localhost' = '*6C8989366EAF75BB670AD8EA7A7FC1176A95CEF4';
```

The string must be hashed in the format required by the account authentication plugin. A string not hashed appropriately causes client connections for the account to fail with an `Access denied` error.

- Use a `GRANT USAGE` statement at the global level (`ON *.* TO`) to change an account password without affecting the account's current privileges:

```
mysql> GRANT USAGE ON *.* TO 'jeffrey'@'localhost'
-> IDENTIFIED BY 'mypass';
```

For this `GRANT` syntax, MySQL automatically hashes the password before storing it in the `mysql.user` table.

**Note**

Use of `GRANT` for password modification is deprecated as of MySQL 5.7.6. Use `ALTER USER` instead.

- To change an account password from the command line, use the `mysqladmin` command:

```
shell> mysqladmin -u user_name -h host_name password "new_password"
```

The account for which this command sets the password is the one with a `mysql.user` table row that matches `user_name` in the `User` column and the client host *from which you connect* in the `Host` column.

For password changes made using `mysqladmin`, MySQL automatically hashes the password before storing it in the `mysql.user` table.

## 7.3.6 Password Expiration Policy

MySQL enables database administrators to expire account passwords manually, and to establish a policy for automatic password expiration.

To expire a password manually, the database administrator uses the `ALTER USER` statement:

```
ALTER USER 'jeffrey'@'localhost' PASSWORD EXPIRE;
```

This operation marks the password expired in the corresponding `mysql.user` table row.

Automatic password expiration is available in MySQL 5.7.4 and later. The `mysql.user` table indicates for each account when its password was last changed, and the server automatically treats the password as expired at client connection time if it is past its permitted lifetime. This works with no explicit manual password expiration.

The `default_password_lifetime` system variable defines the global automatic password expiration policy. It applies to accounts that use MySQL built-in authentication methods (accounts that use an authentication plugin of `mysql_native_password`, `mysql_old_password`, or `sha256_password`).

The default `default_password_lifetime` value is 0, which disables automatic password expiration. If the value of `default_password_lifetime` is a positive integer *N*, it indicates the permitted password lifetime; passwords must be changed every *N* days.

#### Note

From MySQL 5.7.4 to 5.7.10, the default `default_password_lifetime` value is 360 (passwords must be changed approximately once per year). For those versions, be aware that, if you make no changes to the `default_password_lifetime` variable or to individual user accounts, all user passwords will expire after 360 days, and all user accounts will start running in restricted mode when this happens. Clients (which are effectively users) connecting to the server will then get an error indicating that the password must be changed: `ERROR 1820 (HY000): You must reset your password using ALTER USER statement before executing this statement.`

However, this is easy to miss for clients that automatically connect to the server, such as connections made from scripts. To avoid having such clients suddenly stop working due to a password expiring, make sure to change the password expiration settings for those clients, like this:

```
ALTER USER 'script'@'localhost' PASSWORD EXPIRE NEVER
```

Alternatively, set the `default_password_lifetime` variable to 0, thus disabling automatic password expiration for all users.

Examples:

- To establish a global policy that passwords have a lifetime of approximately six months, start the server with these lines in an option file:

```
[mysqld]
default_password_lifetime=180
```

- To establish a global policy such that passwords never expire, set `default_password_lifetime` to 0:

```
[mysqld]
default_password_lifetime=0
```

- `default_password_lifetime` can also be changed at runtime (this requires the `SUPER` privilege):

```
SET GLOBAL default_password_lifetime = 180;
SET GLOBAL default_password_lifetime = 0;
```

No matter the global policy, it can be overridden for individual accounts with `ALTER USER`:

- Require the password to be changed every 90 days:

```
ALTER USER 'jeffrey'@'localhost' PASSWORD EXPIRE INTERVAL 90 DAY;
```

- Disable password expiration:

```
ALTER USER 'jeffrey'@'localhost' PASSWORD EXPIRE NEVER;
```

- Defer to the global expiration policy:

```
ALTER USER 'jeffrey'@'localhost' PASSWORD EXPIRE DEFAULT;
```

These `ALTER USER` statements update the corresponding `mysql.user` table row.

When a client successfully connects, the server determines whether the account password is expired:

- The server checks whether the password has been manually expired and, if so, restricts the session.
- Otherwise, the server checks whether the password is past its lifetime according to the automatic password expiration policy. If so, the server considers the password expired and restricts the session.

A restricted client operates in “sandbox mode,” which limits the operations permitted to the client (see [Section 7.3.7, “Password Expiration and Sandbox Mode”](#)). Operations performed by a restricted client result in an error until the user establishes a new account password:

```
mysql> SELECT 1;
ERROR 1820 (HY000): You must SET PASSWORD before executing this statement

mysql> ALTER USER USER() IDENTIFIED BY 'new_password';
Query OK, 0 rows affected (0.01 sec)

mysql> SELECT 1;
+----+
| 1 |
+----+
| 1 |
+----+
1 row in set (0.00 sec)
```

This restricted mode of operation permits `SET` statements, which is useful before MySQL 5.7.6 if `SET PASSWORD` must be used instead of `ALTER USER` and the account password has a hashing format that requires `old_passwords` to be set to a value different from its default.

It is possible for an administrative user to reset the account password, but any existing sessions for that account remain restricted. A client using the account must disconnect and reconnect before statements can be executed successfully.

#### Note

It is possible to “reset” a password by setting it to its current value. As a matter of good policy, it is preferable to choose a different password.

## 7.3.7 Password Expiration and Sandbox Mode

MySQL provides password-expiration capability to enable database administrators to expire account passwords and require users to reset their password. This section describes how password expiration works.

To expire an account password, use the `ALTER USER` statement. For example:

```
ALTER USER 'myuser'@'localhost' PASSWORD EXPIRE;
```

This statement modifies the row of the `mysql.user` table associated with the named account, setting the `password_expired` column to 'Y'. This does not affect any current connections the account has open. For each subsequent connection that uses the account, the server either disconnects the client or handles the client in “sandbox mode,” in which the server permits to the client only those operations necessary to reset the expired password. The action taken by the server depends on both client and server settings.

If the server disconnects the client, it returns an `ER_MUST_CHANGE_PASSWORD_LOGIN` error:

```
shell> mysql -u myuser -p
Password: *****
ERROR 1862 (HY000): Your password has expired. To log in you must
change it using a client that supports expired passwords.
```

If the server puts the client in sandbox mode, these operations are permitted within the client session:

- The client can reset the account password with `ALTER USER` or `SET PASSWORD`. This modifies the row of the `mysql.user` table associated with the current account, setting the `password_expired` column to 'N'. After the password has been reset, the server restores normal access for the session, as well as for subsequent connections that use the account.

It is possible to “reset” a password by setting it to its current value. As a matter of good policy, it is preferable to choose a different password.

- The client can use `SET` statements, which is useful before MySQL 5.7.6 if `SET PASSWORD` must be used instead of `ALTER USER` and the account password has a hashing format that requires `old_passwords` to be set to a value different from its default.

For any operation not permitted within the session, the server returns an `ER_MUST_CHANGE_PASSWORD` error:

```
mysql> USE performance_schema;
ERROR 1820 (HY000): You must SET PASSWORD before executing this statement

mysql> SELECT 1;
ERROR 1820 (HY000): You must SET PASSWORD before executing this statement
```

For noninteractive invocations of the `mysql` client (for example, in batch mode), the server normally disconnects the client if the password is expired. To permit `mysql` to stay connected so that the password can be changed (using the statements just described), add the `--connect-expired-password` option to the `mysql` command.

As mentioned previously, whether the server disconnects an expired-password client or puts it in sandbox mode depends on a combination of client and server settings. The following discussion describes the relevant settings and how they interact.

On the client side, a given client indicates whether it can handle sandbox mode for expired passwords. For clients that use the C client library, there are two ways to do this:

- Pass the `MYSQL_OPT_CAN_HANDLE_EXPIRED_PASSWORDS` flag to `mysql_options()` prior to connecting:

```
arg = 1;
result = mysql_options(mysql,
                        MYSQL_OPT_CAN_HANDLE_EXPIRED_PASSWORDS, &arg);
```

The `mysql` client enables `MYSQL_OPT_CAN_HANDLE_EXPIRED_PASSWORDS` if invoked interactively or the `--connect-expired-password` option is given.

- Pass the `CLIENT_CAN_HANDLE_EXPIRED_PASSWORDS` flag to `mysql_real_connect()` at connection time:

```
mysql = mysql_real_connect(mysql,
                           host, user, password, "test",
                           port, unix_socket,
                           CLIENT_CAN_HANDLE_EXPIRED_PASSWORDS);
```

Other MySQL Connectors have their own conventions for indicating readiness to handle sandbox mode. See the relevant Connector documentation.

On the server side, if a client indicates that it can handle expired passwords, the server puts it in sandbox mode.

If a client does not indicate that it can handle expired passwords (or uses an older version of the client library that cannot so indicate), the server action depends on the value of the `disconnect_on_expired_password` system variable:

- If `disconnect_on_expired_password` is enabled (the default), the server disconnects the client with an `ER_MUST_CHANGE_PASSWORD_LOGIN` error.
- If `disconnect_on_expired_password` is disabled, the server puts the client in sandbox mode.

The preceding client and server settings apply only for accounts with expired passwords. If a client connects using a nonexpired password, the server handles the client normally.

## 7.3.8 Pluggable Authentication

When a client connects to the MySQL server, the server uses the user name provided by the client and the client host to select the appropriate account row from the `mysql.user` table. The server then authenticates the client, determining from the account row which authentication plugin applies for the client:

- If the account row specifies a plugin, the server invokes it to authenticate the user. If the server cannot find the plugin, an error occurs.
- If the account row specifies no plugin name, the server authenticates the account using either the `mysql_native_password` or `mysql_old_password` plugin, depending on whether the password hash value in the `Password` column used native hashing or the older pre-4.1 hashing method. Clients must match the password in the `Password` column of the account row. As of MySQL 5.7.2, the server requires the plugin value to be nonempty, and as of 5.7.5, support for `mysql_old_password` is removed.

The plugin returns a status to the server indicating whether the user is permitted to connect.

Pluggable authentication enables two important capabilities:

- **External authentication:** Pluggable authentication makes it possible for clients to connect to the MySQL server with credentials that are appropriate for authentication methods other than native authentication based on passwords stored in the `mysql.user` table. For example, plugins can be created to use external authentication methods such as PAM, Windows login IDs, LDAP, or Kerberos.
- **Proxy users:** If a user is permitted to connect, an authentication plugin can return to the server a user name different from the name of the connecting user, to indicate that the connecting user is a proxy for another user. While the connection lasts, the proxy user is treated, for purposes of access control, as having the privileges of a different user. In effect, one user impersonates another. For more information, see [Section 7.3.9, “Proxy Users”](#).

Several authentication plugins are available in MySQL:

- Plugins that perform native authentication that matches the password against the `Password` column of the account row. The `mysql_native_password` plugin implements authentication based on the native password hashing method. The `mysql_old_password` plugin

implements native authentication based on the older (pre-4.1) password hashing method (and is deprecated and removed in MySQL 5.7.5). See [Section 7.5.1.1, “The Native Authentication Plugin”](#), and [Section 7.5.1.2, “The Old Native Authentication Plugin”](#). Native authentication using `mysql_native_password` is the default for new accounts, unless the `default_authentication_plugin` system variable is set otherwise.

- A plugin that performs authentication using SHA-256 password hashing. This plugin matches the password against the `authentication_string` column of the account row. This is stronger encryption than that available with native authentication. See [Section 7.5.1.4, “The SHA-256 Authentication Plugin”](#).
- A plugin prevents all client connections to any account that uses it. Use cases for such a plugin includes accounts that must be able to execute stored programs and views with elevated privileges without exposing those privileges to ordinary users, and proxy accounts that should never permit direct login. See [Section 7.5.1.7, “The No-Login Authentication Plugin”](#).
- A client-side plugin that sends the password to the server without hashing or encryption. This plugin can be used by server-side plugins that require access to the password exactly as provided by the client user. See [Section 7.5.1.8, “The Cleartext Client-Side Authentication Plugin”](#).
- A plugin that authenticates clients that connect from the local host through the Unix socket file. See [Section 7.5.1.9, “The Socket Peer-Credential Authentication Plugin”](#).
- A test plugin that authenticates using MySQL native authentication. This plugin is intended for testing and development purposes, and as an example of how to write an authentication plugin. See [Section 7.5.1.10, “The Test Authentication Plugin”](#).

**Note**

For information about current restrictions on the use of pluggable authentication, including which connectors support which plugins, see [Section C.9, “Restrictions on Pluggable Authentication”](#).

Third-party connector developers should read that section to determine the extent to which a connector can take advantage of pluggable authentication capabilities and what steps to take to become more compliant.

If you are interested in writing your own authentication plugins, see [Section 27.2.4.9, “Writing Authentication Plugins”](#).

## Authentication Plugin Usage Instructions

This section provides general instructions for installing and using authentication plugins.

In general, pluggable authentication uses corresponding plugins on the server and client sides, so you use a given authentication method like this:

- On the server host, install the library containing the appropriate server plugin, if necessary, so that the server can use it to authenticate client connections. Similarly, on each client host, install the library containing the appropriate client plugin for use by client programs.
- Create MySQL accounts that specify use of the plugin for authentication.
- When a client connects, the server plugin tells the client program which client plugin to use for authentication.

The instructions here use an example authentication plugin included in MySQL distributions (see [Section 7.5.1.10, “The Test Authentication Plugin”](#)). The procedure is similar for other authentication plugins; substitute the appropriate plugin and file names.

The example authentication plugin has these characteristics:

- The server-side plugin name is `test_plugin_server`.

- The client-side plugin name is `auth_test_plugin`.
- Both plugins are located in the shared library file named `auth_test_plugin.so` in the plugin directory (the directory named by the `plugin_dir` system variable). The file name suffix might differ on your system.

Install and use the example authentication plugin as follows:

1. Make sure that the plugin library is installed on the server and client hosts.
2. Install the server-side test plugin at server startup or at runtime:
  - To install the plugin at startup, use the `--plugin-load` option. With this plugin-loading method, the option must be given each time you start the server. For example, use these lines in a `my.cnf` option file:

```
[mysqld]
plugin-load=test_plugin_server=auth_test_plugin.so
```

- To install the plugin at runtime, use the `INSTALL PLUGIN` statement:

```
INSTALL PLUGIN test_plugin_server SONAME 'auth_test_plugin.so';
```

This installs the plugin permanently and need be done only once.

3. Verify that the plugin is installed. For example, use `SHOW PLUGINS`:

```
mysql> SHOW PLUGINS\G
...
***** 21. row *****
Name: test_plugin_server
Status: ACTIVE
Type: AUTHENTICATION
Library: auth_test_plugin.so
License: GPL
```

For other ways to check the plugin, see [Section 6.5.3, “Obtaining Server Plugin Information”](#).

4. To specify that a MySQL user must be authenticated using a specific server plugin, name the plugin in the `IDENTIFIED WITH` clause of the `CREATE USER` statement that creates the user:

```
CREATE USER 'testuser'@'localhost' IDENTIFIED WITH test_plugin_server;
```

5. Connect to the server using a client program. The test plugin authenticates the same way as native MySQL authentication, so provide the usual `--user` and `--password` options that you normally use to connect to the server. For example:

```
shell> mysql --user=your_name --password=your_pass
```

For connections by `testuser`, the server sees that the account must be authenticated using the server-side plugin named `test_plugin_server` and communicates to the client program which client-side plugin it must use—in this case, `auth_test_plugin`.

In the case that the account uses the authentication method that is the default for both the server and the client program, the server need not communicate to the client which plugin to use, and a round trip in client/server negotiation can be avoided. This is true for accounts that use native MySQL authentication (`mysql_native_password`).

The `--default-auth=plugin_name` option can be specified on the `mysql` command line as a hint about which client-side plugin the program can expect to use, although the server will override this if the user account requires a different plugin.

If the client program does not find the plugin, specify a `--plugin-dir=dir_name` option to indicate where the plugin is located.

#### Note

If you start the server with the `--skip-grant-tables` option, authentication plugins are not used even if loaded because the server performs no client authentication and permits any client to connect. Because this is insecure, you might want to use `--skip-grant-tables` in conjunction with `--skip-networking` to prevent remote clients from connecting.

## 7.3.9 Proxy Users

Authentication to the MySQL server occurs by means of authentication plugins. The plugin that authenticates a given connection may request that the connecting (external) user be treated as a different user for privilege-checking purposes. This enables the external user to be a proxy for the second user; that is, to have the privileges of the second user:

- The external user is a “proxy user” (a user who can impersonate or become known as another user).
- The second user is a “proxied user” (a user whose identity can be taken on by a proxy user).

This section describes how the proxy user capability works. For general information about authentication plugins, see [Section 7.3.8, “Pluggable Authentication”](#). For information about specific plugins, see [Section 7.5.1, “Authentication Plugins”](#). For information about writing authentication plugins that support proxy users, see [Implementing Proxy User Support in Authentication Plugins](#).

For proxying to occur for a given authentication plugin, these conditions must be satisfied:

- The plugin must support proxying, either for itself, or by the MySQL server on behalf of the plugin. In the latter case, server support may need to be enabled explicitly; see [Server Support for Proxy User Mapping](#).
- A proxy user account must be set up to be authenticated by the plugin. Use the `CREATE USER` statement to associate an account with an authentication plugin, or `ALTER USER` to change its plugin.
- For a client connecting to the proxy account to be treated as a proxy user, the authentication plugin must return a user name different from the client user name, to indicate the user name for the proxied account.
- The proxy user account must have the `PROXY` privilege for the proxied account. Use the `GRANT` statement for this.

The proxy mechanism permits mapping only the client user name to the proxied user name. There is no provision for mapping host names. When a connecting client matches a proxy account, the server attempts to find a match for a proxied account using the user name returned by the authentication plugin and the host name of the proxy account.

Consider the following definitions:

```
-- create proxy user
CREATE USER 'employee_ext'@'localhost'
  IDENTIFIED WITH my_auth_plugin AS 'my_auth_string';

-- create proxied user
CREATE USER 'employee'@'localhost'
  IDENTIFIED BY 'employee_pass';

-- grant PROXY privilege for proxy user to proxied user
GRANT PROXY
  ON 'employee'@'localhost'
```

```
TO 'employee_ext'@'localhost';
```

When a client connects as `employee_ext` from the local host, MySQL uses `my_auth_plugin` to perform authentication. Suppose that `my_auth_plugin` returns a user name of `employee` to the server, based on the content of `'my_auth_string'` and perhaps by consulting some external authentication system. The name `employee` differs from `employee_ext`, so returning `employee` serves as a request to the server to treat the `employee_ext` client, for purposes of privilege checking, as the `employee` local user.

In this case, `employee_ext` is the proxy user and `employee` is the proxied user.

The server verifies that proxy authentication for `employee` is possible for the `employee_ext` user by checking whether `employee_ext` (the proxy user) has the `PROXY` privilege for `employee` (the proxied user). If this privilege has not been granted, an error occurs.

When proxying occurs, the `USER()` and `CURRENT_USER()` functions can be used to see the difference between the connecting user (the proxy user) and the account whose privileges apply during the current session (the proxied user). For the example just described, those functions return these values:

```
mysql> SELECT USER(), CURRENT_USER();
+-----+-----+
| USER()           | CURRENT_USER() |
+-----+-----+
| employee_ext@localhost | employee@localhost |
+-----+-----+
```

In the `CREATE USER` statement that creates the proxy user account, the `IDENTIFIED WITH` clause that names the authentication plugin is optionally followed by an `AS 'auth_string'` clause specifying a string that the server passes to the plugin when the user connects. If present, the string provides information that helps the plugin determine how to map the external client user name to a proxied user name. It is up to each plugin whether it requires the `AS` clause. If so, the format of the authentication string depends on how the plugin intends to use it. Consult the documentation for a given plugin for information about the authentication string values it accepts.

## Granting the Proxy Privilege

The `PROXY` privilege is needed to enable an external user to connect as and have the privileges of another user. To grant this privilege, use the `GRANT` statement. For example:

```
GRANT PROXY ON 'proxied_user' TO 'proxy_user';
```

The statement creates a row in the `mysql.proxies_priv` grant table.

At connection time, `proxy_user` must represent a valid externally authenticated MySQL user, and `proxied_user` must represent a valid locally authenticated user. Otherwise, the connection attempt fails.

The corresponding `REVOKE` syntax is:

```
REVOKE PROXY ON 'proxied_user' FROM 'proxy_user';
```

MySQL `GRANT` and `REVOKE` syntax extensions work as usual. For example:

```
GRANT PROXY ON 'a' TO 'b', 'c', 'd';
GRANT PROXY ON 'a' TO 'd' WITH GRANT OPTION;
GRANT PROXY ON 'a' TO '@';
REVOKE PROXY ON 'a' FROM 'b', 'c', 'd';
```

In the preceding example, `'@'` is the default proxy user and means “any user.” Default proxy user are discussed in [Default Proxy Users](#).

The `PROXY` privilege can be granted in these cases:

- By a user that has `GRANT PROXY ... WITH GRANT OPTION` for `proxied_user`.
- By `proxied_user` for itself: The value of `USER()` must exactly match `CURRENT_USER()` and `proxied_user`, for both the user name and host name parts of the account name.

The initial `root` account created during MySQL installation has the `PROXY ... WITH GRANT OPTION` privilege for `'@'`, that is, for all users and all hosts. This enables `root` to set up proxy users, as well as to delegate to other accounts the authority to set up proxy users. For example, `root` can do this:

```
CREATE USER 'admin'@'localhost' IDENTIFIED BY 'test';
GRANT PROXY ON ''@'' TO 'admin'@'localhost' WITH GRANT OPTION;
```

Those statements create an `admin` user that can manage all `GRANT PROXY` mappings. For example, `admin` can do this:

```
GRANT PROXY ON sally TO joe;
```

## Default Proxy Users

To specify that some or all users should connect using a given authentication plugin, create a “blank” MySQL user, associate it with that plugin for authentication, and let the plugin return the real authenticated user name (if different from the blank user). For example, suppose that there exists a plugin named `ldap_auth` that implements LDAP authentication and maps connecting users onto either a developer or manager account. To set up proxying of users onto these accounts, use the following statements:

```
-- create default proxy user
CREATE USER ''@'' IDENTIFIED WITH ldap_auth AS 'O=Oracle, OU=MySQL';

-- create proxied users
CREATE USER 'developer'@'localhost' IDENTIFIED BY 'developer_pass';
CREATE USER 'manager'@'localhost' IDENTIFIED BY 'manager_pass';

-- grant PROXY privilege for default proxy user to proxied users
GRANT PROXY ON 'manager'@'localhost' TO ''@'';
GRANT PROXY ON 'developer'@'localhost' TO ''@'';
```

Now assume that a client tries to connect as follows:

```
mysql --user=myuser --password='myuser_pass' ...
```

The server will not find `myuser` defined as a MySQL user. But because there is a blank user account (`'@'`), that matches the client user name and host name, the server authenticates the client against that account: The server invokes the `ldap_auth` authentication plugin and passes `myuser` and `myuser_pass` to it as the user name and password.

If the `ldap_auth` plugin finds in the LDAP directory that `myuser_pass` is not the correct password for `myuser`, authentication fails and the server rejects the connection.

If the password is correct and `ldap_auth` finds that `myuser` is a developer, it returns the user name `developer` to the MySQL server, rather than `myuser`. Returning a user name different from the client user name of `myuser` signals to the server that it should treat `myuser` as a proxy. The server verifies that `'@'` can authenticate as `developer` (because it has the `PROXY` privilege to do so) and accepts the connection. The session proceeds with `myuser` having the privileges of `developer`, the proxied user. (These privileges should be set up by the DBA using `GRANT` statements, not shown.) The `USER()` and `CURRENT_USER()` functions return these values:

```
mysql> SELECT USER(), CURRENT_USER();
+-----+-----+
| USER() | CURRENT_USER() |
+-----+-----+
| myuser@localhost | developer@localhost |
+-----+-----+
```

If the plugin instead finds in the LDAP directory that `myuser` is a manager, it returns `manager` as the user name and the session proceeds with `myuser` having the privileges of `manager`.

```
mysql> SELECT USER(), CURRENT_USER();
+-----+-----+
| USER() | CURRENT_USER() |
+-----+-----+
| myuser@localhost | manager@localhost |
+-----+-----+
```

For simplicity, external authentication cannot be multilevel: Neither the credentials for `developer` nor those for `manager` are taken into account in the preceding example. However, they are still used if a client tries to connect and authenticate directly as the `developer` or `manager` account, which is why those accounts should be assigned passwords.

## Default Proxy User and Anonymous User Conflicts

If you intend to create a default proxy user, check for other existing “match any user” accounts that take precedence over the default proxy user and thus prevent that user from working as intended.

In the preceding discussion, the default proxy user account has `' '` in the host part, which matches any host. If you set up a default proxy user, take care to also check whether nonproxy accounts exist with the same user part and `' % '` in the host part, because `' % '` also matches any host, but has precedence over `' '` by the rules that the server uses to sort account rows internally (see [Section 7.2.4, “Access Control, Stage 1: Connection Verification”](#)).

Suppose that a MySQL installation includes these two accounts:

```
-- create default proxy user
CREATE USER ''@'
  IDENTIFIED WITH some_plugin AS 'some_auth_string';
-- create anonymous user
CREATE USER ''@'%'
  IDENTIFIED BY 'some_password';
```

The first account (`' '@'`) is intended as the default proxy user, used to authenticate connections for users who do not otherwise match a more-specific account. The second account (`' '@' % '`) is an anonymous-user account, which might have been created, for example, to enable users without their own account to connect anonymously.

Both accounts have the same user part (`' '`), which matches any user. And each account has a host part that matches any host. Nevertheless, there is a priority in account matching for connection attempts because the matching rules sort a host of `' % '` ahead of `' '`. For accounts that do not match any more-specific account, the server attempts to authenticate them against `' '@' % '` (the anonymous user) rather than `' '@'` (the default proxy user). The result is that the default proxy account is never used.

To avoid this problem, use one of the following strategies:

- Remove the anonymous account so that it does not conflict with the default proxy user. This might be a good idea anyway if you want to associate every connection with a named user.
- Use a more-specific default proxy user that matches ahead of the anonymous user. For example, to permit only `localhost` proxy connections, use `' '@'localhost'`:

```
CREATE USER ''@'localhost'
```

```
IDENTIFIED WITH some_plugin AS 'some_auth_string';
```

In addition, modify any `GRANT PROXY` statements to name `'@'localhost'` rather than `'@'` as the proxy user.

Be aware that this strategy prevents anonymous-user connections from `localhost`.

- Create multiple proxy users, one for local connections and one for “everything else” (remote connections). This can be useful particularly when local users should have different privileges from remote users.

Create the proxy users:

```
-- create proxy user for local connections
CREATE USER '@'localhost'
  IDENTIFIED WITH some_plugin AS 'some_auth_string';
-- create proxy user for remote connections
CREATE USER '@%'
  IDENTIFIED WITH some_plugin AS 'some_auth_string';
```

Create the proxied users:

```
-- create proxied user for local connections
CREATE USER 'developer'localhost'
  IDENTIFIED BY 'some_password';
-- create proxied user for remote connections
CREATE USER 'developer'%'
  IDENTIFIED BY 'some_password';
```

Grant the proxy privilege to each proxy user for the corresponding proxied user:

```
GRANT PROXY ON 'developer'localhost' TO '@'localhost';
GRANT PROXY ON 'developer'%' TO '@%';
```

Finally, grant appropriate privileges to the local and remote proxied users (not shown).

Assume that the `some_plugin/'some_auth_string'` combination causes `some_plugin` to map the client user name to `developer`. Local connections match the `'@'localhost'` proxy user, which maps to the `'developer'localhost'` proxied user. Remote connections match the `'@%'` proxy user, which maps to the `'developer'%'` proxied user.

## Server Support for Proxy User Mapping

Some authentication plugins implement proxy user mapping for themselves. As of MySQL 5.7.7, the MySQL server itself can map proxy users according to granted proxy privileges. If the `check_proxy_users` system variable is enabled, the server performs proxy user mapping for any authentication plugins that request it:

- By default, `check_proxy_users` is disabled, so the server performs no proxy user mapping even for authentication plugins that request it.
- With `check_proxy_users` enabled, it may also be necessary to enable plugin-specific system variables to take advantage of server proxy user mapping support:
  - For the `mysql_native_password` plugin, enable `mysql_native_password_proxy_users`.
  - For the `sha256_password` plugin, enable `sha256_password_proxy_users`.

Proxy user mapping performed by the server is subject to some restrictions:

- The server will not proxy to or from an anonymous user, even if the associated `PROXY` privilege is granted.

- When a single account has been granted proxy privileges for more than one account, server proxy user mapping is nondeterministic. Therefore, granting proxy privileges for multiple accounts to a single account is discouraged.

## Proxy User System Variables

Two system variables help trace the proxy login process:

- `proxy_user`: This value is `NULL` if proxying is not used. Otherwise, it indicates the proxy user account. For example, if a client authenticates through the `'@'` proxy account, this variable is set as follows:

```
mysql> SELECT @@proxy_user;
+-----+
| @@proxy_user |
+-----+
| '@'          |
+-----+
```

- `external_user`: Sometimes the authentication plugin may use an external user to authenticate to the MySQL server. For example, when using Windows native authentication, a plugin that authenticates using the windows API does not need the login ID passed to it. However, it still uses a Windows user ID to authenticate. The plugin may return this external user ID (or the first 512 UTF-8 bytes of it) to the server using the `external_user` read-only session variable. If the plugin does not set this variable, its value is `NULL`.

### 7.3.10 User Account Locking

As of version 5.7.6, MySQL supports locking and unlocking user accounts using the `ACCOUNT LOCK` and `ACCOUNT UNLOCK` clauses for the `CREATE USER` and `ALTER USER` statements:

- When used with `CREATE USER`, these clauses specify the initial locking state for a new account. In the absence of either clause, the account is created in an unlocked state.
- When used with `ALTER USER`, these clauses specify the new locking state for an existing account. In the absence of either clause, the account locking state remains unchanged.

Account locking state is recorded in the `account_locked` column of the `mysql.user` table. The output from `SHOW CREATE USER` indicates whether an account is locked or unlocked.

If a client attempts to connect to a locked account, the attempt fails. The server increments the `Locked_connects` status variable that indicates the number of attempts to connect to a locked account, returns an `ER_ACCOUNT_HAS_BEEN_LOCKED` error, and writes a message to the error log:

```
Access denied for user 'user_name'@'host_name'.
Account is locked.
```

Locking an account does not affect being able to connect using a proxy user that assumes the identity of the locked account. It also does not affect the ability to execute stored programs or views that have a `DEFINER` clause naming the locked account. That is, the ability to use a proxied account or stored programs or views is not affected by locking the account.

The account-locking capability depends on the presence of the `account_locked` column in the `mysql.user` table. For upgrades to MySQL 5.7.6 and later from older versions, run `mysql_upgrade` to ensure that this column exists. For nonupgraded installations that have no `account_locked` column, the server treats all accounts as unlocked, and using the `ACCOUNT LOCK` or `ACCOUNT UNLOCK` clauses produces an error.

### 7.3.11 SQL-Based MySQL Account Activity Auditing

Applications can use the following guidelines to perform SQL-based auditing that ties database activity to MySQL accounts.

MySQL accounts correspond to rows in the `mysql.user` table. When a client connects successfully, the server authenticates the client to a particular row in this table. The `User` and `Host` column values in this row uniquely identify the account and correspond to the `'user_name'@'host_name'` format in which account names are written in SQL statements.

The account used to authenticate a client determines which privileges the client has. Normally, the `CURRENT_USER()` function can be invoked to determine which account this is for the client user. Its value is constructed from the `User` and `Host` columns of the `user` table row for the account.

However, there are circumstances under which the `CURRENT_USER()` value corresponds not to the client user but to a different account. This occurs in contexts when privilege checking is not based the client's account:

- Stored routines (procedures and functions) defined with the `SQL SECURITY DEFINER` characteristic
- Views defined with the `SQL SECURITY DEFINER` characteristic
- Triggers and events

In those contexts, privilege checking is done against the `DEFINER` account and `CURRENT_USER()` refers to that account, not to the account for the client who invoked the stored routine or view or who caused the trigger to activate. To determine the invoking user, you can call the `USER()` function, which returns a value indicating the actual user name provided by the client and the host from which the client connected. However, this value does not necessarily correspond directly to an account in the `user` table, because the `USER()` value never contains wildcards, whereas account values (as returned by `CURRENT_USER()`) may contain user name and host name wildcards.

For example, a blank user name matches any user, so an account of `'@localhost'` enables clients to connect as an anonymous user from the local host with any user name. In this case, if a client connects as `user1` from the local host, `USER()` and `CURRENT_USER()` return different values:

```
mysql> SELECT USER(), CURRENT_USER();
+-----+-----+
| USER()          | CURRENT_USER() |
+-----+-----+
| user1@localhost | @localhost     |
+-----+-----+
```

The host name part of an account can contain wildcards, too. If the host name contains a `'%'` or `'_'` pattern character or uses netmask notation, the account can be used for clients connecting from multiple hosts and the `CURRENT_USER()` value will not indicate which one. For example, the account `'user2'@'%.example.com'` can be used by `user2` to connect from any host in the `example.com` domain. If `user2` connects from `remote.example.com`, `USER()` and `CURRENT_USER()` return different values:

```
mysql> SELECT USER(), CURRENT_USER();
+-----+-----+
| USER()          | CURRENT_USER() |
+-----+-----+
| user2@remote.example.com | user2@%.example.com |
+-----+-----+
```

If an application must invoke `USER()` for user auditing (for example, if it does auditing from within triggers) but must also be able to associate the `USER()` value with an account in the `user` table, it is necessary to avoid accounts that contain wildcards in the `User` or `Host` column. Specifically, do not permit `User` to be empty (which creates an anonymous-user account), and do not permit pattern characters or netmask notation in `Host` values. All accounts must have a nonempty `User` value and literal `Host` value.

With respect to the previous examples, the `'@localhost'` and `'user2'@'%.example.com'` accounts should be changed not to use wildcards:

```
RENAME USER ''@'localhost' TO 'user1'@'localhost';
RENAME USER 'user2'@'%.example.com' TO 'user2'@'remote.example.com';
```

If `user2` must be able to connect from several hosts in the `example.com` domain, there should be a separate account for each host.

To extract the user name or host name part from a `CURRENT_USER()` or `USER()` value, use the `SUBSTRING_INDEX()` function:

```
mysql> SELECT SUBSTRING_INDEX(CURRENT_USER(), '@', 1);
+-----+
| SUBSTRING_INDEX(CURRENT_USER(), '@', 1) |
+-----+
| user1                                   |
+-----+

mysql> SELECT SUBSTRING_INDEX(CURRENT_USER(), '@', -1);
+-----+
| SUBSTRING_INDEX(CURRENT_USER(), '@', -1) |
+-----+
| localhost                                |
+-----+
```

## 7.4 Using Secure Connections

With an unencrypted connection between the MySQL client and the server, someone with access to the network could watch all your traffic and inspect the data being sent or received between client and server.

When you must move information over a network in a secure fashion, an unencrypted connection is unacceptable. To make any kind of data unreadable, use encryption. Encryption algorithms must include security elements to resist many kinds of known attacks such as changing the order of encrypted messages or replaying data twice.

MySQL supports secure (encrypted) connections between clients and the server using the TLS (Transport Layer Security) protocol. TLS is sometimes referred to as SSL (Secure Sockets Layer) but MySQL does not actually use the SSL protocol for secure connections because it provides weak encryption (see [Section 7.4.3, “Secure Connection Protocols and Ciphers”](#)).

TLS uses encryption algorithms to ensure that data received over a public network can be trusted. It has mechanisms to detect data change, loss, or replay. TLS also incorporates algorithms that provide identity verification using the X509 standard.

X509 makes it possible to identify someone on the Internet. In basic terms, there should be some entity called a “Certificate Authority” (or CA) that assigns electronic certificates to anyone who needs them. Certificates rely on asymmetric encryption algorithms that have two encryption keys (a public key and a secret key). A certificate owner can present the certificate to another party as proof of identity. A certificate consists of its owner's public key. Any data encrypted using this public key can be decrypted only using the corresponding secret key, which is held by the owner of the certificate.

MySQL can be compiled for secure-connection support using OpenSSL or yaSSL. For a comparison of the two packages, see [Section 7.4.1, “OpenSSL Versus yaSSL”](#). For information about the encryption protocols and ciphers each package supports, see [Section 7.4.3, “Secure Connection Protocols and Ciphers”](#).

MySQL performs encryption on a per-connection basis, and use of encryption for a given user can be optional or mandatory. This enables you to choose an encrypted or unencrypted connection according to the requirements of individual applications. For information on how to require users to use encrypted connections, see the discussion of the `REQUIRE` clause of the `CREATE USER` statement in [Section 14.7.1.2, “CREATE USER Syntax”](#). See also the description of the `require_secure_transport` system variable at [Section 6.1.5, “Server System Variables”](#)

Several improvements were made to secure-connection support in MySQL 5.7. The following timeline summarizes the changes:

- 5.7.3: On the client side, an explicit `--ssl` option is no longer advisory but prescriptive. Given a server enabled to support secure connections, a client program can require a secure connection by specifying only the `--ssl` option. The connection attempt fails if a secure connection cannot be established. Other `--ssl-xxx` options on the client side mean that a secure connection is advisory (the connection attempt falls back to an unencrypted connection if a secure connection cannot be established).
- 5.7.5: The server-side `--ssl` option value is enabled by default.

For servers compiled using OpenSSL, the `auto_generate_certs` and `sha256_password_auto_generate_rsa_keys` system variables are available to enable autogeneration and autodiscovery of SSL/RSA certificate and key files at startup. For certificate and key autodiscovery, if `--ssl` is enabled and other `--ssl-xxx` options are not given to configure secure connections explicitly, the server attempts to enable support for secure connections automatically at startup if it discovers the requisite certificate and key files in the data directory.

- 5.7.6: The `mysql_ssl_rsa_setup` utility is available to make it easier to manually generate SSL/RSA certificate and key files. Autodiscovery of SSL/RSA files at startup is expanded to apply to all servers, whether compiled using OpenSSL or yaSSL. (This means that `auto_generate_certs` need not be enabled for autodiscovery to occur.)

If the server discovers at startup that the CA certificate is self-signed, it writes a warning to its error log. (The certificate will be self-signed if created automatically by the server or manually using `mysql_ssl_rsa_setup`.)

- 5.7.7: The C client library attempts to establish a secure connection by default whenever the server supports secure connections. This affects client programs as follows:
  - In the absence of an `--ssl` option, the client falls back to an unencrypted connection if a secure connection cannot be established.
  - To require a secure connection and fail if one cannot be established, invoke the client with an explicit `--ssl` option or a synonym (`--ssl=1`, `--enable-ssl`).
  - To use an unencrypted connection, invoke the client with an `--ssl=0` option or a synonym (`--skip-ssl`, `--disable-ssl`).

This change also affects subsequent releases of MySQL Connectors that are based on the C client library: Connector/C, Connector/C++, and Connector/ODBC.

- 5.7.8: The `require_secure_transport` system variable is available to control whether client connections to the server must use some form of secure transport.
- 5.7.10: TLS protocol support is extended from TLSv1 to also include TLSv1.1 and TLSv1.2. The `tls_version` system variable on the server side and `--tls-version` option on the client side enable the level of support to be selected. See [Section 7.4.3, “Secure Connection Protocols and Ciphers”](#).
- 5.7.11: MySQL client programs support an `--ssl-mode` option that enables you to specify the security state of the connection to the server. The `--ssl-mode` option comprises the capabilities of the client-side `--ssl` and `--ssl-verify-server-cert` options. Consequently, both of those options are deprecated, to be removed in MySQL 8.0.

Secure connections are available through the MySQL C API using the `mysql_ssl_set()` and `mysql_options()` functions. See [Section 26.8.7.73, “mysql\\_ssl\\_set\(\)”](#), and [Section 26.8.7.50, “mysql\\_options\(\)”](#).

Replication uses the C API, so secure connections can be used between master and slave servers. See [Section 18.3.8, “Setting Up Replication to Use Secure Connections”](#).

It is also possible to connect securely from within an SSH connection to the MySQL server host. For an example, see [Section 7.4.7, “Connecting to MySQL Remotely from Windows with SSH”](#).

## 7.4.1 OpenSSL Versus yaSSL

MySQL can be compiled using OpenSSL or yaSSL, both of which enable secure connections based on the OpenSSL API:

- MySQL Enterprise Edition binary distributions are compiled using OpenSSL. It is not possible to use yaSSL with MySQL Enterprise Edition.
- MySQL Community Edition binary distributions are compiled using yaSSL.
- MySQL Community Edition source distributions can be compiled using either OpenSSL or yaSSL (see [Section 7.4.2, “Building MySQL with Support for Secure Connections”](#)).

OpenSSL and yaSSL offer the same basic functionality, but MySQL distributions compiled using OpenSSL have additional features:

- OpenSSL supports a wider range of encryption ciphers from which to choose for the `--ssl-cipher` option. OpenSSL supports the `--ssl-capath`, `--ssl-crl`, and `--ssl-crlpath` options. See [Section 7.4.5, “Command Options for Secure Connections”](#).
- Accounts that authenticate using the `sha256_password` plugin can use RSA key files for secure password exchange over unencrypted connections. See [Section 7.5.1.4, “The SHA-256 Authentication Plugin”](#).
- The server can automatically generate missing SSL and RSA certificate and key files at startup. See [Section 7.4.6.1, “Creating SSL and RSA Certificates and Keys using MySQL”](#).
- OpenSSL supports more encryption modes for the `AES_ENCRYPT()` and `AES_DECRYPT()` functions. See [Section 13.13, “Encryption and Compression Functions”](#)

Certain OpenSSL-related system and status variables are present only if MySQL was compiled using OpenSSL:

- `auto_generate_certs` (added in MySQL 5.7.5)
- `sha256_password_auto_generate_rsa_keys` (added in MySQL 5.7.5)
- `sha256_password_private_key_path`
- `sha256_password_public_key_path`
- `Rsa_public_key`

To determine whether your server was compiled using OpenSSL, test the existence of any of those variables. For example, this statement returns a row if OpenSSL was used and an empty result if yaSSL was used:

```
SHOW STATUS LIKE 'Rsa_public_key';
```

Such tests assume that your server version is not older than the first appearance of the variable tested. For example, you cannot test for `auto_generate_certs` before MySQL 5.7.6.

## 7.4.2 Building MySQL with Support for Secure Connections

To use SSL connections between the MySQL server and client programs, your system must support either OpenSSL or yaSSL:

- MySQL Enterprise Edition binary distributions are compiled using OpenSSL. It is not possible to use yaSSL with MySQL Enterprise Edition.
- MySQL Community Edition binary distributions are compiled using yaSSL.
- MySQL Community Edition source distributions can be compiled using either OpenSSL or yaSSL.

If you compile MySQL from a source distribution, `CMake` configures the distribution to use yaSSL by default. To compile using OpenSSL instead, use this procedure:

1. Ensure OpenSSL 1.0.1 or higher is installed on your system. To obtain OpenSSL, visit <http://www.openssl.org>.

If the installed OpenSSL version is lower than 1.0.1, `CMake` produces an error at MySQL configuration time.

2. To use OpenSSL, add the `-DWITH_SSL=system` option to the `CMake` command you normally use to configure the MySQL source distribution. For example:

```
shell> cmake . -DWITH_SSL=system
```

That command configures the distribution to use the installed OpenSSL library. Alternatively, to explicitly specify the path name to the OpenSSL installation, use the following syntax. This can be useful if you have multiple versions of OpenSSL installed, to prevent `CMake` from choosing the wrong one:

```
shell> cmake . -DWITH_SSL=path_name
```

See [Section 2.9.4, “MySQL Source-Configuration Options”](#).

3. Compile and install the distribution.

To check whether a `mysqld` server supports secure connections, examine the value of the `have_ssl` system variable:

```
mysql> SHOW VARIABLES LIKE 'have_ssl';
+-----+-----+
| Variable_name | Value |
+-----+-----+
| have_ssl      | YES   |
+-----+-----+
```

If the value is `YES`, the server supports secure connections. If the value is `DISABLED`, the server is capable of supporting secure connections but was not started with the appropriate `--ssl-xxx` options to enable secure connections to be used; see [Section 7.4.4, “Configuring MySQL to Use Secure Connections”](#).

To determine whether a server was compiled using OpenSSL or yaSSL, check the existence of any of the system or status variables that are present only for OpenSSL. See [Section 7.4.1, “OpenSSL Versus yaSSL”](#)

### 7.4.3 Secure Connection Protocols and Ciphers

To determine which encryption protocol and cipher are in use for an encrypted connection, use the following statements to check the values of the `Ssl_version` and `Ssl_cipher` status variables:

```
mysql> SHOW SESSION STATUS LIKE 'Ssl_version';
+-----+-----+
| Variable_name | Value |
+-----+-----+
```

```

| Ssl_version | TLSv1 |
+-----+
mysql> SHOW SESSION STATUS LIKE 'Ssl_cipher';
+-----+
| Variable_name | Value |
+-----+
| Ssl_cipher    | DHE-RSA-AES128-GCM-SHA256 |
+-----+

```

If the connection is not encrypted, both variables have an empty value.

MySQL supports encrypted connections using TLS protocols:

- When compiled using OpenSSL 1.0.1 or higher, MySQL supports the TLSv1, TLSv1.1, and TLSv1.2 protocols.
- When compiled using the bundled version of yaSSL, MySQL supports the TLSv1 and TLSv1.1 protocols.

The value of the `tls_version` system variable determines which protocols the server is permitted to use from those that are available. The `tls_version` value is a comma-separated list containing one or more of these protocols (not case sensitive): TLSv1, TLSv1.1, TLSv1.2. By default, this variable lists all protocols supported by the SSL library used to compile MySQL (`TLSv1,TLSv1.1,TLSv1.2` for OpenSSL, `TLSv1,TLSv1.1` for yaSSL). To determine the value of `tls_version` at runtime, use this statement:

```

mysql> SHOW GLOBAL VARIABLES LIKE 'tls_version';
+-----+
| Variable_name | Value |
+-----+
| tls_version   | TLSv1,TLSv1.1,TLSv1.2 |
+-----+

```

To change the value of `tls_version`, set it at server startup. For example, to prohibit connections that use the less-secure TLSv1 protocol, use these lines in the server `my.cnf` file:

```

[mysqld]
tls_version=TLSv1.1,TLSv1.2

```

To be even more restrict and permit only TLSv1.2 connections, set `tls_version` like this (assuming that your server is compiled using OpenSSL because yaSSL does not support TLSv1.2):

```

[mysqld]
tls_version=TLSv1.2

```

For client programs, the `--tls-version` option enables specifying the TLS protocols permitted per client invocation. The value format is the same as for `tls_version`.

By default, MySQL attempts to use the highest TLS protocol version available, depending on which SSL library was used to compile the server and client, which key size is used, and whether the server or client are restricted from using some protocols; for example, by means of `tls_version/--tls-version`:

- If the server and client are compiled using OpenSSL, TLSv1.2 is used if possible.
- If either or both the server and client are compiled using yaSSL, TLSv1.1 is used if possible.
- TLSv1.2 does not work with all ciphers that have a key size of 512 bits or less. To use this protocol with such a key, use `--ssl-cipher` to specify the cipher name explicitly:

```
AES128-SHA
```

```
AES128-SHA256
AES256-SHA
AES256-SHA256
CAMELLIA128-SHA
CAMELLIA256-SHA
DES-CBC3-SHA
DHE-RSA-AES256-SHA
RC4-MD5
RC4-SHA
SEED-SHA
```

- For better security, use a certificate with an RSA key size of 2048 bits or more.

#### Note

Prior to MySQL 5.7.10, MySQL supports only TLSv1, for both OpenSSL and yaSSL, and no system variable or client option exist for specifying which TLS protocols to permit.

If the server and client protocol capabilities have no protocol in common, the server terminates the connection request. For example, if the server is configured with `tls_version=TLSv1.1,TLSv1.2`, connection attempts will fail for clients invoked with `--tls-version=TLSv1`, and for older clients that do not support the `--tls-version` option and implicitly support only TLSv1.

To determine which ciphers a given server supports, use the following statement to check the value of the `Ssl_cipher_list` status variable:

```
SHOW SESSION STATUS LIKE 'Ssl_cipher_list';
```

The set of available ciphers depends on your MySQL version and whether MySQL was compiled using OpenSSL or yaSSL, and (for OpenSSL) the library version used to compile MySQL.

As of MySQL 5.7.10, order of ciphers passed by MySQL to the SSL library is significant. More secure ciphers are mentioned first in the list, and the first cipher supported by the provided certificate is selected.

MySQL passes this cipher list to OpenSSL:

```
ECDHE-ECDSA-AES128-GCM-SHA256
ECDHE-ECDSA-AES256-GCM-SHA384
ECDHE-RSA-AES128-GCM-SHA256
ECDHE-RSA-AES256-GCM-SHA384
ECDHE-ECDSA-AES128-SHA256
ECDHE-RSA-AES128-SHA256
ECDHE-ECDSA-AES256-SHA384
ECDHE-RSA-AES256-SHA384
DHE-RSA-AES128-GCM-SHA256
DHE-DSS-AES128-GCM-SHA256
DHE-RSA-AES128-SHA256
DHE-DSS-AES128-SHA256
DHE-DSS-AES256-GCM-SHA384
DHE-RSA-AES256-SHA256
DHE-DSS-AES256-SHA256
ECDHE-RSA-AES128-SHA
ECDHE-ECDSA-AES128-SHA
ECDHE-RSA-AES256-SHA
ECDHE-ECDSA-AES256-SHA
DHE-DSS-AES128-SHA
DHE-RSA-AES128-SHA
TLS_DHE_DSS_WITH_AES_256_CBC_SHA
DHE-RSA-AES256-SHA
AES128-GCM-SHA256
DH-DSS-AES128-GCM-SHA256
ECDH-ECDSA-AES128-GCM-SHA256
AES256-GCM-SHA384
DH-DSS-AES256-GCM-SHA384
```

```
ECDH-ECDSA-AES256-GCM-SHA384
AES128-SHA256
DH-DSS-AES128-SHA256
ECDH-ECDSA-AES128-SHA256
AES256-SHA256
DH-DSS-AES256-SHA256
ECDH-ECDSA-AES256-SHA384
AES128-SHA
DH-DSS-AES128-SHA
ECDH-ECDSA-AES128-SHA
AES256-SHA
DH-DSS-AES256-SHA
ECDH-ECDSA-AES256-SHA
DHE-RSA-AES256-GCM-SHA384
DH-RSA-AES128-GCM-SHA256
ECDH-RSA-AES128-GCM-SHA256
DH-RSA-AES256-GCM-SHA384
ECDH-RSA-AES256-GCM-SHA384
DH-RSA-AES128-SHA256
ECDH-RSA-AES128-SHA256
DH-RSA-AES256-SHA256
ECDH-RSA-AES256-SHA384
ECDHE-RSA-AES128-SHA
ECDHE-ECDSA-AES128-SHA
ECDHE-RSA-AES256-SHA
ECDHE-ECDSA-AES256-SHA
DHE-DSS-AES128-SHA
DHE-RSA-AES128-SHA
TLS_DHE_DSS_WITH_AES_256_CBC_SHA
DHE-RSA-AES256-SHA
AES128-SHA
DH-DSS-AES128-SHA
ECDH-ECDSA-AES128-SHA
AES256-SHA
DH-DSS-AES256-SHA
ECDH-ECDSA-AES256-SHA
DH-RSA-AES128-SHA
ECDH-RSA-AES128-SHA
DH-RSA-AES256-SHA
ECDH-RSA-AES256-SHA
DES-CBC3-SHA
```

MySQL passes this cipher list to yaSSL:

```
DHE-RSA-AES256-SHA
DHE-RSA-AES128-SHA
AES128-RMD
DES-CBC3-RMD
DHE-RSA-AES256-RMD
DHE-RSA-AES128-RMD
DHE-RSA-DES-CBC3-RMD
AES256-SHA
RC4-SHA
RC4-MD5
DES-CBC3-SHA
DES-CBC-SHA
EDH-RSA-DES-CBC3-SHA
EDH-RSA-DES-CBC-SHA
AES128-SHA:AES256-RMD
```

As of MySQL 5.7.10, these cipher restrictions are in place:

- The following ciphers are permanently restricted:

```
!DHE-DSS-DES-CBC3-SHA
!DHE-RSA-DES-CBC3-SHA
!ECDH-RSA-DES-CBC3-SHA
!ECDH-ECDSA-DES-CBC3-SHA
!ECDHE-RSA-DES-CBC3-SHA
!ECDHE-ECDSA-DES-CBC3-SHA
```

- The following categories of ciphers are permanently restricted:

```
!aNULL
!eNULL
!EXPORT
!LOW
!MD5
!DES
!RC2
!RC4
!PSK
!SSLv3
```

If the server is started using a compatible certificate that uses any of the preceding restricted ciphers or cipher categories, the server starts with support for secure connections disabled.

## 7.4.4 Configuring MySQL to Use Secure Connections

To enable secure connections, the proper options must be used to specify the appropriate certificate and key files. For a complete list of options related to establishment of secure connections, see [Section 7.4.5, “Command Options for Secure Connections”](#).

If you need to create the required certificate and key files, see [Section 7.4.6, “Creating SSL and RSA Certificates and Keys”](#).

### Server-Side Configuration for Secure Connections

To start the MySQL server so that it permits clients to connect securely, use options that identify the certificate and key files the server uses when establishing a secure connection:

- `--ssl-ca` identifies the Certificate Authority (CA) certificate.
- `--ssl-cert` identifies the server public key certificate. This can be sent to the client and authenticated against the CA certificate that it has.
- `--ssl-key` identifies the server private key.

For example, start the server with these lines in the `my.cnf` file, changing the file names as necessary:

```
[mysqld]
ssl-ca=ca.pem
ssl-cert=server-cert.pem
ssl-key=server-key.pem
```

Each option names a file in PEM format. If you have a MySQL source distribution, you can test your setup using the demonstration certificate and key files in its `mysql-test/std_data` directory.

As of MySQL 5.7.5, the server-side `--ssl` option value is enabled by default. Also as of MySQL 5.7.5, MySQL servers compiled using OpenSSL can generate missing certificate and key files automatically at startup. See [Section 7.4.6.1, “Creating SSL and RSA Certificates and Keys using MySQL”](#).

The server performs certificate and key file autodiscovery as of MySQL 5.7.5 (for servers compiled using OpenSSL) or 5.7.6 (for servers compiled using yaSSL). If `--ssl` is enabled (possibly along with `--ssl-cipher`) and other `--ssl-xxx` options are not given to configure secure connections explicitly, the server attempts to enable support for secure connections automatically at startup:

- If the server discovers valid certificate and key files named `ca.pem`, `server-cert.pem`, and `server-key.pem` in the data directory, it enables support for secure connections by clients. (The files need not have been autogenerated; what matters is that they have the indicated names and are valid.)
- If the server does not find valid certificate and key files in the data directory, it continues executing but does not enable secure connections.

If the server automatically enables support for secure connections, it writes a message to the error log. As of MySQL 5.7.6, if the server discovers that the CA certificate is self-signed, it writes a warning to the error log. (The certificate will be self-signed if created automatically by the server or manually using `mysql_ssl_rsa_setup`.)

For any certificate and key files that the server discovers and uses automatically, it uses the file names to set the corresponding system variables (`ssl_ca`, `ssl_cert`, `ssl_key`).

For further control over whether clients must connect securely, use the `require_secure_transport` system variable; see [Section 6.1.5, “Server System Variables”](#). For information about permitted encryption protocols and ciphers, see [Section 7.4.3, “Secure Connection Protocols and Ciphers”](#).

## Client-Side Configuration for Secure Connections

For client programs, options for secure connections are similar to those used on the server side, but `--ssl-cert` and `--ssl-key` identify the client public and private key:

- `--ssl-ca` identifies the Certificate Authority (CA) certificate. This option, if used, must specify the same certificate used by the server.
- `--ssl-cert` identifies the client public key certificate.
- `--ssl-key` identifies the client private key.

To connect securely to a MySQL server that supports secure connections, the options that a client must specify depend on the encryption requirements of the MySQL account used by the client. (See the discussion of the `REQUIRE` clause in [Section 14.7.1.2, “CREATE USER Syntax”](#).)

Suppose that you want to connect using an account that has no special encryption requirements or was created using a `CREATE USER` statement that includes the `REQUIRE SSL` option. As a recommended set of secure-connection options, start the server with at least `--ssl-cert` and `--ssl-key`, and invoke the client with `--ssl-ca`. A client can connect securely like this:

```
shell> mysql --ssl-ca=ca.pem
```

To require that a client certificate also be specified, create the account using the `REQUIRE X509` option. Then the client must also specify the proper client key and certificate files or the server will reject the connection:

```
shell> mysql --ssl-ca=ca.pem \  
        --ssl-cert=client-cert.pem \  
        --ssl-key=client-key.pem
```

To prevent use of encryption and override other `--ssl-xxx` options, invoke the client program with `--ssl-mode=DISABLED`, `--ssl=0`, or a synonym (`--skip-ssl`, `--disable-ssl`):

```
shell> mysql --ssl-mode=DISABLED
```

As of MySQL 5.7.7, client programs attempt to establish a secure connection by default whenever the server supports secure connections:

- In the absence of an `--ssl-mode` or `--ssl` option, the client falls back to an unencrypted connection if a secure connection cannot be established.
- To require a secure connection and fail if one cannot be established, invoke the client with `--ssl-mode=REQUIRED`, `--ssl`, or a synonym (`--ssl=1`, `--enable-ssl`).
- To use an unencrypted connection, invoke the client with `--ssl-mode=DISABLED`, `--ssl=0`, or a synonym (`--skip-ssl`, `--disable-ssl`).

From MySQL 5.7.3 to 5.7.6, `--ssl` on the client side is prescriptive (not advisory as before MySQL 5.7.3): With `--ssl`, connection attempts fail if a secure connection cannot be established.

Before MySQL 5.7.3, `--ssl` on the client side is advisory: `--ssl` permits but does not require the client to connect to the server using encryption. Therefore, this option is not sufficient in itself to cause a secure connection to be used. For example, if you specify this option for a client program but the server has not been configured to support secure connections, the client falls back to an unencrypted connection.

For information about permitted encryption protocols and ciphers, see [Section 7.4.3, “Secure Connection Protocols and Ciphers”](#).

A client can determine whether the current connection with the server uses encryption by checking the value of the `Ssl_cipher` status variable. If the value is empty, the connection is not encrypted. Otherwise, the connection is encrypted and the value indicates the encryption cipher. For example:

```
mysql> SHOW STATUS LIKE 'Ssl_cipher';
+-----+-----+
| Variable_name | Value                |
+-----+-----+
| Ssl_cipher    | DHE-RSA-AES256-SHA |
+-----+-----+
```

For the `mysql` client, an alternative is to use the `STATUS` or `\s` command and check the `SSL` line:

```
mysql> \s
...
SSL: Cipher in use is DHE-RSA-AES256-SHA
...
```

Or:

```
mysql> \s
...
SSL: Not in use
...
```

## C API Configuration for Secure Connections

The C API enables application programs to use secure connections:

- To establish a secure connection, use the `mysql_ssl_set()` C API function to set the appropriate certificate options before calling `mysql_real_connect()`. See [Section 26.8.7.73, “mysql\\_ssl\\_set\(\)”](#). To require the use of a secure connection, call `mysql_options()` with the `MYSQL_OPT_SSL_MODE` option (use the `MYSQL_OPT_SSL_ENFORCE` option before MySQL 5.7.11). To establish permitted encryption protocols, call `mysql_options()` with the `MYSQL_OPT_TLS_VERSION` option.
- To determine whether encryption is in use after the connection is established, use `mysql_get_ssl_cipher()`. A non-`NULL` return value indicates an encrypted connection and names the cipher used for encryption. A `NULL` return value indicates that encryption is not being used. See [Section 26.8.7.34, “mysql\\_get\\_ssl\\_cipher\(\)”](#).

Replication uses the C API, so secure connections can be used between master and slave servers. See [Section 18.3.8, “Setting Up Replication to Use Secure Connections”](#).

## 7.4.5 Command Options for Secure Connections

This section describes options that specify whether to use secure connections and the names of certificate and key files. These options can be given on the command line or in an option file. For examples of suggested use and how to check whether a connection is secure, see [Section 7.4.4, “Configuring MySQL to Use Secure Connections”](#).

**Table 7.8 Secure-Connection Option Summary**

| Format                                | Description  | Introduced |
|---------------------------------------|--|------------|
| <code>--skip-ssl</code>               | Do not use secure connection   |            |
| <code>--ssl</code>                    | Enable secure connection   |            |
| <code>--ssl-ca</code>                 | Path of file that contains list of trusted SSL CAs   |            |
| <code>--ssl-capath</code>             | Path of directory that contains trusted SSL CA certificates in PEM format                    |            |
| <code>--ssl-cert</code>               | Path of file that contains X509 certificate in PEM format                                    |            |
| <code>--ssl-cipher</code>             | List of permitted ciphers to use for connection encryption                                   |            |
| <code>--ssl-crl</code>                | Path of file that contains certificate revocation lists                                      |            |
| <code>--ssl-crlpath</code>            | Path of directory that contains certificate revocation list files                            |            |
| <code>--ssl-key</code>                | Path of file that contains X509 key in PEM format  |            |
| <code>--ssl-mode</code>               | Security state of connection to server   | 5.7.11     |
| <code>--ssl-verify-server-cert</code> | Verify server certificate Common Name value against host name used when connecting to server |            |
| <code>--tls-version</code>            | Protocols permitted for secure connections   | 5.7.10     |

- `--ssl`

This option has different effects on the server and client sides.

#### Note

The client-side `--ssl` option is deprecated as of MySQL 5.7.11 and is removed in MySQL 8.0. For client programs, it is preferable to use `--ssl-mode` instead:

- Use `--ssl-mode=REQUIRED` instead of `--ssl=1` or `--enable-ssl`.
- Use `--ssl-mode=DISABLED` instead of `--ssl=0`, `--skip-ssl`, or `--disable-ssl`.
- No explicit `--ssl-mode` option is equivalent to no explicit `--ssl` option.

The server-side `--ssl` option is *not* deprecated.

For the MySQL server, this option specifies that the server permits but does not require secure connections. The option is enabled on the server side by default as of MySQL 5.7.5, and disabled before 5.7.5. Also as of MySQL 5.7.5, MySQL servers compiled using OpenSSL can generate missing certificate and key files automatically at startup. See [Section 7.4.6.1, “Creating SSL and RSA Certificates and Keys using MySQL”](#).

The server performs certificate and key file autodiscovery as of MySQL 5.7.5 (for servers compiled using OpenSSL) or 5.7.6 (for servers compiled using yaSSL). If `--ssl` is enabled (possibly along with `--ssl-cipher`) and other `--ssl-xxx` options are not given to configure secure connections explicitly, the server attempts to enable support for secure connections automatically at startup:

- If the server discovers valid certificate and key files named `ca.pem`, `server-cert.pem`, and `server-key.pem` in the data directory, it enables support for secure connections by clients. (The files need not have been autogenerated; what matters is that they have the indicated names and are valid.)
- If the server does not find valid certificate and key files in the data directory, it continues executing but does not enable secure connections.

For MySQL client programs, the `--ssl` option is used as follows:

- As of MySQL 5.7.7, client programs attempt to establish a secure connection by default whenever the server supports secure connections:
  - In the absence of an `--ssl` option, the client falls back to an unencrypted connection if a secure connection cannot be established.
  - To require a secure connection and fail if one cannot be established, invoke the client with `--ssl` or a synonym (`--ssl=1`, `--enable-ssl`).
  - To use an unencrypted connection, invoke the client with `--ssl=0` or a synonym (`--skip-ssl`, `--disable-ssl`).
- From MySQL 5.7.3 to 5.7.6, `--ssl` is prescriptive (not advisory as before MySQL 5.7.3): With `--ssl`, connection attempts fail if a secure connection cannot be established.
- Before MySQL 5.7.3, `--ssl` is advisory: `--ssl` permits but does not require the client to connect to the server using encryption. Therefore, this option is not sufficient in itself to cause a secure connection to be used. For example, if you specify this option for a client program but the server has not been configured to support secure connections, the client falls back to an unencrypted connection.

If other `--ssl-xxx` options are given in the absence of `--ssl`, the client attempts to connect securely. If the server is configured to support secure connections, the connection attempt fails if a secure connection cannot be established. If the server is not configured for secure connections, the client falls back to an unencrypted connection.

As a recommended set of options to enable secure connections, use at least `--ssl-cert` and `--ssl-key` on the server side and `--ssl-ca` on the client side. See [Section 7.4.4, “Configuring MySQL to Use Secure Connections”](#).

`--ssl` is implied by other `--ssl-xxx` options, as indicated in the descriptions for those options.

The `--ssl` option in negated form overrides other `--ssl-xxx` options and indicates that encryption should *not* be used. To do this, specify the option as `--ssl=0` or a synonym (`--skip-ssl`, `--disable-ssl`). For example, you might have options specified in the `[client]` group of your option file to use secure connections by default when you invoke MySQL client programs. To use an unencrypted connection instead, invoke the client program with `--ssl=0` on the command line to override the options in the option file.

To require use of secure connections by a MySQL account, use `CREATE USER` to create the account with at least a `REQUIRE SSL` clause, or use `ALTER USER` for an existing account to add a `REQUIRE` clause. Connections for the account will be rejected unless MySQL supports secure connections and the server and client have been started with the proper secure-connection options.

The `REQUIRE` clause permits other encryption-related options, which can be used to enforce stricter requirements than `REQUIRE SSL`. For additional details about which command options may or must be specified by clients that connect using accounts configured using the various `REQUIRE` options, see the description of `REQUIRE` in [Section 14.7.1.2, “CREATE USER Syntax”](#).

- `--ssl-ca=file_name`

The path to a file in PEM format that contains a list of trusted SSL certificate authorities. This option implies `--ssl` when used on the server side, and on the client side before MySQL 5.7.3.

If you use encryption when establishing a client connection, to tell the client not to authenticate the server certificate, specify neither `--ssl-ca` nor `--ssl-capath`. The server still verifies the client

according to any applicable requirements established for the client account, and it still uses any `--ssl-ca` or `--ssl-capath` option values specified at server startup.

- `--ssl-capath=dir_name`

The path to a directory that contains trusted SSL certificate authority certificates in PEM format. This option implies `--ssl` when used on the server side, and on the client side before MySQL 5.7.3.

If you use encryption when establishing a client connection, to tell the client not to authenticate the server certificate, specify neither `--ssl-ca` nor `--ssl-capath`. The server still verifies the client according to any applicable requirements established for the client account, and it still uses any `--ssl-ca` or `--ssl-capath` option values specified at server startup.

MySQL distributions compiled using OpenSSL support the `--ssl-capath` option (see [Section 7.4.1, “OpenSSL Versus yaSSL”](#)). Distributions compiled using yaSSL do not because yaSSL does not look in any directory and does not follow a chained certificate tree. yaSSL requires that all components of the CA certificate tree be contained within a single CA certificate tree and that each certificate in the file has a unique SubjectName value. To work around this yaSSL limitation, concatenate the individual certificate files comprising the certificate tree into a new file and specify that file as the value of the `--ssl-ca` option.

- `--ssl-cert=file_name`

The name of the SSL certificate file in PEM format to use for establishing a secure connection. This option implies `--ssl` when used on the server side, and on the client side before MySQL 5.7.3.

- `--ssl-cipher=cipher_list`

A list of permissible ciphers to use for connection encryption. If no cipher in the list is supported, encrypted connections will not work. This option implies `--ssl` when used on the server side, and on the client side before MySQL 5.7.3.

For greatest portability, `cipher_list` should be a list of one or more cipher names, separated by colons. This format is understood both by OpenSSL and yaSSL. Examples:

```
--ssl-cipher=AES128-SHA
--ssl-cipher=DHE-RSA-AES256-SHA:AES128-SHA
```

OpenSSL supports a more flexible syntax for specifying ciphers, as described in the OpenSSL documentation at <http://www.openssl.org/docs/apps/ciphers.html>. yaSSL does not, so attempts to use that extended syntax fail for a MySQL distribution compiled using yaSSL.

For information about which encryption ciphers MySQL supports, see [Section 7.4.3, “Secure Connection Protocols and Ciphers”](#).

- `--ssl-crl=file_name`

The path to a file containing certificate revocation lists in PEM format. This option implies `--ssl` when used on the server side, and on the client side before MySQL 5.7.3.

If neither `--ssl-crl` nor `--ssl-crlpath` is given, no CRL checks are performed, even if the CA path contains certificate revocation lists.

MySQL distributions compiled using OpenSSL support the `--ssl-crl` option (see [Section 7.4.1, “OpenSSL Versus yaSSL”](#)). Distributions compiled using yaSSL do not because revocation lists do not work with yaSSL.

- `--ssl-crlpath=dir_name`

The path to a directory that contains files containing certificate revocation lists in PEM format. This option implies `--ssl` when used on the server side, and on the client side before MySQL 5.7.3.

If neither `--ssl-crl` nor `--ssl-crlpath` is given, no CRL checks are performed, even if the CA path contains certificate revocation lists.

MySQL distributions compiled using OpenSSL support the `--ssl-crlpath` option (see [Section 7.4.1, “OpenSSL Versus yaSSL”](#)). Distributions compiled using yaSSL do not because revocation lists do not work with yaSSL.

- `--ssl-key=file_name`

The name of the SSL key file in PEM format to use for establishing a secure connection. This option implies `--ssl` when used on the server side, and on the client side before MySQL 5.7.3.

If the key file is protected by a passphrase, the program prompts the user for the passphrase. The password must be given interactively; it cannot be stored in a file. If the passphrase is incorrect, the program continues as if it could not read the key.

For better security, use a certificate with an RSA key size of 2048 bits or more.

- `--ssl-mode=mode`

This option is available only for client programs, not the server. It specifies the security state of the connection to the server. The following option values are permitted:

- **PREFERRED**: Establish a secure (encrypted) connection if the server supports secure connections. Fall back to an unencrypted connection otherwise. This is the default if `--ssl-mode` is not specified.
- **DISABLED**: Establish an unencrypted connection. This is like the legacy `--ssl=0` option or its synonyms (`--skip-ssl`, `--disable-ssl`).
- **REQUIRED**: Establish a secure connection if the server supports secure connections. The connection attempt fails if a secure connection cannot be established.
- **VERIFY\_CA**: Like **REQUIRED**, but additionally verify the server TLS certificate against the configured Certificate Authority (CA) certificates. The connection attempt fails if no valid matching CA certificates are found.
- **VERIFY\_IDENTITY**: Like **VERIFY\_CA**, but additionally verify that the server certificate matches the host to which the connection is attempted. This is like the legacy `--ssl-verify-server-cert` option.

Use of the `--ssl-ca` or `--ssl-capath` option implies `--ssl-mode=VERIFY_CA`, if `--ssl-mode` is not explicitly set otherwise.

If `--ssl-mode` is explicit, use of a value other than **VERIFY\_CA** or **VERIFY\_IDENTITY** with an explicit `--ssl-ca` or `--ssl-capath` option produces a warning that no verification of the server certificate will be done, despite CA certificate options being specified.

The `--ssl-mode` option was added in MySQL 5.7.11.

To require use of secure connections by a MySQL account, use **CREATE USER** to create the account with at least a **REQUIRE SSL** clause, or use **ALTER USER** for an existing account to add a **REQUIRE** clause. Connections for the account will be rejected unless MySQL supports secure connections and the server and client have been started with the proper secure-connection options.

The **REQUIRE** clause permits other encryption-related options, which can be used to enforce stricter requirements than **REQUIRE SSL**. For additional details about which command options may or must be specified by clients that connect using accounts configured using the various **REQUIRE** options, see the description of **REQUIRE** in [Section 14.7.1.2, “CREATE USER Syntax”](#).

- `--ssl-verify-server-cert`

**Note**

This option is deprecated as of MySQL 5.7.11 and is removed in MySQL 8.0. It is preferable to use `--ssl-mode=VERIFY_IDENTITY` instead.

This option is available only for client programs, not the server. It causes the client to check the server's Common Name value in the certificate that the server sends to the client. The client verifies that name against the host name the client uses for connecting to the server, and the connection fails if there is a mismatch. For encrypted connections, this option helps prevent man-in-the-middle attacks. Verification is disabled by default.

- `--tls-version=protocol_list`

For client programs, the protocols permitted by the client for encrypted connections. The value is a comma-separated list containing one or more protocol names. The protocols that can be named for this option depend on the SSL library used to compile MySQL. For details, see [Section 7.4.3, “Secure Connection Protocols and Ciphers”](#).

This option was added in MySQL 5.7.10.

On the server side, the `tls_version` system variable can be used instead.

## 7.4.6 Creating SSL and RSA Certificates and Keys

The following discussion describes how to create the files required for SSL and RSA support in MySQL. File creation can be performed using facilities provided by MySQL itself, or by invoking the `openssl` command directly.

SSL certificate and key files enable MySQL to support secure connections using SSL. See [Section 7.4.4, “Configuring MySQL to Use Secure Connections”](#).

RSA key files enable MySQL to support secure password exchange over unencrypted connections for accounts authenticated by the `sha256_password` plugin. See [Section 7.5.1.4, “The SHA-256 Authentication Plugin”](#).

### 7.4.6.1 Creating SSL and RSA Certificates and Keys using MySQL

MySQL provides two ways to create the SSL certificate and key files and RSA key-pair files required to support secure connections using SSL and secure password exchange using RSA over unencrypted connections, if those files are missing:

- The server can autogenerate these files at startup.
- Users can invoke the `mysql_ssl_rsa_setup` utility manually.

**Important**

Server autogeneration and `mysql_ssl_rsa_setup` help lower the barrier to using SSL by making it easier to generate the required files. However, certificates generated by these methods are self-signed, which may not be very secure. After you gain experience using such files, consider obtaining certificate/key material from a registered certificate authority.

### Automatic Generation of SSL and RSA Files

As of MySQL 5.7.5, MySQL servers have the capability of automatically generating missing SSL and RSA files at startup, for MySQL distributions compiled using OpenSSL. The `auto_generate_certs` and `sha256_password_auto_generate_rsa_keys` system variables control automatic generation of these files. Both variables are enabled by default. They can be enabled at startup and inspected but not set at runtime.

At startup, the server automatically generates server-side and client-side SSL certificate and key files in the data directory if the `auto_generate_certs` system variable is enabled, no SSL options other than `--ssl` are specified, and the server-side SSL files are missing from the data directory. These files enable secure client connections using SSL; see [Section 7.4.4, “Configuring MySQL to Use Secure Connections”](#).

1. The server checks the data directory for SSL files with the following names:

```
ca.pem
server-cert.pem
server-key.pem
```

2. If any of those files are present, the server creates no SSL files. Otherwise, it creates them, plus some additional files:

|                 |                            |
|-----------------|----------------------------|
| ca.pem          | Self-signed CA certificate |
| ca-key.pem      | CA private key             |
| server-cert.pem | Server certificate         |
| server-key.pem  | Server private key         |
| client-cert.pem | Client certificate         |
| client-key.pem  | Client private key         |

3. If the server autogenerates SSL files, it uses the names of the `ca.pem`, `server-cert.pem`, and `server-key.pem` files to set the corresponding system variables (`ssl_ca`, `ssl_cert`, `ssl_key`).

At startup, the server automatically generates RSA private/public key-pair files in the data directory if the `sha256_password_auto_generate_rsa_keys` system variable is enabled, no RSA options are specified, and the RSA files are missing from the data directory. These files enable secure password exchange using RSA over unencrypted connections for accounts authenticated by the `sha256_password` plugin; see [Section 7.5.1.4, “The SHA-256 Authentication Plugin”](#).

1. The server checks the data directory for RSA files with the following names:

|                 |   |
|-----------------|---|
| private_key.pem | Private member of private/public key pair |
| public_key.pem  | Public member of private/public key pair  |

2. If any of these files are present, the server creates no RSA files. Otherwise, it creates them.
3. If the server autogenerates the RSA files, it uses their names to set the corresponding system variables (`sha256_password_private_key_path`, `sha256_password_public_key_path`).

## Manual Generation of SSL and RSA Files Using `mysql_ssl_rsa_setup`

As of MySQL 5.7.6, MySQL distributions include a `mysql_ssl_rsa_setup` utility that can be invoked manually to generate SSL and RSA files. This utility is included with all MySQL distributions (whether compiled using OpenSSL or yaSSL), but it does require that the `openssl` command be available. For usage instructions, see [Section 5.4.5, “mysql\\_ssl\\_rsa\\_setup — Create SSL/RSA Files”](#).

## SSL and RSA File Characteristics

SSL and RSA files created automatically by the server or by invoking `mysql_ssl_rsa_setup` have these characteristics:

- SSL and RSA keys are 2048 bit.
- The SSL CA certificate is self signed.
- The SSL server and client certificates are signed with the CA certificate and key, using the `sha256WithRSAEncryption` signature algorithm.
- SSL certificates use these Common Name (CN) values, with the appropriate certificate type (CA, Server, Client):

```
ca.pem:          MySQL_Server_suffix_Auto_Generated_CA_Certificate
server-cert.pm: MySQL_Server_suffix_Auto_Generated_Server_Certificate
client-cert.pm: MySQL_Server_suffix_Auto_Generated_Client_Certificate
```

The [suffix](#) value is based on the MySQL version number. For files generated by [mysql\\_ssl\\_rsa\\_setup](#), the suffix can be specified explicitly using the `--suffix` option.

For files generated by the server, if the resulting CN values exceed 64 characters, the [\\_suffix](#) portion of the name is omitted.

- SSL files have blank values for Country (C), State or Province (ST), Organization (O), Organization Unit Name (OU) and email address.
- SSL files created by the server or by [mysql\\_ssl\\_rsa\\_setup](#) are valid for ten years from the time of generation. (Before MySQL 5.7.6, files created by the server are valid for one year.)
- RSA files do not expire.
- SSL files have different serial numbers for each certificate/key pair (1 for CA, 2 for Server, 3 for Client).
- Files created automatically by the server are owned by the account that runs the server. Files created using [mysql\\_ssl\\_rsa\\_setup](#) are owned by the user who invoked that program. This can be changed on systems that support the `chown()` system call if the program is invoked by [root](#) and the `--uid` option is given to specify the user who should own the files.
- On Unix and Unix-like systems, the file access mode is 644 for certificate files (that is, world readable) and 600 for key files (that is, accessible only by the account that runs the server).

To see the contents of an SSL certificate (for example, to check the range of dates over which it is valid), invoke [openssl](#) directly:

```
shell> openssl x509 -text -in ca.pem
shell> openssl x509 -text -in server-cert.pem
shell> openssl x509 -text -in client-cert.pem
```

It is also possible to check SSL certificate expiration information using this SQL statement:

```
mysql> SHOW STATUS LIKE 'Ssl_server_not%';
+-----+-----+
| Variable_name | Value |
+-----+-----+
| Ssl_server_not_after | Apr 28 14:16:39 2025 GMT |
| Ssl_server_not_before | May 1 14:16:39 2015 GMT |
+-----+-----+
```

### 7.4.6.2 Creating SSL Certificates and Keys Using openssl

This section describes how to use the [openssl](#) command to set up SSL certificate and key files for use by MySQL servers and clients. The first example shows a simplified procedure such as you might use from the command line. The second shows a script that contains more detail. The first two examples are intended for use on Unix and both use the [openssl](#) command that is part of OpenSSL. The third example describes how to set up SSL files on Windows.

#### Note

There are easier alternatives to generating the files required for SSL than the procedure described here: Let the server autogenerate them or use the [mysql\\_ssl\\_rsa\\_setup](#) program. See [Section 7.4.6.1, “Creating SSL and RSA Certificates and Keys using MySQL”](#).

### Important

Whatever method you use to generate the certificate and key files, the Common Name value used for the server and client certificates/keys must each differ from the Common Name value used for the CA certificate. Otherwise, the certificate and key files will not work for servers compiled using OpenSSL. A typical error in this case is:

```
ERROR 2026 (HY000): SSL connection error:
error:00000001:lib(0):func(0):reason(1)
```

## Example 1: Creating SSL Files from the Command Line on Unix

The following example shows a set of commands to create MySQL server and client certificate and key files. You will need to respond to several prompts by the `openssl` commands. To generate test files, you can press Enter to all prompts. To generate files for production use, you should provide nonempty responses.

```
# Create clean environment
shell> rm -rf newcerts
shell> mkdir newcerts && cd newcerts

# Create CA certificate
shell> openssl genrsa 2048 > ca-key.pem
shell> openssl req -new -x509 -nodes -days 3600 \
    -key ca-key.pem -out ca.pem

# Create server certificate, remove passphrase, and sign it
# server-cert.pem = public key, server-key.pem = private key
shell> openssl req -newkey rsa:2048 -days 3600 \
    -nodes -keyout server-key.pem -out server-req.pem
shell> openssl rsa -in server-key.pem -out server-key.pem
shell> openssl x509 -req -in server-req.pem -days 3600 \
    -CA ca.pem -CAkey ca-key.pem -set_serial 01 -out server-cert.pem

# Create client certificate, remove passphrase, and sign it
# client-cert.pem = public key, client-key.pem = private key
shell> openssl req -newkey rsa:2048 -days 3600 \
    -nodes -keyout client-key.pem -out client-req.pem
shell> openssl rsa -in client-key.pem -out client-key.pem
shell> openssl x509 -req -in client-req.pem -days 3600 \
    -CA ca.pem -CAkey ca-key.pem -set_serial 01 -out client-cert.pem
```

After generating the certificates, verify them:

```
shell> openssl verify -CAfile ca.pem server-cert.pem client-cert.pem
server-cert.pem: OK
client-cert.pem: OK
```

To see the contents of a certificate (for example, to check the range of dates over which a certificate is valid), invoke `openssl` like this:

```
shell> openssl x509 -text -in ca.pem
shell> openssl x509 -text -in server-cert.pem
shell> openssl x509 -text -in client-cert.pem
```

Now you have a set of files that can be used as follows:

- `ca.pem`: Use this as the argument to `--ssl-ca` on the server and client sides. (The CA certificate, if used, must be the same on both sides.)
- `server-cert.pem`, `server-key.pem`: Use these as the arguments to `--ssl-cert` and `--ssl-key` on the server side.

- `client-cert.pem`, `client-key.pem`: Use these as the arguments to `--ssl-cert` and `--ssl-key` on the client side.

To use the files for SSL connections, see [Section 7.4.4, “Configuring MySQL to Use Secure Connections”](#).

## Example 2: Creating SSL Files Using a Script on Unix

Here is an example script that shows how to set up SSL certificate and key files for MySQL. After executing the script, use the files for SSL connections as described in [Section 7.4.4, “Configuring MySQL to Use Secure Connections”](#).

```

DIR=`pwd`/openssl
PRIV=$DIR/private

mkdir $DIR $PRIV $DIR/newcerts
cp /usr/share/ssl/openssl.cnf $DIR
replace ./demoCA $DIR -- $DIR/openssl.cnf

# Create necessary files: $database, $serial and $new_certs_dir
# directory (optional)

touch $DIR/index.txt
echo "01" > $DIR/serial

#
# Generation of Certificate Authority(CA)
#

openssl req -new -x509 -keyout $PRIV/cakey.pem -out $DIR/ca.pem \
    -days 3600 -config $DIR/openssl.cnf

# Sample output:
# Using configuration from /home/finley/openssl/openssl.cnf
# Generating a 1024 bit RSA private key
# .....++++++
# .....++++++
# writing new private key to '/home/finley/openssl/private/cakey.pem'
# Enter PEM pass phrase:
# Verifying password - Enter PEM pass phrase:
# -----
# You are about to be asked to enter information that will be
# incorporated into your certificate request.
# What you are about to enter is what is called a Distinguished Name
# or a DN.
# There are quite a few fields but you can leave some blank
# For some fields there will be a default value,
# If you enter '.', the field will be left blank.
# -----
# Country Name (2 letter code) [AU]:FI
# State or Province Name (full name) [Some-State]:.
# Locality Name (eg, city) []:
# Organization Name (eg, company) [Internet Widgits Pty Ltd]:MySQL AB
# Organizational Unit Name (eg, section) []:
# Common Name (eg, YOUR name) []:MySQL admin
# Email Address []:

#
# Create server request and key
#

openssl req -new -keyout $DIR/server-key.pem -out \
    $DIR/server-req.pem -days 3600 -config $DIR/openssl.cnf

# Sample output:
# Using configuration from /home/finley/openssl/openssl.cnf
# Generating a 1024 bit RSA private key
# .....++++++
# .....++++++
# writing new private key to '/home/finley/openssl/server-key.pem'
# Enter PEM pass phrase:

```

```
# Verifying password - Enter PEM pass phrase:

ssl-cert=$DIR/server-cert.pem
ssl-key=$DIR/server-key.pem
EOF
```

### Example 3: Creating SSL Files on Windows

Download OpenSSL for Windows if it is not installed on your system. An overview of available packages can be seen here:

<http://www.slproweb.com/products/Win32OpenSSL.html>

Choose the Win32 OpenSSL Light or Win64 OpenSSL Light package, depending on your architecture (32-bit or 64-bit). The default installation location will be `C:\OpenSSL-Win32` or `C:\OpenSSL-Win64`, depending on which package you downloaded. The following instructions assume a default location of `C:\OpenSSL-Win32`. Modify this as necessary if you are using the 64-bit package.

If a message occurs during setup indicating '`...critical component is missing: Microsoft Visual C++ 2008 Redistributables`', cancel the setup and download one of the following packages as well, again depending on your architecture (32-bit or 64-bit):

- Visual C++ 2008 Redistributables (x86), available at:

<http://www.microsoft.com/downloads/details.aspx?familyid=9B2DA534-3E03-4391-8A4D-074B9F2BC1BF>

- Visual C++ 2008 Redistributables (x64), available at:

<http://www.microsoft.com/downloads/details.aspx?familyid=bd2a6171-e2d6-4230-b809-9a8d7548c1b6>

After installing the additional package, restart the OpenSSL setup procedure.

During installation, leave the default `C:\OpenSSL-Win32` as the install path, and also leave the default option '`Copy OpenSSL DLL files to the Windows system directory`' selected.

When the installation has finished, add `C:\OpenSSL-Win32\bin` to the Windows System Path variable of your server:

1. On the Windows desktop, right-click the **My Computer** icon, and select **Properties**.
2. Select the **Advanced** tab from the **System Properties** menu that appears, and click the **Environment Variables** button.
3. Under **System Variables**, select **Path**, then click the **Edit** button. The **Edit System Variable** dialogue should appear.
4. Add '`C:\OpenSSL-Win32\bin`' to the end (notice the semicolon).
5. Press OK 3 times.
6. Check that OpenSSL was correctly integrated into the Path variable by opening a new command console (`Start>Run>cmd.exe`) and verifying that OpenSSL is available:

```
Microsoft Windows [Version ...]
Copyright (c) 2006 Microsoft Corporation. All rights reserved.

C:\Windows\system32>cd \

C:\>openssl
OpenSSL> exit <<< If you see the OpenSSL prompt, installation was successful.

C:\>
```

Depending on your version of Windows, the preceding path-setting instructions might differ slightly.

After OpenSSL has been installed, use instructions similar to those from Example 1 (shown earlier in this section), with the following changes:

- Change the following Unix commands:

```
# Create clean environment
shell> rm -rf newcerts
shell> mkdir newcerts && cd newcerts
```

On Windows, use these commands instead:

```
# Create clean environment
C:\> md c:\newcerts
C:\> cd c:\newcerts
```

- When a `'\'` character is shown at the end of a command line, this `'\'` character must be removed and the command lines entered all on a single line.

After generating the certificate and key files, to use them for SSL connections, see [Section 7.4.4, “Configuring MySQL to Use Secure Connections”](#).

### 7.4.6.3 Creating RSA Keys Using openssl

This section describes how to use the `openssl` command to set up the RSA key files that enable MySQL to support secure password exchange over unencrypted connections for accounts authenticated by the `sha256_password` plugin.

#### Note

There are easier alternatives to generating the files required for RSA than the procedure described here: Let the server autogenerate them or use the `mysql_ssl_rsa_setup` program. See [Section 7.4.6.1, “Creating SSL and RSA Certificates and Keys using MySQL”](#).

To create the RSA private and public key-pair files, run these commands while logged into the system account used to run the MySQL server so the files will be owned by that account:

```
openssl genrsa -out private_key.pem 2048
openssl rsa -in private_key.pem -pubout -out public_key.pem
```

Those commands create 2,048-bit keys. To create stronger keys, use a larger value.

Then set the access modes for the key files. The private key should be readable only by the server, whereas the public key can be freely distributed to client users:

```
chmod 400 private_key.pem
chmod 444 public_key.pem
```

## 7.4.7 Connecting to MySQL Remotely from Windows with SSH

This section describes how to get a secure connection to a remote MySQL server with SSH. The information was provided by David Carlson [dcarlson@mplcomm.com](mailto:dcarlson@mplcomm.com).

1. Install an SSH client on your Windows machine. For a comparison of SSH clients, see [http://en.wikipedia.org/wiki/Comparison\\_of\\_SSH\\_clients](http://en.wikipedia.org/wiki/Comparison_of_SSH_clients).
2. Start your Windows SSH client. Set `Host_Name = yourmysqlserver_URL_or_IP`. Set `userid=your_userid` to log in to your server. This `userid` value might not be the same as the user name of your MySQL account.
3. Set up port forwarding. Either do a remote forward (Set `local_port: 3306`, `remote_host: yourmysqlservername_or_ip`, `remote_port: 3306`) or a local forward (Set `port: 3306`, `host: localhost`, `remote port: 3306`).
4. Save everything, otherwise you will have to redo it the next time.
5. Log in to your server with the SSH session you just created.
6. On your Windows machine, start some ODBC application (such as Access).

7. Create a new file in Windows and link to MySQL using the ODBC driver the same way you normally do, except type in `localhost` for the MySQL host server, not `yourmysqlservername`.

At this point, you should have an ODBC connection to MySQL, encrypted using SSH.

## 7.5 Security Plugins

MySQL includes several plugins that implement security features:

- Plugins for authenticating attempts by clients to connect to MySQL Server. Plugins are available for several authentication protocols. For general discussion of the authentication process, see [Section 7.3.8, “Pluggable Authentication”](#). For characteristics of specific authentication plugins, see [Section 7.5.1, “Authentication Plugins”](#).
- A password-validation plugin for implementing password strength policies and assessing the strength of potential passwords. See [Section 7.5.3, “The Password Validation Plugin”](#).
- A keyring plugin that provides secure storage for sensitive information. See [Section 7.5.4, “The MySQL Keyring”](#).
- (MySQL Enterprise Edition only) MySQL Enterprise Audit, implemented using a server plugin, uses the open MySQL Audit API to enable standard, policy-based monitoring and logging of connection and query activity executed on specific MySQL servers. Designed to meet the Oracle audit specification, MySQL Enterprise Audit provides an out of box, easy to use auditing and compliance solution for applications that are governed by both internal and external regulatory guidelines.
- (MySQL Enterprise Edition only) MySQL Enterprise Firewall, an application-level firewall that enables database administrators to permit or deny SQL statement execution based on matching against whitelists of accepted statement patterns. This helps harden MySQL Server against attacks such as SQL injection or attempts to exploit applications by using them outside of their legitimate query workload characteristics.

### 7.5.1 Authentication Plugins

The following sections describe the authentication plugins available in MySQL.

The default plugin is `mysql_native_password` unless the `default_authentication_plugin` system variable is set otherwise.

#### 7.5.1.1 The Native Authentication Plugin

MySQL includes two plugins that implement native authentication; that is, authentication against passwords stored in the `Password` column of the `mysql.user` table. This section describes `mysql_native_password`, which implements authentication against the `mysql.user` table using the native password hashing method. For information about `mysql_old_password`, which implements authentication using the older (pre-4.1) password hashing method, see [Section 7.5.1.2, “The Old Native Authentication Plugin”](#). For information about these password hashing methods, see [Section 7.1.2.4, “Password Hashing in MySQL”](#).

The `mysql_native_password` native authentication plugin is backward compatible. Clients older than MySQL 5.5.7 do not support authentication *plugins* but do use the native authentication *protocol*, so they can connect to servers from MySQL 5.5.7 and up.

The following table shows the plugin names on the server and client sides.

**Table 7.9 MySQL Native Password Authentication Plugin**

|                         |                                    |
|-------------------------|------------------------------------|
| Server-side plugin name | <code>mysql_native_password</code> |
|-------------------------|------------------------------------|

|                         |                                    |
|-------------------------|------------------------------------|
| Client-side plugin name | <code>mysql_native_password</code> |
| Library file name       | None (plugins are built in)        |

The plugin exists in both client and server form:

- The server-side plugin is built into the server, need not be loaded explicitly, and cannot be disabled by unloading it.
- The client-side plugin is built into the `libmysqlclient` client library as of MySQL 5.5.7 and available to any program linked against `libmysqlclient` from that version or newer.
- MySQL client programs use `mysql_native_password` by default. The `--default-auth` option can be used as a hint about which client-side plugin the program can expect to use:

```
shell> mysql --default-auth=mysql_native_password ...
```

If an account row specifies no plugin name, the server authenticates the account using either the `mysql_native_password` or `mysql_old_password` plugin, depending on whether the password hash value in the `Password` column used native hashing or the older pre-4.1 hashing method. Clients must match the password in the `Password` column of the account row. As of MySQL 5.7.2, the server requires the plugin value to be nonempty, and as of 5.7.5, support for `mysql_old_password` is removed.

For general information about pluggable authentication in MySQL, see [Section 7.3.8, “Pluggable Authentication”](#).

### 7.5.1.2 The Old Native Authentication Plugin

MySQL includes two plugins that implement native authentication; that is, authentication against passwords stored in the `Password` column of the `mysql.user` table. This section describes `mysql_old_password`, which implements authentication against the `mysql.user` table using the older (pre-4.1) password hashing method. For information about `mysql_native_password`, which implements authentication using the native password hashing method, see [Section 7.5.1.1, “The Native Authentication Plugin”](#). For information about these password hashing methods, see [Section 7.1.2.4, “Password Hashing in MySQL”](#).

#### Note

Passwords that use the pre-4.1 hashing method are less secure than passwords that use the native password hashing method and should be avoided. Pre-4.1 passwords are deprecated and support for them (including the `mysql_old_password` plugin) is removed in MySQL 5.7.5. For account upgrade instructions, see [Section 7.5.1.3, “Migrating Away from Pre-4.1 Password Hashing and the `mysql\_old\_password` Plugin”](#).

The `mysql_old_password` native authentication plugin is backward compatible. Clients older than MySQL 5.5.7 do not support authentication *plugins* but do use the native authentication *protocol*, so they can connect to servers from MySQL 5.5.7 and up.

The following table shows the plugin names on the server and client sides.

**Table 7.10 MySQL Old Native Authentication Plugin**

|                         |                                 |
|-------------------------|---------------------------------|
| Server-side plugin name | <code>mysql_old_password</code> |
| Client-side plugin name | <code>mysql_old_password</code> |
| Library file name       | None (plugins are built in)     |

The plugin exists in both client and server form:

- The server-side plugin is built into the server, need not be loaded explicitly, and cannot be disabled by unloading it.
- The client-side plugin is built into the `libmysqlclient` client library as of MySQL 5.5.7 and available to any program linked against `libmysqlclient` from that version or newer.
- MySQL client programs can use the `--default-auth` option to specify the `mysql_old_password` plugin as a hint about which client-side plugin the program can expect to use:

```
shell> mysql --default-auth=mysql_old_password ...
```

If an account row specifies no plugin name, the server authenticates the account using either the `mysql_native_password` or `mysql_old_password` plugin, depending on whether the password hash value in the `Password` column used native hashing or the older pre-4.1 hashing method. Clients must match the password in the `Password` column of the account row. As of MySQL 5.7.2, the server requires the plugin value to be nonempty, and as of 5.7.5, support for `mysql_old_password` is removed.

For general information about pluggable authentication in MySQL, see [Section 7.3.8, “Pluggable Authentication”](#). For information about setting up proxy users, see [Section 7.3.9, “Proxy Users”](#).

### 7.5.1.3 Migrating Away from Pre-4.1 Password Hashing and the `mysql_old_password` Plugin

The MySQL server authenticates connection attempts for each account listed in the `mysql.user` table using the authentication plugin named in the `plugin` column. If the `plugin` column is empty, the server authenticates the account as follows:

- Before MySQL 5.7.2, the server uses the `mysql_native_password` or `mysql_old_password` plugin implicitly, depending on the format of the password hash in the `Password` column. If the `Password` value is empty or a 4.1 password hash (41 characters), the server uses `mysql_native_password`. If the password value is a pre-4.1 password hash (16 characters), the server uses `mysql_old_password`. (For additional information about these hash formats, see [Section 7.1.2.4, “Password Hashing in MySQL”](#).)
- As of MySQL 5.7.2, the server requires the `plugin` column to be nonempty and disables accounts that have an empty `plugin` value.

Pre-4.1 password hashes and the `mysql_old_password` plugin are deprecated as of MySQL 5.6.5 and support for them is removed in MySQL 5.7.5. They provide a level of security inferior to that offered by 4.1 password hashing and the `mysql_native_password` plugin.

Given the requirement in MySQL 5.7.2 that the `plugin` column must be nonempty, coupled with removal of `mysql_old_password` support in 5.7.5, DBAs are advised to upgrade accounts as follows:

- Upgrade accounts that use `mysql_native_password` implicitly to use it explicitly
- Upgrade accounts that use `mysql_old_password` (either implicitly or explicitly) to use `mysql_native_password` explicitly

The instructions in this section describe how to perform those upgrades. The result is that no account has an empty `plugin` value and no account uses pre-4.1 password hashing or the `mysql_old_password` plugin.

As a variant on these instructions, DBAs might offer users the choice to upgrade to the `sha256_password` plugin, which authenticates using SHA-256 password hashes. For information about this plugin, see [Section 7.5.1.4, “The SHA-256 Authentication Plugin”](#).

The following table lists the types of `mysql.user` accounts considered in this discussion.

| plugin Column                      | Password Column | Authentication Result                              | Upgrade Action                  |
|------------------------------------|-----------------|--|---------------------------------|
| Empty                              | Empty           | Implicitly uses <code>mysql_native_password</code> | Assign plugin                   |
| Empty                              | 4.1 hash        | Implicitly uses <code>mysql_native_password</code> | Assign plugin                   |
| Empty                              | Pre-4.1 hash    | Implicitly uses <code>mysql_old_password</code>    | Assign plugin, rehash password  |
| <code>mysql_native_password</code> | Empty           | Explicitly uses <code>mysql_native_password</code> | None                            |
| <code>mysql_native_password</code> | 4.1 hash        | Explicitly uses <code>mysql_native_password</code> | None                            |
| <code>mysql_old_password</code>    | Empty           | Explicitly uses <code>mysql_old_password</code>    | Upgrade plugin                  |
| <code>mysql_old_password</code>    | Pre-4.1 hash    | Explicitly uses <code>mysql_old_password</code>    | Upgrade plugin, rehash password |

Accounts corresponding to lines for the `mysql_native_password` plugin require no upgrade action (because no change of plugin or hash format is required). For accounts corresponding to lines for which the password is empty, consider asking the account owners to choose a password (or require it by using `ALTER USER` to expire empty account passwords).

### Upgrading Accounts from Implicit to Explicit `mysql_native_password` Use

Accounts that have an empty plugin and a 4.1 password hash use `mysql_native_password` implicitly. To upgrade these accounts to use `mysql_native_password` explicitly, execute these statements:

```
UPDATE mysql.user SET plugin = 'mysql_native_password'
WHERE plugin = '' AND (Password = '' OR LENGTH(Password) = 41);
FLUSH PRIVILEGES;
```

Before MySQL 5.7.2, you can execute those statements to upgrade accounts proactively. As of MySQL 5.7.2, you can run `mysql_upgrade`, which performs the same operation among its upgrade actions.

Notes:

- The upgrade operation just described is safe to execute at any time because it makes the `mysql_native_password` plugin explicit only for accounts that already use it implicitly.
- This operation requires no password changes, so it can be performed without affecting users or requiring their involvement in the upgrade process.

### Upgrading Accounts from `mysql_old_password` to `mysql_native_password`

Accounts that use `mysql_old_password` (either implicitly or explicitly) should be upgraded to use `mysql_native_password` explicitly. This requires changing the plugin *and* changing the password from pre-4.1 to 4.1 hash format.

For the accounts covered in this step that must be upgraded, one of these conditions is true:

- The account uses `mysql_old_password` implicitly because the `plugin` column is empty and the password has the pre-4.1 hash format (16 characters).
- The account uses `mysql_old_password` explicitly.

To identify such accounts, use this query:

```
SELECT User, Host, Password FROM mysql.user
WHERE (plugin = '' AND LENGTH(Password) = 16)
OR plugin = 'mysql_old_password';
```

The following discussion provides two methods for updating that set of accounts. They have differing characteristics, so read both and decide which is most suitable for a given MySQL installation.

### Method 1.

Characteristics of this method:

- It requires that server and clients be run with `secure_auth=0` until all users have been upgraded to `mysql_native_password`. (Otherwise, users cannot connect to the server using their old-format password hashes for the purpose of upgrading to a new-format hash.)
- It works for MySQL 5.5 through 5.7.1. As of 5.7.2, it does not work because the server requires accounts to have a nonempty plugin and disables them otherwise. Therefore, if you have already upgraded to 5.7.2 or later, choose Method 2, described later.

You should ensure that the server is running with `secure_auth=0`.

For all accounts that use `mysql_old_password` explicitly, set them to the empty plugin:

```
UPDATE mysql.user SET plugin = ''
WHERE plugin = 'mysql_old_password';
FLUSH PRIVILEGES;
```

To also expire the password for affected accounts, use these statements instead:

```
UPDATE mysql.user SET plugin = '', password_expired = 'Y'
WHERE plugin = 'mysql_old_password';
FLUSH PRIVILEGES;
```

Now affected users can reset their password to use 4.1 hashing. Ask each user who now has an empty plugin to connect to the server and execute these statements:

```
SET old_passwords = 0;
SET PASSWORD = PASSWORD('user-chosen-password');
```

#### Note

The client-side `--secure-auth` option is enabled by default, so remind users to disable it or they will be unable to connect:

```
shell> mysql -u user_name -p --secure-auth=0
```

After an affected user has executed those statements, you can set the corresponding account plugin to `mysql_native_password` to make the plugin explicit. Or you can periodically run these statements to find and fix any accounts for which affected users have reset their password:

```
UPDATE mysql.user SET plugin = 'mysql_native_password'
WHERE plugin = '' AND (Password = '' OR LENGTH(Password) = 41);
FLUSH PRIVILEGES;
```

When there are no more accounts with an empty plugin, this query returns an empty result:

```
SELECT User, Host, Password FROM mysql.user
WHERE (plugin = '' AND LENGTH(Password) = 16);
```

At that point, all accounts have been migrated away from pre-4.1 password hashing and the server no longer need be run with `secure_auth=0`.

## Method 2.

Characteristics of this method:

- It assigns each affected account a new password, so you must tell each such user the new password and ask the user to choose a new one. Communication of passwords to users is outside the scope of MySQL, but should be done carefully.
- It does not require server or clients to be run with `secure_auth=0`.
- It works for any version of MySQL 5.5 or later (and for 5.7.6 or later has an easier variant).

With this method, you update each account separately due to the need to set passwords individually. *Choose a different password for each account.*

Suppose that `'user1'@'localhost'` is one of the accounts to be upgraded. Modify it as follows:

- In MySQL 5.7.6 and higher, `ALTER USER` provides the capability of modifying both the account password and its authentication plugin, so you need not modify the `mysql.user` table directly:

```
ALTER USER 'user1'@'localhost'
IDENTIFIED WITH mysql_native_password BY 'DBA-chosen-password';
```

To also expire the account password, use this statement instead:

```
ALTER USER 'user1'@'localhost'
IDENTIFIED WITH mysql_native_password BY 'DBA-chosen-password'
PASSWORD EXPIRE;
```

Then tell the user the new password and ask the user to connect to the server with that password and execute this statement to choose a new password:

```
ALTER USER USER() IDENTIFIED BY 'user-chosen-password';
```

- Before MySQL 5.7.6, you must modify the `mysql.user` table directly using these statements:

```
SET old_passwords = 0;
UPDATE mysql.user SET plugin = 'mysql_native_password',
Password = PASSWORD('DBA-chosen-password')
WHERE (User, Host) = ('user1', 'localhost');
FLUSH PRIVILEGES;
```

To also expire the account password, use these statements instead:

```
SET old_passwords = 0;
UPDATE mysql.user SET plugin = 'mysql_native_password',
Password = PASSWORD('DBA-chosen-password'), password_expired = 'Y'
WHERE (User, Host) = ('user1', 'localhost');
FLUSH PRIVILEGES;
```

Then tell the user the new password and ask the user to connect to the server with that password and execute these statements to choose a new password:

```
SET old_passwords = 0;
```

```
SET PASSWORD = PASSWORD( 'user-chosen-password' );
```

Repeat for each account to be upgraded.

### 7.5.1.4 The SHA-256 Authentication Plugin

MySQL provides an authentication plugin that implements SHA-256 hashing for user account passwords.

#### Important

To connect to the server using an account that authenticates with the `sha256_password` plugin, you must use either an SSL connection or an unencrypted connection that encrypts the password using RSA, as described later in this section. Either way, use of the `sha256_password` plugin requires that MySQL be built with SSL capabilities. See [Section 7.4, “Using Secure Connections”](#).

The following table shows the plugin names on the server and client sides.

**Table 7.11 MySQL SHA-256 Authentication Plugin**

|                         |                              |
|-------------------------|------------------------------|
| Server-side plugin name | <code>sha256_password</code> |
| Client-side plugin name | <code>sha256_password</code> |
| Library file name       | None (plugins are built in)  |

The server-side `sha256_password` plugin is built into the server, need not be loaded explicitly, and cannot be disabled by unloading it. Similarly, clients need not specify the location of the client-side plugin.

To set up an account that uses the `sha256_password` plugin for SHA-256 password hashing, use the following statement for MySQL 5.7.6 and up:

```
CREATE USER 'sha256user'@'localhost'
IDENTIFIED WITH sha256_password BY 'Sh@256Pa33';
```

Before MySQL 5.7.6, use this procedure:

1. Create the account and specify that it authenticates using the `sha256_password` plugin:

```
CREATE USER 'sha256user'@'localhost' IDENTIFIED WITH sha256_password;
```

2. Set the `old_passwords` system variable to 2 to cause the `PASSWORD( )` function to use SHA-256 hashing of password strings, then set the account password:

```
SET old_passwords = 2;
SET PASSWORD FOR 'sha256user'@'localhost' = PASSWORD( 'Sh@256Pa33' );
```

Alternatively, start the server with the default authentication plugin set to `sha256_password`. For example, put these lines in the server option file:

```
[mysqld]
default_authentication_plugin=sha256_password
```

That causes the `sha256_password` plugin to be used by default for new accounts. As a result, it is possible to create the account and set its password without naming the plugin explicitly using this `CREATE USER` syntax:

```
CREATE USER 'sha256user'@'localhost' IDENTIFIED BY 'Sh@256Pa33';
```

In this case, the server assigns the `sha256_password` plugin to the account and encrypts the password using SHA-256.

Accounts in the `mysql.user` table that use SHA-256 passwords can be identified as rows with `'sha256_password'` in the `plugin` column and a SHA-256 password hash in the `authentication_string` column.

Another consequence of using `sha256_password` as the default authentication plugin is that to create an account that uses a different plugin, you must specify the plugin using an `IDENTIFIED WITH` clause in the `CREATE USER` statement. For example, to use the `mysql_native_password` plugin, use this statement for MySQL 5.7.6 and up:

```
CREATE USER 'nativeuser'@'localhost'  
IDENTIFIED WITH mysql_native_password BY 'N@tivePa33';
```

Before MySQL 5.7.6, create the account, then set `old_passwords` appropriately for the plugin before using `SET PASSWORD` to set the account password.

```
CREATE USER 'nativeuser'@'localhost' IDENTIFIED WITH mysql_native_password;  
SET old_passwords = 0;  
SET PASSWORD FOR 'nativeuser'@'localhost' = PASSWORD('N@tivePa33');
```

Before MySQL 5.7.6, to set or change the password for an account that authenticates using the `sha256_password` plugin, be sure that the value of `old_passwords` is 2 before using `SET PASSWORD`. If `old_passwords` has a value other than 2, an error occurs for attempts to set the password:

```
mysql> SET old_passwords = 0;  
mysql> SET PASSWORD FOR 'sha256user'@'localhost' = PASSWORD('NewSh@256Pa33');  
ERROR 1827 (HY000): The password hash doesn't have the expected format.  
Check if the correct password algorithm is being used with the  
PASSWORD() function.
```

For more information about `old_passwords` and `PASSWORD()`, see [Section 6.1.5, “Server System Variables”](#), and [Section 13.13, “Encryption and Compression Functions”](#).

MySQL can be compiled using either OpenSSL or yaSSL (see [Section 7.4.1, “OpenSSL Versus yaSSL”](#)). The `sha256_password` plugin works with distributions compiled using either package, but if MySQL is compiled using OpenSSL, RSA encryption is available and `sha256_password` implements the following additional capabilities. (To enable these capabilities, you must also follow the RSA configuration procedure given later in this section.)

- It is possible for the client to transmit passwords to the server using RSA encryption during the client connection process, as described later.
- The server exposes two additional system variables, `sha256_password_private_key_path` and `sha256_password_public_key_path`. It is intended that the database administrator will set these to the names of the RSA private and public key-pair files at server startup if the key files have names that differ from the system variable default values.
- The server exposes a status variable, `Rsa_public_key`, that displays the RSA public key value.
- The `mysql` and `mysqltest` client programs support a `--server-public-key-path` option for specifying an RSA public key file explicitly.

For clients that use the `sha256_password` plugin, passwords are never exposed as cleartext when connecting to the server. How password transmission occurs depends on whether an SSL connection is used and whether RSA encryption is available:

- If an SSL connection is used, the password is sent as cleartext but cannot be snooped because the connection is encrypted using SSL.
- If an SSL connection is not used but RSA encryption is available, the password is sent within an unencrypted connection, but the password is RSA-encrypted to prevent snooping. When the server receives the password, it decrypts it. A scramble is used in the encryption to prevent repeat attacks.
- If an SSL connection is not used and RSA encryption is not available, the `sha256_password` plugin causes the connection attempt to fail because the password cannot be sent without being exposed as cleartext.

As mentioned previously, RSA password encryption is available only if MySQL was compiled using OpenSSL. The implication for MySQL distributions compiled using yaSSL is that SHA-256 passwords can be used only when clients use SSL to access the server. See [Section 7.4.4, “Configuring MySQL to Use Secure Connections”](#).

Assuming that MySQL has been compiled using OpenSSL, the following procedure describes how to enable RSA encryption of passwords during the client connection process:

1. Create the RSA private and public key-pair files using the instructions in [Section 7.4.6, “Creating SSL and RSA Certificates and Keys”](#).
2. If the private and public key files are located in the data directory and are named `private_key.pem` and `public_key.pem` (the default values of the `sha256_password_private_key_path` and `sha256_password_public_key_path` system variables), the server will use them automatically at startup.

Otherwise, in the server option file, set the system variables to the key file names. If the files are located in the server data directory, you need not specify their full path names:

```
[mysqld]
sha256_password_private_key_path=myprivkey.pem
sha256_password_public_key_path=mypubkey.pem
```

If the key files are not located in the data directory, or to make their locations explicit in the system variable values, use full path names:

```
[mysqld]
sha256_password_private_key_path=/usr/local/mysql/myprivkey.pem
sha256_password_public_key_path=/usr/local/mysql/mypubkey.pem
```

3. Restart the server, then connect to it and check the `Rsa_public_key` status variable value. The value will differ from that shown here, but should be nonempty:

```
mysql> SHOW STATUS LIKE 'Rsa_public_key'\G
***** 1. row *****
Variable_name: Rsa_public_key
Value: -----BEGIN PUBLIC KEY-----
MIGfMA0GCsGSIb3DQEBAQUAA4GNADCBiQKBgQDO9nRUdd+KvSZgY7cNBZMNpwX6
MvElPbJFXO7u18nJ9lwc99Du/E7lw6CVXw7VKrXPehbVQUzGyUNkf45Nz/ckaaJa
aLgJOBcIDmNVnyU54OT/1lcs2xiyfaDMe8fCJ64ZwTnKbY2gkt1IMjUAB5Ogd5kJ
g8aV7EtKwyhHb0c30QIDAQAB
-----END PUBLIC KEY-----
```

If the value is empty, the server found some problem with the key files. Check the error log for diagnostic information.

After the server has been configured with the RSA key files, clients have the option of using them to connect to the server using accounts that authenticate with the `sha256_password` plugin. As mentioned previously, such accounts can use either an SSL connection (in which case RSA is not used) or an unencrypted connection that encrypts the password using RSA. Assume for the following

discussion that SSL is not used. Connecting to the server involves no special preparation on the client side. For example:

```
shell> mysql --ssl-mode=DISABLED -u sha256user -p
Enter password: Sh@256Pa33
```

For connection attempts by `sha256user`, the server determines that `sha256_password` is the appropriate authentication plugin and invokes it. The plugin finds that the connection does not use SSL and thus requires the password to be transmitted using RSA encryption. In this case, the plugin sends the RSA public key to the client, which uses it to encrypt the password and returns the result to the server. The plugin uses the RSA key on the server side to decrypt the password and accepts or rejects the connection based on whether the password is correct.

The server sends the public key to the client as needed, but if a copy of the RSA public key is available on the client host, the client can use it to save a round trip in the client/server protocol:

```
shell> mysql --ssl-mode=DISABLED -u sha256user -p --server-public-key-path=file_name
```

The public key value in the file named by the `--server-public-key-path` option should be the same as the key value in the server-side file named by the `sha256_password_public_key_path` system variable. If the key file contains a valid public key value but the value is incorrect, an access-denied error occurs. If the key file does not contain a valid public key, the client program cannot use it. In this case, the `sha256_password` plugin sends the public key to the client as if no `--server-public-key-path` option had been specified.

Client users can get the RSA public key two ways:

- The database administrator can provide a copy of the public key file.
- A client user who can connect to the server some other way can use a `SHOW STATUS LIKE 'Rsa_public_key'` statement and save the returned key value in a file.

### 7.5.1.5 The PAM Authentication Plugin

#### Note

The PAM authentication plugin is an extension included in MySQL Enterprise Edition, a commercial product. To learn more about commercial products, see <http://www.mysql.com/products/>.

As of MySQL 5.7.9, MySQL Enterprise Edition includes an authentication plugin that enables MySQL Server to use PAM (Pluggable Authentication Modules) to authenticate MySQL users. PAM enables a system to use a standard interface to access various kinds of authentication methods, such as Unix passwords or an LDAP directory.

The PAM authentication plugin provides these capabilities:

- External authentication: The plugin enables MySQL Server to accept connections from users defined outside the MySQL grant tables and that authenticate using methods supported by PAM.
- Proxy user support: The plugin can return to MySQL a user name different from the login user, based on the groups the external user is in and the authentication string provided. This means that the plugin can return the MySQL user that defines the privileges the external PAM-authenticated user should have. For example, a PAM user named `joe` can connect and have the privileges of the MySQL user named `developer`.

The PAM authentication plugin has been tested on Linux and Mac OS X.

The PAM plugin uses the information passed to it by MySQL Server (such as user name, host name, password, and authentication string), plus whatever method is available for PAM lookup. The plugin

checks the user credentials against PAM and returns 'Authentication succeeded, Username is user\_name' or 'Authentication failed'.

The following table shows the plugin and library file names. The file name suffix might be different on your system. The file location must be the directory named by the `plugin_dir` system variable. For installation information, see [Installing the PAM Authentication Plugin](#).

**Table 7.12 MySQL PAM Authentication Plugin**

|                         |                                    |
|-------------------------|------------------------------------|
| Server-side plugin name | <code>authentication_pam</code>    |
| Client-side plugin name | <code>mysql_clear_password</code>  |
| Library file name       | <code>authentication_pam.so</code> |

The library file includes only the server-side plugin. The client-side plugin is built into the `libmysqlclient` client library. See [Section 7.5.1.8, “The Cleartext Client-Side Authentication Plugin”](#).

The server-side PAM authentication plugin is included only in MySQL Enterprise Edition. It is not included in MySQL community distributions. The client-side clear-text plugin that communicates with the server-side plugin is built into the MySQL client library and is included in all distributions, including community distributions. This permits clients from any MySQL distribution to connect to a server that has the server-side plugin loaded.

For general information about pluggable authentication in MySQL, see [Section 7.3.8, “Pluggable Authentication”](#). For proxy user information, see [Section 7.3.9, “Proxy Users”](#).

## Installing the PAM Authentication Plugin

The PAM authentication plugin must be located in the MySQL plugin directory (the directory named by the `plugin_dir` system variable). If necessary, set the value of `plugin_dir` at server startup to tell the server the plugin directory location.

To enable the plugin, start the server with the `--plugin-load` option. For example, put the following lines in your `my.cnf` file. If library files have a suffix different from `.so` on your system, substitute the correct suffix.

```
[mysqld]
plugin-load=authentication_pam.so
```

To verify plugin installation, examine the `INFORMATION_SCHEMA.PLUGINS` table or use the `SHOW PLUGINS` statement (see [Section 6.5.3, “Obtaining Server Plugin Information”](#)). For example:

```
mysql> SELECT PLUGIN_NAME, PLUGIN_STATUS FROM INFORMATION_SCHEMA.PLUGINS
-> WHERE PLUGIN_NAME LIKE 'authentication%';
+-----+-----+
| PLUGIN_NAME | PLUGIN_STATUS |
+-----+-----+
| authentication_pam | ACTIVE |
+-----+-----+
```

To associate a MySQL account with the PAM plugin, use the plugin name `authentication_pam` in the `IDENTIFIED WITH` clause of `CREATE USER` or `GRANT` statement that creates the account.

## Using the PAM Authentication Plugin

This section describes how to use the PAM authentication plugin to connect from MySQL client programs to the server. It is assumed that the server-side plugin is enabled, as described previously.

### Note

The client-side plugin with which the PAM plugin communicates simply sends the password to the server in clear text so it can be passed to PAM. This

may be a security problem in some configurations, but is necessary to use the server-side PAM library. To avoid problems if there is any possibility that the password would be intercepted, clients should connect to MySQL Server using a secure connection. See [Section 7.5.1.8, “The Cleartext Client-Side Authentication Plugin”](#).

To refer to the PAM authentication plugin in the `IDENTIFIED WITH` clause of a `CREATE USER` or `GRANT` statement, use the name `authentication_pam`. For example:

```
CREATE USER user
  IDENTIFIED WITH authentication_pam
  AS 'authentication_string';
```

The authentication string specifies the following types of information:

- PAM supports the notion of “service name,” which is a name that the system administrator can use to configure the authentication method for a particular application. There can be several such “applications” associated with a single database server instance, so the choice of service name is left to the SQL application developer. When you define an account that should authenticate using PAM, specify the service name in the authentication string.
- PAM provides a way for a PAM module to return to the server a MySQL user name other than the login name supplied at login time. Use the authentication string to control the mapping between login name and MySQL user name. If you want to take advantage of proxy user capabilities, the authentication string must include this kind of mapping.

For example, if the service name is `mysql` and users in the `root` and `users` PAM groups should be mapped to the `developer` and `data_entry` MySQL users, respectively, use a statement like this:

```
CREATE USER user
  IDENTIFIED WITH authentication_pam
  AS 'mysql, root=developer, users=data_entry';
```

Authentication string syntax for the PAM authentication plugin follows these rules:

- The string consists of a PAM service name, optionally followed by a group mapping list consisting of one or more keyword/value pairs each specifying a group name and a MySQL user name:

```
pam_service_name[,group_name=mysql_user_name]...
```

The plugin parses the authentication string on each login check. To minimize overhead, keep the string as short as possible.

- Each `group_name=mysql_user_name` pair must be preceded by a comma.
- Leading and trailing spaces not inside double quotation marks are ignored.
- Unquoted `pam_service_name`, `group_name`, and `mysql_user_name` values can contain anything except equal sign, comma, or space.
- If a `pam_service_name`, `group_name`, or `mysql_user_name` value is quoted with double quotation marks, everything between the quotation marks is part of the value. This is necessary, for example, if the value contains space characters. All characters are legal except double quotation mark and backslash (`\`). To include either character, escape it with a backslash.

If the plugin successfully authenticates a login name, it looks for a group mapping list in the authentication string and, if present, uses it to return a different user name to the MySQL server based on the groups the external user is a member of:

- If the authentication string contains no group mapping list, the plugin returns the login name.

- If the authentication string does contain a group mapping list, the plugin examines each `group_name=mysql_user_name` pair in the list from left to right and tries to find a match for the `group_name` value in a non-MySQL directory of the groups assigned to the authenticated user and returns `mysql_user_name` for the first match it finds. If the plugin finds no match for any group, it returns the login name. If the plugin is not capable of looking up a group in a directory, it ignores the group mapping list and returns the login name.

The following sections describe how to set up several authentication scenarios that use the PAM authentication plugin:

- No proxy users. This uses PAM only to check login names and passwords. Every external user permitted to connect to MySQL Server should have a matching MySQL account that is defined to use external PAM authentication. (For a MySQL account of `user_name@host_name` to match the external user, `user_name` must be the login name and `host_name` must match the host from which the client connects.) Authentication can be performed by various PAM-supported methods. The discussion shows how to use traditional Unix passwords and LDAP.

PAM authentication, when not done through proxy users or groups, requires the MySQL account to have the same user name as the Unix account. Because MySQL user names are limited to 32 characters (16 before MySQL 5.7.8; see [Section 7.2.2, “Grant Tables”](#)), this limits PAM nonproxy authentication to Unix accounts with names of at most 16 characters.

- Proxy login only and group mapping. For this scenario, create one or a few MySQL accounts that define different sets of privileges. (Ideally, nobody should connect using those accounts directly.) Then define a default user authenticating through PAM that uses some mapping scheme (usually by the external groups the users are in) to map all the external logins to the few MySQL accounts holding the privilege sets. Any user that logs in is mapped to one of the MySQL accounts and uses its privileges. The discussion shows how to set this up using Unix passwords, but other PAM methods such as LDAP could be used instead.

Variations on these scenarios are possible. For example, you can permit some users to log in directly (without proxying) but require others to connect through proxy users.

The examples make the following assumptions. You might need to make some adjustments if your system is set up differently.

- The PAM configuration directory is `/etc/pam.d`.
- The PAM service name is `mysql`, which means that you must set up a PAM file named `mysql` in the PAM configuration directory (creating the file if it does not exist). If you use a service name different from `mysql`, the file name will be different and you must use a different name in the `AS 'auth_string'` clause of `CREATE USER` and `GRANT` statements.
- The examples use a login name of `antonio` and password of `verysecret`. Change these to correspond to the users you want to authenticate.

The PAM authentication plugin checks at initialization time whether the `AUTHENTICATION_PAM_LOG` environment value is set in the server's startup environment. If so, the plugin enables logging of diagnostic messages to the standard output. Depending on how your server is started, the message might appear on the console or in the error log. These messages can be helpful for debugging PAM-related problems that occur when the plugin performs authentication. For more information, see [PAM Authentication Plugin Debugging](#).

## Unix Password Authentication without Proxy Users

This authentication scenario uses PAM only to check Unix user login names and passwords. Every external user permitted to connect to MySQL Server should have a matching MySQL account that is defined to use external PAM authentication.

1. Verify that Unix authentication in PAM permits you to log in as `antonio` with password `verysecret`.

- Set up PAM to authenticate the `mysql` service by creating a file named `/etc/pam.d/mysql`. The file contents are system dependent, so check existing login-related files in the `/etc/pam.d` directory to see what they look like. On Linux, the `mysql` file might look like this:

```
#%PAM-1.0
auth            include      password-auth
account         include      password-auth
```

For Gentoo Linux, use `system-login` rather than `password-auth`. For OS X, use `login` rather than `password-auth`.

On Ubuntu and other Debian-based systems, use these file contents instead:

```
@include common-auth
@include common-account
@include common-session-noninteractive
```

- Create a MySQL account with the same user name as the Unix login name and define it to authenticate using the PAM plugin:

```
CREATE USER 'antonio'@'localhost'
  IDENTIFIED WITH authentication_pam AS 'mysql';
GRANT ALL PRIVILEGES ON mydb.* TO 'antonio'@'localhost';
```

- Connect to the MySQL server using the `mysql` command-line client. For example:

```
mysql --user=antonio --password=verysecret --enable-cleartext-plugin mydb
```

The server should permit the connection and the following query should return output as shown:

```
mysql> SELECT USER(), CURRENT_USER(), @@proxy_user;
+-----+-----+-----+
| USER()          | CURRENT_USER() | @@proxy_user |
+-----+-----+-----+
| antonio@localhost | antonio@localhost | NULL         |
+-----+-----+-----+
```

This demonstrates that `antonio` uses the privileges granted to the `antonio` MySQL account, and that no proxying has occurred.

## LDAP Authentication without Proxy Users

This authentication scenario uses PAM only to check LDAP user login names and passwords. Every external user permitted to connect to MySQL Server should have a matching MySQL account that is defined to use external PAM authentication.

- Verify that LDAP authentication in PAM permits you to log in as `antonio` with password `verysecret`.
- Set up PAM to authenticate the `mysql` service through LDAP by creating a file named `/etc/pam.d/mysql`. The file contents are system dependent, so check existing login-related files in the `/etc/pam.d` directory to see what they look like. On Linux, the `mysql` file might look like this:

```
#%PAM-1.0
auth            required      pam_ldap.so
account         required      pam_ldap.so
```

If PAM object files have a suffix different from `.so` on your system, substitute the correct suffix.

The PAM file might have a different format on some systems.

3. MySQL account creation and connecting to the server is the same as previously described in [Unix Password Authentication without Proxy Users](#).

## Unix Password Authentication with Proxy Users and Group Mapping

This authentication scheme uses proxying and group mapping to map users who connect to the MySQL server through PAM onto MySQL accounts that define different sets of privileges. Users do not connect directly through the accounts that define the privileges. Instead, they connect through a default proxy user authenticating through PAM that uses a mapping scheme to map all the external logins to the few MySQL accounts holding the privileges. Any user who connects is mapped to one of the MySQL accounts and uses its privileges.

The procedure shown here uses Unix password authentication. To use LDAP instead, see the early steps of [LDAP Authentication without Proxy Users](#).

1. Verify that Unix authentication in PAM permits you to log in as `antonio` with password `verysecret` and that `antonio` is a member of the `root` or `users` group.
2. Set up PAM to authenticate the `mysql` service. Put the following in `/etc/pam.d/mysql`:

```
#%PAM-1.0
auth            include      password-auth
account         include      password-auth
```

use `system-login` rather than `password-auth`. For OS X, use `login` rather than `password-auth`.

The PAM file might have a different format on some systems. For example, on Ubuntu and other Debian-based systems, use these file contents instead:

```
@include common-auth
@include common-account
@include common-session-noninteractive
```

3. Create a default proxy user (`'@'`) that maps the external PAM users to the proxied accounts. It maps external users from the `root` PAM group to the `developer` MySQL account and the external users from the `users` PAM group to the `data_entry` MySQL account:

```
CREATE USER '@'
  IDENTIFIED WITH authentication_pam
  AS 'mysql, root=developer, users=data_entry';
```

The mapping list following the service name is required when you set up proxy users. Otherwise, the plugin cannot tell how to map the name of PAM groups to the proper proxied user name.

If your MySQL installation has anonymous users, they might conflict with the default proxy user. For more information about this problem, and ways of dealing with it, see [Default Proxy User and Anonymous User Conflicts](#).

4. Create the proxied accounts that will be used to access the databases:

```
CREATE USER 'developer'@'localhost' IDENTIFIED BY 'very secret password';
GRANT ALL PRIVILEGES ON mydevdb.* TO 'developer'@'localhost';
CREATE USER 'data_entry'@'localhost' IDENTIFIED BY 'very secret password';
GRANT ALL PRIVILEGES ON mydb.* TO 'data_entry'@'localhost';
```

If you do not let anyone know the passwords for these accounts, other users cannot use them to connect directly to the MySQL server. Instead, it is expected that users will authenticate using PAM and that they will use the `developer` or `data_entry` account by proxy based on their PAM group.

- Grant the `PROXY` privilege to the proxy account for the proxied accounts:

```
GRANT PROXY ON 'developer'@'localhost' TO '@';
GRANT PROXY ON 'data_entry'@'localhost' TO '@';
```

- Connect to the MySQL server using the `mysql` command-line client. For example:

```
mysql --user=antonio --password=verysecret --enable-cleartext-plugin mydb
```

The server authenticates the connection using the `'@'` account. The privileges `antonio` will have depends on what PAM groups he is a member of. If `antonio` is a member of the `root` PAM group, the PAM plugin maps `root` to the `developer` MySQL user name and returns that name to the server. The server verifies that `'@'` has the `PROXY` privilege for `developer` and permits the connection. the following query should return output as shown:

```
mysql> SELECT USER(), CURRENT_USER(), @@proxy_user;
+-----+-----+-----+
| USER()          | CURRENT_USER()      | @@proxy_user |
+-----+-----+-----+
| antonio@localhost | developer@localhost | '@'          |
+-----+-----+-----+
```

This demonstrates that `antonio` uses the privileges granted to the `developer` MySQL account, and that proxying occurred through the default proxy user account.

If `antonio` is not a member of the `root` PAM group but is a member of the `users` group, a similar process occurs, but the plugin maps `user` group membership to the `data_entry` MySQL user name and returns that name to the server. In this case, `antonio` uses the privileges of the `data_entry` MySQL account:

```
mysql> SELECT USER(), CURRENT_USER(), @@proxy_user;
+-----+-----+-----+
| USER()          | CURRENT_USER()      | @@proxy_user |
+-----+-----+-----+
| antonio@localhost | data_entry@localhost | '@'          |
+-----+-----+-----+
```

## PAM Authentication Plugin Debugging

The PAM authentication plugin checks at initialization time whether the `AUTHENTICATION_PAM_LOG` environment value is set (the value does not matter). If so, the plugin enables logging of diagnostic messages to the standard output. These messages may be helpful for debugging PAM-related problems that occur when the plugin performs authentication.

Some messages include reference to PAM plugin source files and line numbers, which enables plugin actions to be tied more closely to the location in the code where they occur.

The following transcript demonstrates the kind of information produced by enabling logging. It resulted from a successful proxy authentication attempt.

### 7.5.1.6 The Windows Native Authentication Plugin

#### Note

The Windows authentication plugin is an extension included in MySQL Enterprise Edition, a commercial product. To learn more about commercial products, see <http://www.mysql.com/products/>.

As of MySQL 5.7.9, MySQL Enterprise Edition for Windows includes an authentication plugin that performs external authentication on Windows, enabling MySQL Server to use native Windows services

to authenticate client connections. Users who have logged in to Windows can connect from MySQL client programs to the server based on the information in their environment without specifying an additional password.

The client and server exchange data packets in the authentication handshake. As a result of this exchange, the server creates a security context object that represents the identity of the client in the Windows OS. This identity includes the name of the client account. The Windows authentication plugin uses the identity of the client to check whether it is a given account or a member of a group. By default, negotiation uses Kerberos to authenticate, then NTLM if Kerberos is unavailable.

The Windows authentication plugin provides these capabilities:

- External authentication: The plugin enables MySQL Server to accept connections from users defined outside the MySQL grant tables.
- Proxy user support: The plugin can return to MySQL a user name different from the client user. This means that the plugin can return the MySQL user that defines the privileges the external Windows-authenticated user should have. For example, a Windows user named `joe` can connect and have the privileges of the MySQL user named `developer`.

The following table shows the plugin and library file names. The file location must be the directory named by the `plugin_dir` system variable. For installation information, see [Installing the Windows Authentication Plugin](#).

**Table 7.13 MySQL Windows Authentication Plugin**

|                         |  |
|-------------------------|--|
| Server-side plugin name | <code>authentication_windows</code>        |
| Client-side plugin name | <code>authentication_windows_client</code> |
| Library file name       | <code>authentication_windows.dll</code>    |

The library file includes only the server-side plugin. The client-side plugin is built into the `libmysqlclient` client library.

The server-side Windows authentication plugin is included only in MySQL Enterprise Edition. It is not included in MySQL community distributions. The client-side plugin is included in all distributions, including community distributions. This permits clients from any distribution to connect to a server that has the server-side plugin loaded.

The Windows authentication plugin is supported on any version of Windows supported by MySQL 5.7 (see <http://www.mysql.com/support/supportedplatforms/database.html>).

For general information about pluggable authentication in MySQL, see [Section 7.3.8, “Pluggable Authentication”](#). For proxy user information, see [Section 7.3.9, “Proxy Users”](#).

## Installing the Windows Authentication Plugin

This section describes how to install the Windows authentication plugin. For general information about installing plugins, see [Section 6.5.2, “Installing and Uninstalling Plugins”](#).

To be usable by the server, the plugin library file must be located in the MySQL plugin directory (the directory named by the `plugin_dir` system variable). If necessary, set the value of `plugin_dir` at server startup to tell the server the plugin directory location.

To enable the plugin, start the server with the `--plugin-load` option. For example, put these lines in your `my.ini` file:

```
[mysqld]
```

```
plugin-load=authentication_windows.dll
```

To verify plugin installation, examine the `INFORMATION_SCHEMA.PLUGINS` table or use the `SHOW PLUGINS` statement (see [Section 6.5.3, “Obtaining Server Plugin Information”](#)). For example:

```
mysql> SELECT PLUGIN_NAME, PLUGIN_STATUS FROM INFORMATION_SCHEMA.PLUGINS
-> WHERE PLUGIN_NAME LIKE 'authentication%';
```

| PLUGIN_NAME            | PLUGIN_STATUS |
|------------------------|---------------|
| authentication_windows | ACTIVE        |

To associate a MySQL account with the Windows authentication plugin, use the plugin name `authentication_windows` in the `IDENTIFIED WITH` clause of `CREATE USER` or `GRANT` statement that creates the account.

## Using the Windows Authentication Plugin

The Windows authentication plugin supports the use of MySQL accounts such that users who have logged in to Windows can connect to the MySQL server without having to specify an additional password. It is assumed that the server-side plugin is enabled, as described previously. Once the DBA has enabled the server-side plugin and set up accounts to use it, clients can connect using those accounts with no other setup required on their part.

To refer to the Windows authentication plugin in the `IDENTIFIED WITH` clause of a `CREATE USER` or `GRANT` statement, use the name `authentication_windows`. Suppose that the Windows users `Rafal` and `Tasha` should be permitted to connect to MySQL, as well as any users in the `Administrators` or `Power Users` group. To set this up, create a MySQL account named `sql_admin` that uses the Windows plugin for authentication:

```
CREATE USER sql_admin
  IDENTIFIED WITH authentication_windows
  AS 'Rafal, Tasha, Administrators, "Power Users"';
```

The plugin name is `authentication_windows`. The string following the `AS` keyword is the authentication string. It specifies that the Windows users named `Rafal` or `Tasha` are permitted to authenticate to the server as the MySQL user `sql_admin`, as are any Windows users in the `Administrators` or `Power Users` group. The latter group name contains a space, so it must be quoted with double quote characters.

After you create the `sql_admin` account, a user who has logged in to Windows can attempt to connect to the server using that account:

```
C:\> mysql --user=sql_admin
```

No password is required here. The `authentication_windows` plugin uses the Windows security API to check which Windows user is connecting. If that user is named `Rafal` or `Tasha`, or is in the `Administrators` or `Power Users` group, the server grants access and the client is authenticated as `sql_admin` and has whatever privileges are granted to the `sql_admin` account. Otherwise, the server denies access.

Authentication string syntax for the Windows authentication plugin follows these rules:

- The string consists of one or more user mappings separated by commas.
- Each user mapping associates a Windows user or group name with a MySQL user name:

```
win_user_or_group_name=mysql_user_name
```

`win_user_or_group_name`

For the latter syntax, with no `mysql_user_name` value given, the implicit value is the MySQL user created by the `CREATE USER` statement. Thus, these statements are equivalent:

```
CREATE USER sql_admin
  IDENTIFIED WITH authentication_windows
  AS 'Rafal, Tasha, Administrators, "Power Users"';

CREATE USER sql_admin
  IDENTIFIED WITH authentication_windows
  AS 'Rafal=sql_admin, Tasha=sql_admin, Administrators=sql_admin,
    "Power Users"=sql_admin';
```

- Each backslash (`'\'`) in a value must be doubled because backslash is the escape character in MySQL strings.
- Leading and trailing spaces not inside double quotation marks are ignored.
- Unquoted `win_user_or_group_name` and `mysql_user_name` values can contain anything except equal sign, comma, or space.
- If a `win_user_or_group_name` and or `mysql_user_name` value is quoted with double quotation marks, everything between the quotation marks is part of the value. This is necessary, for example, if the name contains space characters. All characters within double quotes are legal except double quotation mark and backslash. To include either character, escape it with a backslash.
- `win_user_or_group_name` values use conventional syntax for Windows principals, either local or in a domain. Examples (note the doubling of backslashes):

```
domain\\user
.\\user
domain\\group
.\\group
BUILTIN\\WellKnownGroup
```

When invoked by the server to authenticate a client, the plugin scans the authentication string left to right for a user or group match to the Windows user. If there is a match, the plugin returns the corresponding `mysql_user_name` to the MySQL server. If there is no match, authentication fails.

A user name match takes preference over a group name match. Suppose that the Windows user named `win_user` is a member of `win_group` and the authentication string looks like this:

```
'win_group = sql_user1, win_user = sql_user2'
```

When `win_user` connects to the MySQL server, there is a match both to `win_group` and to `win_user`. The plugin authenticates the user as `sql_user2` because the more-specific user match takes precedence over the group match, even though the group is listed first in the authentication string.

Windows authentication always works for connections from the same computer on which the server is running. For cross-computer connections, both computers must be registered with Windows Active Directory. If they are in the same Windows domain, it is unnecessary to specify a domain name. It is also possible to permit connections from a different domain, as in this example:

```
CREATE USER sql_accounting
  IDENTIFIED WITH authentication_windows
  AS 'SomeDomain\\Accounting';
```

Here `SomeDomain` is the name of the other domain. The backslash character is doubled because it is the MySQL escape character within strings.

MySQL supports the concept of proxy users whereby a client can connect and authenticate to the MySQL server using one account but while connected has the privileges of another account (see [Section 7.3.9, “Proxy Users”](#)). Suppose that you want Windows users to connect using a single user name but be mapped based on their Windows user and group names onto specific MySQL accounts as follows:

- The `local_user` and `MyDomain\domain_user` local and domain Windows users should map to the `local_wlad` MySQL account.
- Users in the `MyDomain\Developers` domain group should map to the `local_dev` MySQL account.
- Local machine administrators should map to the `local_admin` MySQL account.

To set this up, create a proxy account for Windows users to connect to, and configure this account so that users and groups map to the appropriate MySQL accounts (`local_wlad`, `local_dev`, `local_admin`). In addition, grant the MySQL accounts the privileges appropriate to the operations they need to perform. The following instructions use `win_proxy` as the proxy account, and `local_wlad`, `local_dev`, and `local_admin` as the proxied accounts.

1. Create the proxy MySQL account:

```
CREATE USER win_proxy
  IDENTIFIED WITH authentication_windows
  AS 'local_user = local_wlad,
     MyDomain\domain_user = local_wlad,
     MyDomain\Developers = local_dev,
     BUILTIN\Administrators = local_admin';
```

2. For proxying to work, the proxied accounts must exist, so create them:

```
CREATE USER local_wlad IDENTIFIED BY 'wlad_pass';
CREATE USER local_dev IDENTIFIED BY 'dev_pass';
CREATE USER local_admin IDENTIFIED BY 'admin_pass';
```

If you do not let anyone know the passwords for these accounts, other users cannot use them to connect directly to the MySQL server.

You should also issue `GRANT` statements (not shown) that grant each proxied account the privileges it needs.

3. The proxy account must have the `PROXY` privilege for each of the proxied accounts:

```
GRANT PROXY ON local_wlad TO win_proxy;
GRANT PROXY ON local_dev TO win_proxy;
GRANT PROXY ON local_admin TO win_proxy;
```

Now the Windows users `local_user` and `MyDomain\domain_user` can connect to the MySQL server as `win_proxy` and when authenticated have the privileges of the account given in the authentication string—in this case, `local_wlad`. A user in the `MyDomain\Developers` group who connects as `win_proxy` has the privileges of the `local_dev` account. A user in the `BUILTIN\Administrators` group has the privileges of the `local_admin` account.

To configure authentication so that all Windows users who do not have their own MySQL account go through a proxy account, substitute the default proxy user (`' '@'`) for `win_proxy` in the preceding instructions. For information about the default proxy user, see [Section 7.3.9, “Proxy Users”](#).

If your MySQL installation has anonymous users, they might conflict with the default proxy user. For more information about this problem, and ways of dealing with it, see [Default Proxy User and Anonymous User Conflicts](#).

To use the Windows authentication plugin with Connector/Net connection strings in Connection/Net 6.4.4 and higher, see [Using the Windows Native Authentication Plugin](#).

Additional control over the Windows authentication plugin is provided by the `authentication_windows_use_principal_name` and `authentication_windows_log_level` system variables. See [Section 6.1.5, “Server System Variables”](#).

### 7.5.1.7 The No-Login Authentication Plugin

The `mysql_no_login` server-side authentication plugin prevents all client connections to any account that uses it. Use cases for such a plugin includes accounts that must be able to execute stored programs and views with elevated privileges without exposing those privileges to ordinary users, and proxy accounts that should never permit direct login.

The following table shows the plugin and library file names. The file name suffix might differ on your system. The file location is the directory named by the `plugin_dir` system variable. For installation information, see [Section 7.3.8, “Pluggable Authentication”](#).

**Table 7.14 MySQL “No Login” Authentication Plugin**

|                         |                                |
|-------------------------|--------------------------------|
| Server-side plugin name | <code>mysql_no_login</code>    |
| Client-side plugin name | None                           |
| Library file name       | <code>mysql_no_login.so</code> |

An account that authenticates using `mysql_no_login` may be used as the `DEFINER` for stored program and view objects. If such an object definition also includes `SQL SECURITY DEFINER`, it executes with that account's privileges. DBAs can use this behavior to provide access to confidential or sensitive data that is exposed only through well-controlled interfaces.

The following example provides a simple illustration of these principles. It defines an account that does not permit client connections, and associates with it a view that exposes only certain columns of the `mysql.user` table:

```
CREATE DATABASE nologindb;
CREATE USER 'nologin'@'localhost' IDENTIFIED WITH mysql_no_login;
GRANT ALL ON nologindb.* TO 'nologin'@'localhost';
GRANT SELECT ON mysql.user TO 'nologin'@'localhost';
CREATE DEFINER = 'nologin'@'localhost' SQL SECURITY DEFINER
VIEW nologindb.myview AS SELECT User, Host FROM mysql.user;
```

To provide protected access to the view to ordinary users, do this:

```
GRANT SELECT ON nologindb.myview TO 'ordinaryuser'@'localhost';
```

Now the ordinary user can use the view to access the limited information it presents:

```
SELECT * FROM nologindb.myview;
```

Attempts by the user to access columns other than those exposed by the view result in an error.

#### Note

Because the `nologin` account cannot be used directly, the operations required to set up objects that it uses must be performed by `root` or similar account with the privileges required to create the objects and set `DEFINER` values.

An account that authenticates using `mysql_no_login` may be used as a base user for proxy accounts:

```
CREATE USER 'proxy_base'@'localhost' IDENTIFIED WITH mysql_no_login;
... grant to 'proxy_base'@'localhost' any privileges it requires ...
GRANT PROXY ON 'proxy_base'@'localhost' TO 'real_user'@'localhost';
```

This enables clients to access MySQL through the proxy account but not to bypass the proxy mechanism by connecting directly as the proxy user.

For general information about pluggable authentication in MySQL, see [Section 7.3.8, “Pluggable Authentication”](#).

### 7.5.1.8 The Cleartext Client-Side Authentication Plugin

A client-side authentication plugin is available that sends the password to the server without hashing or encryption. This plugin is built into the MySQL client library.

The following table shows the plugin name.

**Table 7.15 MySQL Cleartext Authentication Plugin**

|                         |                                   |
|-------------------------|-----------------------------------|
| Server-side plugin name | None, see discussion              |
| Client-side plugin name | <code>mysql_clear_password</code> |
| Library file name       | None (plugin is built in)         |

With native MySQL authentication, the client performs one-way hashing on the password before sending it to the server. This enables the client to avoid sending the password in clear text. See [Section 7.1.2.4, “Password Hashing in MySQL”](#). However, because the hash algorithm is one way, the original password cannot be recovered on the server side.

One-way hashing cannot be done for authentication schemes that require the server to receive the password as entered on the client side. In such cases, the `mysql_clear_password` client-side plugin can be used to send the password to the server in clear text. There is no corresponding server-side plugin. Rather, the client-side plugin can be used by any server-side plugin that needs a clear text password. (The PAM authentication plugin is one such; see [Section 7.5.1.5, “The PAM Authentication Plugin”](#).)

For general information about pluggable authentication in MySQL, see [Section 7.3.8, “Pluggable Authentication”](#).

#### Note

Sending passwords in clear text may be a security problem in some configurations. To avoid problems if there is any possibility that the password would be intercepted, clients should connect to MySQL Server using a method that protects the password. Possibilities include SSL (see [Section 7.4, “Using Secure Connections”](#)), IPsec, or a private network.

To make inadvertent use of this plugin less likely, it is required that clients explicitly enable it. This can be done several ways:

- Set the `LIBMYSQL_ENABLE_CLEARTEXT_PLUGIN` environment variable to a value that begins with `1`, `Y`, or `y`. This enables the plugin for all client connections.
- The `mysql`, `mysqladmin`, and `mysqlslap` client programs support an `--enable-cleartext-plugin` option that enables the plugin on a per-invocation basis.
- The `mysql_options()` C API function supports a `MYSQL_ENABLE_CLEARTEXT_PLUGIN` option that enables the plugin on a per-connection basis. Also, any program that uses `libmysqlclient`

and reads option files can enable the plugin by including an `enable-cleartext-plugin` option in an option group read by the client library.

### 7.5.1.9 The Socket Peer-Credential Authentication Plugin

A server-side authentication plugin is available that authenticates clients that connect from the local host through the Unix socket file.

The source code for this plugin can be examined as a relatively simple example demonstrating how to write a loadable authentication plugin.

The following table shows the plugin and library file names. The file name suffix might differ on your system. The file location is the directory named by the `plugin_dir` system variable. For installation information, see [Section 7.3.8, “Pluggable Authentication”](#).

**Table 7.16 MySQL Socket Peer-Credential Authentication Plugin**

|                         |                             |
|-------------------------|-----------------------------|
| Server-side plugin name | <code>auth_socket</code>    |
| Client-side plugin name | None, see discussion        |
| Library file name       | <code>auth_socket.so</code> |

The `auth_socket` authentication plugin authenticates clients that connect from the local host through the Unix socket file. The plugin uses the `SO_PEERCREC` socket option to obtain information about the user running the client program. Thus, the plugin can be built only on systems that support the `SO_PEERCREC` option, such as Linux.

The plugin checks whether the socket user name matches the MySQL user name specified by the client program to the server. As of MySQL 5.7.6, if the names do not match, the plugin also checks whether the socket user name matches the name specified in the `authentication_string` column of the `mysql.user` table row. If a match is found, the plugin permits the connection.

Suppose that a MySQL account is created for a user named `valerie` who is to be authenticated by the `auth_socket` plugin for connections from the local host through the socket file:

```
CREATE USER 'valerie'@'localhost' IDENTIFIED WITH auth_socket;
```

If a user on the local host with a login name of `stefanie` invokes `mysql` with the option `--user=valerie` to connect through the socket file, the server uses `auth_socket` to authenticate the client. The plugin determines that the `--user` option value (`valerie`) differs from the client user's name (`stefanie`) and refuses the connection. If a user named `valerie` tries the same thing, the plugin finds that the user name and the MySQL user name are both `valerie` and permits the connection. However, the plugin refuses the connection even for `valerie` if the connection is made using a different protocol, such as TCP/IP.

For general information about pluggable authentication in MySQL, see [Section 7.3.8, “Pluggable Authentication”](#).

### 7.5.1.10 The Test Authentication Plugin

MySQL includes a test plugin that authenticates using MySQL native authentication, but is a loadable plugin (not built in) and must be installed prior to use. It can authenticate against either normal or older (shorter) password hash values.

This plugin is intended for testing and development purposes, and not for use in production environments. The test plugin source code is separate from the server source, unlike the built-in native plugin, so it can be examined as a relatively simple example demonstrating how to write a loadable authentication plugin.

The following table shows the plugin and library file names. The file name suffix might differ on your system. The file location is the directory named by the `plugin_dir` system variable. For installation information, see [Section 7.3.8, “Pluggable Authentication”](#).

**Table 7.17 MySQL Test Authentication Plugin**

|                         |                                  |
|-------------------------|----------------------------------|
| Server-side plugin name | <code>test_plugin_server</code>  |
| Client-side plugin name | <code>auth_test_plugin</code>    |
| Library file name       | <code>auth_test_plugin.so</code> |

Because the test plugin authenticates the same way as native MySQL authentication, provide the usual `--user` and `--password` options that you normally use for accounts that use native authentication when you connect to the server. For example:

```
shell> mysql --user=your_name --password=your_pass
```

For general information about pluggable authentication in MySQL, see [Section 7.3.8, “Pluggable Authentication”](#).

## 7.5.2 The Connection-Control Plugin

As of MySQL 5.7.17, MySQL Server includes a plugin library that enables administrators to introduce an increasing delay in server response to clients after a certain number of consecutive failed connection attempts. This capability provides a deterrent that slows down brute force attacks that attempt to access MySQL user accounts. The plugin library contains two plugins:

- `connection_control` checks incoming connections and adds a delay to server responses as necessary. This plugin also exposes system variables that enable plugin operation to be configured and a status variable that provides rudimentary monitoring information.

The `connection_control` plugin uses the audit plugin interface (see [Section 27.2.4.8, “Writing Audit Plugins”](#)). To collect information, it subscribes to the `MYSQL_AUDIT_CONNECTION_CLASSMASK` event class, and processes `MYSQL_AUDIT_CONNECTION_CONNECT` and `MYSQL_AUDIT_CONNECTION_CHANGE_USER` subevents to check whether the server should introduce a delay before responding to client connection attempts.

- `CONNECTION_CONTROL_FAILED_LOGIN_ATTEMPTS` implements an `INFORMATION_SCHEMA` table that exposes more detailed monitoring information for failed connection attempts.

The following sections provide information about connection-control plugin installation and configuration. For information about the `CONNECTION_CONTROL_FAILED_LOGIN_ATTEMPTS` table, see [Section 23.33.1, “The INFORMATION\\_SCHEMA CONNECTION\\_CONTROL\\_FAILED\\_LOGIN\\_ATTEMPTS Table”](#).

### 7.5.2.1 Connection-Control Plugin Installation

This section describes how to install the connection-control plugins, `connection_control` and `CONNECTION_CONTROL_FAILED_LOGIN_ATTEMPTS`. For general information about installing plugins, see [Section 6.5.2, “Installing and Uninstalling Plugins”](#).

To be usable by the server, the plugin library file must be located in the MySQL plugin directory (the directory named by the `plugin_dir` system variable). If necessary, set the value of `plugin_dir` at server startup to tell the server the plugin directory location.

The plugin library file base name is `connection_control`. The file name suffix differs per platform (for example, `.so` for Unix and Unix-like systems, `.dll` for Windows).

To load the plugins at server startup, use the `--plugin-load` option to name the library file that contains them. With this plugin-loading method, the option must be given each time the server starts. For example, put these lines in your `my.cnf` file (adjust the `.so` suffix for your platform as necessary):

```
[mysqld]
plugin-load=connection_control.so
```

Alternatively, to register the plugins at runtime, use these statements (adjust the extension as necessary):

```
INSTALL PLUGIN connection_control SONAME 'connection_control.so';
INSTALL PLUGIN connection_control_failed_login_attempts SONAME 'connection_control.so';
```

`INSTALL PLUGIN` loads a plugin, and also registers it in the `mysql.plugins` table to cause the plugin to be loaded for each subsequent normal server startup.

To verify plugin installation, examine the `INFORMATION_SCHEMA.PLUGINS` table or use the `SHOW PLUGINS` statement (see [Section 6.5.3, “Obtaining Server Plugin Information”](#)). For example:

```
mysql> SELECT PLUGIN_NAME, PLUGIN_STATUS FROM INFORMATION_SCHEMA.PLUGINS
       WHERE PLUGIN_NAME LIKE 'connection%';
```

| PLUGIN_NAME                              | PLUGIN_STATUS |
|--|---------------|
| CONNECTION_CONTROL                       | ACTIVE        |
| CONNECTION_CONTROL_FAILED_LOGIN_ATTEMPTS | ACTIVE        |

If the plugins have been previously registered with `INSTALL PLUGIN` or are loaded with `--plugin-load`, you can use the `--connection-control` and `--connection-control-failed-login-attempts` options at server startup to control plugin activation. For example, to load the plugins at startup and prevent them from being removed at runtime, use these options:

```
[mysqld]
plugin-load=connection_control.so
connection-control=FORCE_PLUS_PERMANENT
connection-control-failed-login-attempts=FORCE_PLUS_PERMANENT
```

If it is desired to prevent the server from running without a given connection-control plugin, use an option value of `FORCE` or `FORCE_PLUS_PERMANENT` to force server startup to fail if the plugin does not initialize successfully.

#### Note

It is possible to install one plugin without the other, but both must be installed for full connection-control capability. In particular, installing only the `CONNECTION_CONTROL_FAILED_LOGIN_ATTEMPTS` plugin is of little use because without the `connection_control` plugin to provide the data that populates the `CONNECTION_CONTROL_FAILED_LOGIN_ATTEMPTS` table, retrievals from the table will always be empty.

## Connection Delay Configuration

To enable you to configure its operation, the `connection_control` plugin exposes several system variables:

- `connection_control_failed_connections_threshold`: The number of consecutive failed connection attempts permitted to clients before the server adds a delay for subsequent connection attempts.

- `connection_control_min_connection_delay`: The amount of delay to add for each consecutive connection failure above the threshold.
- `connection_control_max_connection_delay`: The maximum delay to add.

To entirely disable checking for failed connection attempts, set `connection_control_failed_connections_threshold` to zero. If `connection_control_failed_connections_threshold` is nonzero, the amount of delay is zero up through that many consecutive failed connection attempts. Thereafter, the amount of delay is the number of failed attempts above the threshold, multiplied by `connection_control_min_connection_delay` milliseconds. For example, with the default `connection_control_failed_connections_threshold` and `connection_control_min_connection_delay` values of 3 and 1000, respectively, there is no delay for the first three consecutive failed connection attempts by a client, a delay of 1000 milliseconds for the fourth failed attempt, 2000 milliseconds for the fifth failed attempt, and so on, up to the maximum delay permitted by `connection_control_max_connection_delay`.

You can set the `connection_control` system variables at server startup or runtime. Suppose that you want to permit four consecutive failed connection attempts before the server starts delaying its responses, and to increase the delay by 1500 milliseconds for each additional failure after that. To set the relevant variables at server startup, put these lines in your `my.cnf` file:

```
[mysqld]
plugin-load=connection_control.so
connection_control_failed_connections_threshold=4
connection_control_min_connection_delay=1500
```

To set the variables at runtime, use these statements:

```
SET GLOBAL connection_control_failed_connections_threshold = 4;
SET GLOBAL connection_control_min_connection_delay = 1500;
```

`SET GLOBAL` sets the value for the running MySQL instance. To make the change permanent, add a line in your `my.cnf` file, as shown previously.

The `connection_control_min_connection_delay` and `connection_control_max_connection_delay` system variables have fixed minimum and maximum values of 1000 and 2147483647, respectively. In addition, the permitted range of values of each variable also depends on the current value of the other:

- `connection_control_min_connection_delay` cannot be set greater than the current value of `connection_control_max_connection_delay`.
- `connection_control_max_connection_delay` cannot be set less than the current value of `connection_control_min_connection_delay`.

Thus, to make the changes required for some configurations, you might need to set the variables in a specific order. Suppose that the current minimum and maximum delays are 1000 and 2000, and that you want to set them to 3000 and 5000. You cannot first set `connection_control_min_connection_delay` to 3000 because that is greater than the current `connection_control_max_connection_delay` value of 2000. Instead, set `connection_control_max_connection_delay` to 5000, then set `connection_control_min_connection_delay` to 3000.

## Connection Failure Assessment

When the `connection_control` plugin is installed, it checks connection attempts and tracks whether they fail or succeed. For this purpose, a failed connection attempt is one for which the client user and host match a known MySQL account but the provided credentials are incorrect, or do not match any known account.

Failed-connection counting is based on the user/host combination for each connection attempt. Determination of the applicable user name and host name takes proxying into account and occurs as follows:

- If the client user proxies another user, the proxying user's information is used. For example, if `external_user@example.com` proxies `proxy_user@example.com`, connection counting uses the proxying user, `external_user@example.com`, rather than the proxied user, `proxy_user@example.com`. Both `external_user@example.com` and `proxy_user@example.com` must have valid entries in the `mysql.user` system table and a proxy relationship between them must be defined in the `mysql.proxies_priv` system table (see [Section 7.3.9, “Proxy Users”](#)).
- If the client user does not proxy another user, but does match a `mysql.user` entry, counting uses the `CURRENT_USER()` value corresponding to that entry. For example, if a user `user1` connecting from a host `host1.example.com` matches a `user1@host1.example.com` entry, counting uses `user1@host1.example.com`. If the user matches a `user1@%.example.com`, `user1@%.com`, or `user1@%` entry instead, counting uses `user1@%.example.com`, `user1@%.com`, or `user1@%`, respectively.

For the cases just described, the connection attempt matches some `mysql.user` entry, and whether the request succeeds or fails depends on whether the client provides the correct authentication credentials. For example, if the client presents an incorrect password, the connection attempt fails.

If the connection attempt matches no `mysql.user` entry, the attempt fails. In this case, no `CURRENT_USER()` value is available and connection-failure counting uses the user name provided by the client and the client host as determined by the server. For example, if a client attempts to connect as user `user2` from host `host2.example.com`, the user name part is available in the client request and the server determines the host information. The user/host combination used for counting is `user2@host2.example.com`.

#### Note

The server maintains information about which client hosts can possibly connect to the server (essentially the union of host values for `mysql.user` entries). If a client attempts to connect from any other host, the server rejects the attempt at an early stage of connection setup:

```
ERROR 1130 (HY000): Host 'host_name' is not
allowed to connect to this MySQL server
```

Because this type of rejection occurs so early, `connection_control` does not see it, and does not count it.

## Connection Failure Monitoring

To monitor failed connections, use these information sources:

- The `Connection_control_delay_generated` status variable indicates the number of times the server added a delay to its response to a failed connection attempt. This does not count attempts that occur before reaching the threshold defined by the `connection_control_failed_connections_threshold` system variable.
- The `INFORMATION_SCHEMA CONNECTION_CONTROL_FAILED_LOGIN_ATTEMPTS` table provides information about the current number of consecutive failed connection attempts per client user/host combination. This counts all failed attempts, regardless of whether they were delayed.

Assigning a value to `connection_control_failed_connections_threshold` at runtime resets all accumulated failed-connection counters to zero, which has these visible effects:

- The `Connection_control_delay_generated` status variable is reset to zero.
- The `CONNECTION_CONTROL_FAILED_LOGIN_ATTEMPTS` table becomes empty.

### 7.5.2.2 Connection-Control System and Status Variables

This section describes the system and status variables that the `connection_control` plugin provides to enable its operation to be configured and monitored.

If the `connection_control` plugin is installed, it exposes these system variables:

- `connection_control_failed_connections_threshold`

|                            |  |  |
|----------------------------|--|--|
| <b>Introduced</b>          | 5.7.17   |  |
| <b>Command-Line Format</b> | <code>--connection_control_failed_connections_threshold=#</code> |  |
| <b>System Variable</b>     | <b>Name</b>  | <code>connection_control_failed_connections_threshold</code> |
|                            | <b>Variable Scope</b>  | Global   |
|                            | <b>Dynamic Variable</b>  | Yes  |
| <b>Permitted Values</b>    | <b>Type</b>  | integer  |
|                            | <b>Default</b>   | 3  |
|                            | <b>Min Value</b>   | 0  |
|                            | <b>Max Value</b>   | 2147483647   |

The number of consecutive failed connection attempts permitted to clients before the server adds a delay for subsequent connection attempts:

- If the variable has a nonzero value *N*, the server adds a delay beginning with consecutive failed attempt *N*+1. If a client has reached the point where connection responses are delayed, the delay also occurs for the next subsequent successful connection.
- Setting this variable to zero disables failed-connection counting. In this case, the server never adds delays.

For information about how `connection_control_failed_connections_threshold` interacts with other connection-control system and status variables, see [Section 7.5.2.1, “Connection-Control Plugin Installation”](#).

- `connection_control_max_connection_delay`

|                            |  |  |
|----------------------------|--|--|
| <b>Introduced</b>          | 5.7.17   |  |
| <b>Command-Line Format</b> | <code>--connection_control_max_connection_delay=#</code> |  |
| <b>System Variable</b>     | <b>Name</b>  | <code>connection_control_max_connection_delay</code> |
|                            | <b>Variable Scope</b>                                    | Global   |
|                            | <b>Dynamic Variable</b>                                  | Yes  |
| <b>Permitted Values</b>    | <b>Type</b>  | integer  |
|                            | <b>Default</b>   | 2147483647   |
|                            | <b>Min Value</b>   | 1000   |
|                            | <b>Max Value</b>   | 2147483647   |

The maximum delay in milliseconds for server response to failed connection attempts, if `connection_control_failed_connections_threshold` is greater than zero.

For information about how `connection_control_max_connection_delay` interacts with other connection-control system and status variables, see [Section 7.5.2.1, “Connection-Control Plugin Installation”](#).

- `connection_control_min_connection_delay`

|                            |  |  |
|----------------------------|--|--|
| <b>Introduced</b>          | 5.7.17   |  |
| <b>Command-Line Format</b> | <code>--connection_control_min_connection_delay=#</code> |  |
| <b>System Variable</b>     | <b>Name</b>  | <code>connection_control_min_connection_delay</code> |
|                            | <b>Variable Scope</b>                                    | Global   |
|                            | <b>Dynamic Variable</b>                                  | Yes  |
| <b>Permitted Values</b>    | <b>Type</b>  | integer  |
|                            | <b>Default</b>   | 1000   |
|                            | <b>Min Value</b>   | 1000   |
|                            | <b>Max Value</b>   | 2147483647   |

The minimum delay in milliseconds for server response to failed connection attempts, if `connection_control_failed_connections_threshold` is greater than zero. This is also the amount by which the server increases the delay for additional successive failures once it begins delaying.

For information about how `connection_control_min_connection_delay` interacts with other connection-control system and status variables, see [Section 7.5.2.1, “Connection-Control Plugin Installation”](#).

If the `connection_control` plugin is installed, it exposes this status variable:

- `Connection_control_delay_generated`

The number of times the server added a delay to its response to a failed connection attempt. This does not count attempts that occur before reaching the threshold defined by the `connection_control_failed_connections_threshold` system variable.

This variable provides a simple counter. For more detailed connection-control monitoring information, examine the `INFORMATION_SCHEMA CONNECTION_CONTROL_FAILED_LOGIN_ATTEMPTS` table; see [Section 23.33.1, “The INFORMATION\\_SCHEMA CONNECTION\\_CONTROL\\_FAILED\\_LOGIN\\_ATTEMPTS Table”](#).

Assigning a value to `connection_control_failed_connections_threshold` at runtime resets `Connection_control_delay_generated` to zero.

This variable was added in MySQL 5.7.17.

## 7.5.3 The Password Validation Plugin

The `validate_password` plugin serves to test passwords and improve security. The plugin exposes a set of system variables that enable you to define password policy.

This plugin implements two capabilities:

- In statements that assign a password supplied as a cleartext value, the plugin checks the password against the current password policy and rejects it if it is weak (the statement returns an `ER_NOT_VALID_PASSWORD` error). This affects the `ALTER USER`, `CREATE USER`, `GRANT`, and `SET PASSWORD` statements. Passwords given as arguments to the `PASSWORD( )` and `OLD_PASSWORD( )` functions are checked as well.
- The `VALIDATE_PASSWORD_STRENGTH( )` SQL function assesses the strength of potential passwords. The function takes a password argument and returns an integer from 0 (weak) to 100 (strong).

For example, the cleartext password in the following statement is checked. Under the default password policy, which requires passwords to be at least 8 characters long, the password is weak and the statement produces an error:

```
mysql> ALTER USER USER() IDENTIFIED BY 'abc';
ERROR 1819 (HY000): Your password does not satisfy the current
policy requirements
```

Passwords specified as hashed values are not checked because the original password value is not available:

```
mysql> ALTER USER 'jeffrey'@'localhost'
-> IDENTIFIED WITH mysql_native_password
-> AS '*0D3CED9BEC10A777AEC23CCC353A8C08A633045E';
Query OK, 0 rows affected (0.01 sec)
```

System variables having names of the form `validate_password_xxx` represent the parameters that control password policy. To configure password checking, modify these variables; see [Section 7.5.3.2, “Password Validation Plugin Options and Variables”](#).

If the `validate_password` plugin is not installed, the `validate_password_xxx` system variables are not available, passwords in statements are not checked, and the `VALIDATE_PASSWORD_STRENGTH( )` function always returns 0. For example, without the plugin installed, accounts can be assigned passwords shorter than 8 characters.

Assuming that the `validate_password` plugin is installed, it implements three levels of password checking: `LOW`, `MEDIUM`, and `STRONG`. The default is `MEDIUM`; to change this, modify the value of `validate_password_policy`. The policies implement increasingly strict password tests. The following descriptions refer to default parameter values, which can be modified by changing the appropriate system variables.

- `LOW` policy tests password length only. Passwords must be at least 8 characters long.
- `MEDIUM` policy adds the conditions that passwords must contain at least 1 numeric character, 1 lowercase character, 1 uppercase character, and 1 special (nonalphanumeric) character.
- `STRONG` policy adds the condition that password substrings of length 4 or longer must not match words in the dictionary file, if one has been specified.

In addition, as of MySQL 5.7.15, the `validate_password` plugin supports the capability of rejecting passwords that match the user name part of the effective user account for the current session, either forward or in reverse. To enable control over this capability, the plugin exposes a `validate_password_check_user_name` system variable. By default, this variable is disabled.

### 7.5.3.1 Password Validation Plugin Installation

This section describes how to install the `validate_password` password-validation plugin. For general information about installing plugins, see [Section 6.5.2, “Installing and Uninstalling Plugins”](#).

To be usable by the server, the plugin library file must be located in the MySQL plugin directory (the directory named by the `plugin_dir` system variable). If necessary, set the value of `plugin_dir` at server startup to tell the server the plugin directory location.

The plugin library file base name is `validate_password`. The file name suffix differs per platform (for example, `.so` for Unix and Unix-like systems, `.dll` for Windows).

To load the plugin at server startup, use the `--plugin-load` option to name the library file that contains the plugin. With this plugin-loading method, the option must be given each time the server starts. For example, put these lines in your `my.cnf` file (adjust the `.so` suffix for your platform as necessary):

```
[mysqld]
plugin-load=validate_password.so
```

Alternatively, to register the plugin at runtime, use this statement (adjust the extension as necessary):

```
INSTALL PLUGIN validate_password SONAME 'validate_password.so';
```

`INSTALL PLUGIN` loads the plugin, and also registers it in the `mysql.plugins` table to cause the plugin to be loaded for each subsequent normal server startup.

To verify plugin installation, examine the `INFORMATION_SCHEMA.PLUGINS` table or use the `SHOW PLUGINS` statement (see [Section 6.5.3, “Obtaining Server Plugin Information”](#)). For example:

```
mysql> SELECT PLUGIN_NAME, PLUGIN_STATUS FROM INFORMATION_SCHEMA.PLUGINS
-> WHERE PLUGIN_NAME LIKE 'validate%';
+-----+-----+
| PLUGIN_NAME | PLUGIN_STATUS |
+-----+-----+
| validate_password | ACTIVE |
+-----+-----+
```

If the plugin has been previously registered with `INSTALL PLUGIN` or is loaded with `--plugin-load`, you can use the `--validate-password` option at server startup to control plugin activation. For example, to load the plugin at startup and prevent it from being removed at runtime, use these options:

```
[mysqld]
plugin-load=validate_password.so
validate-password=FORCE_PLUS_PERMANENT
```

If it is desired to prevent the server from running without the password-validation plugin, use `--validate-password` with a value of `FORCE` or `FORCE_PLUS_PERMANENT` to force server startup to fail if the plugin does not initialize successfully.

### 7.5.3.2 Password Validation Plugin Options and Variables

To control the activation of the `validate_password` plugin, use this option:

- `--validate-password[=value]`

| Command-Line Format | <code>--validate-password[=value]</code> |                      |
|---------------------|--|----------------------|
| Permitted Values    | Type                                     | enumeration          |
|                     | Default                                  | ON                   |
|                     | Valid Values                             | ON                   |
|                     |  | OFF                  |
|                     |  | FORCE                |
|                     |  | FORCE_PLUS_PERMANENT |

This option controls how the server loads the `validate_password` plugin at startup. The value should be one of those available for plugin-loading options, as described in [Section 6.5.2, “Installing and Uninstalling Plugins”](#). For example, `--validate-password=FORCE_PLUS_PERMANENT`

tells the server to load the plugin at startup and prevents it from being removed while the server is running.

This option is available only if the `validate_password` plugin has been previously registered with `INSTALL PLUGIN` or is loaded with `--plugin-load`. See [Section 7.5.3.1, “Password Validation Plugin Installation”](#).

If the `validate_password` plugin is enabled, it exposes several system variables representing the parameters that control password checking:

```
mysql> SHOW VARIABLES LIKE 'validate_password%';
+-----+-----+
| Variable_name | Value |
+-----+-----+
| validate_password_check_user_name | OFF |
| validate_password_dictionary_file | |
| validate_password_length | 8 |
| validate_password_mixed_case_count | 1 |
| validate_password_number_count | 1 |
| validate_password_policy | MEDIUM |
| validate_password_special_char_count | 1 |
+-----+-----+
```

To change how passwords are checked, you can set these system variables at server startup or at runtime. The following list describes the meaning of each variable.

- `validate_password_check_user_name`

|                            |  |  |
|----------------------------|--|--|
| <b>Introduced</b>          | 5.7.15   |  |
| <b>Command-Line Format</b> | <code>--validate_password_check_user_name</code> |  |
| <b>System Variable</b>     | <b>Name</b>                                      | <code>validate_password_check_user_name</code> |
|                            | <b>Variable Scope</b>                            | Global   |
|                            | <b>Dynamic Variable</b>                          | Yes  |
| <b>Permitted Values</b>    | <b>Type</b>                                      | boolean  |
|                            | <b>Default</b>                                   | <code>OFF</code>                               |

Whether passwords are compared to the user name part of the effective user account for the current session and rejected if they match. By default, `validate_password_check_user_name` is disabled. This variable controls user name matching independent of the value of `validate_password_policy`.

When `validate_password_check_user_name` is enabled, it has these effects:

- Checking occurs in all contexts for which the `validate_password` plugin is invoked, which includes statements such as `ALTER USER` and `SET PASSWORD`, and invocation of functions such as `PASSWORD()` and `VALIDATE_PASSWORD_STRENGTH()`.
- If a password is the same as the user name or its reverse, a match occurs and the password is rejected.
- If a password matches the user name, `VALIDATE_PASSWORD_STRENGTH()` returns 0 regardless of how other `validate_password` system variables are set.
- The user names used for comparison are taken from the values of the `USER()` and `CURRENT_USER()` functions for the current session. (An implication is that a user who has the `SUPER` privilege can execute a statement to set another user's password to that user name, and cannot set that user's password to the name of the user executing the statement.)

- Only the user name part of the `USER()` and `CURRENT_USER()` function values is used, not the host name part. If a user name is empty, no comparison is done.
- User name matching is case sensitive. The password and user name values are compared as binary strings on a byte-by-byte basis.
- `validate_password_dictionary_file`

|                                   |                         |  |
|-----------------------------------|-------------------------|--|
| <b>System Variable</b> (<= 5.7.7) | <b>Name</b>             | <code>validate_password_dictionary_file</code> |
|                                   | <b>Variable Scope</b>   | Global   |
|                                   | <b>Dynamic Variable</b> | No   |
| <b>System Variable</b> (>= 5.7.8) | <b>Name</b>             | <code>validate_password_dictionary_file</code> |
|                                   | <b>Variable Scope</b>   | Global   |
|                                   | <b>Dynamic Variable</b> | Yes  |
| <b>Permitted Values</b>           | <b>Type</b>             | file name                                      |

The path name of the dictionary file used by the `validate_password` plugin for checking passwords. This variable is unavailable unless that plugin is installed.

By default, this variable has an empty value and dictionary checks are not performed. To enable dictionary checks, you must set this variable to a nonempty value. If the file is named as a relative path, it is interpreted relative to the server data directory. Its contents should be lowercase, one word per line. Contents are treated as having a character set of `utf8`. The maximum permitted file size is 1MB.

For the dictionary file to be used during password checking, the password policy must be set to 2 (`STRONG`); see the description of the `validate_password_policy` system variable. Assuming that is true, each substring of the password of length 4 up to 100 is compared to the words in the dictionary file. Any match causes the password to be rejected. Comparisons are not case sensitive.

For `VALIDATE_PASSWORD_STRENGTH()`, the password is checked against all policies, including `STRONG`, so the strength assessment includes the dictionary check regardless of the `validate_password_policy` value.

Before MySQL 5.7.8, changes to the dictionary file while the server is running require a restart for the server to recognize the changes. As of MySQL 5.7.8, `validate_password_dictionary_file` can be set at runtime and assigning a value causes the named file to be read without a restart.

- `validate_password_length`

|                         |                         |                                       |
|-------------------------|-------------------------|---------------------------------------|
| <b>System Variable</b>  | <b>Name</b>             | <code>validate_password_length</code> |
|                         | <b>Variable Scope</b>   | Global                                |
|                         | <b>Dynamic Variable</b> | Yes                                   |
| <b>Permitted Values</b> | <b>Type</b>             | integer                               |
|                         | <b>Default</b>          | 8                                     |
|                         | <b>Min Value</b>        | 0                                     |

The minimum number of characters that passwords checked by the `validate_password` plugin must have. This variable is unavailable unless that plugin is installed.

The `validate_password_length` minimum value is a function of several other related system variables. The server will not set the value less than the value of this expression:

```
validate_password_number_count
+ validate_password_special_char_count
+ ( 2 * validate_password_mixed_case_count )
```

If the `validate_password` plugin adjusts the value of `validate_password_length` due to the preceding constraint, it writes a message to the error log.

- `validate_password_mixed_case_count`

|                         |                         |   |
|-------------------------|-------------------------|---|
| <b>System Variable</b>  | <b>Name</b>             | <code>validate_password_mixed_case_count</code> |
|                         | <b>Variable Scope</b>   | Global  |
|                         | <b>Dynamic Variable</b> | Yes   |
| <b>Permitted Values</b> | <b>Type</b>             | integer   |
|                         | <b>Default</b>          | 1   |
|                         | <b>Min Value</b>        | 0   |

The minimum number of lowercase and uppercase characters that passwords checked by the `validate_password` plugin must have if the password policy is `MEDIUM` or stronger. For a given value, the password must have that many lowercase characters, and that many uppercase characters. This variable is unavailable unless that plugin is installed.

- `validate_password_number_count`

|                         |                         |   |
|-------------------------|-------------------------|---|
| <b>System Variable</b>  | <b>Name</b>             | <code>validate_password_number_count</code> |
|                         | <b>Variable Scope</b>   | Global                                      |
|                         | <b>Dynamic Variable</b> | Yes   |
| <b>Permitted Values</b> | <b>Type</b>             | integer                                     |
|                         | <b>Default</b>          | 1   |
|                         | <b>Min Value</b>        | 0   |

The minimum number of numeric (digit) characters that passwords checked by the `validate_password` plugin must have if the password policy is `MEDIUM` or stronger. This variable is unavailable unless that plugin is installed.

- `validate_password_policy`

|                        |                         |                                       |
|------------------------|-------------------------|---------------------------------------|
| <b>System Variable</b> | <b>Name</b>             | <code>validate_password_policy</code> |
|                        | <b>Variable Scope</b>   | Global                                |
|                        | <b>Dynamic Variable</b> | Yes                                   |

|                         |                     |             |
|-------------------------|---------------------|-------------|
| <b>Permitted Values</b> | <b>Type</b>         | enumeration |
|                         | <b>Default</b>      | 1           |
|                         | <b>Valid Values</b> | 0           |
|                         |                     | 1           |
|                         |                     | 2           |

The password policy enforced by the `validate_password` plugin. This variable is unavailable unless that plugin is installed.

`validate_password_policy` affects how the plugin uses its other policy-setting system variables, except for checking passwords against user names, which is controlled independently by `validate_password_check_user_name`.

The `validate_password_policy` value can be specified using numeric values 0, 1, 2, or the corresponding symbolic values `LOW`, `MEDIUM`, `STRONG`. The following table describes the tests performed for each policy. For the length test, the required length is the value of the `validate_password_length` system variable. Similarly, the required values for the other tests are given by other `validate_password_xxx` variables.

| Policy                   | Tests Performed   |
|--------------------------|---|
| 0 or <code>LOW</code>    | Length  |
| 1 or <code>MEDIUM</code> | Length; numeric, lowercase/uppercase, and special characters                  |
| 2 or <code>STRONG</code> | Length; numeric, lowercase/uppercase, and special characters; dictionary file |

- `validate_password_special_char_count`

|                         |                         |   |
|-------------------------|-------------------------|---|
| <b>System Variable</b>  | <b>Name</b>             | <code>validate_password_special_char_count</code> |
|                         | <b>Variable Scope</b>   | Global  |
|                         | <b>Dynamic Variable</b> | Yes   |
| <b>Permitted Values</b> | <b>Type</b>             | integer   |
|                         | <b>Default</b>          | 1   |
|                         | <b>Min Value</b>        | 0   |

The minimum number of nonalphanumeric characters that passwords checked by the `validate_password` plugin must have if the password policy is `MEDIUM` or stronger. This variable is unavailable unless that plugin is installed.

If the `validate_password` plugin is enabled, it exposes status variables that provide operational information:

```
mysql> SHOW STATUS LIKE 'validate_password%';
```

| Variable_name                                 | Value               |
|---|---------------------|
| validate_password_dictionary_file_last_parsed | 2015-06-29 11:08:51 |
| validate_password_dictionary_file_words_count | 1902                |

The following list describes the meaning of each status variable.

- `validate_password_dictionary_file_last_parsed`

When the dictionary file was last parsed.

This variable was added in MySQL 5.7.8.

- `validate_password_dictionary_file_words_count`

The number of words read from the dictionary file.

This variable was added in MySQL 5.7.8.

## 7.5.4 The MySQL Keyring

MySQL Server supports a keyring service that enables internal server components and plugins to securely store sensitive information for later retrieval. The implementation is plugin-based:

- MySQL 5.7.11 and higher includes the initial keyringing plugin, `keyring_file`, which stores keyring data in a file local to the server host. This plugin is available in all MySQL distributions, Community Edition and Enterprise Edition included.

### Warning

The `keyring_file` plugin for encryption key management is not intended as a regulatory compliance solution. Security standards such as PCI, FIPS, and others require use of key management systems to secure, manage, and protect encryption keys in key vaults or hardware security modules (HSMs).

- MySQL 5.7.12 and higher includes `keyring_okv`, a plugin that uses Oracle Key Vault for keyring backend storage. This plugin is available in MySQL Enterprise Edition distributions.
- MySQL 5.7.13 and higher includes an SQL interface for keyring key management, implemented as a set of user-defined functions (UDFs).

The `InnoDB` storage engine uses the keyring to store its key for tablespace encryption. `InnoDB` can use any supported keyring plugin.

For keyring installation instructions, see [Section 7.5.4.1, “Keyring Plugin Installation”](#).

For information about using the keyring UDFs, see [Section 7.5.4.5, “General-Purpose Keyring Key-Management Functions”](#).

Keyring plugins and UDFs access a keyring service that provides the interface for server components to the keyring. For information about writing keyring plugins or accessing the keyring plugin service, see [Section 27.2.4.12, “Writing Keyring Plugins”](#), and [Section 27.3.2, “The Keyring Service”](#).

### 7.5.4.1 Keyring Plugin Installation

Keyring service consumers require a keyring plugin to be installed. MySQL provides these plugin choices:

- `keyring_file`: A plugin that stores keyring data in a file local to the server host. Available in all MySQL distributions as of MySQL 5.7.11.
- `keyring_okv`: A plugin that uses Oracle Key Vault for keyring backend storage. Available in MySQL Enterprise Edition distributions as of MySQL 5.7.12.

This section describes how to install the keyring plugin of your choosing. For general information about installing plugins, see [Section 6.5.2, “Installing and Uninstalling Plugins”](#).

To be usable by the server, the plugin library file must be located in the MySQL plugin directory (the directory named by the `plugin_dir` system variable). If necessary, set the value of `plugin_dir` at server startup to tell the server the plugin directory location.

Installation for each keyring plugin is similar. The following instructions use `keyring_file`. Users of a different keyring plugin can substitute its name for `keyring_file`.

The `keyring_file` plugin library file base name is `keyring_file`. The file name suffix differs per platform (for example, `.so` for Unix and Unix-like systems, `.dll` for Windows).

#### Note

Only one keyring plugin should be enabled at a time. Enabling multiple keyring plugins is unsupported and results may not be as anticipated.

The keyring plugin must be loaded early during the server startup sequence so that server components can access it as necessary during their own initialization. For example, the `InnoDB` storage engine uses the keyring for tablespace encryption, so the keyring plugin must be loaded and available prior to `InnoDB` initialization.

To load the plugin, use the `--early-plugin-load` option to name the plugin library file. For example, on platforms where the plugin library file suffix is `.so`, use these lines in the server `my.cnf` file (adjust the `.so` suffix for your platform as necessary):

```
[mysqld]
early-plugin-load=keyring_file.so
```

As of MySQL 5.7.12, the default `--early-plugin-load` value is empty. To load a keyring plugin, you must use an explicit `--early-plugin-load` option with a nonempty value.

#### Important

In MySQL 5.7.11, the default `--early-plugin-load` value was the name of the `keyring_file` plugin library file, so that plugin was loaded by default. `InnoDB` tablespace encryption requires the `keyring_file` plugin to be loaded prior to `InnoDB` initialization, so this change of default `--early-plugin-load` value introduces an incompatibility for upgrades from 5.7.11 to 5.7.12 or higher. Administrators who have encrypted `InnoDB` tablespaces must take explicit action to ensure continued loading of the `keyring_file` plugin: Start the server with an `--early-plugin-load` option that names the plugin library file.

Before starting the server, check the notes for your chosen keyring plugin to see whether it permits or requires additional configuration:

- For `keyring_file`: [Section 7.5.4.2, “Configuring the keyring\\_file File-Based Plugin”](#).
- For `keyring_okv`: [Section 7.5.4.3, “Configuring the keyring\\_okv Oracle Key Vault Plugin”](#).

After performing any plugin-specific configuration, verify plugin installation. With the MySQL server running, examine the `INFORMATION_SCHEMA.PLUGINS` table or use the `SHOW PLUGINS` statement (see [Section 6.5.3, “Obtaining Server Plugin Information”](#)). For example:

```
mysql> SELECT PLUGIN_NAME, PLUGIN_STATUS FROM INFORMATION_SCHEMA.PLUGINS
        WHERE PLUGIN_NAME LIKE 'keyring%';
+-----+-----+
| PLUGIN_NAME | PLUGIN_STATUS |
+-----+-----+
| keyring_file | ACTIVE        |
+-----+-----+
```

If no keyring plugin is available when a server component tries to access the keyring service, the service cannot be used by that component. As a result, the component may fail to initialize or may initialize with limited functionality. For example, if `InnoDB` finds that there are encrypted tablespaces when it initializes, it attempts to access the keyring. If the keyring is unavailable, `InnoDB` can access

only unencrypted tablespaces. To ensure that [InnoDB](#) can access encrypted tablespaces as well, use `--early-plugin-load` to load the keyring plugin.

Plugins can be loaded by other methods, such as the `--plugin-load` or `--plugin-load-add` option or the `INSTALL PLUGIN` statement. However, keyring plugins loaded using those methods may be available too late in the server startup sequence for certain server components, such as [InnoDB](#):

- Plugin loading using `--plugin-load` or `--plugin-load-add` occurs after [InnoDB](#) initialization.
- Plugins installed using `INSTALL PLUGIN` are registered in the `mysql.plugin` system table and loaded automatically for subsequent server restarts. However, because `mysql.plugin` is an [InnoDB](#) table, any plugins named in it can be loaded during startup only after [InnoDB](#) initialization.

#### 7.5.4.2 Configuring the `keyring_file` File-Based Plugin

The `keyring_file` plugin is a keyring plugin that stores keyring data in a file local to the server host.

##### Warning

The `keyring_file` plugin for encryption key management is not intended as a regulatory compliance solution. Security standards such as PCI, FIPS, and others require use of key management systems to secure, manage, and protect encryption keys in key vaults or hardware security modules (HSMs).

To install the `keyring_file` plugin, use the general installation instructions found in [Section 7.5.4.1, “Keyring Plugin Installation”](#), together with the plugin-specific configuration information found here.

`keyring_file` must be loaded at each server startup using the `--early-plugin-load` option. The `keyring_file_data` system variable optionally configures the location of the file used by the `keyring_file` plugin for data storage. The default value is platform specific. To configure the file location explicitly, set the variable value at startup. For example, use these lines in the server `my.cnf` file (adjust the `.so` suffix and file location for your platform as necessary):

```
[mysqld]
early-plugin-load=keyring_file.so
keyring_file_data=/usr/local/mysql/mysql-keyring/keyring
```

Keyring operations are transactional: The `keyring_file` plugin uses a backup file during write operations to ensure that it can roll back to the original file if an operation fails. The backup file has the same name as the value of the `keyring_file_data` system variable with an extension of `.backup`.

For additional information about `keyring_file_data`, see [Section 7.5.4.7, “Keyring System Variables”](#).

As of MySQL 5.7.17, to ensure that keys are flushed only when the correct keyring storage file exists, `keyring_file` stores a SHA-256 checksum of the keyring in the file. Before updating the file, the plugin verifies that it contains the expected checksum.

The `keyring_file` plugin supports the functions that comprise the standard keyring service interface. Keyring operations performed by these functions are accessible at two levels:

- C interface: In C-language code, call the keyring service functions described in [Section 27.3.2, “The Keyring Service”](#).
- SQL interface: In SQL statements, call the user-defined functions (UDFs) described in [Section 7.5.4.5, “General-Purpose Keyring Key-Management Functions”](#).

Example (using UDFs):

```
SELECT keyring_key_generate('MyKey', 'AES', 32);
SELECT keyring_key_remove('MyKey');
```

The key types permitted by `keyring_file` are described in [Section 7.5.4.4, “Supported Keyring Types”](#).

### 7.5.4.3 Configuring the `keyring_okv` Oracle Key Vault Plugin

#### Note

The `keyring_okv` plugin is an extension included in MySQL Enterprise Edition, a commercial product. To learn more about commercial products, see <http://www.mysql.com/products/>.

The `keyring_okv` plugin is a keyring plugin that uses Oracle Key Vault for keyring backend storage. `keyring_okv` communicates securely with Oracle Key Vault. All keyring material is generated exclusively by the Oracle Key Vault server, not by `keyring_okv`.

The discussion here assumes that you are familiar with Oracle Key Vault. Some pertinent information sources:

- [Oracle Key Vault site](#)
- [Oracle Key Vault documentation](#)

To install the `keyring_okv` plugin, use the general installation instructions found in [Section 7.5.4.1, “Keyring Plugin Installation”](#), together with the plugin-specific configuration information found here.

In Oracle Key Vault terminology, clients that use Oracle Key Vault to store and retrieve security objects are called endpoints. To communicate with Oracle Key Vault, it is necessary to register as an endpoint and enroll by downloading and installing endpoint support files.

The `keyring_okv_conf_dir` system variable configures the location of the directory used by `keyring_okv` for Oracle Key Vault support files. The default value is empty, so you must set it before the plugin can communicate with Oracle Key Vault. The following procedure briefly summarizes the process of configuring this directory:

1. Register an endpoint with Oracle Key Vault to obtain an enrollment token.
2. Use the enrollment token to obtain the `okvclient.jar` client software download.
3. Install the client software to populate a directory for use by `keyring_okv` that contains Oracle Key Vault support files.
4. Set the `keyring_okv_conf_dir` system variable to the directory containing the support files.

Unless you set `keyring_okv_conf_dir` to a properly configured directory, `keyring_okv` writes a message to the error log that it cannot communicate with Oracle Key Vault:

```
[Warning] Plugin keyring_okv reported: 'For keyring_okv to be
initialized, please point the keyring_okv_conf_dir variable to a directory
containing Oracle Key Vault configuration file and ssl materials'
```

Use the following procedure to register with Oracle Key Vault as an endpoint and install the required software. This procedure summarizes only briefly how to interact with Oracle Key Vault. For details, visit the [Oracle Key Vault](#) site and consult the Oracle Key Vault Administrator's Guide.

1. Log in to the Oracle Key Vault management console as a user who has the System Administrator role.
2. Select the Endpoints tab to arrive at the Endpoints page, then click Add on the Endpoints page.
3. Provide the required endpoint information and click Register. The endpoint type should be Other. Successful registration results in an enrollment token.
4. Log out from the Oracle Key Vault server.

5. Connect again to the Oracle Key Vault server, this time without logging in. Use the endpoint enrollment token to enroll and request the `okvclient.jar` software download. Save this file to your system.
6. Install the `okvclient.jar` using following command (you must have JDK 1.4 or higher):

```
java -jar okvclient.jar -d dir_name [-v]
```

The directory name following the `-d` option is the location in which to install extracted files. The `-v` option, if given, causes log information to be produced that may be useful if the command fails.

When the command asks for an Oracle Key Vault endpoint password, do not provide one. Instead, press Enter. (The result is that no password will be required when the endpoint connects to Oracle Key Vault.)

7. The preceding command produces an `okvclient.ora` file, which should be in this location under the directory named by the `-d` option in the preceding `java -jar` command:

```
install_dir/conf/okvclient.ora
```

The `okvclient.ora` file should contain settings for `SERVER` and `STANDBY_SERVER` variables. The `keyring_okv` plugin will attempt to communicate with `SERVER` and fall back to `STANDBY_SERVER` if that fails.

If the `okvclient.ora` is generated with no setting for `STANDBY_SERVER`, `keyring_okv` will fail to initialize. The workaround is to check `oraclient.ora` file and add a “dummy” setting for `STANDBY_SERVER`, if one is missing:

```
STANDBY_SERVER=127.0.0.1:5696
```

8. Go to the Oracle Key Vault installer directory and test the setup by running this command:

```
okvutil/bin/okvutil list
```

The output should look something like this:

| Unique ID                            | Type            | Identifier |
|--------------------------------------|-----------------|------------|
| 255AB8DE-C97F-482C-E053-0100007F28B9 | Symmetric Key - |            |
| 264BF6E0-A20E-7C42-E053-0100007FB29C | Symmetric Key - |            |

For a fresh Oracle Key Vault server (a server without any key in it), the output looks like this instead, to indicate that there are no keys in the vault:

```
no objects found
```

9. Use this command to extract the `ssl` directory containing SSL materials from the `okvclient.jar` file:

```
jar xf okvclient.jar ssl
```

Create a directory to be used by `keyring_okv` as the location for its support files. Into that directory, copy the `okvclient.ora` file and the `ssl` directory extracted using the preceding procedure. The directory for `keyring_okv` should have a restrictive mode and be accessible only to the account used to run the MySQL server. For example, on Unix and Unix-like systems, to use `/usr/local/mysql/mysql-keyring-okv`, the following commands (executed as `root`) create the directory and set its mode and ownership:

```

shell> cd /usr/local/mysql
shell> mkdir mysql-keyring-okv
shell> chmod 750 mysql-keyring-okv
shell> chown mysql mysql-keyring-okv
shell> chgrp mysql mysql-keyring-okv

```

After installing the Oracle Key Vault support files, tell `keyring_okv` where to find them by setting the `keyring_okv_conf_dir` system variable. For example, use these lines in the server `my.cnf` file (adjust the `.so` suffix and directory location for your platform as necessary):

```

[mysqld]
early-plugin-load=keyring_okv.so
keyring_okv_conf_dir=/usr/local/mysql/mysql-keyring-okv

```

For additional information about `keyring_okv_conf_dir`, see [Section 7.5.4.7, “Keyring System Variables”](#).

The `keyring_okv` plugin supports the functions that comprise the standard keyring service interface. Keyring operations performed by these functions are accessible at two levels:

- C interface: In C-language code, call the keyring service functions described in [Section 27.3.2, “The Keyring Service”](#).
- SQL interface: In SQL statements, call the user-defined functions (UDFs) described in [Section 7.5.4.5, “General-Purpose Keyring Key-Management Functions”](#).

Example (using UDFs):

```

SELECT keyring_key_generate('MyKey', 'AES', 32);
SELECT keyring_key_remove('MyKey');

```

The key types permitted by `keyring_okv` are described in [Section 7.5.4.4, “Supported Keyring Types”](#).

#### 7.5.4.4 Supported Keyring Types

MySQL Keyring supports generating keys of different types (encryption algorithms) and lengths. The available key types depend on which keyring plugin is installed. A given plugin may also impose constraints on key lengths per key type.

[Table 7.18, “Keyring Plugin Key Types”](#) summarizes the permitted key types per keyring plugin. Lengths are in bytes. For a key generated using one of the keyring user-defined functions (UDFs) described in [Section 7.5.4.5, “General-Purpose Keyring Key-Management Functions”](#), the length can be no more than 2,048 bytes, due to limitations of the UDF interface.

**Table 7.18 Keyring Plugin Key Types**

| Plugin Name               | Permitted Key Type | Permitted Key Lengths for Key Type |
|---------------------------|--------------------|------------------------------------|
| <code>keyring_file</code> | AES                | No special restrictions            |
|                           | DSA                | No special restrictions            |
|                           | RSA                | No special restrictions            |
| <code>keyring_okv</code>  | AES                | 16, 24, 32                         |
|                           | DSA                | 128, 256, 384                      |
|                           | RSA                | 128, 256, 512                      |

#### 7.5.4.5 General-Purpose Keyring Key-Management Functions

MySQL Server supports a keyring service that enables internal server components and plugins to securely store sensitive information for later retrieval.

As of MySQL 5.7.13, MySQL Server includes an SQL interface for keyring key management, implemented as a set of general-purpose user-defined functions (UDFs) that access the functions provided by the internal keyring service. The keyring UDFs are contained in a plugin library file, which also contains a `keyring_udf` plugin that must be enabled prior to UDF invocation. For these UDFs to be used, a keyring plugin such as `keyring_file` or `keyring_okv` must be enabled.

The UDFs described here are general purpose and intended for use with any keyring plugin. A given keyring plugin might have UDFs of its own that are intended for use only with that plugin; see [Section 7.5.4.6, “Plugin-Specific Keyring Key-Management Functions”](#).

The following sections provide installation instructions for the keyring UDFs and demonstrate how to use them. For information about the keyring service functions invoked by the UDFs, see [Section 27.3.2, “The Keyring Service”](#). For general keyring information, see [Section 7.5.4, “The MySQL Keyring”](#).

## Installing or Uninstalling General-Purpose Keyring Functions

This section describes how to install or uninstall the keyring user-defined functions (UDFs), which are implemented in a plugin library file that also contains a `keyring_udf` plugin. For general information about installing or uninstalling plugins and UDFs, see [Section 6.5.2, “Installing and Uninstalling Plugins”](#), and [Section 27.4.2.5, “UDF Compiling and Installing”](#).

The keyring UDFs enable keyring key management operations, but the `keyring_udf` plugin must also be installed because the UDFs will not work correctly without it. Attempts to use the UDFs without the `keyring_udf` plugin result in an error.

To be usable by the server, the plugin library file must be located in the MySQL plugin directory (the directory named by the `plugin_dir` system variable). If necessary, set the value of `plugin_dir` at server startup to tell the server the plugin directory location.

The plugin library file base name is `keyring_udf`. The file name suffix differs per platform (for example, `.so` for Unix and Unix-like systems, `.dll` for Windows).

To install the `keyring_udf` plugin and the UDFs, use the `INSTALL PLUGIN` and `CREATE FUNCTION` statements (adjust the `.so` suffix for your platform as necessary):

```
INSTALL PLUGIN keyring_udf SONAME 'keyring_udf.so';
CREATE FUNCTION keyring_key_generate RETURNS INTEGER SONAME 'keyring_udf.so';
CREATE FUNCTION keyring_key_fetch RETURNS STRING SONAME 'keyring_udf.so';
CREATE FUNCTION keyring_key_length_fetch RETURNS INTEGER SONAME 'keyring_udf.so';
CREATE FUNCTION keyring_key_type_fetch RETURNS STRING SONAME 'keyring_udf.so';
CREATE FUNCTION keyring_key_store RETURNS INTEGER SONAME 'keyring_udf.so';
CREATE FUNCTION keyring_key_remove RETURNS INTEGER SONAME 'keyring_udf.so';
```

If the plugin and the UDFs are used on a master replication server, install them on all slave servers as well to avoid replication problems.

Once installed as just described, the `keyring_udf` plugin and the UDFs remain installed until uninstalled. To remove them, use the `UNINSTALL PLUGIN` and `DROP FUNCTION` statements:

```
UNINSTALL PLUGIN keyring_udf;
DROP FUNCTION keyring_key_generate;
DROP FUNCTION keyring_key_fetch;
DROP FUNCTION keyring_key_length_fetch;
DROP FUNCTION keyring_key_type_fetch;
DROP FUNCTION keyring_key_store;
DROP FUNCTION keyring_key_remove;
```

## Using General-Purpose Keyring Functions

Before using the keyring user-defined functions (UDFs), install them according to the instructions provided in [Installing or Uninstalling General-Purpose Keyring Functions](#).

The keyring UDFs are subject to these constraints:

- To use any keyring UDF, the `keyring_udf` plugin must be enabled. Otherwise, an error occurs:

```
ERROR 1123 (HY000): Can't initialize function 'keyring_key_generate';
This function requires keyring_udf plugin which is not installed.
Please install
```

To install the `keyring_udf` plugin, see [Installing or Uninstalling General-Purpose Keyring Functions](#).

- The keyring UDFs invoke keyring service functions (see [Section 27.3.2, “The Keyring Service”](#)). The service functions in turn use whatever keyring plugin is installed (for example, `keyring_file` or `keyring_okv`). Therefore, to use any keyring UDF, some underlying keyring plugin must be enabled. Otherwise, an error occurs:

```
ERROR 3188 (HY000): Function 'keyring_key_generate' failed because
underlying keyring service returned an error. Please check if a
keyring plugin is installed and that provided arguments are valid
for the keyring you are using.
```

To install a keyring plugin, see [Section 7.5.4.1, “Keyring Plugin Installation”](#).

- To use any keyring UDF, a user must possess the global `EXECUTE` privilege. Otherwise, an error occurs:

```
ERROR 1123 (HY000): Can't initialize function 'keyring_key_generate';
The user is not privileged to execute this function. User needs to
have EXECUTE
```

To grant the global `EXECUTE` privilege to a user, use this statement:

```
GRANT EXECUTE ON *.* TO user;
```

Alternatively, should you prefer to avoid granting the global `EXECUTE` privilege while still permitting users to access specific key-management operations, “wrapper” stored programs can be defined (a technique described later in this section).

- A key stored in the keyring by a given user can be manipulated later only by the same user. That is, the value of the `CURRENT_USER()` function at the time of key manipulation must have the same value as when the key was stored in the keyring. (This constraint rules out the use of the keyring UDFs for manipulation of instance-wide keys, such as those created by `InnoDB` to support tablespace encryption.)

To enable multiple users to perform operations on the same key, “wrapper” stored programs can be defined (a technique described later in this section).

- Keyring UDFs support the key types and lengths supported by the underlying keyring plugin, with the additional constraint that keys cannot be longer than 2,048 bytes (16,384 bits), due to limitations of the UDF interface. See [Section 7.5.4.4, “Supported Keyring Types”](#).

To create a new random key and store it in the keyring, call `keyring_key_generate()`, passing to it an ID for the key, along with the key type (encryption method) and its length in bytes. The following call creates a 2,048-bit DSA-encrypted key named `MyKey`:

```
mysql> SELECT keyring_key_generate('MyKey', 'DSA', 256);
+-----+
| keyring_key_generate('MyKey', 'DSA', 256) |
+-----+
|                                           1 |
+-----+
```

A return value of 1 indicates success. If the key cannot be created, the return value is `NULL` and an error occurs. To be able to check the return type regardless of whether an error occurs, use `SELECT ... INTO @var_name` and test the variable value:

```
mysql> SELECT keyring_key_generate('', '', -1) INTO @x;
ERROR 3188 (HY000): Function 'keyring_key_generate' failed because
underlying keyring service returned an error. Please check if a
keyring plugin is installed and that provided arguments are valid
for the keyring you are using.
mysql> SELECT @x;
+-----+
| @x    |
+-----+
| NULL  |
+-----+
mysql> SELECT keyring_key_generate('x', 'AES', 16) INTO @x;
mysql> SELECT @x;
+-----+
| @x    |
+-----+
| 1     |
+-----+
```

This technique also applies to other keyring UDFs that for failure return a value and an error.

The ID passed to `keyring_key_generate()` provides a means by which to refer to the key in subsequent UDF calls. For example, use the key ID to retrieve its type as a string or its length in bytes as an integer:

```
mysql> SELECT keyring_key_type_fetch('MyKey');
+-----+
| keyring_key_type_fetch('MyKey') |
+-----+
| DSA                             |
+-----+
mysql> SELECT keyring_key_length_fetch('MyKey');
+-----+
| keyring_key_length_fetch('MyKey') |
+-----+
| 256                               |
+-----+
```

To retrieve a key value, pass the key ID to `keyring_key_fetch()`. The following example uses `HEX()` to display the key value because it may contain nonprintable characters. The example also uses a short key for brevity, but be aware that longer keys provide better security:

```
mysql> SELECT keyring_key_generate('MyShortKey', 'DSA', 8);
+-----+
| keyring_key_generate('MyShortKey', 'DSA', 8) |
+-----+
| 1                                             |
+-----+
mysql> SELECT HEX(keyring_key_fetch('MyShortKey'));
+-----+
| HEX(keyring_key_fetch('MyShortKey')) |
+-----+
| 1DB3B0FC3328A24C                     |
+-----+
```

Keyring UDFs treat key IDs, types, and values as binary strings, so comparisons are case sensitive. For example, IDs of `MyKey` and `mykey` refer to different keys.

To remove a key, pass the key ID to `keyring_key_remove()`:

```
mysql> SELECT keyring_key_remove('MyKey');
```

```

+-----+
| keyring_key_remove('MyKey') |
+-----+
| 1 |
+-----+

```

To obfuscate and store a key that you provide, pass the key ID, type, and value to `keyring_key_store()`:

```

mysql> SELECT keyring_key_store('AES_key', 'AES', 'Secret string');
+-----+
| keyring_key_store('AES_key', 'AES', 'Secret string') |
+-----+
| 1 |
+-----+

```

As indicated previously, a user must have the global `EXECUTE` privilege to call keyring UDFs, and the user who stores a key in the keyring initially must be the same user who performs subsequent operations on the key later, as determined from the `CURRENT_USER()` value in effect for each UDF call. To permit key operations to users who do not have the global `EXECUTE` privilege or who may not be the key “owner,” use this technique:

1. Define “wrapper” stored programs that encapsulate the required key operations and have a `DEFINER` value equal to the key owner.
2. Grant the `EXECUTE` privilege for specific stored programs to the individual users who should be able to invoke them.
3. If the operations implemented by the wrapper stored programs do not include key creation, create any necessary keys in advance, using the account named as the `DEFINER` in the stored program definitions.

This technique enables keys to be shared among users and provides to DBAs more fine-grained control over who can do what with keys, without having to grant global privileges.

The following example shows how to set up a shared key named `SharedKey` that is owned by the DBA, and a `get_shared_key()` stored function that provides access to the current key value. The value can be retrieved by any user with the `EXECUTE` privilege for that function, which is created in the `key_schema` schema.

From a MySQL administrative account (`'root'@'localhost'` in this example), create the administrative schema and the stored function to access the key:

```

mysql> CREATE SCHEMA key_schema;

mysql> CREATE DEFINER = 'root'@'localhost'
      FUNCTION key_schema.get_shared_key()
      RETURNS BLOB READS SQL DATA
      RETURN keyring_key_fetch('SharedKey');

```

From the administrative account, ensure that the shared key exists:

```

mysql> SELECT keyring_key_generate('SharedKey', 'DSA', 8);
+-----+
| keyring_key_generate('SharedKey', 'DSA', 8) |
+-----+
| 1 |
+-----+

```

From the administrative account, create an ordinary user account to which key access is to be granted:

```
mysql> CREATE USER 'key_user'@'localhost'
IDENTIFIED BY 'key_user_pwd';
```

From the `key_user` account, verify that, without the proper `EXECUTE` privilege, the new account cannot access the shared key:

```
mysql> SELECT HEX(key_schema.get_shared_key());
ERROR 1370 (42000): execute command denied to user 'key_user'@'localhost'
for routine 'key_schema.get_shared_key'
```

From the administrative account, grant `EXECUTE` to `key_user` for the stored function:

```
mysql> GRANT EXECUTE ON FUNCTION key_schema.get_shared_key
TO 'key_user'@'localhost';
```

From the `key_user` account, verify that the key is now accessible:

```
mysql> SELECT HEX(key_schema.get_shared_key());
+-----+
| HEX(key_schema.get_shared_key()) |
+-----+
| 9BAFB9E75CEE013                  |
+-----+
```

## General-Purpose Keyring Function Reference

For each general-purpose keyring user-defined function (UDF), this section describes its purpose, calling sequence, and return value. For information about the conditions under which these UDFs can be invoked, see [Using General-Purpose Keyring Functions](#).

- `keyring_key_fetch()`

Given a key ID, deobfuscates and returns the key value.

Syntax:

```
STRING keyring_key_fetch(STRING key_id)
```

Arguments:

- `key_id`: The key ID as a string.

Return values:

Returns the key value for success, `NULL` if the key does not exist, or `NULL` and an error for failure.

### Note

Keyring values retrieved using `keyring_key_fetch()` are limited to 2,048 bytes, due to limitations of the UDF interface. A keyring value longer than that length can be stored using a keyring service function (see [Section 27.3.2, “The Keyring Service”](#)), but if retrieved using `keyring_key_fetch()`, is truncated to 2,048 bytes.

Example:

```
mysql> SELECT keyring_key_generate('RSA_key', 'RSA', 16);
+-----+
| keyring_key_generate('RSA_key', 'RSA', 16) |
+-----+
|                                             1 |
+-----+
```

```
mysql> SELECT HEX(keyring_key_fetch('RSA_key'));
+-----+
| HEX(keyring_key_fetch('RSA_key')) |
+-----+
| 91C2253B696064D3556984B6630F891A |
+-----+
mysql> SELECT keyring_key_type_fetch('RSA_key');
+-----+
| keyring_key_type_fetch('RSA_key') |
+-----+
| RSA                                |
+-----+
mysql> SELECT keyring_key_length_fetch('RSA_key');
+-----+
| keyring_key_length_fetch('RSA_key') |
+-----+
|                                     16 |
+-----+
```

The example uses `HEX()` to display the key value because it may contain nonprintable characters. The example also uses a short key for brevity, but be aware that longer keys provide better security.

- `keyring_key_generate()`

Generates a new random key with a given ID, type, and length, and stores it in the keyring. The type and length values must be consistent with the values supported by the underlying keyring plugin, with the additional constraint that keys cannot be longer than 2,048 bytes (16,384 bits), due to limitations of the UDF interface. For the permitted types per plugin, see [Section 27.3.2, “The Keyring Service”](#).

Syntax:

```
STRING keyring_key_generate(STRING key_id, STRING key_type, INTEGER key_length)
```

Arguments:

- `key_id`: The key ID as a string.
- `key_type`: The key type as a string.
- `key_length`: The key length in bytes as an integer. The maximum length is 2,048.

Return values:

Returns 1 for success, or `NULL` and an error for failure.

Example:

```
mysql> SELECT keyring_key_generate('RSA_key', 'RSA', 384);
+-----+
| keyring_key_generate('RSA_key', 'RSA', 384) |
+-----+
|                                     1 |
+-----+
```

- `keyring_key_length_fetch()`

Given a key ID, returns the key length.

Syntax:

```
INTEGER keyring_key_length_fetch(STRING key_id)
```

Arguments:

- `key_id`: The key ID as a string.

Return values:

Returns the key length in bytes as an integer for success, `NULL` if the key does not exist, or `NULL` and an error for failure.

Example:

See the description of `keyring_key_fetch()`.

- `keyring_key_remove()`

Removes the key with a given ID from the keyring.

Syntax:

```
INTEGER keyring_key_remove(String key_id)
```

Arguments:

- `key_id`: The key ID as a string.

Return values:

Returns 1 for success, or `NULL` for failure.

Example:

```
mysql> SELECT keyring_key_remove('AES_key');
+-----+
| keyring_key_remove('AES_key') |
+-----+
|                               1 |
+-----+
```

- `keyring_key_store()`

Obfuscates and stores a key in the keyring.

Syntax:

```
INTEGER keyring_key_store(String key_id, String key_type, String key)
```

Arguments:

- `key_id`: The key ID as a string.
- `key_type`: The key type as a string.
- `key`: The key value as a string.

Return values:

Returns 1 for success, or `NULL` and an error for failure.

Example:

```
mysql> SELECT keyring_key_store('new key', 'DSA', 'My key value');
+-----+
| keyring_key_store('new key', 'DSA', 'My key value') |
+-----+
```

$$\left| \begin{array}{cc} 1 & 1 \\ 1 & 1 \end{array} \right| = 0$$

- `keyring_key_type_fetch()`

Given a key ID, returns the key type.

Syntax:

```
STRING keyring_key_type_fetch(STRING key_id)
```

Arguments:

- `key_id`: The key ID as a string.

Return values:

Returns the key type as a string for success, `NULL` if the key does not exist, or `NULL` and an error for failure.

Example:

See the description of `keyring_key_fetch()`.

#### 7.5.4.6 Plugin-Specific Keyring Key-Management Functions

This section describes user-defined functions (UDFs) that are specific to individual keyring plugins. Currently, no keyring plugin in MySQL 5.7 has plugin-specific UDFs. For information about general-purpose keyring UDFs, see [Section 7.5.4.5, “General-Purpose Keyring Key-Management Functions”](#).

#### 7.5.4.7 Keyring System Variables

MySQL Keyring plugins support the following system variables. Use them to configure keyring plugin operation. These variables are unavailable unless the appropriate keyring plugin is installed (see [Section 7.5.4.1, “Keyring Plugin Installation”](#)).

- keyring\_file\_data

|                            |  |                                |
|----------------------------|--|--------------------------------|
| <b>Introduced</b>          | 5.7.11                                     |                                |
| <b>Command-Line Format</b> | <code>--keyring_file_data=file_name</code> |                                |
| <b>System Variable</b>     | <b>Name</b>                                | <code>keyring_file_data</code> |
|                            | <b>Variable Scope</b>                      | Global                         |
|                            | <b>Dynamic Variable</b>                    | Yes                            |
| <b>Permitted Values</b>    | <b>Type</b>                                | file name                      |
|                            | <b>Default</b>                             | <code>platform specific</code> |

The path name of the data file used for secure data storage by the `keyring_file` plugin. This variable is unavailable unless that plugin is installed. The file location should be in a directory considered for use only by the `keyring_file` plugin. For example, do not locate the file under the data directory.

Keyring operations are transactional: The `keyring_file` plugin uses a backup file during write operations to ensure that it can roll back to the original file if an operation fails. The backup file has the same name as the value of the `keyring_file_data` system variable with an extension of `.backup`.

Do not use the same `keyring_file` data file for multiple MySQL instances. Each instance should have its own unique data file.

The default file name is `keyring`, located in a directory that is platform specific and depends on the value of the `INSTALL_LAYOUT` CMake option, as shown in the following table. To specify the default directory for the file explicitly if you are building from source, use the `INSTALL_MYSQLKEYRINGDIR` CMake option.

| <code>INSTALL_LAYOUT</code> Value | Default <code>keyring_file_data</code> Value                                   |
|-----------------------------------|--|
| DEB, RPM, SLES, SVR4              | <code>/var/lib/mysql-keyring/keyring</code>                                    |
| Otherwise                         | <code>keyring/keyring</code> under the <code>CMAKE_INSTALL_PREFIX</code> value |

At plugin startup, if the value assigned to `keyring_file_data` specifies a file that does not exist, the `keyring_file` plugin attempts to create it (as well as its parent directory, if necessary).

If you create the directory manually, it should have a restrictive mode and be accessible only to the account used to run the MySQL server. For example, on Unix and Unix-like systems, to use `/usr/local/mysql/mysql-keyring/keyring`, the following commands (executed as `root`) create the directory and set its mode and ownership:

```
shell> cd /usr/local/mysql
shell> mkdir mysql-keyring
shell> chmod 750 mysql-keyring
shell> chown mysql mysql-keyring
shell> chgrp mysql mysql-keyring
```

If the `keyring_file` plugin cannot create or access the file, it writes an error message to the error log. If an attempted runtime assignment to `keyring_file_data` results in an error, the variable value remains unchanged.

### Important

Once the `keyring_file` plugin has created the `keyring_file` plugin data file and started to use it, it is important not to remove the file. For example, `InnoDB` uses the file to store the master key used to decrypt the data in tables that use tablespace encryption; see [Section 15.7.10, “InnoDB Tablespace Encryption”](#). Loss of the file will cause data in such tables to become inaccessible. (It is permissible to rename or move the file, as long as you change the value of `keyring_file_data` to match.) It is recommended that you create a separate backup of the `keyring` file immediately after you create the first encrypted table and before and after master key rotation.

- `keyring_okv_conf_dir`

|                            |  |                                   |
|----------------------------|--|-----------------------------------|
| <b>Introduced</b>          | 5.7.12                                       |                                   |
| <b>Command-Line Format</b> | <code>--keyring_okv_conf_dir=dir_name</code> |                                   |
| <b>System Variable</b>     | <b>Name</b>                                  | <code>keyring_okv_conf_dir</code> |
|                            | <b>Variable Scope</b>                        | Global                            |
|                            | <b>Dynamic Variable</b>                      | Yes                               |
| <b>Permitted Values</b>    | <b>Type</b>                                  | directory name                    |
|                            | <b>Default</b>                               | empty string                      |

The path name of the directory that stores configuration information used by the `keyring_okv` plugin. This variable is unavailable unless that plugin is installed. The location should be a directory considered for use only by the `keyring_okv` plugin. For example, do not locate the directory under the data directory.

The default `keyring_okv_conf_dir` value is empty. For the `keyring_okv` plugin to be able to access Oracle Key Vault, the value must be set to a directory that contains Oracle Key Vault configuration and SSL materials. For instructions on setting up this directory, see [Section 7.5.4.3, “Configuring the keyring\\_okv Oracle Key Vault Plugin”](#).

The directory should have a restrictive mode and be accessible only to the account used to run the MySQL server. For example, on Unix and Unix-like systems, to use `/usr/local/mysql/mysql-keyring-okv`, the following commands (executed as `root`) create the directory and set its mode and ownership:

```
shell> cd /usr/local/mysql
shell> mkdir mysql-keyring-okv
shell> chmod 750 mysql-keyring-okv
shell> chown mysql mysql-keyring-okv
shell> chgrp mysql mysql-keyring-okv
```

If the value assigned to `keyring_okv_conf_dir` specifies a directory that does not exist, or that does not contain configuration information that enables a connection to Oracle Key Vault to be established, `keyring_okv` writes an error message to the error log. If an attempted runtime assignment to `keyring_okv_conf_dir` results in an error, the variable value and keyring operation remain unchanged.

## 7.5.5 MySQL Enterprise Audit

### Note

MySQL Enterprise Audit is an extension included in MySQL Enterprise Edition, a commercial product. To learn more about commercial products, see <http://www.mysql.com/products/>.

As of MySQL 5.7.9, MySQL Enterprise Edition includes MySQL Enterprise Audit, implemented using a server plugin named `audit_log`. MySQL Enterprise Audit uses the open MySQL Audit API to enable standard, policy-based monitoring and logging of connection and query activity executed on specific MySQL servers. Designed to meet the Oracle audit specification, MySQL Enterprise Audit provides an out of box, easy to use auditing and compliance solution for applications that are governed by both internal and external regulatory guidelines.

When installed, the audit plugin enables MySQL Server to produce a log file containing an audit record of server activity. The log contents include when clients connect and disconnect, and what actions they perform while connected, such as which databases and tables they access.

After you install the plugin (see [Section 7.5.5.2, “Installing or Uninstalling MySQL Enterprise Audit”](#)), it writes an audit log file. By default, the file is named `audit.log` in the server data directory. To change the name of the file, set the `audit_log_file` system variable at server startup.

Audit log file contents are not encrypted. See [Section 7.5.5.3, “MySQL Enterprise Audit Security Considerations”](#).

The audit log file is written in XML, with auditable events encoded as `<AUDIT_RECORD>` elements. To select the file format, set the `audit_log_format` system variable at server startup. For details on file format and contents, see [Section 7.5.5.4, “The Audit Log File”](#).

For more information about controlling how logging occurs, see [Section 7.5.5.5, “Audit Log Logging Control”](#). To perform filtering of audited events, see [Section 7.5.5.6, “Audit Log Filtering”](#). For

descriptions of the parameters used to configure the audit log plugin, see [Audit Log Options and Variables](#).

If the `audit_log` plugin is enabled, the Performance Schema (see [Chapter 24, MySQL Performance Schema](#)) has instrumentation for the audit log plugin. To identify the relevant instruments, use this query:

```
SELECT NAME FROM performance_schema.setup_instruments
WHERE NAME LIKE '%/alog/%';
```

### 7.5.5.1 Audit Log Components

MySQL Enterprise Audit is based on the `audit_log` plugin and related components:

- A server-side plugin named `audit_log` examines auditable events and determines whether to write them to the audit log.
- User-defined functions enable manipulation of filtering definitions that control logging behavior.
- Tables in the `mysql` system database provide persistent storage of filter and user account data.
- The `audit_log_filter_id` system variable provides information about whether the current session has an audit filter assigned.

Prior to MySQL 5.7.13, MySQL Enterprise Audit consists only of the `audit_log` plugin and operates in legacy mode. See [Legacy Mode Audit Log Filtering](#).

### 7.5.5.2 Installing or Uninstalling MySQL Enterprise Audit

This section describes how to install or uninstall MySQL Enterprise Audit, which is implemented using the `audit_log` plugin and related components described in [Section 7.5.5.1, “Audit Log Components”](#). For general information about installing plugins, see [Section 6.5.2, “Installing and Uninstalling Plugins”](#).

The instructions here apply for MySQL 5.7.13 or higher. For MySQL versions prior to 5.7.13, see [Installing MySQL Enterprise Audit](#) in [MySQL 5.6 Reference Manual](#).

#### Note

If installed, the `audit_log` plugin involves some minimal overhead even when disabled. To avoid this overhead, do not install MySQL Enterprise Audit unless you plan to use it.

To be usable by the server, the plugin library file must be located in the MySQL plugin directory (the directory named by the `plugin_dir` system variable). If necessary, set the value of `plugin_dir` at server startup to tell the server the plugin directory location.

Prior to MySQL 5.7.13, MySQL Enterprise Audit consists only of the `audit_log` plugin and includes none of the other components described in [Section 7.5.5.1, “Audit Log Components”](#). If the `audit_log` plugin is already installed from a version of MySQL before 5.7.13, uninstall it using the following statement and restart the server before installing the current version:

```
UNINSTALL PLUGIN audit_log;
```

To install MySQL Enterprise Audit, look in the `share` directory of your MySQL installation and choose the script that is appropriate for your platform. The available scripts differ in the suffix used to refer to the plugin library file:

- `audit_log_filter_win_install.sql`: Choose this script for Windows systems that use `.dll` as the file name suffix.
- `audit_log_filter_linux_install.sql`: Choose this script for Linux and similar systems that use `.so` as the file name suffix.

Run the script as follows. The example here uses the Linux installation script. Make the appropriate substitution for your system.

```
shell> mysql -u root -p < audit_log_filter_linux_install.sql
Enter password: (enter root password here)
```

To verify plugin installation, examine the `INFORMATION_SCHEMA.PLUGINS` table or use the `SHOW PLUGINS` statement (see [Section 6.5.3, “Obtaining Server Plugin Information”](#)). For example:

```
mysql> SELECT PLUGIN_NAME, PLUGIN_STATUS FROM INFORMATION_SCHEMA.PLUGINS
-> WHERE PLUGIN_NAME LIKE 'audit%';
+-----+-----+
| PLUGIN_NAME | PLUGIN_STATUS |
+-----+-----+
| audit_log   | ACTIVE        |
+-----+-----+
```

After MySQL Enterprise Audit is installed, you can use the `--audit-log` option for subsequent server startups to control `audit_log` plugin activation. For example, to prevent the plugin from being removed at runtime, use this option:

```
[mysqld]
audit-log=FORCE_PLUS_PERMANENT
```

If it is desired to prevent the server from running without the audit plugin, use `--audit-log` with a value of `FORCE` or `FORCE_PLUS_PERMANENT` to force server startup to fail if the plugin does not initialize successfully.

#### Note

By default, rule-based audit log filtering logs no auditable events for any users. This differs from legacy audit log behavior (before MySQL 5.7.13), which logs all auditable events for all users. Should you wish to produce log-everything behavior with rule-based filtering, create a simple filter to enable logging and assign it to the default account:

```
SELECT audit_log_filter_set_filter('log_all', '{ "filter": { "log": true } }');
SELECT audit_log_filter_set_user('%', 'log_all');
```

The filter assigned to `%` is used for connections from any account that has no explicitly assigned filter (which initially is true for all accounts).

Once installed as just described, MySQL Enterprise Audit remains installed until uninstalled. To remove it, execute the following statements:

```
DROP TABLE IF EXISTS mysql.audit_log_filter;
DROP TABLE IF EXISTS mysql.audit_log_user;
UNINSTALL PLUGIN audit_log;
DROP FUNCTION audit_log_filter_set_filter;
DROP FUNCTION audit_log_filter_remove_filter;
DROP FUNCTION audit_log_filter_set_user;
DROP FUNCTION audit_log_filter_remove_user;
DROP FUNCTION audit_log_filter_flush;
```

### 7.5.5.3 MySQL Enterprise Audit Security Considerations

Contents of the audit log file produced by the `audit_log` plugin are not encrypted and may contain sensitive information, such as the text of SQL statements. For security reasons, this file should be written to a directory accessible only to the MySQL server and users with a legitimate reason to view the log. The default file is `audit.log` in the data directory. This can be changed by setting the `audit_log_file` system variable at server startup.

### 7.5.5.4 The Audit Log File

Audit log file contents are not encrypted. See [Section 7.5.5.3, “MySQL Enterprise Audit Security Considerations”](#).

The audit log file is written as XML, using UTF-8 (up to 4 bytes per character). The root element is `<AUDIT>`. The closing `</AUDIT>` tag of the root element is written when the audit log plugin terminates, so the tag is not present in the file while the plugin is active.

The root element contains `<AUDIT_RECORD>` elements, each of which provides information about an audited event.

MySQL 5.7 changed audit log file output to a new format, it is possible to select either the old or new format using the `audit_log_format` system variable, which has permitted values of `OLD` and `NEW` (default `NEW`).

This section describes only the new log file format. For details about the old format, see [The Audit Log File](#) in [MySQL 5.6 Reference Manual](#).

If you change the value of `audit_log_format`, use this procedure to avoid writing log entries in one format to an existing log file that contains entries in a different format:

1. Stop the server.
2. Rename the current audit log file manually.
3. Restart the server with the new value of `audit_log_format`. The audit log plugin will create a new log file, which will contain log entries in the selected format.

Here is a sample log file in the default (new) format, reformatted slightly for readability:

```
<?xml version="1.0" encoding="utf-8"?>
<AUDIT>
  <AUDIT_RECORD>
    <TIMESTAMP>2013-09-17T15:03:24 UTC</TIMESTAMP>
    <RECORD_ID>1_2013-09-17T15:03:24</RECORD_ID>
    <NAME>Audit</NAME>
    <SERVER_ID>1</SERVER_ID>
    <VERSION>1</VERSION>
    <STARTUP_OPTIONS>/usr/local/mysql/bin/mysqld
      --socket=/usr/local/mysql/mysql.sock
      --port=3306</STARTUP_OPTIONS>
    <OS_VERSION>x86_64-osx10.6</OS_VERSION>
    <MYSQL_VERSION>5.7.2-m12-log</MYSQL_VERSION>
  </AUDIT_RECORD>
  <AUDIT_RECORD>
    <TIMESTAMP>2013-09-17T15:03:40 UTC</TIMESTAMP>

  <COMMAND_CLASS></COMMAND_CLASS>
</AUDIT_RECORD>
<AUDIT_RECORD>
  <TIMESTAMP>2013-09-17T15:03:47 UTC</TIMESTAMP>
  <RECORD_ID>10_2013-09-17T15:03:24</RECORD_ID>
  <NAME>Quit</NAME>
  <CONNECTION_ID>3</CONNECTION_ID>
  <STATUS>0</STATUS>
  <STATUS_CODE>0</STATUS_CODE>
  <USER></USER>
  <OS_LOGIN></OS_LOGIN>
  <HOST></HOST>
  <IP></IP>
  <COMMAND_CLASS>connect</COMMAND_CLASS>
</AUDIT_RECORD>
<AUDIT_RECORD>
  <TIMESTAMP>2013-09-17T15:03:49 UTC</TIMESTAMP>
  <RECORD_ID>11_2013-09-17T15:03:24</RECORD_ID>

```

```
<NAME>NoAudit</NAME>
<SERVER_ID>1</SERVER_ID>
</AUDIT_RECORD>
</AUDIT>
```

Elements within `<AUDIT_RECORD>` elements have these characteristics:

- Some elements appear in every `<AUDIT_RECORD>` element, but many are optional and do not necessarily appear in every element.
- Order of elements within an `<AUDIT_RECORD>` element is not guaranteed.
- Element values are not fixed length. Long values may be truncated as indicated in the element descriptions given later.
- The `<`, `>`, `"`, and `&` characters are encoded as `&lt;`, `&gt;`, `&quot;`, and `&amp;`, respectively. NUL bytes (U+00) are encoded as the `?` character.
- Characters not valid as XML characters are encoded using numeric character references. Valid XML characters are:

```
#x9 | #xA | #xD | [#x20-#xD7FF] | [#xE000-#xFFFF] | [#x10000-#x10FFFF]
```

Every `<AUDIT_RECORD>` element contains a set of mandatory elements. Other optional elements may appear, depending on the audit record type.

The following elements are mandatory in every `<AUDIT_RECORD>` element:

- `<NAME>`

A string representing the type of instruction that generated the audit event, such as a command that the server received from a client.

Example:

```
<NAME>Query</NAME>
```

Some common `<NAME>` values:

|          |  |
|----------|--|
| Audit    | When auditing starts, which may be server startup time       |
| Connect  | When a client connects, also known as logging in             |
| Query    | An SQL statement (executed directly)                         |
| Prepare  | Preparation of an SQL statement; usually followed by Execute |
| Execute  | Execution of an SQL statement; usually follows Prepare       |
| Shutdown | Server shutdown  |
| Quit     | When a client disconnects                                    |
| NoAudit  | Auditing has been turned off                                 |

The possible values are `Audit`, `Binlog Dump`, `Change user`, `Close stmt`, `Connect Out`, `Connect`, `Create DB`, `Daemon`, `Debug`, `Delayed insert`, `Drop DB`, `Execute`, `Fetch`, `Field List`, `Init DB`, `Kill`, `Long Data`, `NoAudit`, `Ping`, `Prepare`, `Processlist`, `Query`, `Quit`, `Refresh`, `Register Slave`, `Reset stmt`, `Set option`, `Shutdown`, `Sleep`, `Statistics`, `Table Dump`, `Time`.

With the exception of `Audit` and `NoAudit`, these values correspond to the `COM_xxx` command values listed in the `mysql_com.h` header file. For example, `Create DB` and `Shutdown` correspond to `COM_CREATE_DB` and `COM_SHUTDOWN`, respectively.

- `<RECORD_ID>`

A unique identifier for the audit record. The value is composed from a sequence number and timestamp, in the format `SEQ_TIMESTAMP`. The sequence number is initialized to the size of the audit log file at the time the audit log plugin opens it and increments by 1 for each record logged. The

timestamp is a UTC value in `yyyy-mm-ddThh:mm:ss` format indicating the time when the audit log plugin opened the file.

Example:

```
<RECORD_ID>28743_2013-09-18T21:03:24</RECORD_ID>
```

- `<TIMESTAMP>`

The date and time that the audit event was generated. For example, the event corresponding to execution of an SQL statement received from a client has a `<TIMESTAMP>` value occurring after the statement finishes, not when it is received. The value has the format `yyyy-mm-ddThh:mm:ss UTC` (with `T`, no decimals). The format includes a time zone specifier at the end. The time zone is always UTC.

Example:

```
<TIMESTAMP>2013-09-17T15:03:49 UTC</TIMESTAMP>
```

The following elements are optional in `<AUDIT_RECORD>` elements. Many of them occur only with specific `<NAME>` values.

- `<COMMAND_CLASS>`

A string that indicates the type of action performed.

Example:

```
<COMMAND_CLASS>drop_table</COMMAND_CLASS>
```

The values come from the `com_status_vars` array in the `sql/mysqld.cc` file in a MySQL source distribution. They correspond to the status variables displayed by this statement:

```
SHOW STATUS LIKE 'Com%';
```

- `<CONNECTION_ID>`

An unsigned integer representing the client connection identifier. This is the same as the `CONNECTION_ID( )` function value within the session.

Example:

```
<CONNECTION_ID>127</CONNECTION_ID>
```

- `<DB>`

A string representing the default database name. This element appears only if the `<NAME>` value is `Connect` or `Change user`.

- `<HOST>`

A string representing the client host name. This element appears only if the `<NAME>` value is `Connect`, `Change user`, or `Query`.

Example:

```
<HOST>localhost</HOST>
```

- `<IP>`

A string representing the client IP address. This element appears only if the `<NAME>` value is `Connect`, `Change user`, or `Query`.

Example:

```
<IP>127.0.0.1</IP>
```

- `<MYSQL_VERSION>`

A string representing the MySQL server version. This is the same as the value of the `VERSION()` function or `version` system variable. This element appears only if the `<NAME>` value is `Audit`.

Example:

```
<MYSQL_VERSION>5.7.1-m11-log</MYSQL_VERSION>
```

- `<OS_LOGIN>`

A string representing the external user name used during the authentication process, as set by the plugin used to authenticate the client. With native (built-in) MySQL authentication, or if the plugin does not set the value, this variable is `NULL`. The value is the same as that of the `external_user` system variable. See [Section 7.3.9, “Proxy Users”](#).

This element appears only if the `<NAME>` value is `Connect`, `Change user`, or `Query`.

- `<OS_VERSION>`

A string representing the operating system on which the server was built or is running. This element appears only if the `<NAME>` value is `Audit`.

Example:

```
<OS_VERSION>x86_64-Linux</OS_VERSION>
```

- `<PRIV_USER>`

A string representing the user that the server authenticated the client as. This is the user name that the server uses for privilege checking, and may differ from the `<USER>` value. This element appears only if the `<NAME>` value is `Connect` or `Change user`.

- `<PROXY_USER>`

A string representing the proxy user. The value is empty if user proxying is not in effect. This element appears only if the `<NAME>` value is `Connect` or `Change user`.

- `<SERVER_ID>`

An unsigned integer representing the server ID. This is the same as the value of the `server_id` system variable. This element appears only if the `<NAME>` value is `Audit` or `NoAudit`.

Example:

```
<SERVER_ID>1</SERVER_ID>
```

- `<SQLTEXT>`

A string representing the text of an SQL statement. The value can be empty. Long values may be truncated. This element appears only if the `<NAME>` value is `Query` or `Execute`.

The string, like the audit log file itself, is written using UTF-8 (up to 4 bytes per character), so the value may be the result of conversion. For example, the original statement might have been received from the client as an SJIS string.

Example:

```
<SQLTEXT>DELETE FROM t1</SQLTEXT>
```

- [<STARTUP\\_OPTIONS>](#)

A string representing the options that were given on the command line or in option files when the MySQL server was started. This element appears only if the [<NAME>](#) value is [Audit](#).

Example:

```
<STARTUP_OPTIONS>/usr/local/mysql/bin/mysqld  
--port=3306 --log-output=FILE</STARTUP_OPTIONS>
```

- [<STATUS>](#)

An unsigned integer representing the command status: 0 for success, nonzero if an error occurred. This is the same as the value of the [mysql\\_errno\(\)](#) C API function.

The audit log does not contain the SQLSTATE value or error message. To see the associations between error codes, SQLSTATE values, and messages, see [Section B.3, “Server Error Codes and Messages”](#).

Warnings are not logged.

See the description for [<STATUS\\_CODE>](#) for information about how it differs from [<STATUS>](#).

Example:

```
<STATUS>1051</STATUS>
```

- [<STATUS\\_CODE>](#)

An unsigned integer representing the command status: 0 for success, 1 if an error occurred.

The [STATUS\\_CODE](#) value differs from the [STATUS](#) value: [STATUS\\_CODE](#) is 0 for success and 1 for error, which is compatible with the EZ\_collector consumer for Audit Vault. [STATUS](#) is the value of the [mysql\\_errno\(\)](#) C API function. This is 0 for success and nonzero for error, and thus is not necessarily 1 for error.

Example:

```
<STATUS_CODE>0</STATUS_CODE>
```

- [<USER>](#)

A string representing the user name sent by the client. This may differ from the [<PRIV\\_USER>](#) value. This element appears only if the [<NAME>](#) value is [Connect](#), [Change user](#), or [Query](#).

Example:

```
<USER>root[root] @ localhost [127.0.0.1]</USER>
```

- [<VERSION>](#)

An unsigned integer representing the version of the audit log file format. This element appears only if the `<NAME>` value is `Audit`.

Example:

```
<VERSION>1</VERSION>
```

### 7.5.5.5 Audit Log Logging Control

This section describes how the `audit_log` plugin performs logging and the system variables that control how logging occurs. It assumes familiarity with the log file format described in [Section 7.5.5.4, “The Audit Log File”](#).

The `audit_log` plugin can also control whether audited events are written to the audit log file based on the account from which events originate or event status. See [Section 7.5.5.6, “Audit Log Filtering”](#).

When the audit log plugin opens its log file, it checks whether the XML declaration and opening `<AUDIT>` root element tag must be written and writes them if so. When the audit log plugin terminates, it writes a closing `</AUDIT>` tag to the file.

If the log file exists at open time, the plugin checks whether the file ends with an `</AUDIT>` tag and truncates it if so before writing any `<AUDIT_RECORD>` elements. If the log file exists but does not end with `</AUDIT>` or the `</AUDIT>` tag cannot be truncated, the plugin considers the file malformed and fails to initialize. This can occur if the server crashes or is killed with the audit log plugin running. No logging occurs until the problem is rectified. Check the error log for diagnostic information:

```
[ERROR] Plugin 'audit_log' init function returned error.
```

To deal with this problem, either remove or rename the malformed log file and restart the server.

The MySQL server calls the audit log plugin to write an `<AUDIT_RECORD>` element whenever an auditable event occurs, such as when it completes execution of an SQL statement received from a client. Typically the first `<AUDIT_RECORD>` element written after server startup has the server description and startup options. Elements following that one represent events such as client connect and disconnect events, executed SQL statements, and so forth. Only top-level statements are logged, not statements within stored programs such as triggers or stored procedures. Contents of files referenced by statements such as `LOAD DATA INFILE` are not logged.

To permit control over how logging occurs, the `audit_log` plugin provides several system variables, described following. For more information, see [Audit Log Options and Variables](#).

### Audit Log File Naming

To control the audit log file name, set the `audit_log_file` system variable at server startup. By default, the name is `audit.log` in the server data directory. For security reasons, the audit log file should be written to a directory accessible only to the MySQL server and users with a legitimate reason to view the log.

### Audit Logging Strategy

The audit log plugin can use any of several strategies for log writes. To specify a strategy, set the `audit_log_strategy` system variable at server startup. By default, the strategy value is `ASYNCHRONOUS` and the plugin logs asynchronously to a buffer, waiting if the buffer is full. It's possible to tell the plugin not to wait (`PERFORMANCE`) or to log synchronously, either using file system caching (`SEMIASYNCHRONOUS`) or forcing output with a `sync()` call after each write request (`SYNCHRONOUS`).

Asynchronous logging strategy has these characteristics:

- Minimal impact on server performance and scalability.

- Blocking of threads that generate audit events for the shortest possible time; that is, time to allocate the buffer plus time to copy the event to the buffer.
- Output goes to the buffer. A separate thread handles writes from the buffer to the log file.

A disadvantage of `PERFORMANCE` strategy is that it drops events when the buffer is full. For a heavily loaded server, it is more likely that the audit log will be missing events.

With asynchronous logging, the integrity of the log file may be compromised if a problem occurs during a write to the file or if the plugin does not shut down cleanly (for example, in the event that the server host crashes). To reduce this risk, set `audit_log_strategy` to use synchronous logging. Regardless of strategy, logging occurs on a best-effort basis, with no guarantee of consistency.

## Audit Log Space Management

The audit log plugin provides several system variables that enable you to manage the space used by its log files:

- `audit_log_buffer_size`: Set this variable at server startup to set the size of the buffer for asynchronous logging. The plugin uses a single buffer, which it allocates when it initializes and removes when it terminates. The plugin allocates this buffer only if logging is asynchronous.
- `audit_log_rotate_on_size`, `audit_log_flush`: These variables permit audit log file rotation and flushing. The audit log file has the potential to grow very large and consume a lot of disk space. To manage the space used, either enable automatic log rotation, or manually rename the audit file and flush the log to open a new file. The renamed file can be removed or backed up as desired.

By default, `audit_log_rotate_on_size=0` and there is no log rotation. In this case, the audit log plugin closes and reopens the log file when the `audit_log_flush` value changes from disabled to enabled. Log file renaming must be done externally to the server. Suppose that you want to maintain the three most recent log files, which cycle through the names `audit.log.1.xml` through `audit.log.3.xml`. On Unix, perform rotation manually like this:

1. From the command line, rename the current log files:

```
mv audit.log.2.xml audit.log.3.xml
mv audit.log.1.xml audit.log.2.xml
mv audit.log audit.log.1.xml
```

At this point, the plugin is still writing to the current log file, which has been renamed to `audit.log.1.xml`.

2. Connect to the server and flush the log file so the plugin closes it and reopens a new `audit.log` file:

```
SET GLOBAL audit_log_flush = ON;
```

If `audit_log_rotate_on_size` is greater than 0, setting `audit_log_flush` has no effect. In this case, the audit log plugin closes and reopens its log file whenever a write to the file causes its size to exceed the `audit_log_rotate_on_size` value. The plugin renames the original file to have an extension consisting of a timestamp and `.xml` suffix. For example, `audit.log` might be renamed to `audit.log.13792588477726520.xml`. The last 7 digits of the timestamp are a fractional second part. The first 10 digits are a Unix timestamp value that can be interpreted using the `FROM_UNIXTIME()` function:

```
mysql> SELECT FROM_UNIXTIME(1379258847);
+-----+
| FROM_UNIXTIME(1379258847) |
+-----+
| 2013-09-15 10:27:27       |
+-----+
```

### 7.5.5.6 Audit Log Filtering

**Note**

This section describes how audit log filtering works as of MySQL 5.7.13 if the `audit_log` plugin and the accompanying audit tables and UDFs are installed. If the plugin is installed but not the accompanying audit tables and UDFs, the plugin operates in legacy filtering mode, described in [Legacy Mode Audit Log Filtering](#). Legacy mode is the behavior that applies prior to MySQL 5.7.13; that is, before the introduction of rule-based filtering.

Prior to MySQL 5.7.13, the audit log plugin had the capability of controlling logging of audited events by filtering them based on the account from which events originate or event status. As of MySQL 5.7.13, filtering capabilities are extended:

- Audited events can be filtered using these characteristics:
  - User account
  - Audit event class
  - Audit event subclass
  - Value of event fields such as those that indicate operation status or SQL statement executed
- Audit filtering is rule based:
  - A filter definition creates a set of auditing rules. Definitions can be configured to include or exclude events based on the characteristics just described.
  - Multiple filters can be defined, and any given filter can be assigned to any number of user accounts.
  - It is possible to define a default filter to use with any user account that has no explicitly assigned filter.
- Audit filters can be defined, displayed, and modified using an SQL interface based on user-defined functions (UDFs).
- Audit filter definitions are stored in the tables in the `mysql` system database.
- Within a given session, the value of the read-only `audit_log_filter_id` system variable indicates whether a filter has been assigned to the session.

The following list provides a brief summary of the UDFs that implement the SQL interface for audit filtering control:

- `audit_log_filter_set_filter()`: Define a filter
- `audit_log_filter_remove_filter()`: Remove a filter
- `audit_log_filter_set_user()`: Start filtering a user account
- `audit_log_filter_remove_user()`: Stop filtering a user account
- `audit_log_filter_flush()`: Flush manual changes to the filter tables to affect ongoing filtering

For usage examples and complete details about the filtering functions, see [Using Audit Log Filtering Functions](#), and [Audit Log Functions](#).

The audit log filtering UDFs are subject to these constraints:

- To use any filtering UDF, the `audit_log` plugin must be enabled. Otherwise, an error occurs:

```
mysql> SELECT audit_log_filter_flush();
+-----+
| audit_log_filter_flush() |
+-----+
| ERROR: audit_log plugin has not been installed with INSTALL PLUGIN syntax. |
+-----+
```

The audit tables must also exist or an error occurs:

```
mysql> SELECT audit_log_filter_flush();
+-----+
| audit_log_filter_flush() |
+-----+
| ERROR: Could not reinitialize audit log filters. |
+-----+
```

To install the `audit_log` plugin, see [Section 7.5.5.2, “Installing or Uninstalling MySQL Enterprise Audit”](#).

- To use any filtering UDF, a user must possess the `SUPER` privilege. Otherwise, an error occurs:

```
mysql> SELECT audit_log_filter_flush()\G
***** 1. row *****
audit_log_filter_flush(): ERROR: Request ignored for 'user1'@'localhost'.
      SUPER_ACL needed to perform operation
```

To grant the `SUPER` privilege to a user account, use this statement:

```
GRANT SUPER ON *.* TO user;
```

Alternatively, should you prefer to avoid granting the `SUPER` privilege while still permitting users to access specific filtering functions, “wrapper” stored programs can be defined. This technique is described in the context of keyring UDFs in [Using General-Purpose Keyring Functions](#); it can be adapted for use with filtering UDFs.

- The `audit_log` plugin operates in legacy mode if it is installed but the accompanying audit tables and UDFs are not created. These messages are written to the error log at server startup:

```
[Warning] Plugin audit_log reported: 'Failed to open the audit log filter tables.'
[Warning] Plugin audit_log reported: 'Audit Log plugin supports a filtering,
which has not been installed yet. Audit Log plugin will run in the legacy
mode, which will be disabled in the next release.'
```

In legacy mode, filtering can be done based only on event account or status. For details, see [Legacy Mode Audit Log Filtering](#).

## Using Audit Log Filtering Functions

Before using the audit log user-defined functions (UDFs), install them according to the instructions provided in [Section 7.5.5.2, “Installing or Uninstalling MySQL Enterprise Audit”](#).

The audit log filtering functions enable filtering control by providing an interface to create, modify, and remove filter definitions and assign filters to user accounts.

Filter definitions are `JSON` values. For information about using `JSON` data in MySQL, see [Section 12.6, “The JSON Data Type”](#). This section shows some simple filter definitions. For more information about filter definitions, see [Writing Audit Log Filter Definitions](#).

When a connection arrives, the `audit_log` plugin determines which filter to use for the new session by searching for the user account name in the current filter assignments:

- If a filter is assigned to the user, that filter is used.
- Otherwise, if no assignment exists, but there is a filter assigned to the default account (`%`), the default filter is used.
- Otherwise, no audit events are logged for the session.

If a change-user operation occurs during a session (see [Section 26.8.7.3, “mysql\\_change\\_user\(\)”](#)), filter assignment for the session is updated using the same rules but for the new user.

By default, no accounts have a filter assigned, so no logging of auditable events occurs for any account.

Suppose that instead you want the default to be to log only connection-related activity (for example, to see connect, change-user, and disconnect events, but not the SQL statements users execute while connected). To achieve this, define a filter (shown here named `log_conn_events`) that enables logging only of events in the `connection` class, and assign that filter to the default account, represented by the `%` account name:

```
SET @f = '{ "filter": { "class": { "name": "connection" } } }';
SELECT audit_log_filter_set_filter('log_conn_events', @f);
SELECT audit_log_filter_set_user('%', 'log_conn_events');
```

Now connections from any account that has no explicitly defined filter use this default account filter.

To assign a filter explicitly to a particular user account or accounts, define the filter, then assign it to the relevant accounts:

```
SELECT audit_log_filter_set_filter('log_all', '{ "filter": { "log": true } }');
SELECT audit_log_filter_set_user('user1@localhost', 'log_all');
SELECT audit_log_filter_set_user('user2@localhost', 'log_all');
```

Now full logging is enabled for `user1@localhost` and `user2@localhost`. Connections from other accounts continue to be filtered using the default account filter.

To disassociate a user account from its current filter, either unassign the filter or assign a different filter:

- Unassign the filter from the user account:

```
SELECT audit_log_filter_remove_user('user1@localhost');
```

Filtering of current sessions for the account remains unaffected. Subsequent connections from the account are filtered using the default account filter if there is one, and are not logged otherwise.

- Assign a different filter to the user account:

```
SELECT audit_log_filter_set_filter('log_nothing', '{ "filter": { "log": false } }');
SELECT audit_log_filter_set_user('user1@localhost', 'log_nothing');
```

Filtering of current sessions for the account remains unaffected. Subsequent connections from the account are filtered using the new filter. For the filter shown here, that means no logging for new connections from `user1@localhost`.

For audit log filtering, user name and host name comparisons are case sensitive. This differs from comparisons for privilege checking, for which host name comparisons are not case sensitive.

To remove a filter, do this:

```
SELECT audit_log_filter_remove_filter('log_nothing');
```

Removing a filter also unassigns it from any users to whom it has been assigned, including any current sessions for those users.

The filtering UDFs just described affect audit filtering immediately and update the audit log tables in the `mysql` system database that store filters and user accounts (see [Audit Log Tables](#)). It is also possible to modify those tables directly using statements such as `INSERT`, `UPDATE`, and `DELETE`, but such changes do not affect filtering immediately. To flush your changes and make them operational, call `audit_log_filter_flush()`:

```
SELECT audit_log_filter_flush();
```

To determine whether a filter has been assigned to the current session, check the session value of the read-only `audit_log_filter_id` system variable. If the value is 0, no filter is assigned. If the value is nonzero, it is the internally maintained ID of the assigned filter:

```
mysql> SELECT @@audit_log_filter_id;
+-----+
| @@audit_log_filter_id |
+-----+
|                      2 |
+-----+
```

## Writing Audit Log Filter Definitions

Filter definitions are `JSON` values. For information about using `JSON` data in MySQL, see [Section 12.6, “The JSON Data Type”](#).

Filter definitions have this form, where *actions* indicates how filtering takes place:

```
{ "filter": actions }
```

The following discussion describes permitted constructs in filter definitions.

## Logging All Events

To explicitly enable or disable logging of all events, use a `log` element in the filter:

```
{
  "filter": { "log": true }
}
```

The `log` value can be either `true` or `false`.

The preceding filter enables logging of all events. It is equivalent to:

```
{
  "filter": { }
}
```

Logging behavior depends on the `log` value and whether `class` or `event` items are specified:

- With `log` specified, its given value is used.
- Without `log` specified, logging is `true` if no `class` or `event` item is specified, and `false` otherwise (in which case, `class` or `event` can include their own `log` item).

## Logging Specific Event Classes

To log events of a specific class, use a `class` element in the filter, with its `name` field denoting the name of the class to log:

```
{
  "filter": {
    "class": { "name": "connection" }
  }
}
```

The `name` value can be `connection`, `general`, or `table_access` to log connection, general, or table-access events, respectively.

The preceding filter enables logging of events in the `connection` class. It is equivalent to the following filter with `log` items made explicit:

```
{
  "filter": {
    "log": false,
    "class": { "log": true,
               "name": "connection" }
  }
}
```

To enable logging of multiple classes, define the `class` value as a `JSON` array element that names the classes:

```
{
  "filter": {
    "class": [
      { "name": "connection" },
      { "name": "general" },
      { "name": "table_access" }
    ]
  }
}
```

#### Note

When multiple instances of a given item appear at the same level within a filter definition, the item values can be combined into a single instance of that item within an array value. The preceding definition can be written like this:

```
{
  "filter": {
    "class": [
      { "name": [ "connection", "general", "table_access" ] }
    ]
  }
}
```

### Logging Specific Event Subclasses

To enable logging for specific event subclasses, use an `event` item:

```
{
  "filter": {
    "class": [
      {
        "name": "connection",
        "event": [
          { "name": "connect" },
          { "name": "disconnect" }
        ]
      },
      { "name": "general" },
      {
        "name": "table_access",
        "event": [
          { "name": "insert" },
          { "name": "delete" },
          { "name": "update" }
        ]
      }
    ]
  }
}
```

}

Table 7.19, “Subclass Values Per Event Class” describes the permitted subclass values for each event class.

**Table 7.19 Subclass Values Per Event Class**

| Event Class  | Event Subclass | Description   |
|--------------|----------------|---|
| connection   | connect        | Connection initiation (successful or unsuccessful)  |
|              | change_user    | User re-authentication with different user/password during session                        |
|              | disconnect     | Connection termination  |
| general      | status         | General operation information   |
| table_access | read           | Table read statements, such as <code>SELECT</code> or <code>INSERT INTO ... SELECT</code> |
|              | delete         | Table delete statements, such as <code>DELETE</code> or <code>TRUNCATE TABLE</code>       |
|              | insert         | Table insert statements, such as <code>INSERT</code> or <code>REPLACE</code>              |
|              | update         | Table update statements, such as <code>UPDATE</code>                                      |

### Inclusive and Exclusive Logging

A filter can be defined in inclusive or exclusive mode:

- Inclusive mode logs only explicitly specified items.
- Exclusive mode logs everything but explicitly specified items.

To perform inclusive logging, disable logging globally and enable logging for specific classes. This filter logs `connect` and `disconnect` events in the `connection` class, and events in the `general` class:

```
{
  "filter": {
    "log": false,
    "class": [
      {
        "name": "connection",
        "event": [
          { "name": "connect", "log": true },
          { "name": "disconnect", "log": true }
        ]
      },
      { "name": "general", "log": true }
    ]
  }
}
```

To perform exclusive logging, enable logging globally and disable logging for specific classes. This filter logs everything except events in the `general` class:

```
{
  "filter": {
    "log": true,
    "class": [
      { "name": "general", "log": false }
    ]
  }
}
```

This filter logs `change_user` events in the `connection` class, and `table_access` events:

```
{
  "filter": {
```

```

    "log": true,
    "class": [
      {
        "name": "connection",
        "event": [
          { "name": "connect", "log": false },
          { "name": "disconnect", "log": false }
        ]
      },
      { "name": "general", "log": false }
    ]
  }
}

```

## Testing Event Field Values

To enable logging based on specific event field values, specify a `field` item within the `log` item that indicates the field name and its expected value:

```

{
  "filter": {
    "class": {
      "name": "general",
      "event": {
        "name": "status",
        "log": {
          "field": { "name": "general_command.str", "value": "Query" }
        }
      }
    }
  }
}

```

Each event contains event class-specific fields that can be accessed from within a filter to perform custom filtering.

A connection event indicates when a connection-related activity occurs during a session, such as a user connecting to or disconnecting from the server. [Table 7.20, “Connection Event Fields”](#) indicates the permitted fields for connection events.

**Table 7.20 Connection Event Fields**

| Field Name                        | Field Type       | Description  |
|-----------------------------------|------------------|--|
| <code>status</code>               | integer          | Event status:  |
|                                   |                  | 0: OK  |
|                                   |                  | Otherwise: Failed  |
| <code>connection_id</code>        | unsigned integer | Connection ID  |
| <code>user.str</code>             | string           | User name specified during authentication                          |
| <code>user.length</code>          | unsigned integer | User name length   |
| <code>priv_user.str</code>        | string           | Authenticated user name (account user name)                        |
| <code>priv_user.length</code>     | unsigned integer | Authenticated user name length                                     |
| <code>external_user.str</code>    | string           | External user name (provided by third-party authentication plugin) |
| <code>external_user.length</code> | unsigned integer | External user name length  |
| <code>proxy_user.str</code>       | string           | Proxy user name  |
| <code>proxy_user.length</code>    | unsigned integer | Proxy user name length   |
| <code>host.str</code>             | string           | Connected user host  |
| <code>host.length</code>          | unsigned integer | Connected user host length   |

| Field Name                   | Field Type       | Description  |
|------------------------------|------------------|--|
| <code>ip.str</code>          | string           | Connected user IP address                            |
| <code>ip.length</code>       | unsigned integer | Connected user IP address length                     |
| <code>database.str</code>    | string           | Database name specified at connect time              |
| <code>database.length</code> | unsigned integer | Database name length                                 |
| <code>connection_type</code> | integer          | Connection type:                                     |
|                              |                  | 0 or ":: <code>undefined</code> ": Undefined         |
|                              |                  | 1 or ":: <code>tcp/ip</code> ": TCP/IP               |
|                              |                  | 2 or ":: <code>socket</code> ": Socket               |
|                              |                  | 3 or ":: <code>named_pipe</code> ": Named pipe       |
|                              |                  | 4 or ":: <code>ssl</code> ": SSL                     |
|                              |                  | 5 or ":: <code>shared_memory</code> ": Shared memory |

The "::`xxx`" values are symbolic pseudo-constants that may be given instead of the literal numeric values. They must be quoted as strings and are case sensitive.

A general event indicates the status code of an operation and its details. [Table 7.21, "General Event Fields"](#) indicates the permitted fields for general events.

**Table 7.21 General Event Fields**

| Field Name                                | Field Type       | Description  |
|---|------------------|--|
| <code>general_error_code</code>           | integer          | Event status:  |
|   |                  | 0: OK  |
|   |                  | Otherwise: Failed  |
| <code>general_thread_id</code>            | unsigned integer | Connection/thread ID   |
| <code>general_user.str</code>             | string           | User name specified during authentication                          |
| <code>general_user.length</code>          | unsigned integer | User name length   |
| <code>general_command.str</code>          | string           | Command name   |
| <code>general_command.length</code>       | unsigned integer | Command name length  |
| <code>general_query.str</code>            | string           | SQL statement text   |
| <code>general_query.length</code>         | unsigned integer | SQL statement text length  |
| <code>general_host.str</code>             | string           | Host name  |
| <code>general_host.length</code>          | unsigned integer | Host name length   |
| <code>general_sql_command.str</code>      | string           | SQL command type name  |
| <code>general_sql_command.length</code>   | unsigned integer | SQL command type name length                                       |
| <code>general_external_user.str</code>    | string           | External user name (provided by third-party authentication plugin) |
| <code>general_external_user.length</code> | unsigned integer | External user name length  |
| <code>general_ip.str</code>               | string           | Connected user IP address  |
| <code>general_ip.length</code>            | unsigned integer | Connection user IP address length                                  |

`general_command.str` indicates a command name: `Query`, `Execute`, `Quit`, or `Change user`.

A general event with the `general_command.str` field set to `Query` or `Execute` contains `general_sql_command.str` set to a value that specifies the type of SQL command: `alter_db`, `alter_db_upgrade`, `admin_commands`, and so forth. These values can be seen as the last components of the Performance Schema instruments displayed by this statement:

```
mysql> SELECT NAME FROM performance_schema.setup_instruments
-> WHERE NAME LIKE 'statement/sql/%' ORDER BY NAME;
+-----+-----+
| NAME                                     |
+-----+-----+
| statement/sql/alter_db                  |
| statement/sql/alter_db_upgrade          |
| statement/sql/alter_event                |
| statement/sql/alter_function            |
| statement/sql/alter_instance            |
| statement/sql/alter_procedure           |
| statement/sql/alter_server              |
| ...                                     |
+-----+-----+
```

A table-access event provides information about specific table accesses. [Table 7.22, “Table-Access Event Fields”](#) indicates the permitted fields for table-access events.

**Table 7.22 Table-Access Event Fields**

| Field Name                         | Field Type       | Description                         |
|------------------------------------|------------------|-------------------------------------|
| <code>connection_id</code>         | unsigned integer | Event connection ID                 |
| <code>sql_command_id</code>        | integer          | SQL command ID                      |
| <code>query.str</code>             | string           | SQL statement text                  |
| <code>query.length</code>          | unsigned integer | SQL statement text length           |
| <code>table_database.str</code>    | string           | Database name associated with event |
| <code>table_database.length</code> | unsigned integer | Database name length                |
| <code>table_name.str</code>        | string           | Table name associated with event    |
| <code>table_name.length</code>     | unsigned integer | Table name length                   |

The following list shows which statements produce which table-access events:

- `read` event:
  - `SELECT`
  - `INSERT ... SELECT` (for tables referenced in `SELECT` clause)
  - `REPLACE ... SELECT` (for tables referenced in `SELECT` clause)
  - `UPDATE ... WHERE` (for tables referenced in `WHERE` clause)
  - `HANDLER ... READ`
- `delete` event:
  - `DELETE`
  - `TRUNCATE TABLE`
- `insert` event:
  - `INSERT`
  - `INSERT ... SELECT` (for table referenced in `INSERT` clause)
  - `REPLACE`
  - `REPLACE ... SELECT` (for table referenced in `REPLACE` clause)
  - `LOAD DATA INFILE`

- `LOAD XML INFILE`
- `update` event:
  - `UPDATE`
  - `UPDATE ... WHERE` (for tables referenced in `UPDATE` clause)

## Logical Operators

Logical operators (`and`, `or`, `not`) can be used in `log` items. This permits construction of more advanced filtering configurations:

```
{
  "filter": {
    "class": {
      "name": "general",
      "event": {
        "name": "status",
        "log": {
          "or": [
            {
              "and": [
                { "field": { "name": "general_command.str", "value": "Query" } },
                { "field": { "name": "general_command.length", "value": 5 } }
              ]
            },
            {
              "and": [
                { "field": { "name": "general_command.str", "value": "Execute" } },
                { "field": { "name": "general_command.length", "value": 7 } }
              ]
            }
          ]
        }
      }
    }
  }
}
```

## Referencing Predefined Variables

To refer to a predefined variable in a `log` condition, use a `variable` item, which tests equality against a given value:

```
{
  "filter": {
    "class": {
      "name": "general",
      "event": {
        "name": "status",
        "log": {
          "variable": {
            "name": "audit_log_connection_policy_value", "value": "::none"
          }
        }
      }
    }
  }
}
```

Each predefined variable corresponds to a system variable. By writing a filter that tests a predefined variable, you can modify filter operation by setting the corresponding system variable, without having to redefine the filter. For example, by writing a filter that tests the value of the `audit_log_connection_policy_value` predefined variable, you can modify filter operation by changing the value of the `audit_log_connection_policy` system variable.

The `audit_log_XXX_policy` system variables are used for the legacy mode audit log (see [Legacy Mode Audit Log Filtering](#)). With rule-based audit log filtering, those variables remain visible (for example, using `SHOW VARIABLES`), but changes to them have no effect unless you write filters containing constructs that refer to them.

The following list describes the permitted predefined variables for `variable` items:

- `audit_log_connection_policy_value`

This variable corresponds to the value of the `audit_log_connection_policy` system variable. The value is an unsigned integer. [Table 7.23, “audit\\_log\\_connection\\_policy\\_value Values”](#) shows the permitted values and the corresponding `audit_log_connection_policy` values.

**Table 7.23 audit\_log\_connection\_policy\_value Values**

| Value   | Corresponding audit_log_connection_policy Value |
|---|---|
| 0 or ":: <none"< td=""><td>NONE</td></none"<>       | NONE  |
| 1 or ":: <errors"< td=""><td>ERRORS</td></errors"<> | ERRORS  |
| 2 or ":: <all"< td=""><td>ALL</td></all"<>          | ALL   |

The "::

- `audit_log_policy_value`

This variable corresponds to the value of the `audit_log_policy` system variable. The value is an unsigned integer. [Table 7.24, “audit\\_log\\_policy\\_value Values”](#) shows the permitted values and the corresponding `audit_log_policy` values.

**Table 7.24 audit\_log\_policy\_value Values**

| Value               | Corresponding audit_log_policy Value |
|---------------------|--------------------------------------|
| 0 or "::none"       | NONE                                 |
| 1 or "::logins"     | LOGINS                               |
| 2 or "::all"        | ALL                                  |
| 3 or<br>"::queries" | QUERIES                              |

The "::

- `audit_log_statement_policy_value`

This variable corresponds to the value of the `audit_log_statement_policy` system variable. The value is an unsigned integer. [Table 7.25, “audit\\_log\\_statement\\_policy\\_value Values”](#) shows the permitted values and the corresponding `audit_log_statement_policy` values.

**Table 7.25 audit\_log\_statement\_policy\_value Values**

| Value   | Corresponding audit_log_statement_policy Value |
|---|--|
| 0 or ":: <none"< td=""><td>NONE</td></none"<>       | NONE   |
| 1 or ":: <errors"< td=""><td>ERRORS</td></errors"<> | ERRORS   |
| 2 or ":: <all"< td=""><td>ALL</td></all"<>          | ALL  |

The "::

## Referencing Predefined Functions

To refer to a predefined function in a `log` condition, use a `function` item, which takes `name` and `args` values to specify the function name and its arguments, respectively:

```
{
  "filter": {
    "class": {
      "name": "general",
      "event": {
        "name": "status",
        "log": {
          "function": {
            "name": "find_in_include_list",
            "args": [ { "string": [ { "field": "user.str" },
                                { "string": "@",
                                { "field": "host.str" } ] } ] ]
          }
        }
      }
    }
  }
}
```

The function as specified in the `name` item should be the function name only, without parentheses or the argument list. Arguments in the `args` item, if there is one, must be given in the order listed in the function description. Arguments can refer to predefined variables, event fields, or string or numeric constants.

The preceding filter determines whether to log `general` class `status` events depending on whether the current user is found in the `audit_log_include_accounts` system variable. That user is constructed using fields in the event.

The following list describes the permitted predefined functions for `function` items:

- `audit_log_exclude_accounts_is_null()`

Checks whether the `audit_log_exclude_accounts` system variable is `NULL`. This function can be helpful when defining filters that correspond to the legacy audit log implementation.

Arguments:

None.

- `audit_log_include_accounts_is_null()`

Checks whether the `audit_log_include_accounts` system variable is `NULL`. This function can be helpful when defining filters that correspond to the legacy audit log implementation.

Arguments:

None.

- `debug_sleep(millisecond)`

Sleeps for the given number of milliseconds. This function is used during performance measurement.

`debug_sleep()` is available for debug builds only.

Arguments:

- `millisec`: The number of milliseconds to sleep as an unsigned integer.
- `find_in_exclude_list(account)`

Checks whether an account string exists in the audit log exclude list (the value of the `audit_log_exclude_accounts` system variable).

Arguments:

- `account`: The user account name as a string.
- `find_in_include_list(account)`

Checks whether an account string exists in the audit log include list (the value of the `audit_log_include_accounts` system variable).

Arguments:

- `account`: The user account name as a string.
- `string_find(text, substr)`

Checks whether the `substr` value is contained in the `text` value.

Arguments:

- `text`: The text string to search.
- `substr`: The substring to search for in `text`.

## Replacing a User Filter

In some cases, the filter definition can be changed dynamically. To do this, define a `filter` configuration within an existing `filter`. For example:

```
{
  "filter": {
    "id": "main",
    "class": {
      "name": "table_access",
      "event": {
        "name": [ "update", "delete" ],
        "log": false,
        "filter": {
          "class": {
            "name": "general",
            "event": { "name": "status",
                      "filter": { "ref": "main" } }
          },
          "activate": {
            "or": [
              { "field": { "name": "table_name.str", "value": "temp_1" } },
              { "field": { "name": "table_name.str", "value": "temp_2" } }
            ]
          }
        }
      }
    }
  }
}
```

A new filter is activated when the `activate` element within a subfilter evaluates to `true`. Using `activate` in a top-level `filter` is not permitted.

A new filter can be replaced with the original one by using a `ref` item inside the subfilter to refer to the original filter `id`.

The filter shown operates like this:

- The `main` filter waits for `table_access` events, either `update` or `delete`.
- If the `update` or `delete table_access` event occurs on the `temp_1` or `temp_2` table, the filter is replaced with the internal one (without an `id`, since there is no need to refer to it explicitly).
- If the end of the command is signalled (`general` / `status` event), an entry is written to the audit log file and the filter is replaced with the `main` filter.

The filter is useful to log statements that update or delete anything from the `temp_1` or `temp_2` tables, such as this one:

```
UPDATE temp_1, temp_3 SET temp_1.a=21, temp_3.a=23;
```

The statement generates multiple `table_access` events, but the audit log file will contain only `general` / `status` entries.

#### Note

Any `id` values used in the definition are evaluated with respect only to that definition. They have nothing to do with the value of the `audit_log_filter_id` system variable.

## Legacy Mode Audit Log Filtering

#### Note

This section describes legacy audit log filtering, which applies under either of these circumstances:

- Before MySQL 5.7.13, that is, prior to the introduction of rule-based audit log filtering described in [Section 7.5.5.6, “Audit Log Filtering”](#).
- As of MySQL 5.7.13, if the `audit_log` plugin is installed but not the accompanying audit tables and UDFs needed for rule-based filtering.

The `audit_log` plugin can filter audited events. This enables you to control whether audited events are written to the audit log file based on the account from which events originate or event status. Status filtering occurs separately for connection events and statement events.

## Event Filtering by Account

To filter audited events based on the originating account, set one of these system variables at server startup or runtime:

- `audit_log_include_accounts`: The accounts to include in audit logging. If this variable is set, only these accounts are audited.
- `audit_log_exclude_accounts`: The accounts to exclude from audit logging. If this variable is set, all but these accounts are audited.

The value for either variable can be `NULL` or a string containing one or more comma-separated account names, each in `user_name@host_name` format. By default, both variables are `NULL`, in which case, no account filtering is done and auditing occurs for all accounts.

Modifications to `audit_log_include_accounts` or `audit_log_exclude_accounts` affect only connections created subsequent to the modification, not existing connections.

Example: To enable audit logging only for the `user1` and `user2` local host account accounts, set the `audit_log_include_accounts` system variable like this:

```
SET GLOBAL audit_log_include_accounts = 'user1@localhost,user2@localhost';
```

Only one of `audit_log_include_accounts` or `audit_log_exclude_accounts` can be non-`NULL` at a time:

- If you set `audit_log_include_accounts`, the server sets `audit_log_exclude_accounts` to `NULL`.
- If you attempt to set `audit_log_exclude_accounts`, an error occurs unless `audit_log_include_accounts` is `NULL`. In this case, you must first clear `audit_log_include_accounts` by setting it to `NULL`.

```
-- This sets audit_log_exclude_accounts to NULL
SET GLOBAL audit_log_include_accounts = value;

-- This fails because audit_log_include_accounts is not NULL
SET GLOBAL audit_log_exclude_accounts = value;

-- To set audit_log_exclude_accounts, first set
-- audit_log_include_accounts to NULL
SET GLOBAL audit_log_include_accounts = NULL;
SET GLOBAL audit_log_exclude_accounts = value;
```

If you inspect the value of either variable, be aware that `SHOW VARIABLES` displays `NULL` as an empty string. To avoid this, use `SELECT` instead:

```
mysql> SHOW VARIABLES LIKE 'audit_log_include_accounts';
+-----+-----+
| Variable_name | Value |
+-----+-----+
| audit_log_include_accounts |      |
+-----+-----+
mysql> SELECT @@audit_log_include_accounts;
+-----+
| @@audit_log_include_accounts |
+-----+
| NULL                        |
+-----+
```

If a user name or host name requires quoting because it contains a comma, space, or other special character, quote it using single quotes. If the variable value itself is quoted with single quotes, double each inner single quote or escape it with a backslash. The following statements each enable audit logging for the local `root` account and are equivalent, even though the quoting styles differ:

```
SET GLOBAL audit_log_include_accounts = 'root@localhost';
SET GLOBAL audit_log_include_accounts = '''root''@''localhost''';
SET GLOBAL audit_log_include_accounts = '\\root\\'@\\'localhost\\';
SET GLOBAL audit_log_include_accounts = "'root'@'localhost'";
```

The last statement will not work if the `ANSI_QUOTES` SQL mode is enabled because in that mode double quotes signify identifier quoting, not string quoting.

## Event Filtering by Status

To filter audited events based on status, set these system variables at server startup or runtime:

- `audit_log_connection_policy`: Logging policy for connection events
- `audit_log_statement_policy`: Logging policy for statement events

Each variable takes a value of `ALL` (log all associated events; this is the default), `ERRORS` (log only failed events), or `NONE` (do not log events). For example, to log all statement events but only failed connection events, use these settings:

```
SET GLOBAL audit_log_statement_policy = ALL;
SET GLOBAL audit_log_connection_policy = ERRORS;
```

Another policy system variable, `audit_log_policy`, is available but does not afford as much control as `audit_log_connection_policy` and `audit_log_statement_policy`. It can be set only at server startup. At runtime, it is a read-only variable. It takes a value of `ALL` (log all events; this is the default), `LOGINS` (log connection events), `QUERIES` (log statement events), or `NONE` (do not log events). For any of those values, the audit log plugin logs all selected events without distinction as to success or failure. Use of `audit_log_policy` at startup works as follows:

- If you do not set `audit_log_policy` or set it to its default of `ALL`, any explicit settings for `audit_log_connection_policy` or `audit_log_statement_policy` apply as specified. If not specified, they default to `ALL`.
- If you set `audit_log_policy` to a non-`ALL` value, that value takes precedence over and is used to set `audit_log_connection_policy` and `audit_log_statement_policy`, as indicated in the following table. If you also set either of those variables to a value other than their default of `ALL`, the server writes a message to the error log to indicate that their values are being overridden.

| Startup <code>audit_log_policy</code> Value | Resulting <code>audit_log_connection_policy</code> Value | Resulting <code>audit_log_statement_policy</code> Value |
|---|--|---|
| <code>LOGINS</code>                         | <code>ALL</code>   | <code>NONE</code>                                       |
| <code>QUERIES</code>                        | <code>NONE</code>  | <code>ALL</code>  |
| <code>NONE</code>                           | <code>NONE</code>  | <code>NONE</code>                                       |

## Event Filtering Reporting

To check the effect of filtering, you can inspect the values of these status variables:

- `Audit_log_events`: The number of events handled by the audit log plugin, whether or not they were written to the log based on filtering policy.
- `Audit_log_events_filtered`: The number of events handled by the audit log plugin that were filtered (not written to the log) based on filtering policy.
- `Audit_log_events_written`: The number of events written to the audit log.

### 7.5.5.7 Audit Log Reference

The following discussion serves as a reference to MySQL Enterprise Audit components:

- [Audit Log Tables](#)
- [Audit Log Functions](#)
- [Audit Log Option and Variable Reference](#)
- [Audit Log Options and Variables](#)
- [Audit Log Status Variables](#)

To install the `audit_log` tables and functions, use the instructions provided in [Section 7.5.5.2, “Installing or Uninstalling MySQL Enterprise Audit”](#). Unless those components are installed, the `audit_log` plugin operates in legacy mode. See [Legacy Mode Audit Log Filtering](#).

## Audit Log Tables

MySQL Enterprise Audit uses tables in the `mysql` system database for persistent storage of filter and user account data. The tables can be accessed only by users with privileges for that database. The tables use the `MyISAM` storage engine.

If these tables are missing, the `audit_log` plugin operates in legacy mode. See [Legacy Mode Audit Log Filtering](#).

The `audit_log_filter` table stores filter definitions. The table has these columns:

- `NAME`

The filter name.

- `FILTER`

The filter definition associated with the filter name. Definitions are stored as `JSON` values.

The `audit_log_user` table stores user account information. The table has these columns:

- `USER`

The user name part of an account. For an account `user1@localhost`, the `USER` part is `user1`.

- `HOST`

The host name part of an account. For an account `user1@localhost`, the `HOST` part is `localhost`.

- `FILTERNAME`

The name of the filter assigned to the account. The filter name associates the account with a filter defined in the `audit_log_filter` table.

## Audit Log Functions

This section describes, for each audit log user-defined function (UDF), its purpose, calling sequence, and return value. For information about the conditions under which these UDFs can be invoked, see [Section 7.5.5.6, “Audit Log Filtering”](#).

Each audit log UDF returns `OK` for success, `ERROR: message` for failure.

These audit log UDFs are available:

- `audit_log_filter_flush()`

Calling any of the other filtering UDFs affects operational audit log filtering immediately and updates the audit log tables. If instead you modify the contents of those tables directly using statements such as `INSERT`, `UPDATE`, and `DELETE`, the changes do not affect filtering immediately. To flush your changes and make them operational, call `audit_log_filter_flush()`.

`audit_log_filter_flush()` affects all current sessions and detaches them from their previous filters. Current sessions are no longer logged unless they disconnect and reconnect, or execute a change-user operation.

If this function fails, an error message is returned and the audit log is disabled until the next successful call to `audit_log_filter_flush()`.

Syntax:

```
STRING audit_log_filter_flush()
```

Arguments:

None.

Return values:

`OK` for success, `ERROR: message` for failure.

Example:

```
mysql> SELECT audit_log_filter_flush();
+-----+
| audit_log_filter_flush() |
+-----+
| OK                        |
+-----+
```

- `audit_log_filter_remove_filter()`

Given a filter name, removes the filter from the current set of filters. It is not an error for the filter not to exist.

If a removed filter is assigned to any user accounts, those users stop being filtered (they are removed from the `audit_log_user` table). Termination of filtering includes any current sessions for those users: They are detached from the filter and no longer logged.

Syntax:

```
STRING audit_log_filter_remove_filter(STRING filter_name)
```

Arguments:

- `filter_name`: The filter name as a string.

Return values:

OK for success, **ERROR:** *message* for failure.

Example:

```
mysql> SELECT audit_log_filter_remove_filter('SomeFilter');
+-----+
| audit_log_filter_remove_filter('SomeFilter') |
+-----+
| OK                                            |
+-----+
```

- `audit_log_filter_remove_user()`

Given a user account name, cause the user to be no longer assigned to a filter. It is not an error if the user has no filter assigned. Filtering of current sessions for the user remains unaffected. New connections for the user are filtered using the default account filter if there is one, and are not logged otherwise.

If the name is `%`, the function removes the default account filter that is used for any user account that has no explicitly assigned filter.

Syntax:

```
STRING audit_log_filter_remove_user(STRING user_name)
```

Arguments:

- `user_name`: The user account name as a string in `user_name@host_name` format, or `%` to represent the default account.

Return values:

OK for success, **ERROR:** *message* for failure.

Example:

```
mysql>t; SELECT audit_log_filter_remove_user('user1@localhost');
+-----+
| audit_log_filter_remove_user('user1@localhost') |
+-----+
| OK                                              |
+-----+
```

- `audit_log_filter_set_filter()`

Given a filter name and definition, adds the filter to the current set of filters. If the filter already exists and is used by any current sessions, those sessions are detached from the filter and are no longer logged. This occurs because the new filter definition has a new filter ID that differs from its previous ID.

Syntax:

```
STRING audit_log_filter_set_filter(STRING filter_name, STRING definition)
```

Arguments:

- `filter_name`: The filter name as a string.
- `definition`: The filter definition as a `JSON` value.

Return values:

`OK` for success, `ERROR: message` for failure.

Example:

```
mysql>t; SET @f = '{ "filter": { "log": false } }';
mysql>t; SELECT audit_log_filter_set_filter('SomeFilter', @f);
+-----+
| audit_log_filter_set_filter('SomeFilter', @f) |
+-----+
| OK                                              |
+-----+
```

- `audit_log_filter_set_user()`

Given a user account name and a filter name, assigns the filter to the user. A user can be assigned only one filter, so if the user was already assigned a filter, the assignment is replaced. Filtering of current sessions for the user remains unaffected. New connections are filtered using the new filter.

As a special case, the name `%` represents the default account. The filter is used for connections from any user account that has no explicitly assigned filter.

Syntax:

```
STRING audit_log_filter_set_user(STRING user_name, STRING filter_name)
```

Arguments:

- `user_name`: The user account name as a string in `user_name@host_name` format, or `%` to represent the default account.
- `filter_name`: The filter name as a string.

Return values:

OK for success, ERROR: *message* for failure.

Example:

```
mysql>t; SELECT audit_log_filter_set_user('user1@localhost', 'SomeFilter');
+-----+
| audit_log_filter_set_user('user1@localhost', 'SomeFilter') |
+-----+
| OK                                                         |
+-----+
```

## Audit Log Option and Variable Reference

Table 7.26 Audit Log Option/Variable Reference

| Name                          | Cmd-Line | Option File | System Var | Status Var | Var Scope | Dynamic |
|-------------------------------|----------|-------------|------------|------------|-----------|---------|
| audit-log                     | Yes      | Yes         |            |            |           |         |
| audit_log_buffer_size         | Yes      | Yes         | Yes        |            | Global    | No      |
| audit_log_connective_policy   | Yes      | Yes         | Yes        |            | Global    | Yes     |
| audit_log_current_session     |          |             | Yes        |            | Both      | No      |
| Audit_log_current_size        |          |             |            | Yes        | Global    | No      |

| Audit_log_write_waits         |          |             |            | Yes        | Global    | No      |

## Audit Log Options and Variables

This section describes the command options and system variables that control operation of MySQL Enterprise Audit. If values specified at startup time are incorrect, the `audit_log` plugin may fail to initialize properly and the server does not load it. In this case, the server may also produce error messages for other audit log settings because it will not recognize them.

To control the activation of the `audit_log` plugin, use this option:

- `--audit-log[=value]`

|            |       |
|------------|-------|
| Introduced | 5.7.9 |
|------------|-------|

|                            |                                  |                      |
|----------------------------|----------------------------------|----------------------|
| <b>Command-Line Format</b> | <code>--audit-log[=value]</code> |                      |
| <b>Permitted Values</b>    | <b>Type</b>                      | enumeration          |
|                            | <b>Default</b>                   | ON                   |
|                            | <b>Valid Values</b>              | ON                   |
|                            |                                  | OFF                  |
|                            |                                  | FORCE                |
|                            |                                  | FORCE_PLUS_PERMANENT |

This option controls how the server loads the `audit_log` plugin at startup. It is available only if the plugin has been previously registered with `INSTALL PLUGIN` or is loaded with `--plugin-load`. See [Section 7.5.5.2, “Installing or Uninstalling MySQL Enterprise Audit”](#).

The option value should be one of those available for plugin-loading options, as described in [Section 6.5.2, “Installing and Uninstalling Plugins”](#). For example, `--audit-log=FORCE_PLUS_PERMANENT` tells the server to load the plugin and prevent it from being removed while the server is running.

If the `audit_log` plugin is enabled, it exposes several system variables that permit control over logging:

```
mysql> SHOW VARIABLES LIKE 'audit_log%';
+-----+-----+
| Variable_name | Value |
+-----+-----+
| audit_log_buffer_size | 1048576 |
| audit_log_connection_policy | ALL |
| audit_log_current_session | OFF |
| audit_log_exclude_accounts |  |
| audit_log_file | audit.log |
| audit_log_filter_id | 0 |
| audit_log_flush | OFF |
| audit_log_format | NEW |
| audit_log_include_accounts |  |
| audit_log_policy | ALL |
| audit_log_rotate_on_size | 0 |
| audit_log_statement_policy | ALL |
| audit_log_strategy | ASYNCHRONOUS |
+-----+-----+
```

You can set any of these variables at server startup, and some of them at runtime.

- `audit_log_buffer_size`

|  |  |                                    |
|--|--|------------------------------------|
| <b>Introduced</b>                          | 5.7.9                                      |                                    |
| <b>Command-Line Format</b>                 | <code>--audit_log_buffer_size=value</code> |                                    |
| <b>System Variable</b>                     | <b>Name</b>                                | <code>audit_log_buffer_size</code> |
|  | <b>Variable Scope</b>                      | Global                             |
|  | <b>Dynamic Variable</b>                    | No                                 |
| <b>Permitted Values</b> (32-bit platforms) | <b>Type</b>                                | integer                            |
|  | <b>Default</b>                             | 1048576                            |
|  | <b>Min Value</b>                           | 4096                               |
|  | <b>Max Value</b>                           | 4294967295                         |

|  |                  |                      |
|--|------------------|----------------------|
| <b>Permitted Values</b> (64-bit platforms) | <b>Type</b>      | integer              |
|  | <b>Default</b>   | 1048576              |
|  | <b>Min Value</b> | 4096                 |
|  | <b>Max Value</b> | 18446744073709547520 |

When the audit log plugin writes events to the log asynchronously, it uses a buffer to store event contents prior to writing them. This variable controls the size of that buffer, in bytes. The server adjusts the value to a multiple of 4096. The plugin uses a single buffer, which it allocates when it initializes and removes when it terminates. The plugin allocates this buffer only if logging is asynchronous.

- [audit\\_log\\_connection\\_policy](#)

|                            |  |   |
|----------------------------|--|---|
| <b>Introduced</b>          | 5.7.9  |   |
| <b>Command-Line Format</b> | <code>--audit_log_connection_policy=value</code> |   |
| <b>System Variable</b>     | <b>Name</b>                                      | <a href="#">audit_log_connection_policy</a> |
|                            | <b>Variable Scope</b>                            | Global                                      |
|                            | <b>Dynamic Variable</b>                          | Yes   |
| <b>Permitted Values</b>    | <b>Type</b>                                      | enumeration                                 |
|                            | <b>Default</b>                                   | <a href="#">ALL</a>                         |
|                            | <b>Valid Values</b>                              | <a href="#">ALL</a>                         |
|                            |  | <a href="#">ERRORS</a>                      |
|                            |  | <a href="#">NONE</a>                        |

The policy controlling how the audit log plugin writes connection events to its log file. The following table shows the permitted values.

| Value                  | Description                       |
|------------------------|-----------------------------------|
| <a href="#">ALL</a>    | Log all connection events         |
| <a href="#">ERRORS</a> | Log only failed connection events |
| <a href="#">NONE</a>   | Do not log connection events      |

#### Note

At server startup, any explicit value given for [audit\\_log\\_connection\\_policy](#) may be overridden if [audit\\_log\\_policy](#) is also specified, as described in [Section 7.5.5.5, “Audit Log Logging Control”](#).

- [audit\\_log\\_current\\_session](#)

|                        |                         |   |
|------------------------|-------------------------|---|
| <b>Introduced</b>      | 5.7.9                   |   |
| <b>System Variable</b> | <b>Name</b>             | <a href="#">audit_log_current_session</a> |
|                        | <b>Variable Scope</b>   | Global, Session                           |
|                        | <b>Dynamic Variable</b> | No  |
|                        |                         | 1139                                      |

|                         |                |  |
|-------------------------|----------------|--|
| <b>Permitted Values</b> | <b>Type</b>    | boolean                                  |
|                         | <b>Default</b> | <code>depends on filtering policy</code> |

Whether audit logging is enabled for the current session. The session value of this variable is read only. It is set when the session begins based on the values of the `audit_log_include_accounts` and `audit_log_exclude_accounts` system variables. The audit log plugin uses the session value to determine whether to audit events for the session. (There is a global value, but the plugin does not use it.)

- `audit_log_exclude_accounts`

|                            |   |   |
|----------------------------|---|---|
| <b>Introduced</b>          | 5.7.9   |   |
| <b>Command-Line Format</b> | <code>--audit_log_exclude_accounts=value</code> |   |
| <b>System Variable</b>     | <b>Name</b>                                     | <code>audit_log_exclude_accounts</code> |
|                            | <b>Variable Scope</b>                           | Global                                  |
|                            | <b>Dynamic Variable</b>                         | Yes                                     |
| <b>Permitted Values</b>    | <b>Type</b>                                     | string                                  |
|                            | <b>Default</b>                                  | <code>NULL</code>                       |

The accounts for which events should not be logged. The value should be `NULL` or a string containing a list of one or more comma-separated account names. For more information, see [Section 7.5.5.5, “Audit Log Logging Control”](#).

Modifications to `audit_log_exclude_accounts` affect only connections created subsequent to the modification, not existing connections.

- `audit_log_file`

|                            |   |                             |
|----------------------------|---|-----------------------------|
| <b>Introduced</b>          | 5.7.9                                   |                             |
| <b>Command-Line Format</b> | <code>--audit_log_file=file_name</code> |                             |
| <b>System Variable</b>     | <b>Name</b>                             | <code>audit_log_file</code> |
|                            | <b>Variable Scope</b>                   | Global                      |
|                            | <b>Dynamic Variable</b>                 | No                          |
| <b>Permitted Values</b>    | <b>Type</b>                             | file name                   |
|                            | <b>Default</b>                          | <code>audit.log</code>      |

The name of the file to which the audit log plugin writes events. The default value is `audit.log`. If the value of `audit_log_file` is a relative path name, the server interprets it relative to the data directory. If the value is a full path name, the server uses the value as is. A full path name may be useful if it is desirable to locate audit files on a separate file system or directory. For security reasons, the audit log file should be written to a directory accessible only to the MySQL server and users with a legitimate reason to view the log. For more information, see [Section 7.5.5.5, “Audit Log Logging Control”](#).

- `audit_log_filter_id`

|                        |             |                                  |
|------------------------|-------------|----------------------------------|
| <b>Introduced</b>      | 5.7.13      |                                  |
| <b>System Variable</b> | <b>Name</b> | <code>audit_log_filter_id</code> |

|                         |                         |                 |
|-------------------------|-------------------------|-----------------|
|                         | <b>Variable Scope</b>   | Global, Session |
|                         | <b>Dynamic Variable</b> | No              |
| <b>Permitted Values</b> | <b>Type</b>             | integer         |

The session value of this variable indicates the internally maintained ID of the audit filter for the current session. A value of 0 means that the session has no filter assigned.

- `audit_log_flush`

|                         |                         |                              |
|-------------------------|-------------------------|------------------------------|
| <b>Introduced</b>       | 5.7.9                   |                              |
| <b>System Variable</b>  | <b>Name</b>             | <code>audit_log_flush</code> |
|                         | <b>Variable Scope</b>   | Global                       |
|                         | <b>Dynamic Variable</b> | Yes                          |
| <b>Permitted Values</b> | <b>Type</b>             | boolean                      |
|                         | <b>Default</b>          | <code>OFF</code>             |

When this variable is set to enabled (1 or `ON`), the audit log plugin closes and reopens its log file to flush it. (The value remains `OFF` so that you need not disable it explicitly before enabling it again to perform another flush.) Enabling this variable has no effect unless `audit_log_rotate_on_size` is 0. For more information, see [Section 7.5.5.5, “Audit Log Logging Control”](#).

- `audit_log_format`

|                                       |                                       |                               |
|---------------------------------------|---------------------------------------|-------------------------------|
| <b>Introduced</b>                     | 5.7.9                                 |                               |
| <b>Command-Line Format</b>            | <code>--audit_log_format=value</code> |                               |
| <b>System Variable</b>                | <b>Name</b>                           | <code>audit_log_format</code> |
|                                       | <b>Variable Scope</b>                 | Global                        |
|                                       | <b>Dynamic Variable</b>               | No                            |
| <b>Permitted Values (&gt;= 5.7.9)</b> | <b>Type</b>                           | enumeration                   |
|                                       | <b>Default</b>                        | <code>NEW</code>              |
|                                       | <b>Valid Values</b>                   | <code>OLD</code>              |
|                                       |                                       | <code>NEW</code>              |

The audit log file format. Permitted values are `OLD` and `NEW` (default `NEW`). For details about the new format, see [Section 7.5.5.4, “The Audit Log File”](#). For details about the old format, see [The Audit Log File in MySQL 5.6 Reference Manual](#).

If you change the value of `audit_log_format`, use this procedure to avoid writing log entries in one format to an existing log file that contains entries in a different format:

1. Stop the server.
2. Rename the current audit log file manually.
3. Restart the server with the new value of `audit_log_format`. The audit log plugin will create a new log file, which will contain log entries in the selected format.

- `audit_log_include_accounts`

|                            |   |   |
|----------------------------|---|---|
| <b>Introduced</b>          | 5.7.9   |   |
| <b>Command-Line Format</b> | <code>--audit_log_include_accounts=value</code> |   |
| <b>System Variable</b>     | <b>Name</b>                                     | <code>audit_log_include_accounts</code> |
|                            | <b>Variable Scope</b>                           | Global                                  |
|                            | <b>Dynamic Variable</b>                         | Yes                                     |
| <b>Permitted Values</b>    | <b>Type</b>                                     | string                                  |
|                            | <b>Default</b>                                  | <code>NULL</code>                       |

The accounts for which events should be logged. The value should be `NULL` or a string containing a list of one or more comma-separated account names. For more information, see [Section 7.5.5.5, “Audit Log Logging Control”](#).

Modifications to `audit_log_include_accounts` affect only connections created subsequent to the modification, not existing connections.

- `audit_log_policy`

|                            |                                       |                               |
|----------------------------|---------------------------------------|-------------------------------|
| <b>Introduced</b>          | 5.7.9                                 |                               |
| <b>Command-Line Format</b> | <code>--audit_log_policy=value</code> |                               |
| <b>System Variable</b>     | <b>Name</b>                           | <code>audit_log_policy</code> |
|                            | <b>Variable Scope</b>                 | Global                        |
|                            | <b>Dynamic Variable</b>               | No                            |
| <b>Permitted Values</b>    | <b>Type</b>                           | enumeration                   |
|                            | <b>Default</b>                        | <code>ALL</code>              |
|                            | <b>Valid Values</b>                   | <code>ALL</code>              |
|                            |                                       | <code>LOGINS</code>           |
|                            |                                       | <code>QUERIES</code>          |
|                            |                                       | <code>NONE</code>             |

The policy controlling how the audit log plugin writes events to its log file. The following table shows the permitted values.

| Value                | Description                            |
|----------------------|--|
| <code>ALL</code>     | Log all events                         |
| <code>LOGINS</code>  | Log only login events                  |
| <code>QUERIES</code> | Log only query events                  |
| <code>NONE</code>    | Log nothing (disable the audit stream) |

`audit_log_policy` can be set only at server startup. At runtime, it is a read-only variable. Two other system variables, `audit_log_connection_policy` and `audit_log_statement_policy`, provide finer control over logging policy and can be set either at startup or at runtime. If you use `audit_log_policy` at startup instead of the other two variables, the server uses its value to set those variables. For more information about the policy variables and their interaction, see [Section 7.5.5.5, “Audit Log Logging Control”](#).

- `audit_log_rotate_on_size`

|                            |   |                                       |
|----------------------------|---|---------------------------------------|
| <b>Introduced</b>          | 5.7.9                                     |                                       |
| <b>Command-Line Format</b> | <code>--audit_log_rotate_on_size=N</code> |                                       |
| <b>System Variable</b>     | <b>Name</b>                               | <code>audit_log_rotate_on_size</code> |
|                            | <b>Variable Scope</b>                     | Global                                |
|                            | <b>Dynamic Variable</b>                   | Yes                                   |
| <b>Permitted Values</b>    | <b>Type</b>                               | integer                               |
|                            | <b>Default</b>                            | 0                                     |

If the `audit_log_rotate_on_size` value is greater than 0, the audit log plugin closes and reopens its log file if a write to the file causes its size to exceed this value. The original file is renamed to have a timestamp extension.

If the `audit_log_rotate_on_size` value is 0, the plugin does not close and reopen its log based on size. Instead, use `audit_log_flush` to close and reopen the log on demand. In this case, rename the file externally to the server before flushing it.

For more information about audit log file rotation and timestamp interpretation, see [Section 7.5.5.5, “Audit Log Logging Control”](#).

If you set this variable to a value that is not a multiple of 4096, it is truncated to the nearest multiple. (Thus, setting it to a value less than 4096 has the effect of setting it to 0 and no rotation occurs.)

- `audit_log_statement_policy`

|                            |   |   |
|----------------------------|---|---|
| <b>Introduced</b>          | 5.7.9   |   |
| <b>Command-Line Format</b> | <code>--audit_log_statement_policy=value</code> |   |
| <b>System Variable</b>     | <b>Name</b>                                     | <code>audit_log_statement_policy</code> |
|                            | <b>Variable Scope</b>                           | Global                                  |
|                            | <b>Dynamic Variable</b>                         | Yes                                     |
| <b>Permitted Values</b>    | <b>Type</b>                                     | enumeration                             |
|                            | <b>Default</b>                                  | <code>ALL</code>                        |
|                            | <b>Valid Values</b>                             | <code>ALL</code>                        |
|                            |   | <code>ERRORS</code>                     |
|                            |   | <code>NONE</code>                       |

The policy controlling how the audit log plugin writes statement events to its log file. The following table shows the permitted values.

| Value               | Description                      |
|---------------------|----------------------------------|
| <code>ALL</code>    | Log all statement events         |
| <code>ERRORS</code> | Log only failed statement events |
| <code>NONE</code>   | Do not log statement events      |

**Note**

At server startup, any explicit value given for `audit_log_statement_policy` may be overridden if `audit_log_policy` is also specified, as described in [Section 7.5.5.5, “Audit Log Logging Control”](#).

- `audit_log_strategy`

|                            |   |                                 |
|----------------------------|---|---------------------------------|
| <b>Introduced</b>          | 5.7.9                                   |                                 |
| <b>Command-Line Format</b> | <code>--audit_log_strategy=value</code> |                                 |
| <b>System Variable</b>     | <b>Name</b>                             | <code>audit_log_strategy</code> |
|                            | <b>Variable Scope</b>                   | Global                          |
|                            | <b>Dynamic Variable</b>                 | No                              |
| <b>Permitted Values</b>    | <b>Type</b>                             | enumeration                     |
|                            | <b>Default</b>                          | <code>ASYNCHRONOUS</code>       |
|                            | <b>Valid Values</b>                     | <code>ASYNCHRONOUS</code>       |
|                            |   | <code>PERFORMANCE</code>        |
|                            |   | <code>SEMISYNCHRONOUS</code>    |
|                            |   | <code>SYNCHRONOUS</code>        |

The logging method used by the audit log plugin. The following table describes the permitted values.

**Table 7.27 Audit Log Strategies**

| Value                        | Meaning   |
|------------------------------|---|
| <code>ASYNCHRONOUS</code>    | Log asynchronously, wait for space in output buffer                     |
| <code>PERFORMANCE</code>     | Log asynchronously, drop request if insufficient space in output buffer |
| <code>SEMISYNCHRONOUS</code> | Log synchronously, permit caching by operating system                   |
| <code>SYNCHRONOUS</code>     | Log synchronously, call <code>sync()</code> after each request          |

## Audit Log Status Variables

If the `audit_log` plugin is enabled, it exposes several status variables that provide operational information.

- `Audit_log_current_size`

The size of the current audit log file. The value increases when an event is written to the log and is reset to 0 when the log is rotated.

- `Audit_log_event_max_drop_size`

The size of the largest dropped event in performance logging mode. For a description of logging modes, see [Section 7.5.5.5, “Audit Log Logging Control”](#).

- `Audit_log_events`

The number of events handled by the audit log plugin, whether or not they were written to the log based on filtering policy (see [Section 7.5.5.5, “Audit Log Logging Control”](#)).

- `Audit_log_events_filtered`

The number of events handled by the audit log plugin that were filtered (not written to the log) based on filtering policy (see [Section 7.5.5.5, “Audit Log Logging Control”](#)).

- `Audit_log_events_lost`

The number of events lost in performance logging mode because an event was larger than than the available audit log buffer space. This value may be useful for assessing how to set `audit_log_buffer_size` to size the buffer for performance mode. For a description of logging modes, see [Section 7.5.5.5, “Audit Log Logging Control”](#).

- `Audit_log_events_written`

The number of events written to the audit log.

- `Audit_log_total_size`

The total size of events written to all audit log files. Unlike `Audit_log_current_size`, the value of `Audit_log_total_size` increases even when the log is rotated.

- `Audit_log_write_waits`

The number of times an event had to wait for space in the audit log buffer in asynchronous logging mode. For a description of logging modes, see [Section 7.5.5.5, “Audit Log Logging Control”](#).

### 7.5.5.8 Audit Log Restrictions

MySQL Enterprise Audit is subject to these general restrictions:

- Only SQL statements are logged. Changes made by no-SQL APIs, such as memcached, Node.JS, and the NDB API, are not logged.
- Only top-level statements are logged, not statements within stored programs such as triggers or stored procedures.
- Contents of files referenced by statements such as `LOAD DATA INFILE` are not logged.

**MySQL Cluster.** It is possible to use MySQL Enterprise Audit with MySQL Cluster, subject to the following conditions:

- All changes to be logged must be done using the SQL interface. Changes using no-SQL interfaces, such as those provided by the NDB API, memcached, or ClusterJ, are not logged.
- The plugin must be installed on each MySQL server that is used to execute SQL on the cluster.
- Audit plugin data must be aggregated amongst all MySQL servers used with the cluster. This aggregation is the responsibility of the application or user.

## 7.5.6 MySQL Enterprise Firewall

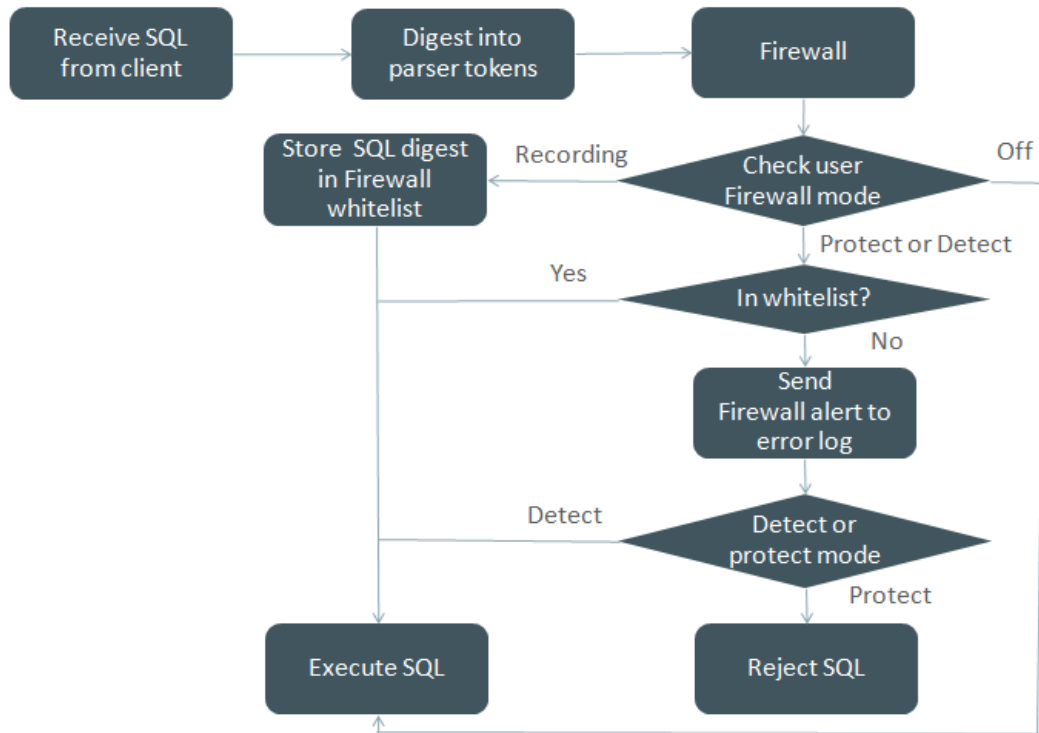

### Note

MySQL Enterprise Firewall is an extension included in MySQL Enterprise Edition, a commercial product. To learn more about commercial products, see <http://www.mysql.com/products/>.

As of MySQL 5.7.9, MySQL Enterprise Edition includes MySQL Enterprise Firewall, an application-level firewall that enables database administrators to permit or deny SQL statement execution based on matching against whitelists of accepted statement patterns. This helps harden MySQL Server against attacks such as SQL injection or attempts to exploit applications by using them outside of their legitimate query workload characteristics.

Each MySQL account registered with the firewall has its own statement whitelist, enabling protection to be tailored per account. For a given account, the firewall can operate in recording, protecting, or detecting mode, for training in the accepted statement patterns, active protection against unacceptable statements, or passive detection of unacceptable statements. The diagram illustrates how the firewall processes incoming statements in each mode.

**Figure 7.1 MySQL Enterprise Firewall Operation**

The following sections describe the components of MySQL Enterprise Firewall, discuss how to install and use it, and provide reference information for its components.

### 7.5.6.1 MySQL Enterprise Firewall Components

MySQL Enterprise Firewall is based on a plugin library that implements these components:

- A server-side plugin named `MYSQL_FIREWALL` examines SQL statements before they execute and, based on its in-memory cache, renders a decision whether to execute or reject each statement.
- Server-side plugins named `MYSQL_FIREWALL_USERS` and `MYSQL_FIREWALL_WHITELIST` implement `INFORMATION_SCHEMA` tables that provide views into the firewall data cache.
- System tables named `firewall_users` and `firewall_whitelist` in the `mysql` database provide persistent storage of firewall data.
- Stored procedures named `sp_set_firewall_mode()` and `sp_reload_firewall_rules()` perform tasks such as registering MySQL accounts with the firewall, establishing their operational mode, and managing transfer of firewall data between the cache and the underlying system tables.
- A set of user-defined functions provides an SQL-level API for lower-level tasks such as synchronizing the cache with the underlying system tables.
- System variables enable firewall configuration and status variables provide runtime operational information.

### 7.5.6.2 Installing or Uninstalling MySQL Enterprise Firewall

MySQL Enterprise Firewall installation is a one-time operation that installs the components described in [Section 7.5.6.1, “MySQL Enterprise Firewall Components”](#). Installation can be performed using a graphical interface or manually:

- On Windows, MySQL Installer includes an option to enable MySQL Enterprise Firewall for you.
- MySQL Workbench 6.3.4 or higher can install MySQL Enterprise Firewall, enable or disable an installed firewall, or uninstall the firewall.
- Manual MySQL Enterprise Firewall installation involves running a script located in the [share](#) directory of your MySQL installation.

**Note**

If installed, MySQL Enterprise Firewall involves some minimal overhead even when disabled. To avoid this overhead, do not install the firewall unless you plan to use it.

**Note**

MySQL Enterprise Firewall does not work together with the query cache. If the query cache is enabled, disable it before installing the firewall (see [Section 9.10.3.3, “Query Cache Configuration”](#)).

For usage instructions, see [Section 7.5.6.3, “Using MySQL Enterprise Firewall”](#). For reference information, see [Section 7.5.6.4, “MySQL Enterprise Firewall Reference”](#).

## Installing MySQL Enterprise Firewall

If MySQL Enterprise Firewall is already installed from an older version of MySQL, uninstall it using the instructions given later in this section and then restart your server before installing the current version. In this case, it is also necessary to register your configuration again.

On Windows, you can use MySQL Installer to install MySQL Enterprise Firewall, as shown in [Figure 7.2, “MySQL Enterprise Firewall Installation on Windows”](#). Check the **Enable Enterprise Firewall** checkbox. (**Open Firewall port for network access** has a different purpose. It refers to Windows Firewall and controls whether Windows blocks the TCP/IP port on which the MySQL server listens for client connections.)

**Figure 7.2 MySQL Enterprise Firewall Installation on Windows**

To install MySQL Enterprise Firewall using MySQL Workbench 6.3.4 or higher, see [MySQL Enterprise Firewall Interface](#).

To install MySQL Enterprise Firewall manually, look in the `share` directory of your MySQL installation and choose the script that is appropriate for your platform. The available scripts differ in the suffix used to refer to the plugin library file:

- `win_install_firewall.sql`: Choose this script for Windows systems that use `.dll` as the file name suffix.
- `linux_install_firewall.sql`: Choose this script for Linux and similar systems that use `.so` as the file name suffix.

The installation script creates stored procedures in the default database, so choose a database to use. Then run the script as follows, naming the chosen database on the command line. The example here uses the `mysql` database and the Linux installation script. Make the appropriate substitutions for your system.

```
shell> mysql -u root -p mysql < linux_install_firewall.sql
Enter password: (enter root password here)
```

Installing MySQL Enterprise Firewall either using a graphical interface or manually should enable the firewall. To verify that, connect to the server and execute this statement:

```
mysql> SHOW GLOBAL VARIABLES LIKE 'mysql_firewall_mode';
+-----+
| Variable_name | Value |
```

```
+-----+
| mysql_firewall_mode | ON |
+-----+
```

## Uninstalling MySQL Enterprise Firewall

MySQL Enterprise Firewall can be uninstalled using MySQL Workbench or manually.

To uninstall MySQL Enterprise Firewall using MySQL Workbench 6.3.4 or higher, see [MySQL Enterprise Firewall Interface](#).

To uninstall MySQL Enterprise Firewall manually, execute the following statements. It is assumed that the stored procedures were created in the `mysql` database. Adjust the `DROP PROCEDURE` statements appropriately if the procedures were created in a different database.

```
DROP TABLE mysql.firewall_whitelist;
DROP TABLE mysql.firewall_users;
UNINSTALL PLUGIN mysql_firewall;
UNINSTALL PLUGIN mysql_firewall_whitelist;
UNINSTALL PLUGIN mysql_firewall_users;
DROP FUNCTION set_firewall_mode;
DROP FUNCTION normalize_statement;
DROP FUNCTION read_firewall_whitelist;
DROP FUNCTION read_firewall_users;
DROP FUNCTION mysql_firewall_flush_status;
DROP PROCEDURE mysql.sp_set_firewall_mode;
DROP PROCEDURE mysql.sp_reload_firewall_rules;
```

### 7.5.6.3 Using MySQL Enterprise Firewall

Before using MySQL Enterprise Firewall, install it according to the instructions provided in [Section 7.5.6.2, “Installing or Uninstalling MySQL Enterprise Firewall”](#). Also, MySQL Enterprise Firewall does not work together with the query cache; disable the query cache if it is enabled (see [Section 9.10.3.3, “Query Cache Configuration”](#)).

This section describes how to configure MySQL Enterprise Firewall using SQL statements. Alternatively, MySQL Workbench 6.3.4 or higher provides a graphical interface for firewall control. See [MySQL Enterprise Firewall Interface](#).

To enable or disable the firewall, set the `mysql_firewall_mode` system variable. By default, this variable is enabled when the firewall is installed. To control the initial firewall state explicitly, you can set the variable at server startup. For example, to enable the firewall in an option file, use these lines:

```
[mysqld]
mysql_firewall_mode=ON
```

It is also possible to disable or enable the firewall at runtime:

```
mysql> SET GLOBAL mysql_firewall_mode = OFF;
mysql> SET GLOBAL mysql_firewall_mode = ON;
```

In addition to the global on/off firewall mode, each account registered with the firewall has its own operational mode. For an account in recording mode, the firewall learns an application's “fingerprint,” that is, the acceptable statement patterns that, taken together, form a whitelist. After training, switch the firewall to protecting mode to harden MySQL against access by statements that deviate from the fingerprint. For additional training, switch the firewall back to recording mode as necessary to update the whitelist with new statement patterns. An intrusion-detection mode is available that writes suspicious statements to the error log but does not deny access.

The firewall maintains whitelist rules on a per-account basis, enabling implementation of protection strategies such as these:

- For an application that has unique protection requirements, configure it to use an account that is not used for any other purpose.
- For applications that are related and share protection requirements, configure them as a group to use the same account.

Firewall operation is based on conversion of SQL statements to normalized digest form. Firewall digests are like the statement digests used by the Performance Schema (see [Section 24.8, “Performance Schema Statement Digests”](#)). However, unlike the Performance Schema, the relevant digest-related system variable is `max_digest_length`.

For a connection from a registered account, the firewall converts each incoming statement to normalized form and processes it according to the account mode:

- In recording mode, the firewall adds the normalized statement to the account whitelist rules.
- In protecting mode, the firewall compares the normalized statement to the account whitelist rules. If there is a match, the statement passes and the server continues to process it. Otherwise, the server rejects the statement and returns an error to the client. The firewall also writes the rejected statement to the error log if the `mysql_firewall_trace` system variable is enabled.
- In detecting mode, the firewall matches statements as in protecting mode, but writes nonmatching statements to the error log without denying access.

Accounts that have a mode of `OFF` or are not registered with the firewall are ignored by it.

To protect an account using MySQL Enterprise Firewall, follow these steps:

1. Register the account and put it in recording mode.
2. Connect to the MySQL server using the registered account and execute statements to be learned. This establishes the account's whitelist of accepted statements.
3. Switch the registered account to protecting mode.

The following example shows how to register an account with the firewall, use the firewall to learn acceptable statements for that account, and protect the account against execution of unacceptable statements. The example account, `'fwuser'@'localhost'`, is for use by an application that accesses tables in the `sakila` database. (This database is available at <http://dev.mysql.com/doc/index-other.html>.)

#### Note

The user and host parts of the account name are quoted separately for statements such as `CREATE USER` and `GRANT`, whereas to specify an account for use with a firewall component, name it as a single quoted string `'fwuser@localhost'`.

The convention for naming accounts as a single quoted string for firewall components means that you cannot use accounts that have embedded `@` characters in the user name.

Perform the steps in the following procedure using an administrative MySQL account, except those designated for execution by the account registered with the firewall. The default database should be `sakila` for statements executed using the registered account.

1. If necessary, create the account to be protected (choose an appropriate password) and grant it privileges for the `sakila` database:

```
mysql> CREATE USER 'fwuser'@'localhost' IDENTIFIED BY 'fWp@3sw0rd';
```

```
mysql> GRANT ALL ON sakila.* TO 'fwuser'@'localhost';
```

2. Use the `sp_set_firewall_mode()` stored procedure to register the account with the firewall and place it in recording mode (if the procedure is located in a database other than `mysql`, adjust the statement accordingly):

```
mysql> CALL mysql.sp_set_firewall_mode('fwuser@localhost', 'RECORDING');
```

During the course of its execution, the stored procedure invokes firewall user-defined functions, which may produce output of their own.

3. Using the registered account, connect to the server, then execute some statements that are legitimate for it:

```
mysql> SELECT first_name, last_name FROM customer WHERE customer_id = 1;
mysql> UPDATE rental SET return_date = NOW() WHERE rental_id = 1;
mysql> SELECT get_customer_balance(1, NOW());
```

The firewall converts the statements to digest form and records them in the account whitelist.

#### Note

Until the account executes statements in recording mode, its whitelist is empty, which is equivalent to “deny all.” If switched to protecting mode, the account will be effectively prohibited from executing statements.

4. At this point, the user and whitelist information is cached and can be seen in the firewall `INFORMATION_SCHEMA` tables:

```
mysql> SELECT MODE FROM INFORMATION_SCHEMA.MYSQL_FIREWALL_USERS
-> WHERE USERHOST = 'fwuser@localhost';
+-----+
| MODE |
+-----+
| RECORDING |
+-----+
mysql> SELECT RULE FROM INFORMATION_SCHEMA.MYSQL_FIREWALL_WHITELIST
-> WHERE USERHOST = 'fwuser@localhost';
+-----+-----+
| RULE |
+-----+-----+
| SELECT `first_name` , `last_name` FROM `customer` WHERE `customer_id` = ? |
| SELECT `get_customer_balance` ( ? , NOW ( ) ) |
| UPDATE `rental` SET `return_date` = NOW ( ) WHERE `rental_id` = ? |
| SELECT @@`version_comment` LIMIT ? |
+-----+-----+
```

#### Note

The `@@version_comment` rule comes from a statement sent automatically by the `mysql` client when you connect to the server as the registered user.

It is important to train the firewall under conditions matching application use. For example, a given MySQL connector might send statements to the server at the beginning of a connection to determine server characteristics and capabilities. If an application normally is used through that connector, train the firewall that way, too. That enables those initial statements to become part of the whitelist for the account associated with the application.

5. Use the stored procedure to switch the registered user to protecting mode:

```
mysql> CALL mysql.sp_set_firewall_mode('fwuser@localhost', 'PROTECTING');
```

### Important

Switching the account out of `RECORDING` mode synchronizes its firewall cache data to the underlying `mysql` system database tables for persistent storage. If you do not switch the mode for a user who is being recorded, the cached whitelist data is not written to the system tables and will be lost when the server is restarted.

- Using the registered account, execute some acceptable and unacceptable statements. The firewall matches each one against the account whitelist and accepts or rejects it.

This statement is not identical to a training statement but produces the same normalized statement as one of them, so the firewall accepts it:

```
mysql> SELECT first_name, last_name FROM customer WHERE customer_id = '48';
+-----+-----+
| first_name | last_name |
+-----+-----+
| ANN        | EVANS     |
+-----+-----+
```

These statements do not match anything in the whitelist and each results in an error:

```
mysql> SELECT first_name, last_name FROM customer WHERE customer_id = 1 OR TRUE;
ERROR 1045 (28000): Statement was blocked by Firewall
mysql> SHOW TABLES LIKE 'customer%';
ERROR 1045 (28000): Statement was blocked by Firewall
mysql> TRUNCATE TABLE mysql.slow_log;
ERROR 1045 (28000): Statement was blocked by Firewall
```

The firewall also writes the rejected statements to the error log if the `mysql_firewall_trace` system variable is enabled. For example:

```
[Note] Plugin MYSQL_FIREWALL reported:
'ACCESS DENIED for fwuser@localhost. Reason: No match in whitelist.
Statement: TRUNCATE TABLE `mysql` . `slow_log` '
```

You can use these log messages in your efforts to identify the source of attacks.

- You can log nonmatching statements as suspicious without denying access. To do this, put the account in intrusion-detecting mode:

```
mysql> CALL mysql.sp_set_firewall_mode('fwuser@localhost', 'DETECTING');
```

- Using the registered account, connect to the server, then execute some statement does not match the whitelist:

```
mysql> SHOW TABLES LIKE 'customer%';
+-----+-----+
| Tables_in_sakila (customer%) |
+-----+-----+
| customer                     |
| customer_list                 |
+-----+-----+
```

In detecting mode, the firewall permits the nonmatching statement to execute but writes a message to the error log:

```
[Note] Plugin MYSQL_FIREWALL reported:
'SUSPICIOUS STATEMENT from 'fwuser@localhost'. Reason: No match in whitelist.
```

```
Statement: SHOW TABLES LIKE ? '
```

9. To assess firewall activity, examine its status variables:

```
mysql> SHOW GLOBAL STATUS LIKE 'Firewall%';
+-----+-----+
| Variable_name | Value |
+-----+-----+
| Firewall_access_denied | 3 |
| Firewall_access_granted | 4 |
| Firewall_access_suspicious | 1 |
| Firewall_cached_entries | 4 |
+-----+-----+
```

The variables indicate the number of statements rejected, accepted, logged as suspicious, and added to the cache, respectively. The `Firewall_access_granted` count is 4 because of the `@@version_comment` statement sent by the `mysql` client each of the three time you used it to connect as the registered user, plus the `SHOW TABLES` statement that was not blocked in `DETECTING` mode.

Should additional training for an account be necessary, switch it to recording mode again, then back to protecting mode after executing statements to be added to the whitelist.

#### 7.5.6.4 MySQL Enterprise Firewall Reference

The following discussion serves as a reference to MySQL Enterprise Firewall components:

- [MySQL Enterprise Firewall Tables](#)
- [MySQL Enterprise Firewall Procedures and Functions](#)
- [MySQL Enterprise Firewall System Variables](#)
- [MySQL Enterprise Firewall Status Variables](#)

#### MySQL Enterprise Firewall Tables

MySQL Enterprise Firewall maintains account and whitelist information. It uses `INFORMATION_SCHEMA` tables to provide views into cached data, and tables in the `mysql` system database to store this data in persistent form. When enabled, the firewall bases its operational decisions on the cached data.

The `INFORMATION_SCHEMA` tables are accessible by anyone. The `mysql` tables can be accessed only by users with privileges for that database.

The `INFORMATION_SCHEMA.MYSQL_FIREWALL_USERS` and `mysql.firewall_users` tables list registered firewall accounts and their operational modes. The tables have these columns:

- `USERHOST`

An account registered with the firewall. Each account has the format `user_name@host_name` and represents actual user and host names as authenticated by the server. Patterns and netmasks should not be used when registering users.

- `MODE`

The current firewall operational mode for the account. The permitted mode values are `OFF`, `DETECTING`, `PROTECTING`, `RECORDING`, and `RESET`. For details about their meanings, see the description of `sp_set_firewall_mode()` in [MySQL Enterprise Firewall Procedures and Functions](#).

The `INFORMATION_SCHEMA.MYSQL_FIREWALL_WHITELIST` and `mysql.firewall_whitelist` tables list registered firewall accounts and their whitelists. The tables have these columns:

- `USERHOST`

An account registered with the firewall. The format is the same as for the user account tables.

- `RULE`

A normalized statement indicating an acceptable statement pattern for the account. An account whitelist is the union of its rules.

## MySQL Enterprise Firewall Procedures and Functions

MySQL Enterprise Firewall has stored procedures that perform tasks such as registering MySQL accounts with the firewall, establishing their operational mode, and managing transfer of firewall data between the cache and the underlying system tables. It also has a set of user-defined functions (UDFs) that provides an SQL-level API for lower-level tasks such as synchronizing the cache with the underlying system tables.

Under normal operation, the stored procedures implement the user interface. The UDFs are invoked by the stored procedures, not directly by users.

To invoke a stored procedure when the default database is not the database that contains the procedure, qualify the procedure name with the database name. For example:

```
CALL mysql.sp_set_firewall_mode(user, mode);
```

The following list describes each firewall stored procedure and UDF:

- `sp_reload_firewall_rules(user)`

This stored procedure uses firewall UDFs to reset a registered account and reload the in-memory rules for it from the rules stored in the `mysql.firewall_whitelist` table. This procedure provides control over firewall operation for individual accounts.

The `user` argument names the affected account, as a string in `user_name@host_name` format.

Example:

```
CALL mysql.sp_reload_firewall_rules('fwuser@localhost');
```

### Warning

This procedure sets the account mode to `RESET`, which clears the account whitelist and sets its mode to `OFF`. If the account mode was not `OFF` prior to the `sp_reload_firewall_rules()` call, use `sp_set_firewall_mode()` to restore its previous mode after reloading the rules. For example, if the account was in `PROTECTING` mode, that is no longer true after calling `sp_reload_firewall_rules()` and you must set it to `PROTECTING` again explicitly.

- `sp_set_firewall_mode(user, mode)`

This stored procedure registers a MySQL account with the firewall and establishes its operational mode. The procedure also invokes firewall UDFs as necessary to transfer firewall data between the cache and the underlying system tables. This procedure may be called even if the `mysql_firewall_mode` system variable is `OFF`, although setting the mode for an account has no operational effect while the firewall is disabled.

The `user` argument names the affected account, as a string in `user_name@host_name` format.

The `mode` is the operational mode for the user, as a string. These mode values are permitted:

- **OFF**: Disable the firewall for the account.
- **DETECTING**: Intrusion-detection mode: Write suspicious (nonmatching) statements to the error log but do not deny access.
- **PROTECTING**: Protect the account by matching incoming statements against the account whitelist.
- **RECORDING**: Training mode: Record acceptable statements for the account. Incoming statements that do not immediately fail with a syntax error are recorded to become part of the account whitelist rules.
- **RESET**: Clear the account whitelist and set the account mode to **OFF**.

Switching the mode for an account to any mode but **RECORDING** synchronizes the firewall cache data to the underlying `mysql` system database tables for persistent storage. Switching the mode from **OFF** to **RECORDING** reloads the whitelist from the `mysql.firewall_whitelist` table into the cache.

If an account has an empty whitelist, setting its mode to **PROTECTING** produces an error message that is returned in a result set, but not an SQL error:

```
mysql> CALL mysql.sp_set_firewall_mode('a@b','PROTECTING');
+-----+
| set_firewall_mode(arg_userhost, arg_mode) |
+-----+
| ERROR: PROTECTING mode requested for a@b but the whitelist is empty. |
+-----+
1 row in set (0.02 sec)

Query OK, 0 rows affected (0.02 sec)
```

- `mysql_firewall_flush_status()`

This UDF resets several firewall status variables to 0:

```
Firewall_access_denied
Firewall_access_granted
Firewall_access_suspicious
```

Example:

```
SELECT mysql_firewall_flush_status();
```

- `normalize_statement(stmt)`

This UDF normalizes an SQL statement into the digest form used for whitelist rules.

Example:

```
SELECT normalize_statement('SELECT * FROM t1 WHERE c1 > 2');
```

- `read_firewall_users(user, mode)`

This aggregate UDF updates the firewall user cache through a `SELECT` statement on the `mysql.firewall_users` table.

Example:

```
SELECT read_firewall_users('fwuser@localhost', 'RECORDING')
FROM mysql.firewall_users;
```

- `read_firewall_whitelist(user, rule)`

This aggregate UDF updates the recorded statement cache through a `SELECT` statement on the `mysql.firewall_whitelist` table.

Example:

```
SELECT read_firewall_whitelist('fwuser@localhost', 'RECORDING')
FROM mysql.firewall_whitelist;
```

- `set_firewall_mode(user, mode)`

This UDF manages the user cache and establishes the user operational mode.

Example:

```
SELECT set_firewall_mode('fwuser@localhost', 'RECORDING');
```

## MySQL Enterprise Firewall System Variables

MySQL Enterprise Firewall supports the following system variables. Use them to configure firewall operation. These variables are unavailable unless the firewall is installed (see [Section 7.5.6.2, “Installing or Uninstalling MySQL Enterprise Firewall”](#)).

- `mysql_firewall_mode`

|                            |   |                                  |
|----------------------------|---|----------------------------------|
| <b>Introduced</b>          | 5.7.9                                       |                                  |
| <b>Command-Line Format</b> | <code>--mysql_firewall_mode={OFF ON}</code> |                                  |
| <b>System Variable</b>     | <b>Name</b>                                 | <code>mysql_firewall_mode</code> |
|                            | <b>Variable Scope</b>                       | Global                           |
|                            | <b>Dynamic Variable</b>                     | Yes                              |
| <b>Permitted Values</b>    | <b>Type</b>                                 | boolean                          |
|                            | <b>Default</b>                              | ON                               |

Whether MySQL Enterprise Firewall is enabled (the default) or disabled.

- `mysql_firewall_trace`

|                            |  |                                   |
|----------------------------|--|-----------------------------------|
| <b>Introduced</b>          | 5.7.9  |                                   |
| <b>Command-Line Format</b> | <code>--mysql_firewall_trace={OFF ON}</code> |                                   |
| <b>System Variable</b>     | <b>Name</b>                                  | <code>mysql_firewall_trace</code> |
|                            | <b>Variable Scope</b>                        | Global                            |
|                            | <b>Dynamic Variable</b>                      | Yes                               |
| <b>Permitted Values</b>    | <b>Type</b>                                  | boolean                           |
|                            | <b>Default</b>                               | OFF                               |

Whether the MySQL Enterprise Firewall trace is enabled or disabled (the default). When `mysql_firewall_trace` is enabled, for `PROTECTING` mode, the firewall writes rejected statements to the error log.

## MySQL Enterprise Firewall Status Variables

MySQL Enterprise Firewall supports the following status variables. Use them to obtain information about firewall operational status. These variables are unavailable unless the firewall is installed (see [Section 7.5.6.2, “Installing or Uninstalling MySQL Enterprise Firewall”](#)). Firewall status variables are set to 0 whenever the `MYSQL_FIREWALL` plugin is installed or the server is started. Many of them are reset to zero by the `mysql_firewall_flush_status()` UDF (see [MySQL Enterprise Firewall Procedures and Functions](#)).

- `Firewall_access_denied`

The number of statements rejected by MySQL Enterprise Firewall.

- `Firewall_access_granted`

The number of statements accepted by MySQL Enterprise Firewall.

- `Firewall_access_suspicious`

The number of statements logged by MySQL Enterprise Firewall as suspicious for users who are in `DETECTING` mode.

- `Firewall_cached_entries`

The number of statements recorded by MySQL Enterprise Firewall, including duplicates.

---

| 8.5.2 Point-in-Time Recovery Using Event Positions .....            | 1176 |
| 8.6 MyISAM Table Maintenance and Crash Recovery .....               | 1177 |
| 8.6.1 Using myisamchk for Crash Recovery .....                      | 1177 |
| 8.6.2 How to Check MyISAM Tables for Errors .....                   | 1178 |
| 8.6.3 How to Repair MyISAM Tables .....                             | 1178 |
| 8.6.4 MyISAM Table Optimization .....                               | 1181 |
| 8.6.5 Setting Up a MyISAM Table Maintenance Schedule .....          | 1181 |

It is important to back up your databases so that you can recover your data and be up and running again in case problems occur, such as system crashes, hardware failures, or users deleting data by mistake. Backups are also essential as a safeguard before upgrading a MySQL installation, and they can be used to transfer a MySQL installation to another system or to set up replication slave servers.

MySQL offers a variety of backup strategies from which you can choose the methods that best suit the requirements for your installation. This chapter discusses several backup and recovery topics with which you should be familiar:

- Types of backups: Logical versus physical, full versus incremental, and so forth.
- Methods for creating backups.
- Recovery methods, including point-in-time recovery.
- Backup scheduling, compression, and encryption.
- Table maintenance, to enable recovery of corrupt tables.

### Additional Resources

Resources related to backup or to maintaining data availability include the following:

- Customers of MySQL Enterprise Edition can use the MySQL Enterprise Backup product for backups. For an overview of the MySQL Enterprise Backup product, see [Section 28.2, “MySQL Enterprise Backup Overview”](#).
- A forum dedicated to backup issues is available at <http://forums.mysql.com/list.php?28>.
- Details for `mysqldump` can be found in [Chapter 5, MySQL Programs](#).
- The syntax of the SQL statements described here is given in [Chapter 14, SQL Statement Syntax](#).

- For additional information about [InnoDB](#) backup procedures, see [Section 15.18, “InnoDB Backup and Recovery”](#).
- Replication enables you to maintain identical data on multiple servers. This has several benefits, such as enabling client query load to be distributed over servers, availability of data even if a given server is taken offline or fails, and the ability to make backups with no impact on the master by using a slave server. See [Chapter 18, Replication](#).
- MySQL Cluster provides a high-availability, high-redundancy version of MySQL adapted for the distributed computing environment. See [Chapter 20, MySQL NDB Cluster 7.5](#), which provides information about MySQL Cluster NDB 7.5 (based on MySQL 5.7 but containing the latest improvements and fixes for the [NDB](#) storage engine).
- Distributed Replicated Block Device (DRBD) is another high-availability solution. It works by replicating a block device from a primary server to a secondary server at the block level. See [Chapter 17, High Availability and Scalability](#)

## 8.1 Backup and Recovery Types

This section describes the characteristics of different types of backups.

### Physical (Raw) Versus Logical Backups

Physical backups consist of raw copies of the directories and files that store database contents. This type of backup is suitable for large, important databases that need to be recovered quickly when problems occur.

Logical backups save information represented as logical database structure ([CREATE DATABASE](#), [CREATE TABLE](#) statements) and content ([INSERT](#) statements or delimited-text files). This type of backup is suitable for smaller amounts of data where you might edit the data values or table structure, or recreate the data on a different machine architecture.

Physical backup methods have these characteristics:

- The backup consists of exact copies of database directories and files. Typically this is a copy of all or part of the MySQL data directory.
- Physical backup methods are faster than logical because they involve only file copying without conversion.
- Output is more compact than for logical backup.
- Because backup speed and compactness are important for busy, important databases, the MySQL Enterprise Backup product performs physical backups. For an overview of the MySQL Enterprise Backup product, see [Section 28.2, “MySQL Enterprise Backup Overview”](#).
- Backup and restore granularity ranges from the level of the entire data directory down to the level of individual files. This may or may not provide for table-level granularity, depending on storage engine. For example, [InnoDB](#) tables can each be in a separate file, or share file storage with other [InnoDB](#) tables; each [MyISAM](#) table corresponds uniquely to a set of files.
- In addition to databases, the backup can include any related files such as log or configuration files.
- Data from [MEMORY](#) tables is tricky to back up this way because their contents are not stored on disk. (The MySQL Enterprise Backup product has a feature where you can retrieve data from [MEMORY](#) tables during a backup.)
- Backups are portable only to other machines that have identical or similar hardware characteristics.
- Backups can be performed while the MySQL server is not running. If the server is running, it is necessary to perform appropriate locking so that the server does not change database contents

during the backup. MySQL Enterprise Backup does this locking automatically for tables that require it.

- Physical backup tools include the `mysqlbackup` of MySQL Enterprise Backup for `InnoDB` or any other tables, or file system-level commands (such as `cp`, `scp`, `tar`, `rsync`) for `MyISAM` tables.
- For restore:
  - MySQL Enterprise Backup restores `InnoDB` and other tables that it backed up.
  - `ndb_restore` restores `NDB` tables.
  - Files copied at the file system level can be copied back to their original locations with file system commands.

Logical backup methods have these characteristics:

- The backup is done by querying the MySQL server to obtain database structure and content information.
- Backup is slower than physical methods because the server must access database information and convert it to logical format. If the output is written on the client side, the server must also send it to the backup program.
- Output is larger than for physical backup, particularly when saved in text format.
- Backup and restore granularity is available at the server level (all databases), database level (all tables in a particular database), or table level. This is true regardless of storage engine.
- The backup does not include log or configuration files, or other database-related files that are not part of databases.
- Backups stored in logical format are machine independent and highly portable.
- Logical backups are performed with the MySQL server running. The server is not taken offline.
- Logical backup tools include the `mysqldump` program and the `SELECT ... INTO OUTFILE` statement. These work for any storage engine, even `MEMORY`.
- To restore logical backups, SQL-format dump files can be processed using the `mysql` client. To load delimited-text files, use the `LOAD DATA INFILE` statement or the `mysqlimport` client.

## Online Versus Offline Backups

Online backups take place while the MySQL server is running so that the database information can be obtained from the server. Offline backups take place while the server is stopped. This distinction can also be described as “hot” versus “cold” backups; a “warm” backup is one where the server remains running but locked against modifying data while you access database files externally.

Online backup methods have these characteristics:

- The backup is less intrusive to other clients, which can connect to the MySQL server during the backup and may be able to access data depending on what operations they need to perform.
- Care must be taken to impose appropriate locking so that data modifications do not take place that would compromise backup integrity. The MySQL Enterprise Backup product does such locking automatically.

Offline backup methods have these characteristics:

- Clients can be affected adversely because the server is unavailable during backup. For that reason, such backups are often taken from a replication slave server that can be taken offline without harming availability.

- The backup procedure is simpler because there is no possibility of interference from client activity.

A similar distinction between online and offline applies for recovery operations, and similar characteristics apply. However, it is more likely that clients will be affected for online recovery than for online backup because recovery requires stronger locking. During backup, clients might be able to read data while it is being backed up. Recovery modifies data and does not just read it, so clients must be prevented from accessing data while it is being restored.

## Local Versus Remote Backups

A local backup is performed on the same host where the MySQL server runs, whereas a remote backup is done from a different host. For some types of backups, the backup can be initiated from a remote host even if the output is written locally on the server. host.

- `mysqldump` can connect to local or remote servers. For SQL output (`CREATE` and `INSERT` statements), local or remote dumps can be done and generate output on the client. For delimited-text output (with the `--tab` option), data files are created on the server host.
- `SELECT ... INTO OUTFILE` can be initiated from a local or remote client host, but the output file is created on the server host.
- Physical backup methods typically are initiated locally on the MySQL server host so that the server can be taken offline, although the destination for copied files might be remote.

## Snapshot Backups

Some file system implementations enable “snapshots” to be taken. These provide logical copies of the file system at a given point in time, without requiring a physical copy of the entire file system. (For example, the implementation may use copy-on-write techniques so that only parts of the file system modified after the snapshot time need be copied.) MySQL itself does not provide the capability for taking file system snapshots. It is available through third-party solutions such as Veritas, LVM, or ZFS.

## Full Versus Incremental Backups

A full backup includes all data managed by a MySQL server at a given point in time. An incremental backup consists of the changes made to the data during a given time span (from one point in time to another). MySQL has different ways to perform full backups, such as those described earlier in this section. Incremental backups are made possible by enabling the server's binary log, which the server uses to record data changes.

## Full Versus Point-in-Time (Incremental) Recovery

A full recovery restores all data from a full backup. This restores the server instance to the state that it had when the backup was made. If that state is not sufficiently current, a full recovery can be followed by recovery of incremental backups made since the full backup, to bring the server to a more up-to-date state.

Incremental recovery is recovery of changes made during a given time span. This is also called point-in-time recovery because it makes a server's state current up to a given time. Point-in-time recovery is based on the binary log and typically follows a full recovery from the backup files that restores the server to its state when the backup was made. Then the data changes written in the binary log files are applied as incremental recovery to redo data modifications and bring the server up to the desired point in time.

## Table Maintenance

Data integrity can be compromised if tables become corrupt. For `InnoDB` tables, this is not a typical issue. For programs to check `MyISAM` tables and repair them if problems are found, see [Section 8.6, “MyISAM Table Maintenance and Crash Recovery”](#).

## Backup Scheduling, Compression, and Encryption

Backup scheduling is valuable for automating backup procedures. Compression of backup output reduces space requirements, and encryption of the output provides better security against unauthorized access of backed-up data. MySQL itself does not provide these capabilities. The MySQL Enterprise Backup product can compress [InnoDB](#) backups, and compression or encryption of backup output can be achieved using file system utilities. Other third-party solutions may be available.

## 8.2 Database Backup Methods

This section summarizes some general methods for making backups.

### Making a Hot Backup with MySQL Enterprise Backup

Customers of MySQL Enterprise Edition can use the [MySQL Enterprise Backup](#) product to do [physical](#) backups of entire instances or selected databases, tables, or both. This product includes features for [incremental](#) and [compressed](#) backups. Backing up the physical database files makes restore much faster than logical techniques such as the `mysqldump` command. [InnoDB](#) tables are copied using a [hot backup](#) mechanism. (Ideally, the [InnoDB](#) tables should represent a substantial majority of the data.) Tables from other storage engines are copied using a [warm backup](#) mechanism. For an overview of the MySQL Enterprise Backup product, see [Section 28.2, “MySQL Enterprise Backup Overview”](#).

### Making Backups with `mysqldump`

The `mysqldump` program can make backups. It can back up all kinds of tables. (See [Section 8.4, “Using `mysqldump` for Backups”](#).)

For [InnoDB](#) tables, it is possible to perform an online backup that takes no locks on tables using the `--single-transaction` option to `mysqldump`. See [Section 8.3.1, “Establishing a Backup Policy”](#).

### Making Backups by Copying Table Files

For storage engines that represent each table using its own files, tables can be backed up by copying those files. For example, [MyISAM](#) tables are stored as files, so it is easy to do a backup by copying files (`*.frm`, `*.MYD`, and `*.MYI` files). To get a consistent backup, stop the server or lock and flush the relevant tables:

```
FLUSH TABLES tbl_list WITH READ LOCK;
```

You need only a read lock; this enables other clients to continue to query the tables while you are making a copy of the files in the database directory. The flush is needed to ensure that the all active index pages are written to disk before you start the backup. See [Section 14.3.5, “LOCK TABLES and UNLOCK TABLES Syntax”](#), and [Section 14.7.6.3, “FLUSH Syntax”](#).

You can also create a binary backup simply by copying all table files, as long as the server isn't updating anything. (But note that table file copying methods do not work if your database contains [InnoDB](#) tables. Also, even if the server is not actively updating data, [InnoDB](#) may still have modified data cached in memory and not flushed to disk.)

### Making Delimited-Text File Backups

To create a text file containing a table's data, you can use `SELECT * INTO OUTFILE 'file_name' FROM tbl_name`. The file is created on the MySQL server host, not the client host. For this statement, the output file cannot already exist because permitting files to be overwritten constitutes a security risk.

See [Section 14.2.9, “SELECT Syntax”](#). This method works for any kind of data file, but saves only table data, not the table structure.

Another way to create text data files (along with files containing `CREATE TABLE` statements for the backed up tables) is to use `mysqldump` with the `--tab` option. See [Section 8.4.3, “Dumping Data in Delimited-Text Format with mysqldump”](#).

To reload a delimited-text data file, use `LOAD DATA INFILE` or `mysqlimport`.

## Making Incremental Backups by Enabling the Binary Log

MySQL supports incremental backups: You must start the server with the `--log-bin` option to enable binary logging; see [Section 6.4.4, “The Binary Log”](#). The binary log files provide you with the information you need to replicate changes to the database that are made subsequent to the point at which you performed a backup. At the moment you want to make an incremental backup (containing all changes that happened since the last full or incremental backup), you should rotate the binary log by using `FLUSH LOGS`. This done, you need to copy to the backup location all binary logs which range from the one of the moment of the last full or incremental backup to the last but one. These binary logs are the incremental backup; at restore time, you apply them as explained in [Section 8.5, “Point-in-Time \(Incremental\) Recovery Using the Binary Log”](#). The next time you do a full backup, you should also rotate the binary log using `FLUSH LOGS` or `mysqldump --flush-logs`. See [Section 5.5.4, “mysqldump — A Database Backup Program”](#).

## Making Backups Using Replication Slaves

If you have performance problems with your master server while making backups, one strategy that can help is to set up replication and perform backups on the slave rather than on the master. See [Section 18.3.1, “Using Replication for Backups”](#).

If you are backing up a slave replication server, you should back up its master info and relay log info repositories (see [Section 18.2.4, “Replication Relay and Status Logs”](#)) when you back up the slave's databases, regardless of the backup method you choose. These information files are always needed to resume replication after you restore the slave's data. If your slave is replicating `LOAD DATA INFILE` statements, you should also back up any `SQL_LOAD-*` files that exist in the directory that the slave uses for this purpose. The slave needs these files to resume replication of any interrupted `LOAD DATA INFILE` operations. The location of this directory is the value of the `--slave-load-tmpdir` option. If the server was not started with that option, the directory location is the value of the `tmpdir` system variable.

## Recovering Corrupt Tables

If you have to restore `MyISAM` tables that have become corrupt, try to recover them using `REPAIR TABLE` or `myisamchk -r` first. That should work in 99.9% of all cases. If `myisamchk` fails, see [Section 8.6, “MyISAM Table Maintenance and Crash Recovery”](#).

## Making Backups Using a File System Snapshot

If you are using a Veritas file system, you can make a backup like this:

1. From a client program, execute `FLUSH TABLES WITH READ LOCK`.
2. From another shell, execute `mount vxfs snapshot`.
3. From the first client, execute `UNLOCK TABLES`.
4. Copy files from the snapshot.
5. Unmount the snapshot.

Similar snapshot capabilities may be available in other file systems, such as LVM or ZFS.

## 8.3 Example Backup and Recovery Strategy

This section discusses a procedure for performing backups that enables you to recover data after several types of crashes:

- Operating system crash
- Power failure
- File system crash
- Hardware problem (hard drive, motherboard, and so forth)

The example commands do not include options such as `--user` and `--password` for the `mysqldump` and `mysql` client programs. You should include such options as necessary to enable client programs to connect to the MySQL server.

Assume that data is stored in the [InnoDB](#) storage engine, which has support for transactions and automatic crash recovery. Assume also that the MySQL server is under load at the time of the crash. If it were not, no recovery would ever be needed.

For cases of operating system crashes or power failures, we can assume that MySQL's disk data is available after a restart. The [InnoDB](#) data files might not contain consistent data due to the crash, but [InnoDB](#) reads its logs and finds in them the list of pending committed and noncommitted transactions that have not been flushed to the data files. [InnoDB](#) automatically rolls back those transactions that were not committed, and flushes to its data files those that were committed. Information about this recovery process is conveyed to the user through the MySQL error log. The following is an example log excerpt:

```
InnoDB: Database was not shut down normally.
InnoDB: Starting recovery from log files...
InnoDB: Starting log scan based on checkpoint at
InnoDB: log sequence number 0 13674004
InnoDB: Doing recovery: scanned up to log sequence number 0 13739520
InnoDB: Doing recovery: scanned up to log sequence number 0 13805056
InnoDB: Doing recovery: scanned up to log sequence number 0 13870592
InnoDB: Doing recovery: scanned up to log sequence number 0 13936128
...
InnoDB: Doing recovery: scanned up to log sequence number 0 20555264
InnoDB: Doing recovery: scanned up to log sequence number 0 20620800
InnoDB: Doing recovery: scanned up to log sequence number 0 20664692
InnoDB: 1 uncommitted transaction(s) which must be rolled back
InnoDB: Starting rollback of uncommitted transactions
InnoDB: Rolling back trx no 16745
InnoDB: Rolling back of trx no 16745 completed
InnoDB: Rollback of uncommitted transactions completed
InnoDB: Starting an apply batch of log records to the database...
InnoDB: Apply batch completed
InnoDB: Started
mysqld: ready for connections
```

For the cases of file system crashes or hardware problems, we can assume that the MySQL disk data is *not* available after a restart. This means that MySQL fails to start successfully because some blocks of disk data are no longer readable. In this case, it is necessary to reformat the disk, install a new one, or otherwise correct the underlying problem. Then it is necessary to recover our MySQL data from backups, which means that backups must already have been made. To make sure that is the case, design and implement a backup policy.

### 8.3.1 Establishing a Backup Policy

To be useful, backups must be scheduled regularly. A full backup (a snapshot of the data at a point in time) can be done in MySQL with several tools. For example, [MySQL Enterprise Backup](#) can perform a [physical backup](#) of an entire instance, with optimizations to minimize overhead and avoid disruption

when backing up InnoDB data files; `mysqldump` provides online [logical backup](#). This discussion uses `mysqldump`.

Assume that we make a full backup of all our InnoDB tables in all databases using the following command on Sunday at 1 p.m., when load is low:

```
shell> mysqldump --single-transaction --all-databases > backup_sunday_1_PM.sql
```

The resulting `.sql` file produced by `mysqldump` contains a set of SQL `INSERT` statements that can be used to reload the dumped tables at a later time.

This backup operation acquires a global read lock on all tables at the beginning of the dump (using `FLUSH TABLES WITH READ LOCK`). As soon as this lock has been acquired, the binary log coordinates are read and the lock is released. If long updating statements are running when the `FLUSH` statement is issued, the backup operation may stall until those statements finish. After that, the dump becomes lock-free and does not disturb reads and writes on the tables.

It was assumed earlier that the tables to back up are InnoDB tables, so `--single-transaction` uses a consistent read and guarantees that data seen by `mysqldump` does not change. (Changes made by other clients to InnoDB tables are not seen by the `mysqldump` process.) If the backup operation includes nontransactional tables, consistency requires that they do not change during the backup. For example, for the MyISAM tables in the `mysql` database, there must be no administrative changes to MySQL accounts during the backup.

Full backups are necessary, but it is not always convenient to create them. They produce large backup files and take time to generate. They are not optimal in the sense that each successive full backup includes all data, even that part that has not changed since the previous full backup. It is more efficient to make an initial full backup, and then to make incremental backups. The incremental backups are smaller and take less time to produce. The tradeoff is that, at recovery time, you cannot restore your data just by reloading the full backup. You must also process the incremental backups to recover the incremental changes.

To make incremental backups, we need to save the incremental changes. In MySQL, these changes are represented in the binary log, so the MySQL server should always be started with the `--log-bin` option to enable that log. With binary logging enabled, the server writes each data change into a file while it updates data. Looking at the data directory of a MySQL server that was started with the `--log-bin` option and that has been running for some days, we find these MySQL binary log files:

```
-rw-rw---- 1 guilhem guilhem 1277324 Nov 10 23:59 gbichot2-bin.000001
-rw-rw---- 1 guilhem guilhem 4 Nov 10 23:59 gbichot2-bin.000002
-rw-rw---- 1 guilhem guilhem 79 Nov 11 11:06 gbichot2-bin.000003
-rw-rw---- 1 guilhem guilhem 508 Nov 11 11:08 gbichot2-bin.000004
-rw-rw---- 1 guilhem guilhem 220047446 Nov 12 16:47 gbichot2-bin.000005
-rw-rw---- 1 guilhem guilhem 998412 Nov 14 10:08 gbichot2-bin.000006
-rw-rw---- 1 guilhem guilhem 361 Nov 14 10:07 gbichot2-bin.index
```

Each time it restarts, the MySQL server creates a new binary log file using the next number in the sequence. While the server is running, you can also tell it to close the current binary log file and begin a new one manually by issuing a `FLUSH LOGS` SQL statement or with a `mysqladmin flush-logs` command. `mysqldump` also has an option to flush the logs. The `.index` file in the data directory contains the list of all MySQL binary logs in the directory.

The MySQL binary logs are important for recovery because they form the set of incremental backups. If you make sure to flush the logs when you make your full backup, the binary log files created afterward contain all the data changes made since the backup. Let's modify the previous `mysqldump` command a bit so that it flushes the MySQL binary logs at the moment of the full backup, and so that the dump file contains the name of the new current binary log:

```
shell> mysqldump --single-transaction --flush-logs --master-data=2 \
--all-databases > backup_sunday_1_PM.sql
```

After executing this command, the data directory contains a new binary log file, `gbichot2-bin.000007`, because the `--flush-logs` option causes the server to flush its logs. The `--master-data` option causes `mysqldump` to write binary log information to its output, so the resulting `.sql` dump file includes these lines:

```
-- Position to start replication or point-in-time recovery from
-- CHANGE MASTER TO MASTER_LOG_FILE='gbichot2-bin.000007',MASTER_LOG_POS=4;
```

Because the `mysqldump` command made a full backup, those lines mean two things:

- The dump file contains all changes made before any changes written to the `gbichot2-bin.000007` binary log file or higher.
- All data changes logged after the backup are not present in the dump file, but are present in the `gbichot2-bin.000007` binary log file or higher.

On Monday at 1 p.m., we can create an incremental backup by flushing the logs to begin a new binary log file. For example, executing a `mysqladmin flush-logs` command creates `gbichot2-bin.000008`. All changes between the Sunday 1 p.m. full backup and Monday 1 p.m. will be in the `gbichot2-bin.000007` file. This incremental backup is important, so it is a good idea to copy it to a safe place. (For example, back it up on tape or DVD, or copy it to another machine.) On Tuesday at 1 p.m., execute another `mysqladmin flush-logs` command. All changes between Monday 1 p.m. and Tuesday 1 p.m. will be in the `gbichot2-bin.000008` file (which also should be copied somewhere safe).

The MySQL binary logs take up disk space. To free up space, purge them from time to time. One way to do this is by deleting the binary logs that are no longer needed, such as when we make a full backup:

```
shell> mysqldump --single-transaction --flush-logs --master-data=2 \
--all-databases --delete-master-logs > backup_sunday_1_PM.sql
```

#### Note

Deleting the MySQL binary logs with `mysqldump --delete-master-logs` can be dangerous if your server is a replication master server, because slave servers might not yet fully have processed the contents of the binary log. The description for the `PURGE BINARY LOGS` statement explains what should be verified before deleting the MySQL binary logs. See [Section 14.4.1.1, “PURGE BINARY LOGS Syntax”](#).

## 8.3.2 Using Backups for Recovery

Now, suppose that we have a catastrophic crash on Wednesday at 8 a.m. that requires recovery from backups. To recover, first we restore the last full backup we have (the one from Sunday 1 p.m.). The full backup file is just a set of SQL statements, so restoring it is very easy:

```
shell> mysql < backup_sunday_1_PM.sql
```

At this point, the data is restored to its state as of Sunday 1 p.m.. To restore the changes made since then, we must use the incremental backups; that is, the `gbichot2-bin.000007` and `gbichot2-bin.000008` binary log files. Fetch the files if necessary from where they were backed up, and then process their contents like this:

```
shell> mysqlbinlog gbichot2-bin.000007 gbichot2-bin.000008 | mysql
```

We now have recovered the data to its state as of Tuesday 1 p.m., but still are missing the changes from that date to the date of the crash. To not lose them, we would have needed to have the MySQL server store its MySQL binary logs into a safe location (RAID disks, SAN, ...) different from the place

where it stores its data files, so that these logs were not on the destroyed disk. (That is, we can start the server with a `--log-bin` option that specifies a location on a different physical device from the one on which the data directory resides. That way, the logs are safe even if the device containing the directory is lost.) If we had done this, we would have the `gbichot2-bin.000009` file (and any subsequent files) at hand, and we could apply them using `mysqlbinlog` and `mysql` to restore the most recent data changes with no loss up to the moment of the crash:

```
shell> mysqlbinlog gbichot2-bin.000009 ... | mysql
```

For more information about using `mysqlbinlog` to process binary log files, see [Section 8.5, “Point-in-Time \(Incremental\) Recovery Using the Binary Log”](#).

### 8.3.3 Backup Strategy Summary

In case of an operating system crash or power failure, `InnoDB` itself does all the job of recovering data. But to make sure that you can sleep well, observe the following guidelines:

- Always run the MySQL server with the `--log-bin` option, or even `--log-bin=log_name`, where the log file name is located on some safe media different from the drive on which the data directory is located. If you have such safe media, this technique can also be good for disk load balancing (which results in a performance improvement).
- Make periodic full backups, using the `mysqldump` command shown earlier in [Section 8.3.1, “Establishing a Backup Policy”](#), that makes an online, nonblocking backup.
- Make periodic incremental backups by flushing the logs with `FLUSH LOGS` or `mysqladmin flush-logs`.

## 8.4 Using mysqldump for Backups

This section describes how to use `mysqldump` to produce dump files, and how to reload dump files. A dump file can be used in several ways:

- As a backup to enable data recovery in case of data loss.
- As a source of data for setting up replication slaves.
- As a source of data for experimentation:
  - To make a copy of a database that you can use without changing the original data.
  - To test potential upgrade incompatibilities.

`mysqldump` produces two types of output, depending on whether the `--tab` option is given:

- Without `--tab`, `mysqldump` writes SQL statements to the standard output. This output consists of `CREATE` statements to create dumped objects (databases, tables, stored routines, and so forth), and `INSERT` statements to load data into tables. The output can be saved in a file and reloaded later using `mysql` to recreate the dumped objects. Options are available to modify the format of the SQL statements, and to control which objects are dumped.
- With `--tab`, `mysqldump` produces two output files for each dumped table. The server writes one file as tab-delimited text, one line per table row. This file is named `tbl_name.txt` in the output directory. The server also sends a `CREATE TABLE` statement for the table to `mysqldump`, which writes it as a file named `tbl_name.sql` in the output directory.

### 8.4.1 Dumping Data in SQL Format with mysqldump

This section describes how to use `mysqldump` to create SQL-format dump files. For information about reloading such dump files, see [Section 8.4.2, “Reloading SQL-Format Backups”](#).

By default, `mysqldump` writes information as SQL statements to the standard output. You can save the output in a file:

```
shell> mysqldump [arguments] > file_name
```

To dump all databases, invoke `mysqldump` with the `--all-databases` option:

```
shell> mysqldump --all-databases > dump.sql
```

To dump only specific databases, name them on the command line and use the `--databases` option:

```
shell> mysqldump --databases db1 db2 db3 > dump.sql
```

The `--databases` option causes all names on the command line to be treated as database names. Without this option, `mysqldump` treats the first name as a database name and those following as table names.

With `--all-databases` or `--databases`, `mysqldump` writes `CREATE DATABASE` and `USE` statements prior to the dump output for each database. This ensures that when the dump file is reloaded, it creates each database if it does not exist and makes it the default database so database contents are loaded into the same database from which they came. If you want to cause the dump file to force a drop of each database before recreating it, use the `--add-drop-database` option as well. In this case, `mysqldump` writes a `DROP DATABASE` statement preceding each `CREATE DATABASE` statement.

To dump a single database, name it on the command line:

```
shell> mysqldump --databases test > dump.sql
```

In the single-database case, it is permissible to omit the `--databases` option:

```
shell> mysqldump test > dump.sql
```

The difference between the two preceding commands is that without `--databases`, the dump output contains no `CREATE DATABASE` or `USE` statements. This has several implications:

- When you reload the dump file, you must specify a default database name so that the server knows which database to reload.
- For reloading, you can specify a database name different from the original name, which enables you to reload the data into a different database.
- If the database to be reloaded does not exist, you must create it first.
- Because the output will contain no `CREATE DATABASE` statement, the `--add-drop-database` option has no effect. If you use it, it produces no `DROP DATABASE` statement.

To dump only specific tables from a database, name them on the command line following the database name:

```
shell> mysqldump test t1 t3 t7 > dump.sql
```

## 8.4.2 Reloading SQL-Format Backups

To reload a dump file written by `mysqldump` that consists of SQL statements, use it as input to the `mysql` client. If the dump file was created by `mysqldump` with the `--all-databases` or `--databases` option, it contains `CREATE DATABASE` and `USE` statements and it is not necessary to specify a default database into which to load the data:

```
shell> mysql < dump.sql
```

Alternatively, from within `mysql`, use a `source` command:

```
mysql> source dump.sql
```

If the file is a single-database dump not containing `CREATE DATABASE` and `USE` statements, create the database first (if necessary):

```
shell> mysqladmin create db1
```

Then specify the database name when you load the dump file:

```
shell> mysql db1 < dump.sql
```

Alternatively, from within `mysql`, create the database, select it as the default database, and load the dump file:

```
mysql> CREATE DATABASE IF NOT EXISTS db1;
mysql> USE db1;
mysql> source dump.sql
```

#### Note

For Windows PowerShell users: Because the "<" character is reserved for future use in PowerShell, an alternative approach is required, such as using quotes  
`cmd.exe /c "mysql < dump.sql".`

### 8.4.3 Dumping Data in Delimited-Text Format with mysqldump

This section describes how to use `mysqldump` to create delimited-text dump files. For information about reloading such dump files, see [Section 8.4.4, “Reloading Delimited-Text Format Backups”](#).

If you invoke `mysqldump` with the `--tab=dir_name` option, it uses `dir_name` as the output directory and dumps tables individually in that directory using two files for each table. The table name is the base name for these files. For a table named `t1`, the files are named `t1.sql` and `t1.txt`. The `.sql` file contains a `CREATE TABLE` statement for the table. The `.txt` file contains the table data, one line per table row.

The following command dumps the contents of the `db1` database to files in the `/tmp` database:

```
shell> mysqldump --tab=/tmp db1
```

The `.txt` files containing table data are written by the server, so they are owned by the system account used for running the server. The server uses `SELECT ... INTO OUTFILE` to write the files, so you must have the `FILE` privilege to perform this operation, and an error occurs if a given `.txt` file already exists.

The server sends the `CREATE` definitions for dumped tables to `mysqldump`, which writes them to `.sql` files. These files therefore are owned by the user who executes `mysqldump`.

It is best that `--tab` be used only for dumping a local server. If you use it with a remote server, the `--tab` directory must exist on both the local and remote hosts, and the `.txt` files will be written by the server in the remote directory (on the server host), whereas the `.sql` files will be written by `mysqldump` in the local directory (on the client host).

For `mysqldump --tab`, the server by default writes table data to `.txt` files one line per row with tabs between column values, no quotation marks around column values, and newline as the line terminator. (These are the same defaults as for `SELECT ... INTO OUTFILE`.)

To enable data files to be written using a different format, `mysqldump` supports these options:

- `--fields-terminated-by=str`

The string for separating column values (default: tab).

- `--fields-enclosed-by=char`

The character within which to enclose column values (default: no character).

- `--fields-optionally-enclosed-by=char`

The character within which to enclose non-numeric column values (default: no character).

- `--fields-escaped-by=char`

The character for escaping special characters (default: no escaping).

- `--lines-terminated-by=str`

The line-termination string (default: newline).

Depending on the value you specify for any of these options, it might be necessary on the command line to quote or escape the value appropriately for your command interpreter. Alternatively, specify the value using hex notation. Suppose that you want `mysqldump` to quote column values within double quotation marks. To do so, specify double quote as the value for the `--fields-enclosed-by` option. But this character is often special to command interpreters and must be treated specially. For example, on Unix, you can quote the double quote like this:

```
--fields-enclosed-by='\"'
```

On any platform, you can specify the value in hex:

```
--fields-enclosed-by=0x22
```

It is common to use several of the data-formatting options together. For example, to dump tables in comma-separated values format with lines terminated by carriage-return/newline pairs (`\r\n`), use this command (enter it on a single line):

```
shell> mysqldump --tab=/tmp --fields-terminated-by=,
        --fields-enclosed-by='\"' --lines-terminated-by=0x0d0a db1
```

Should you use any of the data-formatting options to dump table data, you will need to specify the same format when you reload data files later, to ensure proper interpretation of the file contents.

## 8.4.4 Reloading Delimited-Text Format Backups

For backups produced with `mysqldump --tab`, each table is represented in the output directory by an `.sql` file containing the `CREATE TABLE` statement for the table, and a `.txt` file containing the table data. To reload a table, first change location into the output directory. Then process the `.sql` file with `mysql` to create an empty table and process the `.txt` file to load the data into the table:

```
shell> mysql db1 < t1.sql
shell> mysqlimport db1 t1.txt
```

An alternative to using `mysqlimport` to load the data file is to use the `LOAD DATA INFILE` statement from within the `mysql` client:

```
mysql> USE db1;
mysql> LOAD DATA INFILE 't1.txt' INTO TABLE t1;
```

If you used any data-formatting options with `mysqldump` when you initially dumped the table, you must use the same options with `mysqlimport` or `LOAD DATA INFILE` to ensure proper interpretation of the data file contents:

```
shell> mysqlimport --fields-terminated-by=,
--fields-enclosed-by='"' --lines-terminated-by=0x0d0a db1 t1.txt
```

Or:

```
mysql> USE db1;
mysql> LOAD DATA INFILE 't1.txt' INTO TABLE t1
-> FIELDS TERMINATED BY ',' FIELDS ENCLOSED BY '"'
-> LINES TERMINATED BY '\r\n';
```

## 8.4.5 mysqldump Tips

This section surveys techniques that enable you to use `mysqldump` to solve specific problems:

- How to make a copy a database
- How to copy a database from one server to another
- How to dump stored programs (stored procedures and functions, triggers, and events)
- How to dump definitions and data separately

### 8.4.5.1 Making a Copy of a Database

```
shell> mysqldump db1 > dump.sql
shell> mysqladmin create db2
shell> mysql db2 < dump.sql
```

Do not use `--databases` on the `mysqldump` command line because that causes `USE db1` to be included in the dump file, which overrides the effect of naming `db2` on the `mysql` command line.

### 8.4.5.2 Copy a Database from one Server to Another

On Server 1:

```
shell> mysqldump --databases db1 > dump.sql
```

Copy the dump file from Server 1 to Server 2.

On Server 2:

```
shell> mysql < dump.sql
```

Use of `--databases` with the `mysqldump` command line causes the dump file to include `CREATE DATABASE` and `USE` statements that create the database if it does exist and make it the default database for the reloaded data.

Alternatively, you can omit `--databases` from the `mysqldump` command. Then you will need to create the database on Server 2 (if necessary) and specify it as the default database when you reload the dump file.

On Server 1:

```
shell> mysqldump db1 > dump.sql
```

On Server 2:

```
shell> mysqladmin create db1
shell> mysql db1 < dump.sql
```

You can specify a different database name in this case, so omitting `--databases` from the `mysqldump` command enables you to dump data from one database and load it into another.

### 8.4.5.3 Dumping Stored Programs

Several options control how `mysqldump` handles stored programs (stored procedures and functions, triggers, and events):

- `--events`: Dump Event Scheduler events
- `--routines`: Dump stored procedures and functions
- `--triggers`: Dump triggers for tables

The `--triggers` option is enabled by default so that when tables are dumped, they are accompanied by any triggers they have. The other options are disabled by default and must be specified explicitly to dump the corresponding objects. To disable any of these options explicitly, use its skip form: `--skip-events`, `--skip-routines`, or `--skip-triggers`.

### 8.4.5.4 Dumping Table Definitions and Content Separately

The `--no-data` option tells `mysqldump` not to dump table data, resulting in the dump file containing only statements to create the tables. Conversely, the `--no-create-info` option tells `mysqldump` to suppress `CREATE` statements from the output, so that the dump file contains only table data.

For example, to dump table definitions and data separately for the `test` database, use these commands:

```
shell> mysqldump --no-data test > dump-defs.sql
shell> mysqldump --no-create-info test > dump-data.sql
```

For a definition-only dump, add the `--routines` and `--events` options to also include stored routine and event definitions:

```
shell> mysqldump --no-data --routines --events test > dump-defs.sql
```

### 8.4.5.5 Using `mysqldump` to Test for Upgrade Incompatibilities

When contemplating a MySQL upgrade, it is prudent to install the newer version separately from your current production version. Then you can dump the database and database object definitions from the production server and load them into the new server to verify that they are handled properly. (This is also useful for testing downgrades.)

On the production server:

```
shell> mysqldump --all-databases --no-data --routines --events > dump-defs.sql
```

On the upgraded server:

```
shell> mysql < dump-defs.sql
```

Because the dump file does not contain table data, it can be processed quickly. This enables you to spot potential incompatibilities without waiting for lengthy data-loading operations. Look for warnings or errors while the dump file is being processed.

After you have verified that the definitions are handled properly, dump the data and try to load it into the upgraded server.

On the production server:

```
shell> mysqldump --all-databases --no-create-info > dump-data.sql
```

On the upgraded server:

```
shell> mysql < dump-data.sql
```

Now check the table contents and run some test queries.

## 8.5 Point-in-Time (Incremental) Recovery Using the Binary Log

Point-in-time recovery refers to recovery of data changes made since a given point in time. Typically, this type of recovery is performed after restoring a full backup that brings the server to its state as of the time the backup was made. (The full backup can be made in several ways, such as those listed in [Section 8.2, “Database Backup Methods”](#).) Point-in-time recovery then brings the server up to date incrementally from the time of the full backup to a more recent time.

### Note

Many of the examples here use the `mysql` client to process binary log output produced by `mysqlbinlog`. If your binary log contains `\0` (null) characters, that output cannot be parsed by `mysql` unless you invoke it with the `--binary-mode` option.

Point-in-time recovery is based on these principles:

- The source of information for point-in-time recovery is the set of incremental backups represented by the binary log files generated subsequent to the full backup operation. Therefore, the server must be started with the `--log-bin` option to enable binary logging (see [Section 6.4.4, “The Binary Log”](#)).

To restore data from the binary log, you must know the name and location of the current binary log files. By default, the server creates binary log files in the data directory, but a path name can be specified with the `--log-bin` option to place the files in a different location. [Section 6.4.4, “The Binary Log”](#).

To see a listing of all binary log files, use this statement:

```
mysql> SHOW BINARY LOGS;
```

To determine the name of the current binary log file, issue the following statement:

```
mysql> SHOW MASTER STATUS;
```

- The `mysqlbinlog` utility converts the events in the binary log files from binary format to text so that they can be executed or viewed. `mysqlbinlog` has options for selecting sections of the binary log based on event times or position of events within the log. See [Section 5.6.7, “mysqlbinlog — Utility for Processing Binary Log Files”](#).
- Executing events from the binary log causes the data modifications they represent to be redone. This enables recovery of data changes for a given span of time. To execute events from the binary log, process `mysqlbinlog` output using the `mysql` client:

```
shell> mysqlbinlog binlog_files | mysql -u root -p
```

- Viewing log contents can be useful when you need to determine event times or positions to select partial log contents prior to executing events. To view events from the log, send `mysqlbinlog` output into a paging program:

```
shell> mysqlbinlog binlog_files | more
```

Alternatively, save the output in a file and view the file in a text editor:

```
shell> mysqlbinlog binlog_files > tmpfile
shell> ... edit tmpfile ...
```

- Saving the output in a file is useful as a preliminary to executing the log contents with certain events removed, such as an accidental `DROP DATABASE`. You can delete from the file any statements not to be executed before executing its contents. After editing the file, execute the contents as follows:

```
shell> mysql -u root -p < tmpfile
```

If you have more than one binary log to execute on the MySQL server, the safe method is to process them all using a single connection to the server. Here is an example that demonstrates what may be *unsafe*:

```
shell> mysqlbinlog binlog.000001 | mysql -u root -p # DANGER!!
shell> mysqlbinlog binlog.000002 | mysql -u root -p # DANGER!!
```

Processing binary logs this way using different connections to the server causes problems if the first log file contains a `CREATE TEMPORARY TABLE` statement and the second log contains a statement that uses the temporary table. When the first `mysql` process terminates, the server drops the temporary table. When the second `mysql` process attempts to use the table, the server reports “unknown table.”

To avoid problems like this, use a *single* connection to execute the contents of all binary logs that you want to process. Here is one way to do so:

```
shell> mysqlbinlog binlog.000001 binlog.000002 | mysql -u root -p
```

Another approach is to write all the logs to a single file and then process the file:

```
shell> mysqlbinlog binlog.000001 > /tmp/statements.sql
shell> mysqlbinlog binlog.000002 >> /tmp/statements.sql
shell> mysql -u root -p -e "source /tmp/statements.sql"
```

When writing to a dump file while reading back from a binary log containing GTIDs (see [Section 18.1.3, “Replication with Global Transaction Identifiers”](#)), use the `--skip-gtids` option with `mysqlbinlog`, like this:

```
shell> mysqlbinlog --skip-gtids binlog.000001 > /tmp/dump.sql
shell> mysqlbinlog --skip-gtids binlog.000002 >> /tmp/dump.sql
shell> mysql -u root -p -e "source /tmp/dump.sql"
```

## 8.5.1 Point-in-Time Recovery Using Event Times

To indicate the start and end times for recovery, specify the `--start-datetime` and `--stop-datetime` options for `mysqlbinlog`, in `DATETIME` format. As an example, suppose that exactly at 10:00 a.m. on April 20, 2005 an SQL statement was executed that deleted a large table. To restore

the table and data, you could restore the previous night's backup, and then execute the following command:

```
shell> mysqlbinlog --stop-datetime="2005-04-20 9:59:59" \
/var/log/mysql/bin.123456 | mysql -u root -p
```

This command recovers all of the data up until the date and time given by the `--stop-datetime` option. If you did not detect the erroneous SQL statement that was entered until hours later, you will probably also want to recover the activity that occurred afterward. Based on this, you could run `mysqlbinlog` again with a start date and time, like so:

```
shell> mysqlbinlog --start-datetime="2005-04-20 10:01:00" \
/var/log/mysql/bin.123456 | mysql -u root -p
```

In this command, the SQL statements logged from 10:01 a.m. on will be re-executed. The combination of restoring of the previous night's dump file and the two `mysqlbinlog` commands restores everything up until one second before 10:00 a.m. and everything from 10:01 a.m. on.

To use this method of point-in-time recovery, you should examine the log to be sure of the exact times to specify for the commands. To display the log file contents without executing them, use this command:

```
shell> mysqlbinlog /var/log/mysql/bin.123456 > /tmp/mysql_restore.sql
```

Then open the `/tmp/mysql_restore.sql` file with a text editor to examine it.

Excluding specific changes by specifying times for `mysqlbinlog` does not work well if multiple statements executed at the same time as the one to be excluded.

## 8.5.2 Point-in-Time Recovery Using Event Positions

Instead of specifying dates and times, the `--start-position` and `--stop-position` options for `mysqlbinlog` can be used for specifying log positions. They work the same as the start and stop date options, except that you specify log position numbers rather than dates. Using positions may enable you to be more precise about which part of the log to recover, especially if many transactions occurred around the same time as a damaging SQL statement. To determine the position numbers, run `mysqlbinlog` for a range of times near the time when the unwanted transaction was executed, but redirect the results to a text file for examination. This can be done like so:

```
shell> mysqlbinlog --start-datetime="2005-04-20 9:55:00" \
--stop-datetime="2005-04-20 10:05:00" \
/var/log/mysql/bin.123456 > /tmp/mysql_restore.sql
```

This command creates a small text file in the `/tmp` directory that contains the SQL statements around the time that the deleterious SQL statement was executed. Open this file with a text editor and look for the statement that you do not want to repeat. Determine the positions in the binary log for stopping and resuming the recovery and make note of them. Positions are labeled as `log_pos` followed by a number. After restoring the previous backup file, use the position numbers to process the binary log file. For example, you would use commands something like these:

```
shell> mysqlbinlog --stop-position=368312 /var/log/mysql/bin.123456 \
| mysql -u root -p

shell> mysqlbinlog --start-position=368315 /var/log/mysql/bin.123456 \
| mysql -u root -p
```

The first command recovers all the transactions up until the stop position given. The second command recovers all transactions from the starting position given until the end of the binary log. Because the output of `mysqlbinlog` includes `SET TIMESTAMP` statements before each SQL statement recorded,

the recovered data and related MySQL logs will reflect the original times at which the transactions were executed.

## 8.6 MyISAM Table Maintenance and Crash Recovery

This section discusses how to use `myisamchk` to check or repair MyISAM tables (tables that have `.MYD` and `.MYI` files for storing data and indexes). For general `myisamchk` background, see [Section 5.6.3, “myisamchk — MyISAM Table-Maintenance Utility”](#). Other table-repair information can be found at [Section 2.11.4, “Rebuilding or Repairing Tables or Indexes”](#).

You can use `myisamchk` to check, repair, or optimize database tables. The following sections describe how to perform these operations and how to set up a table maintenance schedule. For information about using `myisamchk` to get information about your tables, see [Section 5.6.3.5, “Obtaining Table Information with myisamchk”](#).

Even though table repair with `myisamchk` is quite secure, it is always a good idea to make a backup *before* doing a repair or any maintenance operation that could make a lot of changes to a table.

`myisamchk` operations that affect indexes can cause MyISAM FULLTEXT indexes to be rebuilt with full-text parameters that are incompatible with the values used by the MySQL server. To avoid this problem, follow the guidelines in [Section 5.6.3.1, “myisamchk General Options”](#).

MyISAM table maintenance can also be done using the SQL statements that perform operations similar to what `myisamchk` can do:

- To check MyISAM tables, use `CHECK TABLE`.
- To repair MyISAM tables, use `REPAIR TABLE`.
- To optimize MyISAM tables, use `OPTIMIZE TABLE`.
- To analyze MyISAM tables, use `ANALYZE TABLE`.

For additional information about these statements, see [Section 14.7.2, “Table Maintenance Statements”](#).

These statements can be used directly or by means of the `mysqlcheck` client program. One advantage of these statements over `myisamchk` is that the server does all the work. With `myisamchk`, you must make sure that the server does not use the tables at the same time so that there is no unwanted interaction between `myisamchk` and the server.

### 8.6.1 Using myisamchk for Crash Recovery

This section describes how to check for and deal with data corruption in MySQL databases. If your tables become corrupted frequently, you should try to find the reason why. See [Section B.5.3.3, “What to Do If MySQL Keeps Crashing”](#).

For an explanation of how MyISAM tables can become corrupted, see [Section 16.2.4, “MyISAM Table Problems”](#).

If you run `mysqld` with external locking disabled (which is the default), you cannot reliably use `myisamchk` to check a table when `mysqld` is using the same table. If you can be certain that no one will access the tables through `mysqld` while you run `myisamchk`, you only have to execute `mysqladmin flush-tables` before you start checking the tables. If you cannot guarantee this, you must stop `mysqld` while you check the tables. If you run `myisamchk` to check tables that `mysqld` is updating at the same time, you may get a warning that a table is corrupt even when it is not.

If the server is run with external locking enabled, you can use `myisamchk` to check tables at any time. In this case, if the server tries to update a table that `myisamchk` is using, the server will wait for `myisamchk` to finish before it continues.

If you use `myisamchk` to repair or optimize tables, you *must* always ensure that the `mysqld` server is not using the table (this also applies if external locking is disabled). If you do not stop `mysqld`, you should at least do a `mysqladmin flush-tables` before you run `myisamchk`. Your tables *may become corrupted* if the server and `myisamchk` access the tables simultaneously.

When performing crash recovery, it is important to understand that each `MyISAM` table `tbl_name` in a database corresponds to the three files in the database directory shown in the following table.

| File                      | Purpose                  |
|---------------------------|--------------------------|
| <code>tbl_name.frm</code> | Definition (format) file |
| <code>tbl_name.MYD</code> | Data file                |
| <code>tbl_name.MYI</code> | Index file               |

Each of these three file types is subject to corruption in various ways, but problems occur most often in data files and index files.

`myisamchk` works by creating a copy of the `.MYD` data file row by row. It ends the repair stage by removing the old `.MYD` file and renaming the new file to the original file name. If you use `--quick`, `myisamchk` does not create a temporary `.MYD` file, but instead assumes that the `.MYD` file is correct and generates only a new index file without touching the `.MYD` file. This is safe, because `myisamchk` automatically detects whether the `.MYD` file is corrupt and aborts the repair if it is. You can also specify the `--quick` option twice to `myisamchk`. In this case, `myisamchk` does not abort on some errors (such as duplicate-key errors) but instead tries to resolve them by modifying the `.MYD` file. Normally the use of two `--quick` options is useful only if you have too little free disk space to perform a normal repair. In this case, you should at least make a backup of the table before running `myisamchk`.

## 8.6.2 How to Check MyISAM Tables for Errors

To check a `MyISAM` table, use the following commands:

- `myisamchk tbl_name`

This finds 99.99% of all errors. What it cannot find is corruption that involves *only* the data file (which is very unusual). If you want to check a table, you should normally run `myisamchk` without options or with the `-s` (silent) option.

- `myisamchk -m tbl_name`

This finds 99.999% of all errors. It first checks all index entries for errors and then reads through all rows. It calculates a checksum for all key values in the rows and verifies that the checksum matches the checksum for the keys in the index tree.

- `myisamchk -e tbl_name`

This does a complete and thorough check of all data (`-e` means “extended check”). It does a check-read of every key for each row to verify that they indeed point to the correct row. This may take a long time for a large table that has many indexes. Normally, `myisamchk` stops after the first error it finds. If you want to obtain more information, you can add the `-v` (verbose) option. This causes `myisamchk` to keep going, up through a maximum of 20 errors.

- `myisamchk -e -i tbl_name`

This is like the previous command, but the `-i` option tells `myisamchk` to print additional statistical information.

In most cases, a simple `myisamchk` command with no arguments other than the table name is sufficient to check a table.

## 8.6.3 How to Repair MyISAM Tables

The discussion in this section describes how to use `myisamchk` on MyISAM tables (extensions `.MYI` and `.MYD`).

You can also use the `CHECK TABLE` and `REPAIR TABLE` statements to check and repair MyISAM tables. See [Section 14.7.2.2, “CHECK TABLE Syntax”](#), and [Section 14.7.2.5, “REPAIR TABLE Syntax”](#).

Symptoms of corrupted tables include queries that abort unexpectedly and observable errors such as these:

- `tbl_name.frm` is locked against change
- Can't find file `tbl_name.MYI` (Errcode: `nnn`)
- Unexpected end of file
- Record file is crashed
- Got error `nnn` from table handler

To get more information about the error, run `pererror nnn`, where `nnn` is the error number. The following example shows how to use `pererror` to find the meanings for the most common error numbers that indicate a problem with a table:

```
shell> pererror 126 127 132 134 135 136 141 144 145
MySQL error code 126 = Index file is crashed
MySQL error code 127 = Record-file is crashed
MySQL error code 132 = Old database file
MySQL error code 134 = Record was already deleted (or record file crashed)
MySQL error code 135 = No more room in record file
MySQL error code 136 = No more room in index file
MySQL error code 141 = Duplicate unique key or constraint on write or update
MySQL error code 144 = Table is crashed and last repair failed
MySQL error code 145 = Table was marked as crashed and should be repaired
```

Note that error 135 (no more room in record file) and error 136 (no more room in index file) are not errors that can be fixed by a simple repair. In this case, you must use `ALTER TABLE` to increase the `MAX_ROWS` and `AVG_ROW_LENGTH` table option values:

```
ALTER TABLE tbl_name MAX_ROWS=xxx AVG_ROW_LENGTH=yyy;
```

If you do not know the current table option values, use `SHOW CREATE TABLE`.

For the other errors, you must repair your tables. `myisamchk` can usually detect and fix most problems that occur.

The repair process involves up to four stages, described here. Before you begin, you should change location to the database directory and check the permissions of the table files. On Unix, make sure that they are readable by the user that `mysqld` runs as (and to you, because you need to access the files you are checking). If it turns out you need to modify files, they must also be writable by you.

This section is for the cases where a table check fails (such as those described in [Section 8.6.2, “How to Check MyISAM Tables for Errors”](#)), or you want to use the extended features that `myisamchk` provides.

The `myisamchk` options used for table maintenance with are described in [Section 5.6.3, “myisamchk — MyISAM Table-Maintenance Utility”](#). `myisamchk` also has variables that you can set to control memory allocation that may improve performance. See [Section 5.6.3.6, “myisamchk Memory Usage”](#).

If you are going to repair a table from the command line, you must first stop the `mysqld` server. Note that when you do `mysqladmin shutdown` on a remote server, the `mysqld` server is still available for a while after `mysqladmin` returns, until all statement-processing has stopped and all index changes have been flushed to disk.

### Stage 1: Checking your tables

Run `myisamchk *.MYI` or `myisamchk -e *.MYI` if you have more time. Use the `-s` (silent) option to suppress unnecessary information.

If the `mysqld` server is stopped, you should use the `--update-state` option to tell `myisamchk` to mark the table as “checked.”

You have to repair only those tables for which `myisamchk` announces an error. For such tables, proceed to Stage 2.

If you get unexpected errors when checking (such as `out of memory` errors), or if `myisamchk` crashes, go to Stage 3.

### Stage 2: Easy safe repair

First, try `myisamchk -r -q tbl_name` (`-r -q` means “quick recovery mode”). This attempts to repair the index file without touching the data file. If the data file contains everything that it should and the delete links point at the correct locations within the data file, this should work, and the table is fixed. Start repairing the next table. Otherwise, use the following procedure:

1. Make a backup of the data file before continuing.
2. Use `myisamchk -r tbl_name` (`-r` means “recovery mode”). This removes incorrect rows and deleted rows from the data file and reconstructs the index file.
3. If the preceding step fails, use `myisamchk --safe-recover tbl_name`. Safe recovery mode uses an old recovery method that handles a few cases that regular recovery mode does not (but is slower).

#### Note

If you want a repair operation to go much faster, you should set the values of the `sort_buffer_size` and `key_buffer_size` variables each to about 25% of your available memory when running `myisamchk`.

If you get unexpected errors when repairing (such as `out of memory` errors), or if `myisamchk` crashes, go to Stage 3.

### Stage 3: Difficult repair

You should reach this stage only if the first 16KB block in the index file is destroyed or contains incorrect information, or if the index file is missing. In this case, it is necessary to create a new index file. Do so as follows:

1. Move the data file to a safe place.
2. Use the table description file to create new (empty) data and index files:

```
shell> mysql db_name
mysql> SET autocommit=1;
mysql> TRUNCATE TABLE tbl_name;
mysql> quit
```

3. Copy the old data file back onto the newly created data file. (Do not just move the old file back onto the new file. You want to retain a copy in case something goes wrong.)

#### Important

If you are using replication, you should stop it prior to performing the above procedure, since it involves file system operations, and these are not logged by MySQL.

Go back to Stage 2. `myisamchk -r -q` should work. (This should not be an endless loop.)

You can also use the `REPAIR TABLE tbl_name USE_FRM` SQL statement, which performs the whole procedure automatically. There is also no possibility of unwanted interaction between a utility and the server, because the server does all the work when you use `REPAIR TABLE`. See [Section 14.7.2.5, “REPAIR TABLE Syntax”](#).

#### Stage 4: Very difficult repair

You should reach this stage only if the `.frm` description file has also crashed. That should never happen, because the description file is not changed after the table is created:

1. Restore the description file from a backup and go back to Stage 3. You can also restore the index file and go back to Stage 2. In the latter case, you should start with `myisamchk -r`.
2. If you do not have a backup but know exactly how the table was created, create a copy of the table in another database. Remove the new data file, and then move the `.frm` description and `.MYI` index files from the other database to your crashed database. This gives you new description and index files, but leaves the `.MYD` data file alone. Go back to Stage 2 and attempt to reconstruct the index file.

## 8.6.4 MyISAM Table Optimization

To coalesce fragmented rows and eliminate wasted space that results from deleting or updating rows, run `myisamchk` in recovery mode:

```
shell> myisamchk -r tbl_name
```

You can optimize a table in the same way by using the `OPTIMIZE TABLE` SQL statement. `OPTIMIZE TABLE` does a table repair and a key analysis, and also sorts the index tree so that key lookups are faster. There is also no possibility of unwanted interaction between a utility and the server, because the server does all the work when you use `OPTIMIZE TABLE`. See [Section 14.7.2.4, “OPTIMIZE TABLE Syntax”](#).

`myisamchk` has a number of other options that you can use to improve the performance of a table:

- `--analyze` or `-a`: Perform key distribution analysis. This improves join performance by enabling the join optimizer to better choose the order in which to join the tables and which indexes it should use.
- `--sort-index` or `-S`: Sort the index blocks. This optimizes seeks and makes table scans that use indexes faster.
- `--sort-records=index_num` or `-R index_num`: Sort data rows according to a given index. This makes your data much more localized and may speed up range-based `SELECT` and `ORDER BY` operations that use this index.

For a full description of all available options, see [Section 5.6.3, “myisamchk — MyISAM Table-Maintenance Utility”](#).

## 8.6.5 Setting Up a MyISAM Table Maintenance Schedule

It is a good idea to perform table checks on a regular basis rather than waiting for problems to occur. One way to check and repair MyISAM tables is with the `CHECK TABLE` and `REPAIR TABLE` statements. See [Section 14.7.2, “Table Maintenance Statements”](#).

Another way to check tables is to use `myisamchk`. For maintenance purposes, you can use `myisamchk -s`. The `-s` option (short for `--silent`) causes `myisamchk` to run in silent mode, printing messages only when errors occur.

It is also a good idea to enable automatic MyISAM table checking. For example, whenever the machine has done a restart in the middle of an update, you usually need to check each table that could have

been affected before it is used further. (These are “expected crashed tables.”) To cause the server to check **MyISAM** tables automatically, start it with the `--myisam-recover-options` option. See [Section 6.1.4, “Server Command Options”](#).

You should also check your tables regularly during normal system operation. For example, you can run a **cron** job to check important tables once a week, using a line like this in a **crontab** file:

```
35 0 * * 0 /path/to/myisamchk --fast --silent /path/to/datadir/*/*.MYI
```

This prints out information about crashed tables so that you can examine and repair them as necessary.

To start with, execute `myisamchk -s` each night on all tables that have been updated during the last 24 hours. As you see that problems occur infrequently, you can back off the checking frequency to once a week or so.

Normally, MySQL tables need little maintenance. If you are performing many updates to **MyISAM** tables with dynamic-sized rows (tables with **VARCHAR**, **BLOB**, or **TEXT** columns) or have tables with many deleted rows you may want to defragment/reclaim space from the tables from time to time. You can do this by using `OPTIMIZE TABLE` on the tables in question. Alternatively, if you can stop the **mysqld** server for a while, change location into the data directory and use this command while the server is stopped:

```
shell> myisamchk -r -s --sort-index --myisam_sort_buffer_size=16M /*/*.MYI
```

---

This chapter explains how to optimize MySQL performance and provides examples. Optimization involves configuring, tuning, and measuring performance, at several levels. Depending on your job role (developer, DBA, or a combination of both), you might optimize at the level of individual SQL statements, entire applications, a single database server, or multiple networked database servers. Sometimes you can be proactive and plan in advance for performance, while other times you might troubleshoot a configuration or code issue after a problem occurs. Optimizing CPU and memory usage can also improve scalability, allowing the database to handle more load without slowing down.

## 9.1 Optimization Overview

Database performance depends on several factors at the database level, such as tables, queries, and configuration settings. These software constructs result in CPU and I/O operations at the hardware level, which you must minimize and make as efficient as possible. As you work on database performance, you start by learning the high-level rules and guidelines for the software side, and measuring performance using wall-clock time. As you become an expert, you learn more about what happens internally, and start measuring things such as CPU cycles and I/O operations.

Typical users aim to get the best database performance out of their existing software and hardware configurations. Advanced users look for opportunities to improve the MySQL software itself, or develop their own storage engines and hardware appliances to expand the MySQL ecosystem.

### Optimizing at the Database Level

The most important factor in making a database application fast is its basic design:

- Are the tables structured properly? In particular, do the columns have the right data types, and does each table have the appropriate columns for the type of work? For example, applications that perform frequent updates often have many tables with few columns, while applications that analyze large amounts of data often have few tables with many columns.

- Are the right [indexes](#) in place to make queries efficient?
- Are you using the appropriate storage engine for each table, and taking advantage of the strengths and features of each storage engine you use? In particular, the choice of a transactional storage engine such as [InnoDB](#) or a nontransactional one such as [MyISAM](#) can be very important for performance and scalability.

**Note**

In MySQL 5.5 and higher, [InnoDB](#) is the default storage engine for new tables. In practice, the advanced [InnoDB](#) performance features mean that [InnoDB](#) tables often outperform the simpler [MyISAM](#) tables, especially for a busy database.

- Does each table use an appropriate row format? This choice also depends on the storage engine used for the table. In particular, compressed tables use less disk space and so require less disk I/O to read and write the data. Compression is available for all kinds of workloads with [InnoDB](#) tables, and for read-only [MyISAM](#) tables.
- Does the application use an appropriate [locking strategy](#)? For example, by allowing shared access when possible so that database operations can run concurrently, and requesting exclusive access when appropriate so that critical operations get top priority. Again, the choice of storage engine is significant. The [InnoDB](#) storage engine handles most locking issues without involvement from you, allowing for better concurrency in the database and reducing the amount of experimentation and tuning for your code.
- Are all [memory areas used for caching](#) sized correctly? That is, large enough to hold frequently accessed data, but not so large that they overload physical memory and cause paging. The main memory areas to configure are the [InnoDB](#) buffer pool, the [MyISAM](#) key cache, and the MySQL query cache.

## Optimizing at the Hardware Level

Any database application eventually hits hardware limits as the database becomes more and more busy. A DBA must evaluate whether it is possible to tune the application or reconfigure the server to avoid these [bottlenecks](#), or whether more hardware resources are required. System bottlenecks typically arise from these sources:

- Disk seeks. It takes time for the disk to find a piece of data. With modern disks, the mean time for this is usually lower than 10ms, so we can in theory do about 100 seeks a second. This time improves slowly with new disks and is very hard to optimize for a single table. The way to optimize seek time is to distribute the data onto more than one disk.
- Disk reading and writing. When the disk is at the correct position, we need to read or write the data. With modern disks, one disk delivers at least 10–20MB/s throughput. This is easier to optimize than seeks because you can read in parallel from multiple disks.
- CPU cycles. When the data is in main memory, we must process it to get our result. Having large tables compared to the amount of memory is the most common limiting factor. But with small tables, speed is usually not the problem.
- Memory bandwidth. When the CPU needs more data than can fit in the CPU cache, main memory bandwidth becomes a bottleneck. This is an uncommon bottleneck for most systems, but one to be aware of.

## Balancing Portability and Performance

To use performance-oriented SQL extensions in a portable MySQL program, you can wrap MySQL-specific keywords in a statement within `/*! */` comment delimiters. Other SQL servers ignore the commented keywords. For information about writing comments, see [Section 10.6, “Comment Syntax”](#).

## 9.2 Optimizing SQL Statements

The core logic of a database application is performed through SQL statements, whether issued directly through an interpreter or submitted behind the scenes through an API. The tuning guidelines in this section help to speed up all kinds of MySQL applications. The guidelines cover SQL operations that read and write data, the behind-the-scenes overhead for SQL operations in general, and operations used in specific scenarios such as database monitoring.

### 9.2.1 Optimizing SELECT Statements

Queries, in the form of `SELECT` statements, perform all the lookup operations in the database. Tuning these statements is a top priority, whether to achieve sub-second response times for dynamic web pages, or to chop hours off the time to generate huge overnight reports.

Besides `SELECT` statements, the tuning techniques for queries also apply to constructs such as `CREATE TABLE...AS SELECT`, `INSERT INTO...SELECT`, and `WHERE` clauses in `DELETE` statements. Those statements have additional performance considerations because they combine write operations with the read-oriented query operations.

MySQL Cluster supports a join pushdown optimization whereby a qualifying join is sent in its entirety to MySQL Cluster data nodes, where it can be distributed among them and executed in parallel. For more information about this optimization, see [Conditions for NDB pushdown joins](#),

#### 9.2.1.1 Speed of SELECT Statements

The main considerations for optimizing queries are:

- To make a slow `SELECT ... WHERE` query faster, the first thing to check is whether you can add an [index](#). Set up indexes on columns used in the `WHERE` clause, to speed up evaluation, filtering, and the final retrieval of results. To avoid wasted disk space, construct a small set of indexes that speed up many related queries used in your application.

Indexes are especially important for queries that reference different tables, using features such as [joins](#) and [foreign keys](#). You can use the `EXPLAIN` statement to determine which indexes are used for a `SELECT`. See [Section 9.3.1, “How MySQL Uses Indexes”](#) and [Section 9.8.1, “Optimizing Queries with EXPLAIN”](#).

- Isolate and tune any part of the query, such as a function call, that takes excessive time. Depending on how the query is structured, a function could be called once for every row in the result set, or even once for every row in the table, greatly magnifying any inefficiency.
- Minimize the number of [full table scans](#) in your queries, particularly for big tables.
- Keep table statistics up to date by using the `ANALYZE TABLE` statement periodically, so the optimizer has the information needed to construct an efficient execution plan.
- Learn the tuning techniques, indexing techniques, and configuration parameters that are specific to the storage engine for each table. Both [InnoDB](#) and [MyISAM](#) have sets of guidelines for enabling and sustaining high performance in queries. For details, see [Section 9.5.6, “Optimizing InnoDB Queries”](#) and [Section 9.6.1, “Optimizing MyISAM Queries”](#).
- You can optimize single-query transactions for [InnoDB](#) tables, using the technique in [Section 9.5.3, “Optimizing InnoDB Read-Only Transactions”](#).
- Avoid transforming the query in ways that make it hard to understand, especially if the optimizer does some of the same transformations automatically.
- If a performance issue is not easily solved by one of the basic guidelines, investigate the internal details of the specific query by reading the `EXPLAIN` plan and adjusting your indexes, `WHERE`

clauses, join clauses, and so on. (When you reach a certain level of expertise, reading the [EXPLAIN](#) plan might be your first step for every query.)

- Adjust the size and properties of the memory areas that MySQL uses for caching. With efficient use of the [InnoDB buffer pool](#), [MyISAM](#) key cache, and the MySQL query cache, repeated queries run faster because the results are retrieved from memory the second and subsequent times.
- Even for a query that runs fast using the cache memory areas, you might still optimize further so that they require less cache memory, making your application more scalable. Scalability means that your application can handle more simultaneous users, larger requests, and so on without experiencing a big drop in performance.
- Deal with locking issues, where the speed of your query might be affected by other sessions accessing the tables at the same time.

### 9.2.1.2 How MySQL Optimizes WHERE Clauses

This section discusses optimizations that can be made for processing [WHERE](#) clauses. The examples use [SELECT](#) statements, but the same optimizations apply for [WHERE](#) clauses in [DELETE](#) and [UPDATE](#) statements.

#### Note

Because work on the MySQL optimizer is ongoing, not all of the optimizations that MySQL performs are documented here.

You might be tempted to rewrite your queries to make arithmetic operations faster, while sacrificing readability. Because MySQL does similar optimizations automatically, you can often avoid this work, and leave the query in a more understandable and maintainable form. Some of the optimizations performed by MySQL follow:

- Removal of unnecessary parentheses:

```
((a AND b) AND c OR (((a AND b) AND (c AND d))))  
-> (a AND b AND c) OR (a AND b AND c AND d)
```

- Constant folding:

```
(a<b AND b=c) AND a=5  
-> b>5 AND b=c AND a=5
```

- Constant condition removal (needed because of constant folding):

```
(B>=5 AND B=5) OR (B=6 AND 5=5) OR (B=7 AND 5=6)  
-> B=5 OR B=6
```

- Constant expressions used by indexes are evaluated only once.
- [COUNT\( \\*\)](#) on a single table without a [WHERE](#) is retrieved directly from the table information for [MyISAM](#) and [MEMORY](#) tables. This is also done for any [NOT NULL](#) expression when used with only one table.
- Early detection of invalid constant expressions. MySQL quickly detects that some [SELECT](#) statements are impossible and returns no rows.
- [HAVING](#) is merged with [WHERE](#) if you do not use [GROUP BY](#) or aggregate functions ([COUNT\( \)](#), [MIN\( \)](#), and so on).
- For each table in a join, a simpler [WHERE](#) is constructed to get a fast [WHERE](#) evaluation for the table and also to skip rows as soon as possible.

- All constant tables are read first before any other tables in the query. A constant table is any of the following:
  - An empty table or a table with one row.
  - A table that is used with a `WHERE` clause on a `PRIMARY KEY` or a `UNIQUE` index, where all index parts are compared to constant expressions and are defined as `NOT NULL`.

All of the following tables are used as constant tables:

```
SELECT * FROM t WHERE primary_key=1;
SELECT * FROM t1,t2
  WHERE t1.primary_key=1 AND t2.primary_key=t1.id;
```

- The best join combination for joining the tables is found by trying all possibilities. If all columns in `ORDER BY` and `GROUP BY` clauses come from the same table, that table is preferred first when joining.
- If there is an `ORDER BY` clause and a different `GROUP BY` clause, or if the `ORDER BY` or `GROUP BY` contains columns from tables other than the first table in the join queue, a temporary table is created.
- If you use the `SQL_SMALL_RESULT` option, MySQL uses an in-memory temporary table.
- Each table index is queried, and the best index is used unless the optimizer believes that it is more efficient to use a table scan. At one time, a scan was used based on whether the best index spanned more than 30% of the table, but a fixed percentage no longer determines the choice between using an index or a scan. The optimizer now is more complex and bases its estimate on additional factors such as table size, number of rows, and I/O block size.
- In some cases, MySQL can read rows from the index without even consulting the data file. If all columns used from the index are numeric, only the index tree is used to resolve the query.
- Before each row is output, those that do not match the `HAVING` clause are skipped.

Some examples of queries that are very fast:

```
SELECT COUNT(*) FROM tbl_name;

SELECT MIN(key_part1),MAX(key_part1) FROM tbl_name;

SELECT MAX(key_part2) FROM tbl_name
  WHERE key_part1=constant;

SELECT ... FROM tbl_name
  ORDER BY key_part1,key_part2,... LIMIT 10;

SELECT ... FROM tbl_name
  ORDER BY key_part1 DESC, key_part2 DESC, ... LIMIT 10;
```

MySQL resolves the following queries using only the index tree, assuming that the indexed columns are numeric:

```
SELECT key_part1,key_part2 FROM tbl_name WHERE key_part1=val;

SELECT COUNT(*) FROM tbl_name
  WHERE key_part1=val1 AND key_part2=val2;

SELECT key_part2 FROM tbl_name GROUP BY key_part1;
```

The following queries use indexing to retrieve the rows in sorted order without a separate sorting pass:

```
SELECT ... FROM tbl_name
```

```
ORDER BY key_part1,key_part2,... ;

SELECT ... FROM tbl_name
ORDER BY key_part1 DESC, key_part2 DESC, ... ;
```

### 9.2.1.3 Range Optimization

The [range](#) access method uses a single index to retrieve a subset of table rows that are contained within one or several index value intervals. It can be used for a single-part or multiple-part index. The following sections give descriptions of conditions under which the optimizer uses range access.

#### The Range Access Method for Single-Part Indexes

For a single-part index, index value intervals can be conveniently represented by corresponding conditions in the [WHERE](#) clause, denoted as *range conditions* rather than “intervals.”

The definition of a range condition for a single-part index is as follows:

- For both [BTREE](#) and [HASH](#) indexes, comparison of a key part with a constant value is a range condition when using the `=`, `<=>`, `IN()`, `IS NULL`, or `IS NOT NULL` operators.
- Additionally, for [BTREE](#) indexes, comparison of a key part with a constant value is a range condition when using the `>`, `<`, `>=`, `<=`, [BETWEEN](#), `!=`, or `<>` operators, or [LIKE](#) comparisons if the argument to [LIKE](#) is a constant string that does not start with a wildcard character.
- For all index types, multiple range conditions combined with [OR](#) or [AND](#) form a range condition.

“Constant value” in the preceding descriptions means one of the following:

- A constant from the query string
- A column of a [const](#) or [system](#) table from the same join
- The result of an uncorrelated subquery
- Any expression composed entirely from subexpressions of the preceding types

Here are some examples of queries with range conditions in the [WHERE](#) clause:

```
SELECT * FROM t1
WHERE key_col > 1
AND key_col < 10;

SELECT * FROM t1
WHERE key_col = 1
OR key_col IN (15,18,20);

SELECT * FROM t1
WHERE key_col LIKE 'ab%'
OR key_col BETWEEN 'bar' AND 'foo';
```

Some nonconstant values may be converted to constants during the optimizer constant propagation phase.

MySQL tries to extract range conditions from the [WHERE](#) clause for each of the possible indexes. During the extraction process, conditions that cannot be used for constructing the range condition are dropped, conditions that produce overlapping ranges are combined, and conditions that produce empty ranges are removed.

Consider the following statement, where [key1](#) is an indexed column and [nonkey](#) is not indexed:

```
SELECT * FROM t1 WHERE
(key1 < 'abc' AND (key1 LIKE 'abcde%' OR key1 LIKE '%b')) OR
(key1 < 'bar' AND nonkey = 4) OR
(key1 < 'uux' AND key1 > 'z');
```

The extraction process for key `key1` is as follows:

1. Start with original `WHERE` clause:

```
(key1 < 'abc' AND (key1 LIKE 'abcde%' OR key1 LIKE '%b')) OR
(key1 < 'bar' AND nonkey = 4) OR
(key1 < 'uux' AND key1 > 'z')
```

2. Remove `nonkey = 4` and `key1 LIKE '%b'` because they cannot be used for a range scan. The correct way to remove them is to replace them with `TRUE`, so that we do not miss any matching rows when doing the range scan. Having replaced them with `TRUE`, we get:

```
(key1 < 'abc' AND (key1 LIKE 'abcde%' OR TRUE)) OR
(key1 < 'bar' AND TRUE) OR
(key1 < 'uux' AND key1 > 'z')
```

3. Collapse conditions that are always true or false:

- `(key1 LIKE 'abcde%' OR TRUE)` is always true
- `(key1 < 'uux' AND key1 > 'z')` is always false

Replacing these conditions with constants, we get:

```
(key1 < 'abc' AND TRUE) OR (key1 < 'bar' AND TRUE) OR (FALSE)
```

Removing unnecessary `TRUE` and `FALSE` constants, we obtain:

```
(key1 < 'abc') OR (key1 < 'bar')
```

4. Combining overlapping intervals into one yields the final condition to be used for the range scan:

```
(key1 < 'bar')
```

In general (and as demonstrated by the preceding example), the condition used for a range scan is less restrictive than the `WHERE` clause. MySQL performs an additional check to filter out rows that satisfy the range condition but not the full `WHERE` clause.

The range condition extraction algorithm can handle nested `AND/OR` constructs of arbitrary depth, and its output does not depend on the order in which conditions appear in `WHERE` clause.

MySQL does not support merging multiple ranges for the `range` access method for spatial indexes. To work around this limitation, you can use a `UNION` with identical `SELECT` statements, except that you put each spatial predicate in a different `SELECT`.

## The Range Access Method for Multiple-Part Indexes

Range conditions on a multiple-part index are an extension of range conditions for a single-part index. A range condition on a multiple-part index restricts index rows to lie within one or several key tuple intervals. Key tuple intervals are defined over a set of key tuples, using ordering from the index.

For example, consider a multiple-part index defined as `key1(key_part1, key_part2, key_part3)`, and the following set of key tuples listed in key order:

| <i>key_part1</i> | <i>key_part2</i> | <i>key_part3</i> |
|------------------|------------------|------------------|
| NULL             | 1                | 'abc'            |
| NULL             | 1                | 'xyz'            |
| NULL             | 2                | 'foo'            |
| 1                | 1                | 'abc'            |
| 1                | 1                | 'xyz'            |
| 1                | 2                | 'abc'            |
| 2                | 1                | 'aaa'            |

The condition *key\_part1* = 1 defines this interval:

```
(1,-inf,-inf) <= (key_part1,key_part2,key_part3) < (1,+inf,+inf)
```

The interval covers the 4th, 5th, and 6th tuples in the preceding data set and can be used by the range access method.

By contrast, the condition *key\_part3* = 'abc' does not define a single interval and cannot be used by the range access method.

The following descriptions indicate how range conditions work for multiple-part indexes in greater detail.

- For [HASH](#) indexes, each interval containing identical values can be used. This means that the interval can be produced only for conditions in the following form:

```
key_part1 cmp const1
AND key_part2 cmp const2
AND ...
AND key_partN cmp constN;
```

Here, *const1*, *const2*, ... are constants, *cmp* is one of the =, <=>, or [IS NULL](#) comparison operators, and the conditions cover all index parts. (That is, there are *N* conditions, one for each part of an *N*-part index.) For example, the following is a range condition for a three-part [HASH](#) index:

```
key_part1 = 1 AND key_part2 IS NULL AND key_part3 = 'foo'
```

For the definition of what is considered to be a constant, see [The Range Access Method for Single-Part Indexes](#).

- For a [BTREE](#) index, an interval might be usable for conditions combined with [AND](#), where each condition compares a key part with a constant value using =, <=>, [IS NULL](#), >, <, >=, <=, !=, <>, [BETWEEN](#), or [LIKE](#) 'pattern' (where 'pattern' does not start with a wildcard). An interval can be used as long as it is possible to determine a single key tuple containing all rows that match the condition (or two intervals if <> or != is used).

The optimizer attempts to use additional key parts to determine the interval as long as the comparison operator is =, <=>, or [IS NULL](#). If the operator is >, <, >=, <=, !=, <>, [BETWEEN](#), or [LIKE](#), the optimizer uses it but considers no more key parts. For the following expression, the optimizer uses = from the first comparison. It also uses >= from the second comparison but considers no further key parts and does not use the third comparison for interval construction:

```
key_part1 = 'foo' AND key_part2 >= 10 AND key_part3 > 10
```

The single interval is:

```
('foo',10,-inf) < (key_part1,key_part2,key_part3) < ('foo',+inf,+inf)
```

It is possible that the created interval contains more rows than the initial condition. For example, the preceding interval includes the value ('foo', 11, 0), which does not satisfy the original condition.

- If conditions that cover sets of rows contained within intervals are combined with **OR**, they form a condition that covers a set of rows contained within the union of their intervals. If the conditions are combined with **AND**, they form a condition that covers a set of rows contained within the intersection of their intervals. For example, for this condition on a two-part index:

```
(key_part1 = 1 AND key_part2 < 2) OR (key_part1 > 5)
```

The intervals are:

```
(1,-inf) < (key_part1,key_part2) < (1,2)
(5,-inf) < (key_part1,key_part2)
```

In this example, the interval on the first line uses one key part for the left bound and two key parts for the right bound. The interval on the second line uses only one key part. The `key_len` column in the **EXPLAIN** output indicates the maximum length of the key prefix used.

In some cases, `key_len` may indicate that a key part was used, but that might be not what you would expect. Suppose that `key_part1` and `key_part2` can be **NULL**. Then the `key_len` column displays two key part lengths for the following condition:

```
key_part1 >= 1 AND key_part2 < 2
```

But, in fact, the condition is converted to this:

```
key_part1 >= 1 AND key_part2 IS NOT NULL
```

The [Range Access Method for Single-Part Indexes](#), describes how optimizations are performed to combine or eliminate intervals for range conditions on a single-part index. Analogous steps are performed for range conditions on multiple-part indexes.

## Equality Range Optimization of Many-Valued Comparisons

Consider these expressions, where `col_name` is an indexed column:

```
col_name IN(val1, ..., valN)
col_name = val1 OR ... OR col_name = valN
```

Each expression is true if `col_name` is equal to any of several values. These comparisons are equality range comparisons (where the “range” is a single value). The optimizer estimates the cost of reading qualifying rows for equality range comparisons as follows:

- If there is a unique index on `col_name`, the row estimate for each range is 1 because at most one row can have the given value.
- Otherwise, any index on `col_name` is nonunique and the optimizer can estimate the row count for each range using dives into the index or index statistics.

With index dives, the optimizer makes a dive at each end of a range and uses the number of rows in the range as the estimate. For example, the expression `col_name IN (10, 20, 30)` has three equality ranges and the optimizer makes two dives per range to generate a row estimate. Each pair of dives yields an estimate of the number of rows that have the given value.

Index dives provide accurate row estimates, but as the number of comparison values in the expression increases, the optimizer takes longer to generate a row estimate. Use of index statistics is less accurate than index dives but permits faster row estimation for large value lists.

The `eq_range_index_dive_limit` system variable enables you to configure the number of values at which the optimizer switches from one row estimation strategy to the other. To permit use of index dives for comparisons of up to *N* equality ranges, set `eq_range_index_dive_limit`

to  $N + 1$ . To disable use of statistics and always use index dives regardless of  $N$ , set `eq_range_index_dive_limit` to 0.

To update table index statistics for best estimates, use `ANALYZE TABLE`.

## Limiting Memory Use for Range Optimization

To control the memory available to the range optimizer, use the `range_optimizer_max_mem_size` system variable:

- A value of 0 means “no limit.”
- With a value greater than 0, the optimizer tracks the memory consumed when considering the range access method. If the specified limit is about to be exceeded, the range access method is abandoned and other methods, including a full table scan, are considered instead. This could be less optimal. If this happens, the following warning occurs (where  $N$  is the current `range_optimizer_max_mem_size` value):

```
Warning      3170      Memory capacity of N bytes for
                    'range_optimizer_max_mem_size' exceeded. Range
                    optimization was not done for this query.
```

For individual queries that exceed the available range optimization memory and for which the optimizer falls back to less optimal plans, increasing the `range_optimizer_max_mem_size` value may improve performance.

To estimate the amount of memory needed to process a range expression, use these guidelines:

- For a simple query such as the following, where there is one candidate key for the range access method, each predicate combined with `OR` uses approximately 230 bytes:

```
SELECT COUNT(*) FROM t
WHERE a=1 OR a=2 OR a=3 OR ... a=N;
```

- Similarly for a query such as the following, each predicate combined with `AND` uses approximately 125 bytes:

```
SELECT COUNT(*) FROM t
WHERE a=1 AND b=1 AND c=1 ... N;
```

- For a query with `IN()` predicates:

```
SELECT COUNT(*) FROM t
WHERE a IN (1,2, ..., M) AND b IN (1,2, ..., N);
```

Each literal value in an `IN()` list counts as a predicate combined with `OR`. If there are two `IN()` lists, the number of predicates combined with `OR` is the product of the number of literal values in each list. Thus, the number of predicates combined with `OR` in the preceding case is  $M \times N$ .

Before 5.7.11, the number of bytes per predicate combined with `OR` was higher, approximately 700 bytes.

Before MySQL 5.7.9 (that is, before the introduction of `range_optimizer_max_mem_size`), the optimizer had a hardcoded limit of 16,000 items that could be present in a `WHERE` clause. When this limit was reached, the optimizer abandoned the plan and considered other plans. A `range_optimizer_max_mem_size` value of 4MB in current MySQL versions corresponds approximately to the same 16,000 item limit applicable before MySQL 5.7.9.

However, note that before MySQL 5.7.9, if a query was written in a certain way, the limitation on the number of items used in a `WHERE` clause could be bypassed. For such queries as of 5.7.9, it may

be necessary to increase the `range_optimizer_max_mem_size` value to make the optimizer consider the range access method again. Also, memory utilized for items in a `WHERE` clause might vary depending on the way the condition is written. Hence, the preceding approximations should be used as guidelines only.

## Function Call Optimization

MySQL functions are tagged internally as deterministic or nondeterministic. A function is nondeterministic if, given fixed values for its arguments, it can return different results for different invocations. Examples of nondeterministic functions: `RAND()`, `UUID()`.

If a function is tagged nondeterministic, a reference to it in a `WHERE` clause is evaluated for every row (when selecting from one table) or combination of rows (when selecting from a multiple-table join).

MySQL also determines when to evaluate functions based on types of arguments, whether the arguments are table columns or constant values. A deterministic function that takes a table column as argument must be evaluated whenever that column changes value.

Nondeterministic functions may affect query performance. For example, some optimizations may not be available, or more locking might be required. The following discussion uses `RAND()` but applies to other nondeterministic functions as well.

Suppose that a table `t` has this definition:

```
CREATE TABLE t (id INT NOT NULL PRIMARY KEY, col_a VARCHAR(100));
```

Consider these two queries:

```
SELECT * FROM t WHERE id = POW(1,2);
SELECT * FROM t WHERE id = FLOOR(1 + RAND() * 49);
```

Both queries appear to use a primary key lookup because of the equality comparison against the primary key, but that is true only for the first of them:

- The first query always produces a maximum of one row because `POW()` with constant arguments is a constant value and is used for index lookup.
- The second query contains an expression that uses the nondeterministic function `RAND()`, which is not constant in the query but in fact has a new value for every row of table `t`. Consequently, the query reads every row of the table, evaluates the predicate for each row, and outputs all rows for which the primary key matches the random value. This might be zero, one, or multiple rows, depending on the `id` column values and the values in the `RAND()` sequence.

The effects of nondeterminism are not limited to `SELECT` statements. This `UPDATE` statement uses a nondeterministic function to select rows to be modified:

```
UPDATE t SET col_a = some_expr WHERE id = FLOOR(1 + RAND() * 49);
```

Presumably the intent is to update at most a single row for which the primary key matches the expression. However, it might update zero, one, or multiple rows, depending on the `id` column values and the values in the `RAND()` sequence.

The behavior just described has implications for performance and replication:

- Because a nondeterministic function does not produce a constant value, the optimizer cannot use strategies that might otherwise be applicable, such as index lookups. The result may be a table scan.
- `InnoDB` might escalate to a range-key lock rather than taking a single row lock for one matching row.

- Updates that do not execute deterministically are unsafe for replication.

The difficulties stem from the fact that the `RAND()` function is evaluated once for every row of the table. To avoid multiple function evaluations, use one of these techniques:

- Move the expression containing the nondeterministic function to a separate statement, saving the value in a variable. In the original statement, replace the expression with a reference to the variable, which the optimizer can treat as a constant value:

```
SET @keyval = FLOOR(1 + RAND() * 49);
UPDATE t SET col_a = some_expr WHERE id = @keyval;
```

- Assign the random value to a variable in a derived table. This technique causes the variable to be assigned a value, once, prior to its use in the comparison in the `WHERE` clause:

```
SET optimizer_switch = 'derived_merge=off'; -- MySQL 5.7.6 and higher only
UPDATE t, (SELECT @keyval := FLOOR(1 + RAND() * 49)) AS dt
SET col_a = some_expr WHERE id = @keyval;
```

Prior to MySQL 5.7.6, derived tables are always materialized, so the variable is assigned its value during materialization. In 5.7.6 and higher, achieve materialization by setting the `optimizer_switch` flag to prevent merging of the derived table into the outer query.

As mentioned previously, a nondeterministic expression in the `WHERE` clause might prevent optimizations and result in a table scan. However, it may be possible to bring the optimizer to bear partially if there are other `WHERE` expressions not involving nondeterminism. For example:

```
SELECT * FROM t WHERE partial_key=5 AND some_column=RAND();
```

If the optimizer can use `partial_key` to reduce the set of rows selected, `RAND()` is executed fewer times, which diminishes the effect of nondeterminism on optimization.

## Range Optimization of Row Constructor Expressions

As of MySQL 5.7.3, the optimizer is able to apply the range scan access method to queries of this form:

```
SELECT ... FROM t1 WHERE ( col_1, col_2 ) IN (( 'a', 'b' ), ( 'c', 'd' ));
```

Previously, for range scans to be used, it was necessary to write the query as:

```
SELECT ... FROM t1 WHERE ( col_1 = 'a' AND col_2 = 'b' )
OR ( col_1 = 'c' AND col_2 = 'd' );
```

For the optimizer to use a range scan, queries must satisfy these conditions:

- Only `IN()` predicates are used, not `NOT IN()`.
- On the left side of the `IN()` predicate, the row constructor contains only column references.
- On the right side of the `IN()` predicate, row constructors contain only runtime constants, which are either literals or local column references that are bound to constants during execution.
- On the right side of the `IN()` predicate, there is more than one row constructor.

Compared to similar queries executed before MySQL 5.7.3, `EXPLAIN` output for applicable queries changes from full table scan or index scan to range scan. Changes are also visible by checking the values of the `Handler_read_first`, `Handler_read_key`, and `Handler_read_next` status variables.

For more information about the optimizer and row constructors, see [Section 9.2.1.20, “Row Constructor Expression Optimization”](#)

### 9.2.1.4 Index Merge Optimization

The *Index Merge* method is used to retrieve rows with several [range](#) scans and to merge their results into one. The merge can produce unions, intersections, or unions-of-intersections of its underlying scans. This access method merges index scans from a single table; it does not merge scans across multiple tables.

In [EXPLAIN](#) output, the Index Merge method appears as [index\\_merge](#) in the [type](#) column. In this case, the [key](#) column contains a list of indexes used, and [key\\_len](#) contains a list of the longest key parts for those indexes.

Examples:

```
SELECT * FROM tbl_name WHERE key1 = 10 OR key2 = 20;

SELECT * FROM tbl_name
  WHERE (key1 = 10 OR key2 = 20) AND non_key=30;

SELECT * FROM t1, t2
  WHERE (t1.key1 IN (1,2) OR t1.key2 LIKE 'value%')
     AND t2.key1=t1.some_col;

SELECT * FROM t1, t2
  WHERE t1.key1=1
     AND (t2.key1=t1.some_col OR t2.key2=t1.some_col2);
```

The Index Merge method has several access algorithms (seen in the [Extra](#) field of [EXPLAIN](#) output):

- Using [intersect\(...\)](#)
- Using [union\(...\)](#)
- Using [sort\\_union\(...\)](#)

The following sections describe these methods in greater detail.

#### Note

The Index Merge optimization algorithm has the following known deficiencies:

- If your query has a complex [WHERE](#) clause with deep [AND/OR](#) nesting and MySQL does not choose the optimal plan, try distributing terms using the following identity laws:

```
(x AND y) OR z = (x OR z) AND (y OR z)
(x OR y) AND z = (x AND z) OR (y AND z)
```

- Index Merge is not applicable to full-text indexes. We plan to extend it to cover these in a future MySQL release.

The choice between different possible variants of the Index Merge access method and other access methods is based on cost estimates of various available options.

### The Index Merge Intersection Access Algorithm

This access algorithm can be employed when a [WHERE](#) clause was converted to several range conditions on different keys combined with [AND](#), and each condition is one of the following:

- In this form, where the index has exactly [N](#) parts (that is, all index parts are covered):

```
key_part1=const1 AND key_part2=const2 ... AND key_partN=constN
```

- Any range condition over a primary key of an [InnoDB](#) table.

Examples:

```
SELECT * FROM innodb_table WHERE primary_key < 10 AND key_coll=20;

SELECT * FROM tbl_name
WHERE (key1_part1=1 AND key1_part2=2) AND key2=2;
```

The Index Merge intersection algorithm performs simultaneous scans on all used indexes and produces the intersection of row sequences that it receives from the merged index scans.

If all columns used in the query are covered by the used indexes, full table rows are not retrieved ([EXPLAIN](#) output contains [Using index](#) in [Extra](#) field in this case). Here is an example of such a query:

```
SELECT COUNT(*) FROM t1 WHERE key1=1 AND key2=1;
```

If the used indexes do not cover all columns used in the query, full rows are retrieved only when the range conditions for all used keys are satisfied.

If one of the merged conditions is a condition over a primary key of an [InnoDB](#) table, it is not used for row retrieval, but is used to filter out rows retrieved using other conditions.

## The Index Merge Union Access Algorithm

The applicability criteria for this algorithm are similar to those for the Index Merge method intersection algorithm. The algorithm can be employed when the table's [WHERE](#) clause was converted to several range conditions on different keys combined with [OR](#), and each condition is one of the following:

- In this form, where the index has exactly *N* parts (that is, all index parts are covered):

```
key_part1=const1 AND key_part2=const2 ... AND key_partN=constN
```

- Any range condition over a primary key of an [InnoDB](#) table.
- A condition for which the Index Merge method intersection algorithm is applicable.

Examples:

```
SELECT * FROM t1 WHERE key1=1 OR key2=2 OR key3=3;

SELECT * FROM innodb_table WHERE (key1=1 AND key2=2) OR
(key3='foo' AND key4='bar') AND key5=5;
```

## The Index Merge Sort-Union Access Algorithm

This access algorithm is employed when the [WHERE](#) clause was converted to several range conditions combined by [OR](#), but for which the Index Merge method union algorithm is not applicable.

Examples:

```
SELECT * FROM tbl_name WHERE key_coll < 10 OR key_coll2 < 20;

SELECT * FROM tbl_name
WHERE (key_coll > 10 OR key_coll2 = 20) AND nonkey_coll=30;
```

The difference between the sort-union algorithm and the union algorithm is that the sort-union algorithm must first fetch row IDs for all rows and sort them before returning any rows.

### 9.2.1.5 Engine Condition Pushdown Optimization

This optimization improves the efficiency of direct comparisons between a nonindexed column and a constant. In such cases, the condition is “pushed down” to the storage engine for evaluation. This optimization can be used only by the [NDB](#) storage engine.

For MySQL Cluster, this optimization can eliminate the need to send nonmatching rows over the network between the cluster's data nodes and the MySQL Server that issued the query, and can speed up queries where it is used by a factor of 5 to 10 times over cases where condition pushdown could be but is not used.

Suppose that a MySQL Cluster table is defined as follows:

```
CREATE TABLE t1 (
  a INT,
  b INT,
  KEY(a)
) ENGINE=NDB;
```

Condition pushdown can be used with queries such as the one shown here, which includes a comparison between a nonindexed column and a constant:

```
SELECT a, b FROM t1 WHERE b = 10;
```

The use of condition pushdown can be seen in the output of [EXPLAIN](#):

```
mysql> EXPLAIN SELECT a,b FROM t1 WHERE b = 10\G
***** 1. row *****
      id: 1
    select_type: SIMPLE
        table: t1
         type: ALL
possible_keys: NULL
         key: NULL
        key_len: NULL
         ref: NULL
         rows: 10
      Extra: Using where with pushed condition
```

However, condition pushdown *cannot* be used with either of these two queries:

```
SELECT a,b FROM t1 WHERE a = 10;
SELECT a,b FROM t1 WHERE b + 1 = 10;
```

Condition pushdown is not applicable to the first query because an index exists on column [a](#). (An index access method would be more efficient and so would be chosen in preference to condition pushdown.) Condition pushdown cannot be employed for the second query because the comparison involving the nonindexed column [b](#) is indirect. (However, condition pushdown could be applied if you were to reduce [b + 1 = 10](#) to [b = 9](#) in the [WHERE](#) clause.)

Condition pushdown may also be employed when an indexed column is compared with a constant using a [>](#) or [<](#) operator:

```
mysql> EXPLAIN SELECT a, b FROM t1 WHERE a < 2\G
***** 1. row *****
      id: 1
    select_type: SIMPLE
        table: t1
```

```

    type: range
possible_keys: a
    key: a
    key_len: 5
    ref: NULL
    rows: 2
Extra: Using where with pushed condition

```

Other supported comparisons for condition pushdown include the following:

- `column [NOT] LIKE pattern`

`pattern` must be a string literal containing the pattern to be matched; for syntax, see [Section 13.5.1, “String Comparison Functions”](#).

- `column IS [NOT] NULL`
- `column IN (value_list)`

Each item in the `value_list` must be a constant, literal value.

- `column BETWEEN constant1 AND constant2`

`constant1` and `constant2` must each be a constant, literal value.

In all of the cases in the preceding list, it is possible for the condition to be converted into the form of one or more direct comparisons between a column and a constant.

Engine condition pushdown is enabled by default. To disable it at server startup, set the `optimizer_switch` system variable. For example, in a `my.cnf` file, use these lines:

```

[mysqld]
optimizer_switch=engine_condition_pushdown=off

```

At runtime, enable condition pushdown like this:

```

SET optimizer_switch='engine_condition_pushdown=off';

```

**Limitations.** Engine condition pushdown is subject to the following limitations:

- Condition pushdown is supported only by the [NDB](#) storage engine.
- Columns may be compared with constants only; however, this includes expressions which evaluate to constant values.
- Columns used in comparisons cannot be of any of the [BLOB](#) or [TEXT](#) types.
- A string value to be compared with a column must use the same collation as the column.
- Joins are not directly supported; conditions involving multiple tables are pushed separately where possible. Use extended [EXPLAIN](#) output to determine which conditions are actually pushed down. See [Section 9.8.3, “EXPLAIN EXTENDED Output Format”](#).

### 9.2.1.6 Index Condition Pushdown Optimization

Index Condition Pushdown (ICP) is an optimization for the case where MySQL retrieves rows from a table using an index. Without ICP, the storage engine traverses the index to locate rows in the base table and returns them to the MySQL server which evaluates the [WHERE](#) condition for the rows. With ICP enabled, and if parts of the [WHERE](#) condition can be evaluated by using only fields from the index, the MySQL server pushes this part of the [WHERE](#) condition down to the storage engine. The storage engine then evaluates the pushed index condition by using the index entry and only if this is satisfied is

the row read from the table. ICP can reduce the number of times the storage engine must access the base table and the number of times the MySQL server must access the storage engine.

Index Condition Pushdown optimization is used for the `range`, `ref`, `eq_ref`, and `ref_or_null` access methods when there is a need to access full table rows. This strategy can be used for `InnoDB` and `MyISAM` tables. Beginning with MySQL 5.7.3, it can also be used with partitioned `InnoDB` and `MyISAM` tables (Bug #17306882, Bug #70001). For `InnoDB` tables, however, ICP is used only for secondary indexes. The goal of ICP is to reduce the number of full-record reads and thereby reduce IO operations. For `InnoDB` clustered indexes, the complete record is already read into the `InnoDB` buffer. Using ICP in this case does not reduce IO.

The ICP optimization is not supported with secondary indexes created on generated virtual columns. `InnoDB` supports secondary indexes on generated virtual columns as of MySQL 5.7.8.

To see how this optimization works, consider first how an index scan proceeds when Index Condition Pushdown is not used:

1. Get the next row, first by reading the index tuple, and then by using the index tuple to locate and read the full table row.
2. Test the part of the `WHERE` condition that applies to this table. Accept or reject the row based on the test result.

When Index Condition Pushdown is used, the scan proceeds like this instead:

1. Get the next row's index tuple (but not the full table row).
2. Test the part of the `WHERE` condition that applies to this table and can be checked using only index columns. If the condition is not satisfied, proceed to the index tuple for the next row.
3. If the condition is satisfied, use the index tuple to locate and read the full table row.
4. Test the remaining part of the `WHERE` condition that applies to this table. Accept or reject the row based on the test result.

When Index Condition Pushdown is used, the `Extra` column in `EXPLAIN` output shows `Using index condition`. It will not show `Index only` because that does not apply when full table rows must be read.

Suppose that we have a table containing information about people and their addresses and that the table has an index defined as `INDEX (zipcode, lastname, firstname)`. If we know a person's `zipcode` value but are not sure about the last name, we can search like this:

```
SELECT * FROM people
WHERE zipcode='95054'
AND lastname LIKE '%etrunia%'
AND address LIKE '%Main Street%';
```

MySQL can use the index to scan through people with `zipcode='95054'`. The second part (`lastname LIKE '%etrunia%'`) cannot be used to limit the number of rows that must be scanned, so without Index Condition Pushdown, this query must retrieve full table rows for all the people who have `zipcode='95054'`.

With Index Condition Pushdown, MySQL will check the `lastname LIKE '%etrunia%'` part before reading the full table row. This avoids reading full rows corresponding to all index tuples that do not match the `lastname` condition.

Index Condition Pushdown is enabled by default; it can be controlled with the `optimizer_switch` system variable by setting the `index_condition_pushdown` flag. See [Section 9.9.2, “Controlling Switchable Optimizations”](#).

### 9.2.1.7 Use of Index Extensions

InnoDB automatically extends each secondary index by appending the primary key columns to it. Consider this table definition:

```
CREATE TABLE t1 (
  i1 INT NOT NULL DEFAULT 0,
  i2 INT NOT NULL DEFAULT 0,
  d DATE DEFAULT NULL,
  PRIMARY KEY (i1, i2),
  INDEX k_d (d)
) ENGINE = InnoDB;
```

This table defines the primary key on columns (*i1*, *i2*). It also defines a secondary index *k\_d* on column (*d*), but internally InnoDB extends this index and treats it as columns (*d*, *i1*, *i2*).

The optimizer takes into account the primary key columns of the extended secondary index when determining how and whether to use that index. This can result in more efficient query execution plans and better performance.

The optimizer can use extended secondary indexes for *ref*, *range*, and *index\_merge* index access, for loose index scans, for join and sorting optimization, and for *MIN()*/*MAX()* optimization.

The following example shows how execution plans are affected by whether the optimizer uses extended secondary indexes. Suppose that *t1* is populated with these rows:

```
INSERT INTO t1 VALUES
(1, 1, '1998-01-01'), (1, 2, '1999-01-01'),
(1, 3, '2000-01-01'), (1, 4, '2001-01-01'),
(1, 5, '2002-01-01'), (2, 1, '1998-01-01'),
(2, 2, '1999-01-01'), (2, 3, '2000-01-01'),
(2, 4, '2001-01-01'), (2, 5, '2002-01-01'),
(3, 1, '1998-01-01'), (3, 2, '1999-01-01'),
(3, 3, '2000-01-01'), (3, 4, '2001-01-01'),
(3, 5, '2002-01-01'), (4, 1, '1998-01-01'),
(4, 2, '1999-01-01'), (4, 3, '2000-01-01'),
(4, 4, '2001-01-01'), (4, 5, '2002-01-01'),
(5, 1, '1998-01-01'), (5, 2, '1999-01-01'),
(5, 3, '2000-01-01'), (5, 4, '2001-01-01'),
(5, 5, '2002-01-01');
```

Now consider this query:

```
EXPLAIN SELECT COUNT(*) FROM t1 WHERE i1 = 3 AND d = '2000-01-01'
```

The optimizer cannot use the primary key in this case because that comprises columns (*i1*, *i2*) and the query does not refer to *i2*. Instead, the optimizer can use the secondary index *k\_d* on (*d*), and the execution plan depends on whether the extended index is used.

When the optimizer does not consider index extensions, it treats the index *k\_d* as only (*d*). *EXPLAIN* for the query produces this result:

```
mysql> EXPLAIN SELECT COUNT(*) FROM t1 WHERE i1 = 3 AND d = '2000-01-01'\G
***** 1. row *****
      id: 1
    select_type: SIMPLE
        table: t1
         type: ref
possible_keys: PRIMARY,k_d
          key: k_d
        key_len: 4
         ref: const
```

```
rows: 5
Extra: Using where; Using index
```

When the optimizer takes index extensions into account, it treats `k_d` as `(d, i1, i2)`. In this case, it can use the leftmost index prefix `(d, i1)` to produce a better execution plan:

```
mysql> EXPLAIN SELECT COUNT(*) FROM t1 WHERE i1 = 3 AND d = '2000-01-01'\G
***** 1. row *****
      id: 1
    select_type: SIMPLE
        table: t1
         type: ref
possible_keys: PRIMARY,k_d
         key: k_d
        key_len: 8
         ref: const,const
         rows: 1
        Extra: Using index
```

In both cases, `key` indicates that the optimizer will use secondary index `k_d` but the `EXPLAIN` output shows these improvements from using the extended index:

- `key_len` goes from 4 bytes to 8 bytes, indicating that key lookups use columns `d` and `i1`, not just `d`.
- The `ref` value changes from `const` to `const,const` because the key lookup uses two key parts, not one.
- The `rows` count decreases from 5 to 1, indicating that `InnoDB` should need to examine fewer rows to produce the result.
- The `Extra` value changes from `Using where; Using index` to `Using index`. This means that rows can be read using only the index, without consulting columns in the data row.

Differences in optimizer behavior for use of extended indexes can also be seen with `SHOW STATUS`:

```
FLUSH TABLE t1;
FLUSH STATUS;
SELECT COUNT(*) FROM t1 WHERE i1 = 3 AND d = '2000-01-01';
SHOW STATUS LIKE 'handler_read%'
```

The preceding statements include `FLUSH TABLE` and `FLUSH STATUS` to flush the table cache and clear the status counters.

Without index extensions, `SHOW STATUS` produces this result:

| Variable_name         | Value |
|-----------------------|-------|
| Handler_read_first    | 0     |
| Handler_read_key      | 1     |
| Handler_read_last     | 0     |
| Handler_read_next     | 5     |
| Handler_read_prev     | 0     |
| Handler_read_rnd      | 0     |
| Handler_read_rnd_next | 0     |

With index extensions, `SHOW STATUS` produces this result. The `Handler_read_next` value decreases from 5 to 1, indicating more efficient use of the index:

| Variable_name         | Value |
|-----------------------|-------|
| Handler_read_first    | 0     |
| Handler_read_key      | 1     |
| Handler_read_last     | 0     |
| Handler_read_next     | 1     |
| Handler_read_prev     | 0     |
| Handler_read_rnd      | 0     |
| Handler_read_rnd_next | 0     |

|                       |   |  |
|-----------------------|---|--|
| Handler_read_first    | 0 |  |
| Handler_read_key      | 1 |  |
| Handler_read_last     | 0 |  |
| Handler_read_next     | 1 |  |
| Handler_read_prev     | 0 |  |
| Handler_read_rnd      | 0 |  |
| Handler_read_rnd_next | 0 |  |
| +-----+-----+         |   |  |

The `use_index_extensions` flag of the `optimizer_switch` system variable permits control over whether the optimizer takes the primary key columns into account when determining how to use an InnoDB table's secondary indexes. By default, `use_index_extensions` is enabled. To check whether disabling use of index extensions will improve performance, use this statement:

```
SET optimizer_switch = 'use_index_extensions=off';
```

Use of index extensions by the optimizer is subject to the usual limits on the number of key parts in an index (16) and the maximum key length (3072 bytes).

### 9.2.1.8 IS NULL Optimization

MySQL can perform the same optimization on `col_name IS NULL` that it can use for `col_name = constant_value`. For example, MySQL can use indexes and ranges to search for `NULL` with `IS NULL`.

Examples:

```
SELECT * FROM tbl_name WHERE key_col IS NULL;

SELECT * FROM tbl_name WHERE key_col <=> NULL;

SELECT * FROM tbl_name
WHERE key_col=const1 OR key_col=const2 OR key_col IS NULL;
```

If a `WHERE` clause includes a `col_name IS NULL` condition for a column that is declared as `NOT NULL`, that expression is optimized away. This optimization does not occur in cases when the column might produce `NULL` anyway; for example, if it comes from a table on the right side of a `LEFT JOIN`.

MySQL can also optimize the combination `col_name = expr OR col_name IS NULL`, a form that is common in resolved subqueries. `EXPLAIN` shows `ref_or_null` when this optimization is used.

This optimization can handle one `IS NULL` for any key part.

Some examples of queries that are optimized, assuming that there is an index on columns `a` and `b` of table `t2`:

```
SELECT * FROM t1 WHERE t1.a=expr OR t1.a IS NULL;

SELECT * FROM t1, t2 WHERE t1.a=t2.a OR t2.a IS NULL;

SELECT * FROM t1, t2
WHERE (t1.a=t2.a OR t2.a IS NULL) AND t2.b=t1.b;

SELECT * FROM t1, t2
WHERE t1.a=t2.a AND (t2.b=t1.b OR t2.b IS NULL);

SELECT * FROM t1, t2
WHERE (t1.a=t2.a AND t2.a IS NULL AND ...)
OR (t1.a=t2.a AND t2.a IS NULL AND ...);
```

`ref_or_null` works by first doing a read on the reference key, and then a separate search for rows with a `NULL` key value.

The optimization can handle only one `IS NULL` level. In the following query, MySQL uses key lookups only on the expression `(t1.a=t2.a AND t2.a IS NULL)` and is not able to use the key part on `b`:

```
SELECT * FROM t1, t2
WHERE (t1.a=t2.a AND t2.a IS NULL)
OR (t1.b=t2.b AND t2.b IS NULL);
```

### 9.2.1.9 LEFT JOIN and RIGHT JOIN Optimization

MySQL implements an `A LEFT JOIN B join_condition` as follows:

- Table `B` is set to depend on table `A` and all tables on which `A` depends.
- Table `A` is set to depend on all tables (except `B`) that are used in the `LEFT JOIN` condition.
- The `LEFT JOIN` condition is used to decide how to retrieve rows from table `B`. (In other words, any condition in the `WHERE` clause is not used.)
- All standard join optimizations are performed, with the exception that a table is always read after all tables on which it depends. If there is a circular dependence, MySQL issues an error.
- All standard `WHERE` optimizations are performed.
- If there is a row in `A` that matches the `WHERE` clause, but there is no row in `B` that matches the `ON` condition, an extra `B` row is generated with all columns set to `NULL`.
- If you use `LEFT JOIN` to find rows that do not exist in some table and you have the following test: `col_name IS NULL` in the `WHERE` part, where `col_name` is a column that is declared as `NOT NULL`, MySQL stops searching for more rows (for a particular key combination) after it has found one row that matches the `LEFT JOIN` condition.

The implementation of `RIGHT JOIN` is analogous to that of `LEFT JOIN` with the roles of the tables reversed.

The join optimizer calculates the order in which tables should be joined. The table read order forced by `LEFT JOIN` or `STRAIGHT_JOIN` helps the join optimizer do its work much more quickly, because there are fewer table permutations to check. Note that this means that if you do a query of the following type, MySQL does a full scan on `b` because the `LEFT JOIN` forces it to be read before `d`:

```
SELECT *
FROM a JOIN b LEFT JOIN c ON (c.key=a.key)
LEFT JOIN d ON (d.key=a.key)
WHERE b.key=d.key;
```

The fix in this case is reverse the order in which `a` and `b` are listed in the `FROM` clause:

```
SELECT *
FROM b JOIN a LEFT JOIN c ON (c.key=a.key)
LEFT JOIN d ON (d.key=a.key)
WHERE b.key=d.key;
```

For a `LEFT JOIN`, if the `WHERE` condition is always false for the generated `NULL` row, the `LEFT JOIN` is changed to a normal join. For example, the `WHERE` clause would be false in the following query if `t2.column1` were `NULL`:

```
SELECT * FROM t1 LEFT JOIN t2 ON (column1) WHERE t2.column2=5;
```

Therefore, it is safe to convert the query to a normal join:

```
SELECT * FROM t1, t2 WHERE t2.column2=5 AND t1.column1=t2.column1;
```

This can be made faster because MySQL can use table `t2` before table `t1` if doing so would result in a better query plan. To provide a hint about the table join order, use `STRAIGHT_JOIN`. (See [Section 14.2.9, “SELECT Syntax”](#).) (However, `STRAIGHT_JOIN` may prevent indexes from being used because it disables semi-join transformations. See [Optimizing Subqueries with Semi-Join Transformations](#).)

### 9.2.1.10 Nested-Loop Join Algorithms

MySQL executes joins between tables using a nested-loop algorithm or variations on it.

#### Nested-Loop Join Algorithm

A simple nested-loop join (NLJ) algorithm reads rows from the first table in a loop one at a time, passing each row to a nested loop that processes the next table in the join. This process is repeated as many times as there remain tables to be joined.

Assume that a join between three tables `t1`, `t2`, and `t3` is to be executed using the following join types:

| Table           | Join Type          |
|-----------------|--------------------|
| <code>t1</code> | <code>range</code> |
| <code>t2</code> | <code>ref</code>   |
| <code>t3</code> | <code>ALL</code>   |

If a simple NLJ algorithm is used, the join is processed like this:

```
for each row in t1 matching range {
  for each row in t2 matching reference key {
    for each row in t3 {
      if row satisfies join conditions,
        send to client
    }
  }
}
```

Because the NLJ algorithm passes rows one at a time from outer loops to inner loops, it typically reads tables processed in the inner loops many times.

#### Block Nested-Loop Join Algorithm

A Block Nested-Loop (BNL) join algorithm uses buffering of rows read in outer loops to reduce the number of times that tables in inner loops must be read. For example, if 10 rows are read into a buffer and the buffer is passed to the next inner loop, each row read in the inner loop can be compared against all 10 rows in the buffer. This reduces the number of times the inner table must be read by an order of magnitude.

MySQL uses join buffering under these conditions:

- The `join_buffer_size` system variable determines the size of each join buffer.
- Join buffering can be used when the join is of type `ALL` or `index` (in other words, when no possible keys can be used, and a full scan is done, of either the data or index rows, respectively), or `range`. Use of buffering is also applicable to outer joins, as described in [Section 9.2.1.14, “Block Nested-Loop and Batched Key Access Joins”](#).
- One buffer is allocated for each join that can be buffered, so a given query might be processed using multiple join buffers.
- A join buffer is never allocated for the first nonconst table, even if it would be of type `ALL` or `index`.

- A join buffer is allocated prior to executing the join and freed after the query is done.
- Only columns of interest to the join are stored in the join buffer, not whole rows.

For the example join described previously for the NLJ algorithm (without buffering), the join is done as follow using join buffering:

```
for each row in t1 matching range {
  for each row in t2 matching reference key {
    store used columns from t1, t2 in join buffer
    if buffer is full {
      for each row in t3 {
        for each t1, t2 combination in join buffer {
          if row satisfies join conditions,
            send to client
        }
      }
      empty buffer
    }
  }
}

if buffer is not empty {
  for each row in t3 {
    for each t1, t2 combination in join buffer {
      if row satisfies join conditions,
        send to client
    }
  }
}
```

If  $S$  is the size of each stored  $t1, t2$  combination in the join buffer and  $C$  is the number of combinations in the buffer, the number of times table  $t3$  is scanned is:

$$(S * C) / \text{join\_buffer\_size} + 1$$

The number of  $t3$  scans decreases as the value of `join_buffer_size` increases, up to the point when `join_buffer_size` is large enough to hold all previous row combinations. At that point, there is no speed to be gained by making it larger.

### 9.2.1.11 Nested Join Optimization

The syntax for expressing joins permits nested joins. The following discussion refers to the join syntax described in [Section 14.2.9.2, “JOIN Syntax”](#).

The syntax of *table\_factor* is extended in comparison with the SQL Standard. The latter accepts only *table\_reference*, not a list of them inside a pair of parentheses. This is a conservative extension if we consider each comma in a list of *table\_reference* items as equivalent to an inner join. For example:

```
SELECT * FROM t1 LEFT JOIN (t2, t3, t4)
      ON (t2.a=t1.a AND t3.b=t1.b AND t4.c=t1.c)
```

is equivalent to:

```
SELECT * FROM t1 LEFT JOIN (t2 CROSS JOIN t3 CROSS JOIN t4)
      ON (t2.a=t1.a AND t3.b=t1.b AND t4.c=t1.c)
```

In MySQL, `CROSS JOIN` is a syntactic equivalent to `INNER JOIN` (they can replace each other). In standard SQL, they are not equivalent. `INNER JOIN` is used with an `ON` clause; `CROSS JOIN` is used otherwise.

In general, parentheses can be ignored in join expressions containing only inner join operations. After removing parentheses and grouping operations to the left, the join expression:

```
t1 LEFT JOIN (t2 LEFT JOIN t3 ON t2.b=t3.b OR t2.b IS NULL)
ON t1.a=t2.a
```

transforms into the expression:

```
(t1 LEFT JOIN t2 ON t1.a=t2.a) LEFT JOIN t3
ON t2.b=t3.b OR t2.b IS NULL
```

Yet, the two expressions are not equivalent. To see this, suppose that the tables `t1`, `t2`, and `t3` have the following state:

- Table `t1` contains rows (1), (2)
- Table `t2` contains row (1,101)
- Table `t3` contains row (101)

In this case, the first expression returns a result set including the rows (1,1,101,101), (2,NULL,NULL,NULL), whereas the second expression returns the rows (1,1,101,101), (2,NULL,NULL,101):

```
mysql> SELECT *
-> FROM t1
-> LEFT JOIN
-> (t2 LEFT JOIN t3 ON t2.b=t3.b OR t2.b IS NULL)
-> ON t1.a=t2.a;
+-----+-----+-----+-----+
| a | a | b | b |
+-----+-----+-----+-----+
| 1 | 1 | 101 | 101 |
| 2 | NULL | NULL | NULL |
+-----+-----+-----+-----+

mysql> SELECT *
-> FROM (t1 LEFT JOIN t2 ON t1.a=t2.a)
-> LEFT JOIN t3
-> ON t2.b=t3.b OR t2.b IS NULL;
+-----+-----+-----+-----+
| a | a | b | b |
+-----+-----+-----+-----+
| 1 | 1 | 101 | 101 |
| 2 | NULL | NULL | 101 |
+-----+-----+-----+-----+
```

In the following example, an outer join operation is used together with an inner join operation:

```
t1 LEFT JOIN (t2, t3) ON t1.a=t2.a
```

That expression cannot be transformed into the following expression:

```
t1 LEFT JOIN t2 ON t1.a=t2.a, t3.
```

For the given table states, the two expressions return different sets of rows:

```
mysql> SELECT *
-> FROM t1 LEFT JOIN (t2, t3) ON t1.a=t2.a;
+-----+-----+-----+-----+
| a | a | b | b |
+-----+-----+-----+-----+
```

|   |      |      |      |
|---|------|------|------|
| 1 | 1    | 101  | 101  |
| 2 | NULL | NULL | NULL |

```
mysql> SELECT *
-> FROM t1 LEFT JOIN t2 ON t1.a=t2.a, t3;
```

|   |      |      |     |
|---|------|------|-----|
| a | a    | b    | b   |
| 1 | 1    | 101  | 101 |
| 2 | NULL | NULL | 101 |

Therefore, if we omit parentheses in a join expression with outer join operators, we might change the result set for the original expression.

More exactly, we cannot ignore parentheses in the right operand of the left outer join operation and in the left operand of a right join operation. In other words, we cannot ignore parentheses for the inner table expressions of outer join operations. Parentheses for the other operand (operand for the outer table) can be ignored.

The following expression:

```
(t1,t2) LEFT JOIN t3 ON P(t2.b,t3.b)
```

is equivalent to this expression:

```
t1, t2 LEFT JOIN t3 ON P(t2.b,t3.b)
```

for any tables `t1`, `t2`, `t3` and any condition `P` over attributes `t2.b` and `t3.b`.

Whenever the order of execution of the join operations in a join expression (*join\_table*) is not from left to right, we talk about nested joins. Consider the following queries:

```
SELECT * FROM t1 LEFT JOIN (t2 LEFT JOIN t3 ON t2.b=t3.b) ON t1.a=t2.a
WHERE t1.a > 1

SELECT * FROM t1 LEFT JOIN (t2, t3) ON t1.a=t2.a
WHERE (t2.b=t3.b OR t2.b IS NULL) AND t1.a > 1
```

Those queries are considered to contain these nested joins:

```
t2 LEFT JOIN t3 ON t2.b=t3.b
t2, t3
```

The nested join is formed in the first query with a left join operation, whereas in the second query it is formed with an inner join operation.

In the first query, the parentheses can be omitted: The grammatical structure of the join expression will dictate the same order of execution for join operations. For the second query, the parentheses cannot be omitted, although the join expression here can be interpreted unambiguously without them. (In our extended syntax the parentheses in `(t2, t3)` of the second query are required, although theoretically the query could be parsed without them: We still would have unambiguous syntactical structure for the query because `LEFT JOIN` and `ON` would play the role of the left and right delimiters for the expression `(t2,t3).`)

The preceding examples demonstrate these points:

- For join expressions involving only inner joins (and not outer joins), parentheses can be removed. You can remove parentheses and evaluate left to right (or, in fact, you can evaluate the tables in any order).

- The same is not true, in general, for outer joins or for outer joins mixed with inner joins. Removal of parentheses may change the result.

Queries with nested outer joins are executed in the same pipeline manner as queries with inner joins. More exactly, a variation of the nested-loop join algorithm is exploited. Recall by what algorithmic schema the nested-loop join executes a query. Suppose that we have a join query over 3 tables  $T_1, T_2, T_3$  of the form:

```
SELECT * FROM T1 INNER JOIN T2 ON P1(T1,T2)
          INNER JOIN T3 ON P2(T2,T3)
WHERE P(T1,T2,T3).
```

Here,  $P_1(T_1, T_2)$  and  $P_2(T_2, T_3)$  are some join conditions (on expressions), whereas  $P(T_1, T_2, T_3)$  is a condition over columns of tables  $T_1, T_2, T_3$ .

The nested-loop join algorithm would execute this query in the following manner:

```
FOR each row t1 in T1 {
  FOR each row t2 in T2 such that P1(t1,t2) {
    FOR each row t3 in T3 such that P2(t2,t3) {
      IF P(t1,t2,t3) {
        t:=t1||t2||t3; OUTPUT t;
      }
    }
  }
}
```

The notation  $t1 || t2 || t3$  means “a row constructed by concatenating the columns of rows  $t_1$ ,  $t_2$ , and  $t_3$ .” In some of the following examples,  $NULL$  where a row name appears means that  $NULL$  is used for each column of that row. For example,  $t1 || t2 || NULL$  means “a row constructed by concatenating the columns of rows  $t_1$  and  $t_2$ , and  $NULL$  for each column of  $t_3$ .”

Now let's consider a query with nested outer joins:

```
SELECT * FROM T1 LEFT JOIN
          (T2 LEFT JOIN T3 ON P2(T2,T3))
          ON P1(T1,T2)
WHERE P(T1,T2,T3).
```

For this query, we modify the nested-loop pattern to get:

```
FOR each row t1 in T1 {
  BOOL f1:=FALSE;
  FOR each row t2 in T2 such that P1(t1,t2) {
    BOOL f2:=FALSE;
    FOR each row t3 in T3 such that P2(t2,t3) {
      IF P(t1,t2,t3) {
        t:=t1||t2||t3; OUTPUT t;
      }
      f2=TRUE;
    }
    f1=TRUE;
  }
  IF (!f2) {
    IF P(t1,t2,NULL) {
      t:=t1||t2||NULL; OUTPUT t;
    }
    f1=TRUE;
  }
}
IF (!f1) {
  IF P(t1,NULL,NULL) {
    t:=t1||NULL||NULL; OUTPUT t;
  }
}
```

```
}
}
}
```

In general, for any nested loop for the first inner table in an outer join operation, a flag is introduced that is turned off before the loop and is checked after the loop. The flag is turned on when for the current row from the outer table a match from the table representing the inner operand is found. If at the end of the loop cycle the flag is still off, no match has been found for the current row of the outer table. In this case, the row is complemented by `NULL` values for the columns of the inner tables. The result row is passed to the final check for the output or into the next nested loop, but only if the row satisfies the join condition of all embedded outer joins.

In our example, the outer join table expressed by the following expression is embedded:

```
(T2 LEFT JOIN T3 ON P2(T2,T3))
```

For the query with inner joins, the optimizer could choose a different order of nested loops, such as this one:

```
FOR each row t3 in T3 {
  FOR each row t2 in T2 such that P2(t2,t3) {
    FOR each row t1 in T1 such that P1(t1,t2) {
      IF P(t1,t2,t3) {
        t:=t1||t2||t3; OUTPUT t;
      }
    }
  }
}
```

For the queries with outer joins, the optimizer can choose only such an order where loops for outer tables precede loops for inner tables. Thus, for our query with outer joins, only one nesting order is possible. For the following query, the optimizer will evaluate two different nestings:

```
SELECT * T1 LEFT JOIN (T2,T3) ON P1(T1,T2) AND P2(T1,T3)
WHERE P(T1,T2,T3)
```

The nestings are these:

```
FOR each row t1 in T1 {
  BOOL f1:=FALSE;
  FOR each row t2 in T2 such that P1(t1,t2) {
    FOR each row t3 in T3 such that P2(t1,t3) {
      IF P(t1,t2,t3) {
        t:=t1||t2||t3; OUTPUT t;
      }
      f1:=TRUE
    }
  }
  IF (!f1) {
    IF P(t1,NULL,NULL) {
      t:=t1||NULL||NULL; OUTPUT t;
    }
  }
}
```

and:

```
FOR each row t1 in T1 {
  BOOL f1:=FALSE;
  FOR each row t3 in T3 such that P2(t1,t3) {
    FOR each row t2 in T2 such that P1(t1,t2) {
      IF P(t1,t2,t3) {
```

```

        t:=t1||t2||t3; OUTPUT t;
    }
    f1:=TRUE
  }
}
IF (!f1) {
  IF P(t1,NULL,NULL) {
    t:=t1||NULL||NULL; OUTPUT t;
  }
}
}
}

```

In both nestings, **T1** must be processed in the outer loop because it is used in an outer join. **T2** and **T3** are used in an inner join, so that join must be processed in the inner loop. However, because the join is an inner join, **T2** and **T3** can be processed in either order.

When discussing the nested-loop algorithm for inner joins, we omitted some details whose impact on the performance of query execution may be huge. We did not mention so-called “pushed-down” conditions. Suppose that our **WHERE** condition **P(T1, T2, T3)** can be represented by a conjunctive formula:

```
P(T1,T2,T2) = C1(T1) AND C2(T2) AND C3(T3).
```

In this case, MySQL actually uses the following nested-loop schema for the execution of the query with inner joins:

```

FOR each row t1 in T1 such that C1(t1) {
  FOR each row t2 in T2 such that P1(t1,t2) AND C2(t2) {
    FOR each row t3 in T3 such that P2(t2,t3) AND C3(t3) {
      IF P(t1,t2,t3) {
        t:=t1||t2||t3; OUTPUT t;
      }
    }
  }
}

```

You see that each of the conjuncts **C1(T1)**, **C2(T2)**, **C3(T3)** are pushed out of the most inner loop to the most outer loop where it can be evaluated. If **C1(T1)** is a very restrictive condition, this condition pushdown may greatly reduce the number of rows from table **T1** passed to the inner loops. As a result, the execution time for the query may improve immensely.

For a query with outer joins, the **WHERE** condition is to be checked only after it has been found that the current row from the outer table has a match in the inner tables. Thus, the optimization of pushing conditions out of the inner nested loops cannot be applied directly to queries with outer joins. Here we have to introduce conditional pushed-down predicates guarded by the flags that are turned on when a match has been encountered.

For our example with outer joins with:

```
P(T1,T2,T3)=C1(T1) AND C(T2) AND C3(T3)
```

the nested-loop schema using guarded pushed-down conditions looks like this:

```

FOR each row t1 in T1 such that C1(t1) {
  BOOL f1:=FALSE;
  FOR each row t2 in T2
    such that P1(t1,t2) AND (f1?C2(t2):TRUE) {
    BOOL f2:=FALSE;
    FOR each row t3 in T3
      such that P2(t2,t3) AND (f1&&f2?C3(t3):TRUE) {
        IF (f1&&f2?TRUE:(C2(t2) AND C3(t3))) {
          t:=t1||t2||t3; OUTPUT t;
        }
      }
    }
  }
}

```

```

    }
    f2=TRUE;
    f1=TRUE;
  }
  IF (!f2) {
    IF (f1?TRUE:C2(t2) && P(t1,t2,NULL)) {
      t:=t1||t2||NULL; OUTPUT t;
    }
    f1=TRUE;
  }
}
IF (!f1 && P(t1,NULL,NULL)) {
  t:=t1||NULL||NULL; OUTPUT t;
}
}

```

In general, pushed-down predicates can be extracted from join conditions such as `P1(T1,T2)` and `P(T2,T3)`. In this case, a pushed-down predicate is guarded also by a flag that prevents checking the predicate for the `NULL`-complemented row generated by the corresponding outer join operation.

Access by key from one inner table to another in the same nested join is prohibited if it is induced by a predicate from the `WHERE` condition. (We could use conditional key access in this case, but this technique is not employed yet in MySQL.)

### 9.2.1.12 Outer Join Simplification

Table expressions in the `FROM` clause of a query are simplified in many cases.

At the parser stage, queries with right outer joins operations are converted to equivalent queries containing only left join operations. In the general case, the conversion is performed according to the following rule:

```

(T1, ...) RIGHT JOIN (T2,...) ON P(T1,...,T2,...) =
(T2, ...) LEFT JOIN (T1,...) ON P(T1,...,T2,...)

```

All inner join expressions of the form `T1 INNER JOIN T2 ON P(T1,T2)` are replaced by the list `T1,T2,P(T1,T2)` being joined as a conjunct to the `WHERE` condition (or to the join condition of the embedding join, if there is any).

When the optimizer evaluates plans for join queries with outer join operation, it takes into consideration only the plans where, for each such operation, the outer tables are accessed before the inner tables. The optimizer options are limited because only such plans enables us to execute queries with outer joins operations by the nested loop schema.

Suppose that we have a query of the form:

```

SELECT * T1 LEFT JOIN T2 ON P1(T1,T2)
WHERE P(T1,T2) AND R(T2)

```

with `R(T2)` narrowing greatly the number of matching rows from table `T2`. If we executed the query as it is, the optimizer would have no other choice besides to access table `T1` before table `T2` that may lead to a very inefficient execution plan.

Fortunately, MySQL converts such a query into a query without an outer join operation if the `WHERE` condition is null-rejected. A condition is called null-rejected for an outer join operation if it evaluates to `FALSE` or to `UNKNOWN` for any `NULL`-complemented row built for the operation.

Thus, for this outer join:

```

T1 LEFT JOIN T2 ON T1.A=T2.A

```

Conditions such as these are null-rejected:

```
T2.B IS NOT NULL,
T2.B > 3,
T2.C <= T1.C,
T2.B < 2 OR T2.C > 1
```

Conditions such as these are not null-rejected:

```
T2.B IS NULL,
T1.B < 3 OR T2.B IS NOT NULL,
T1.B < 3 OR T2.B > 3
```

The general rules for checking whether a condition is null-rejected for an outer join operation are simple. A condition is null-rejected in the following cases:

- If it is of the form `A IS NOT NULL`, where `A` is an attribute of any of the inner tables
- If it is a predicate containing a reference to an inner table that evaluates to `UNKNOWN` when one of its arguments is `NULL`
- If it is a conjunction containing a null-rejected condition as a conjunct
- If it is a disjunction of null-rejected conditions

A condition can be null-rejected for one outer join operation in a query and not null-rejected for another. In the query:

```
SELECT * FROM T1 LEFT JOIN T2 ON T2.A=T1.A
                LEFT JOIN T3 ON T3.B=T1.B
WHERE T3.C > 0
```

the `WHERE` condition is null-rejected for the second outer join operation but is not null-rejected for the first one.

If the `WHERE` condition is null-rejected for an outer join operation in a query, the outer join operation is replaced by an inner join operation.

For example, the preceding query is replaced with the query:

```
SELECT * FROM T1 LEFT JOIN T2 ON T2.A=T1.A
                INNER JOIN T3 ON T3.B=T1.B
WHERE T3.C > 0
```

For the original query, the optimizer would evaluate plans compatible with only one access order `T1, T2, T3`. For the replacing query, it additionally considers the access sequence `T3, T1, T2`.

A conversion of one outer join operation may trigger a conversion of another. Thus, the query:

```
SELECT * FROM T1 LEFT JOIN T2 ON T2.A=T1.A
                LEFT JOIN T3 ON T3.B=T2.B
WHERE T3.C > 0
```

will be first converted to the query:

```
SELECT * FROM T1 LEFT JOIN T2 ON T2.A=T1.A
                INNER JOIN T3 ON T3.B=T2.B
WHERE T3.C > 0
```

which is equivalent to the query:

```
SELECT * FROM (T1 LEFT JOIN T2 ON T2.A=T1.A), T3
WHERE T3.C > 0 AND T3.B=T2.B
```

Now the remaining outer join operation can be replaced by an inner join, too, because the condition `T3.B=T2.B` is null-rejected and we get a query without outer joins at all:

```
SELECT * FROM (T1 INNER JOIN T2 ON T2.A=T1.A), T3
WHERE T3.C > 0 AND T3.B=T2.B
```

Sometimes we succeed in replacing an embedded outer join operation, but cannot convert the embedding outer join. The following query:

```
SELECT * FROM T1 LEFT JOIN
      (T2 LEFT JOIN T3 ON T3.B=T2.B)
      ON T2.A=T1.A
WHERE T3.C > 0
```

is converted to:

```
SELECT * FROM T1 LEFT JOIN
      (T2 INNER JOIN T3 ON T3.B=T2.B)
      ON T2.A=T1.A
WHERE T3.C > 0,
```

That can be rewritten only to the form still containing the embedding outer join operation:

```
SELECT * FROM T1 LEFT JOIN
      (T2,T3)
      ON (T2.A=T1.A AND T3.B=T2.B)
WHERE T3.C > 0.
```

When trying to convert an embedded outer join operation in a query, we must take into account the join condition for the embedding outer join together with the `WHERE` condition. In the query:

```
SELECT * FROM T1 LEFT JOIN
      (T2 LEFT JOIN T3 ON T3.B=T2.B)
      ON T2.A=T1.A AND T3.C=T1.C
WHERE T3.D > 0 OR T1.D > 0
```

the `WHERE` condition is not null-rejected for the embedded outer join, but the join condition of the embedding outer join `T2.A=T1.A AND T3.C=T1.C` is null-rejected. So the query can be converted to:

```
SELECT * FROM T1 LEFT JOIN
      (T2, T3)
      ON T2.A=T1.A AND T3.C=T1.C AND T3.B=T2.B
WHERE T3.D > 0 OR T1.D > 0
```

### 9.2.1.13 Multi-Range Read Optimization

Reading rows using a range scan on a secondary index can result in many random disk accesses to the base table when the table is large and not stored in the storage engine's cache. With the Disk-Sweep Multi-Range Read (MRR) optimization, MySQL tries to reduce the number of random disk access for range scans by first scanning the index only and collecting the keys for the relevant rows. Then the keys are sorted and finally the rows are retrieved from the base table using the order of the primary key. The motivation for Disk-sweep MRR is to reduce the number of random disk accesses and instead achieve a more sequential scan of the base table data.

The Multi-Range Read optimization provides these benefits:

- MRR enables data rows to be accessed sequentially rather than in random order, based on index tuples. The server obtains a set of index tuples that satisfy the query conditions, sorts them according to data row ID order, and uses the sorted tuples to retrieve data rows in order. This makes data access more efficient and less expensive.
- MRR enables batch processing of requests for key access for operations that require access to data rows through index tuples, such as range index scans and equi-joins that use an index for the join attribute. MRR iterates over a sequence of index ranges to obtain qualifying index tuples. As these results accumulate, they are used to access the corresponding data rows. It is not necessary to acquire all index tuples before starting to read data rows.

The MRR optimization is not supported with secondary indexes created on generated virtual columns. [InnoDB](#) supports secondary indexes on generated virtual columns as of MySQL 5.7.8.

The following scenarios illustrate when MRR optimization can be advantageous:

Scenario A: MRR can be used for [InnoDB](#) and [MyISAM](#) tables for index range scans and equi-join operations.

1. A portion of the index tuples are accumulated in a buffer.
2. The tuples in the buffer are sorted by their data row ID.
3. Data rows are accessed according to the sorted index tuple sequence.

Scenario B: MRR can be used for [NDB](#) tables for multiple-range index scans or when performing an equi-join by an attribute.

1. A portion of ranges, possibly single-key ranges, is accumulated in a buffer on the central node where the query is submitted.
2. The ranges are sent to the execution nodes that access data rows.
3. The accessed rows are packed into packages and sent back to the central node.
4. The received packages with data rows are placed in a buffer.
5. Data rows are read from the buffer.

When MRR is used, the [Extra](#) column in [EXPLAIN](#) output shows [Using MRR](#).

[InnoDB](#) and [MyISAM](#) do not use MRR if full table rows need not be accessed to produce the query result. This is the case if results can be produced entirely on the basis on information in the index tuples (through a [covering index](#)); MRR provides no benefit.

Example query for which MRR can be used, assuming that there is an index on [\(key\\_part1, key\\_part2\)](#):

```
SELECT * FROM t
WHERE key\_part1 >= 1000 AND key\_part1 < 2000
AND key\_part2 = 10000;
```

The index consists of tuples of [\(key\\_part1, key\\_part2\)](#) values, ordered first by [key\\_part1](#) and then by [key\\_part2](#).

Without MRR, an index scan covers all index tuples for the [key\\_part1](#) range from 1000 up to 2000, regardless of the [key\\_part2](#) value in these tuples. The scan does extra work to the extent that tuples in the range contain [key\\_part2](#) values other than 10000.

With MRR, the scan is broken up into multiple ranges, each for a single value of [key\\_part1](#) (1000, 1001, ... , 1999). Each of these scans need look only for tuples with [key\\_part2](#) = 10000. If the index

contains many tuples for which `key_part2` is not 10000, MRR results in many fewer index tuples being read.

To express this using interval notation, the non-MRR scan must examine the index range `[{1000, 10000}, {2000, MIN_INT})`, which may include many tuples other than those for which `key_part2 = 10000`. The MRR scan examines multiple single-point intervals `[{1000, 10000}]`, ..., `[{1999, 10000}]`, which includes only tuples with `key_part2 = 10000`.

Two `optimizer_switch` system variable flags provide an interface to the use of MRR optimization. The `mrr` flag controls whether MRR is enabled. If `mrr` is enabled (`on`), the `mrr_cost_based` flag controls whether the optimizer attempts to make a cost-based choice between using and not using MRR (`on`) or uses MRR whenever possible (`off`). By default, `mrr` is `on` and `mrr_cost_based` is `on`. See [Section 9.9.2, “Controlling Switchable Optimizations”](#).

For MRR, a storage engine uses the value of the `read_rnd_buffer_size` system variable as a guideline for how much memory it can allocate for its buffer. The engine uses up to `read_rnd_buffer_size` bytes and determines the number of ranges to process in a single pass.

### 9.2.1.14 Block Nested-Loop and Batched Key Access Joins

In MySQL, a Batched Key Access (BKA) Join algorithm is available that uses both index access to the joined table and a join buffer. The BKA algorithm supports inner join, outer join, and semi-join operations, including nested outer joins. Benefits of BKA include improved join performance due to more efficient table scanning. Also, the Block Nested-Loop (BNL) Join algorithm previously used only for inner joins is extended and can be employed for outer join and semi-join operations, including nested outer joins.

The following sections discuss the join buffer management that underlies the extension of the original BNL algorithm, the extended BNL algorithm, and the BKA algorithm. For information about semi-join strategies, see [Optimizing Subqueries with Semi-Join Transformations](#)

### Join Buffer Management for Block Nested-Loop and Batched Key Access Algorithms

MySQL Server can employ join buffers to execute not only inner joins without index access to the inner table, but also outer joins and semi-joins that appear after subquery flattening. Moreover, a join buffer can be effectively used when there is an index access to the inner table.

The join buffer management code slightly more efficiently utilizes join buffer space when storing the values of the interesting row columns: No additional bytes are allocated in buffers for a row column if its value is `NULL`, and the minimum number of bytes is allocated for any value of the `VARCHAR` type.

The code supports two types of buffers, regular and incremental. Suppose that join buffer `B1` is employed to join tables `t1` and `t2` and the result of this operation is joined with table `t3` using join buffer `B2`:

- A regular join buffer contains columns from each join operand. If `B2` is a regular join buffer, each row `r` put into `B2` is composed of the columns of a row `r1` from `B1` and the interesting columns of a matching row `r2` from table `t3`.
- An incremental join buffer contains only columns from rows of the table produced by the second join operand. That is, it is incremental to a row from the first operand buffer. If `B2` is an incremental join buffer, it contains the interesting columns of the row `r2` together with a link to the row `r1` from `B1`.

Incremental join buffers are always incremental relative to a join buffer from an earlier join operation, so the buffer from the first join operation is always a regular buffer. In the example just given, the buffer `B1` used to join tables `t1` and `t2` must be a regular buffer.

Each row of the incremental buffer used for a join operation contains only the interesting columns of a row from the table to be joined. These columns are augmented with a reference to the interesting

columns of the matched row from the table produced by the first join operand. Several rows in the incremental buffer can refer to the same row *r* whose columns are stored in the previous join buffers insofar as all these rows match row *r*.

Incremental buffers enable less frequent copying of columns from buffers used for previous join operations. This provides a savings in buffer space because in the general case a row produced by the first join operand can be matched by several rows produced by the second join operand. It is unnecessary to make several copies of a row from the first operand. Incremental buffers also provide a savings in processing time due to the reduction in copying time.

The `block_nested_loop` and `batched_key_access` flags of the `optimizer_switch` system variable control how the optimizer uses the Block Nested-Loop and Batched Key Access join algorithms. By default, `block_nested_loop` is `on` and `batched_key_access` is `off`. See [Section 9.9.2, “Controlling Switchable Optimizations”](#).

For information about semi-join strategies, see [Optimizing Subqueries with Semi-Join Transformations](#)

## Block Nested-Loop Algorithm for Outer Joins and Semi-Joins

The original implementation of the MySQL BNL algorithm is extended to support outer join and semi-join operations.

When these operations are executed with a join buffer, each row put into the buffer is supplied with a match flag.

If an outer join operation is executed using a join buffer, each row of the table produced by the second operand is checked for a match against each row in the join buffer. When a match is found, a new extended row is formed (the original row plus columns from the second operand) and sent for further extensions by the remaining join operations. In addition, the match flag of the matched row in the buffer is enabled. After all rows of the table to be joined have been examined, the join buffer is scanned. Each row from the buffer that does not have its match flag enabled is extended by `NULL` complements (`NULL` values for each column in the second operand) and sent for further extensions by the remaining join operations.

The `block_nested_loop` flag of the `optimizer_switch` system variable controls how the optimizer uses the Block Nested-Loop algorithm. By default, `block_nested_loop` is `on`. See [Section 9.9.2, “Controlling Switchable Optimizations”](#).

In `EXPLAIN` output, use of BNL for a table is signified when the `Extra` value contains `Using join buffer (Block Nested Loop)` and the `type` value is `ALL`, `index`, or `range`.

For information about semi-join strategies, see [Optimizing Subqueries with Semi-Join Transformations](#)

## Batched Key Access Joins

MySQL Server implements a method of joining tables called the Batched Key Access (BKA) join algorithm. BKA can be applied when there is an index access to the table produced by the second join operand. Like the BNL join algorithm, the BKA join algorithm employs a join buffer to accumulate the interesting columns of the rows produced by the first operand of the join operation. Then the BKA algorithm builds keys to access the table to be joined for all rows in the buffer and submits these keys in a batch to the database engine for index lookups. The keys are submitted to the engine through the Multi-Range Read (MRR) interface (see [Section 9.2.1.13, “Multi-Range Read Optimization”](#)). After submission of the keys, the MRR engine functions perform lookups in the index in an optimal way, fetching the rows of the joined table found by these keys, and starts feeding the BKA join algorithm with matching rows. Each matching row is coupled with a reference to a row in the join buffer.

When BKA is used, the value of `join_buffer_size` defines how large the batch of keys is in each request to the storage engine. The larger the buffer, the more sequential access will be to the right hand table of a join operation, which can significantly improve performance.

For BKA to be used, the `batched_key_access` flag of the `optimizer_switch` system variable must be set to `on`. BKA uses MRR, so the `mrr` flag must also be `on`. Currently, the cost estimation for MRR is too pessimistic. Hence, it is also necessary for `mrr_cost_based` to be `off` for BKA to be used. The following setting enables BKA:

```
mysql> SET optimizer_switch='mrr=on,mrr_cost_based=off,batched_key_access=on';
```

There are two scenarios by which MRR functions execute:

- The first scenario is used for conventional disk-based storage engines such as `InnoDB` and `MyISAM`. For these engines, usually the keys for all rows from the join buffer are submitted to the MRR interface at once. Engine-specific MRR functions perform index lookups for the submitted keys, get row IDs (or primary keys) from them, and then fetch rows for all these selected row IDs one by one by request from BKA algorithm. Every row is returned with an association reference that enables access to the matched row in the join buffer. The rows are fetched by the MRR functions in an optimal way: They are fetched in the row ID (primary key) order. This improves performance because reads are in disk order rather than random order.
- The second scenario is used for remote storage engines such as `NDB`. A package of keys for a portion of rows from the join buffer, together with their associations, is sent by a MySQL Server (SQL node) to MySQL Cluster data nodes. In return, the SQL node receives a package (or several packages) of matching rows coupled with corresponding associations. The BKA join algorithm takes these rows and builds new joined rows. Then a new set of keys is sent to the data nodes and the rows from the returned packages are used to build new joined rows. The process continues until the last keys from the join buffer are sent to the data nodes, and the SQL node has received and joined all rows matching these keys. This improves performance because fewer key-bearing packages sent by the SQL node to the data nodes means fewer round trips between it and the data nodes to perform the join operation.

With the first scenario, a portion of the join buffer is reserved to store row IDs (primary keys) selected by index lookups and passed as a parameter to the MRR functions.

There is no special buffer to store keys built for rows from the join buffer. Instead, a function that builds the key for the next row in the buffer is passed as a parameter to the MRR functions.

In `EXPLAIN` output, use of BKA for a table is signified when the `Extra` value contains `Using join buffer (Batched Key Access)` and the `type` value is `ref` or `eq_ref`.

### 9.2.1.15 ORDER BY Optimization

In some cases, MySQL can use an index to satisfy an `ORDER BY` clause without doing extra sorting.

The index can also be used even if the `ORDER BY` does not match the index exactly, as long as all unused portions of the index and all extra `ORDER BY` columns are constants in the `WHERE` clause. The following queries use the index to resolve the `ORDER BY` part:

```
SELECT * FROM t1
  ORDER BY key_part1,key_part2,... ;

SELECT * FROM t1
  WHERE key_part1 = constant
  ORDER BY key_part2;

SELECT * FROM t1
  ORDER BY key_part1 DESC, key_part2 DESC;

SELECT * FROM t1
  WHERE key_part1 = 1
  ORDER BY key_part1 DESC, key_part2 DESC;
```

```
SELECT * FROM t1
WHERE key_part1 > constant
ORDER BY key_part1 ASC;

SELECT * FROM t1
WHERE key_part1 < constant
ORDER BY key_part1 DESC;

SELECT * FROM t1
WHERE key_part1 = constant1 AND key_part2 > constant2
ORDER BY key_part2;
```

In some cases, MySQL *cannot* use indexes to resolve the `ORDER BY`, although it still uses indexes to find the rows that match the `WHERE` clause. These cases include the following:

- The query uses `ORDER BY` on different indexes:

```
SELECT * FROM t1 ORDER BY key1, key2;
```

- The query uses `ORDER BY` on nonconsecutive parts of an index:

```
SELECT * FROM t1 WHERE key2=constant ORDER BY key_part2;
```

- The query mixes `ASC` and `DESC`:

```
SELECT * FROM t1 ORDER BY key_part1 DESC, key_part2 ASC;
```

- The index used to fetch the rows differs from the one used in the `ORDER BY`:

```
SELECT * FROM t1 WHERE key2=constant ORDER BY key1;
```

- The query uses `ORDER BY` with an expression that includes terms other than the index column name:

```
SELECT * FROM t1 ORDER BY ABS(key);
SELECT * FROM t1 ORDER BY -key;
```

- The query joins many tables, and the columns in the `ORDER BY` are not all from the first nonconstant table that is used to retrieve rows. (This is the first table in the `EXPLAIN` output that does not have a `const` join type.)
- The query has different `ORDER BY` and `GROUP BY` expressions.
- There is an index on only a prefix of a column named in the `ORDER BY` clause. In this case, the index cannot be used to fully resolve the sort order. For example, if only the first 10 bytes of a `CHAR(20)` column are indexed, the index cannot distinguish values past the 10th byte and a `filesort` will be needed.
- The index does not store rows in order. For example, this is true for a `HASH` index in a `MEMORY` table.

Availability of an index for sorting may be affected by the use of column aliases. Suppose that the column `t1.a` is indexed. In this statement, the name of the column in the select list is `a`. It refers to `t1.a`, so for the reference to `a` in the `ORDER BY`, the index can be used:

```
SELECT a FROM t1 ORDER BY a;
```

In this statement, the name of the column in the select list is also `a`, but it is the alias name. It refers to `ABS(a)`, so for the reference to `a` in the `ORDER BY`, the index cannot be used:

```
SELECT ABS(a) AS a FROM t1 ORDER BY a;
```

In the following statement, the `ORDER BY` refers to a name that is not the name of a column in the select list. But there is a column in `t1` named `a`, so the `ORDER BY` uses that and the index can be used. (The resulting sort order may be completely different from the order for `ABS(a)`, of course.)

```
SELECT ABS(a) AS b FROM t1 ORDER BY a;
```

By default, MySQL sorts all `GROUP BY col1, col2, ...` queries as if you specified `ORDER BY col1, col2, ...` in the query as well. If you include an explicit `ORDER BY` clause that contains the same column list, MySQL optimizes it away without any speed penalty, although the sorting still occurs.

#### Note

Relying on implicit `GROUP BY` sorting is deprecated. To achieve a specific sort order of grouped results, it is preferable to use an explicit `ORDER BY` clause. `GROUP BY` sorting is a MySQL extension that may change in a future release; for example, to make it possible for the optimizer to order groupings in whatever manner it deems most efficient and to avoid the sorting overhead.

If a query includes `GROUP BY` but you want to avoid the overhead of sorting the result, you can suppress sorting by specifying `ORDER BY NULL`. For example:

```
INSERT INTO foo
SELECT a, COUNT(*) FROM bar GROUP BY a ORDER BY NULL;
```

The optimizer may still choose to use sorting to implement grouping operations. `ORDER BY NULL` suppresses sorting of the result, not prior sorting done by grouping operations to determine the result.

With `EXPLAIN SELECT ... ORDER BY`, you can check whether MySQL can use indexes to resolve the query. It cannot if you see `Using filesort` in the `Extra` column. See [Section 9.8.1, “Optimizing Queries with EXPLAIN”](#). `Filesort` uses a fixed-length row-storage format similar to that used by the `MEMORY` storage engine. Variable-length types such as `VARCHAR` are stored using a fixed length.

MySQL has two `filesort` algorithms for sorting and retrieving results. The original method uses only the `ORDER BY` columns. The modified method uses not just the `ORDER BY` columns, but all the columns referenced by the query.

The optimizer selects which `filesort` algorithm to use. It normally uses the modified algorithm except when `BLOB` or `TEXT` columns are involved, in which case it uses the original algorithm. For both algorithms, the sort buffer size is the `sort_buffer_size` system variable value.

The original `filesort` algorithm works as follows:

1. Read all rows according to key or by table scanning. Skip rows that do not match the `WHERE` clause.
2. For each row, store in the sort buffer a tuple consisting of a pair of values (the sort key value and the row ID).
3. If all pairs fit into the sort buffer, no temporary file is created. Otherwise, when the sort buffer becomes full, run a `qsort` (quicksort) on it in memory and write it to a temporary file. Save a pointer to the sorted block.
4. Repeat the preceding steps until all rows have been read.
5. Do a multi-merge of up to `MERGEBUFF` (7) regions to one block in another temporary file. Repeat until all blocks from the first file are in the second file.

6. Repeat the following until there are fewer than `MERGEBUFF2` (15) blocks left.
7. On the last multi-merge, only the row ID (the last part of the value pair) is written to a result file.
8. Read the rows in sorted order using the row IDs in the result file. To optimize this, read in a large block of row IDs, sort them, and use them to read the rows in sorted order into a row buffer. The row buffer size is the `read_rnd_buffer_size` system variable value. The code for this step is in the `sql/records.cc` source file.

One problem with this approach is that it reads rows twice: One time during `WHERE` clause evaluation, and again after sorting the value pairs. And even if the rows were accessed successively the first time (for example, if a table scan is done), the second time they are accessed randomly. (The sort keys are ordered, but the row positions are not.)

The modified `filesort` algorithm incorporates an optimization to avoid reading the rows twice: It records the sort key value, but instead of the row ID, it records the columns referenced by the query. The modified `filesort` algorithm works like this:

1. Read the rows that match the `WHERE` clause.
2. For each row, store in the sort buffer a tuple consisting of the sort key value and the columns referenced by the query.
3. When the sort buffer becomes full, sort the tuples by sort key value in memory and write it to a temporary file.
4. After merge-sorting the temporary file, retrieve the rows in sorted order, but read the columns required by the query directly from the sorted tuples rather than by accessing the table a second time.

The tuples used by the modified `filesort` algorithm are longer than the pairs used by the original algorithm, and fewer of them fit in the sort buffer. As a result, it is possible for the extra I/O to make the modified approach slower, not faster. To avoid a slowdown, the optimizer uses the modified algorithm only if the total size of the extra columns in the sort tuple does not exceed the value of the `max_length_for_sort_data` system variable. (A symptom of setting the value of this variable too high is a combination of high disk activity and low CPU activity.)

As of MySQL 5.7.3, the modified `filesort` algorithm includes an additional optimization designed to enable more tuples to fit into the sort buffer: For additional columns of type `CHAR` or `VARCHAR`, or any nullable fixed-size data type, the values are packed. For example, without packing, a `VARCHAR(255)` column value containing only 3 characters takes 255 characters in the sort buffer. With packing, the value requires only 3 characters plus a two-byte length indicator. `NULL` values require only a bitmask.

For data containing packable strings shorter than the maximum column length or many `NULL` values, more records fit into the sort buffer. This improves in-memory sorting of the sort buffer and performance of disk-based temporary file merge sorting.

In edge cases, packing may be disadvantageous: If packable strings are the maximum column length or there are few `NULL` values, the space required for the length indicators reduces the number of records that fit into the sort buffer and sorting is slower in memory and on disk.

If a `filesort` is done, `EXPLAIN` output includes `Using filesort` in the `Extra` column. Also, optimizer trace output includes a `filesort_summary` block. For example:

```
"filesort_summary": {
  "rows": 100,
  "examined_rows": 100,
  "number_of_tmp_files": 0,
  "sort_buffer_size": 25192,
  "sort_mode": "<sort_key, packed_additional_fields>"
}
```

The `sort_mode` value provides information about the `filesort` algorithm used and the contents of tuples in the sort buffer:

- `<sort_key, rowid>`: This indicates use of the original algorithm. Sort buffer tuples are pairs that contain the sort key value and row ID of the original table row. Tuples are sorted by sort key value and the row ID is used to read the row from the table.
- `<sort_key, additional_fields>`: This indicates use of the modified algorithm. Sort buffer tuples contain the sort key value and columns referenced by the query. Tuples are sorted by sort key value and column values are read directly from the tuple.
- `<sort_key, packed_additional_fields>`: This indicates use of the modified algorithm. Sort buffer tuples contain the sort key value and packed columns referenced by the query. Tuples are sorted by sort key value and column values are read directly from the tuple.

For information about the optimizer trace, see [MySQL Internals: Tracing the Optimizer](#).

Suppose that a table `t1` has four `VARCHAR` columns `a`, `b`, `c`, and `d` and that the optimizer uses `filesort` for this query:

```
SELECT * FROM t1 ORDER BY a, b;
```

The query sorts by `a` and `b`, but returns all columns, so the columns referenced by the query are `a`, `b`, `c`, and `d`. Depending on which `filesort` algorithm the optimizer chooses, the query executes as follows:

For the original algorithm, sort buffer tuples have these contents:

```
(fixed size a value, fixed size b value,  
row ID into t1)
```

The optimizer sorts on the fixed size values. After sorting, the optimizer reads the tuples in order and uses the row ID in each tuple to read rows from `t1` to obtain the select list column values.

For the modified algorithm without packing, sort buffer tuples have these contents:

```
(fixed size a value, fixed size b value,  
a value, b value, c value, d value)
```

The optimizer sorts on the fixed size values. After sorting, the optimizer reads the tuples in order and uses the values for `a`, `b`, `c`, and `d` to obtain the select list column values without reading `t1` again.

For the modified algorithm with packing, sort buffer tuples have these contents:

```
(fixed size a value, fixed size b value,  
a length, packed a value, b length, packed b value,  
c length, packed c value, d length, packed d value)
```

If any of `a`, `b`, `c`, or `d` are `NULL`, they take no space in the sort buffer other than in the bitmask.

The optimizer sorts on the fixed size values. After sorting, the optimizer reads the tuples in order and uses the values for `a`, `b`, `c`, and `d` to obtain the select list column values without reading `t1` again.

For slow queries for which `filesort` is not used, try lowering `max_length_for_sort_data` to a value that is appropriate to trigger a `filesort`.

To increase `ORDER BY` speed, check whether you can get MySQL to use indexes rather than an extra sorting phase. If this is not possible, you can try the following strategies:

- Increase the `sort_buffer_size` variable value. Ideally, the value should be large enough for the entire result set to fit in the sort buffer (to avoid writes to disk and merge passes), but at minimum the value must be large enough to accommodate fifteen tuples.

Take into account that the size of column values stored in the sort buffer is affected by the `max_sort_length` system variable value. For example, if tuples store values of long string columns and you increase the value of `max_sort_length`, the size of sort buffer tuples increases as well and may require you to increase `sort_buffer_size`. For column values calculated as a result of string expressions (such as those that invoke a string-valued function), the `filesort` algorithm cannot tell the maximum length of expression values, so it must allocate `max_sort_length` bytes for each tuple.

To monitor the number of merge passes, check the `Sort_merge_passes` status variable.

- Increase the `read_rnd_buffer_size` variable value.
- Use less RAM per row by declaring columns only as large as they need to be to hold the values stored in them. For example, `CHAR(16)` is better than `CHAR(200)` if values never exceed 16 characters.
- Change the `tmpdir` system variable to point to a dedicated file system with large amounts of free space. The variable value can list several paths that are used in round-robin fashion; you can use this feature to spread the load across several directories. Paths should be separated by colon characters (:) on Unix and semicolon characters (;) on Windows. The paths should name directories in file systems located on different *physical* disks, not different partitions on the same disk.

If an index is not used for `ORDER BY` but a `LIMIT` clause is also present, the optimizer may be able to avoid using a merge file and sort the rows in memory. For details, see [Section 9.2.1.19, “LIMIT Query Optimization”](#).

### 9.2.1.16 GROUP BY Optimization

The most general way to satisfy a `GROUP BY` clause is to scan the whole table and create a new temporary table where all rows from each group are consecutive, and then use this temporary table to discover groups and apply aggregate functions (if any). In some cases, MySQL is able to do much better than that and to avoid creation of temporary tables by using index access.

The most important preconditions for using indexes for `GROUP BY` are that all `GROUP BY` columns reference attributes from the same index, and that the index stores its keys in order (for example, this is a `BTREE` index and not a `HASH` index). Whether use of temporary tables can be replaced by index access also depends on which parts of an index are used in a query, the conditions specified for these parts, and the selected aggregate functions.

There are two ways to execute a `GROUP BY` query through index access, as detailed in the following sections. In the first method, the grouping operation is applied together with all range predicates (if any). The second method first performs a range scan, and then groups the resulting tuples.

In MySQL, `GROUP BY` is used for sorting, so the server may also apply `ORDER BY` optimizations to grouping. However, relying on implicit `GROUP BY` sorting is deprecated. See [Section 9.2.1.15, “ORDER BY Optimization”](#).

#### Loose Index Scan

The most efficient way to process `GROUP BY` is when an index is used to directly retrieve the grouping columns. With this access method, MySQL uses the property of some index types that the keys are ordered (for example, `BTREE`). This property enables use of lookup groups in an index without having to consider all keys in the index that satisfy all `WHERE` conditions. This access method considers only a fraction of the keys in an index, so it is called a *loose index scan*. When there is no `WHERE` clause, a loose index scan reads as many keys as the number of groups, which may be a much smaller number than that of all keys. If the `WHERE` clause contains range predicates (see the discussion of the `range`

join type in [Section 9.8.1, “Optimizing Queries with EXPLAIN”](#)), a loose index scan looks up the first key of each group that satisfies the range conditions, and again reads the least possible number of keys. This is possible under the following conditions:

- The query is over a single table.
- The `GROUP BY` names only columns that form a leftmost prefix of the index and no other columns. (If, instead of `GROUP BY`, the query has a `DISTINCT` clause, all distinct attributes refer to columns that form a leftmost prefix of the index.) For example, if a table `t1` has an index on `(c1,c2,c3)`, loose index scan is applicable if the query has `GROUP BY c1, c2`. It is not applicable if the query has `GROUP BY c2, c3` (the columns are not a leftmost prefix) or `GROUP BY c1, c2, c4` (`c4` is not in the index).
- The only aggregate functions used in the select list (if any) are `MIN()` and `MAX()`, and all of them refer to the same column. The column must be in the index and must immediately follow the columns in the `GROUP BY`.
- Any other parts of the index than those from the `GROUP BY` referenced in the query must be constants (that is, they must be referenced in equalities with constants), except for the argument of `MIN()` or `MAX()` functions.
- For columns in the index, full column values must be indexed, not just a prefix. For example, with `c1 VARCHAR(20)`, `INDEX (c1(10))`, the index cannot be used for loose index scan.

If loose index scan is applicable to a query, the `EXPLAIN` output shows `Using index for group-by` in the `Extra` column.

Assume that there is an index `idx(c1,c2,c3)` on table `t1(c1,c2,c3,c4)`. The loose index scan access method can be used for the following queries:

```
SELECT c1, c2 FROM t1 GROUP BY c1, c2;
SELECT DISTINCT c1, c2 FROM t1;
SELECT c1, MIN(c2) FROM t1 GROUP BY c1;
SELECT c1, c2 FROM t1 WHERE c1 < const GROUP BY c1, c2;
SELECT MAX(c3), MIN(c3), c1, c2 FROM t1 WHERE c2 > const GROUP BY c1, c2;
SELECT c2 FROM t1 WHERE c1 < const GROUP BY c1, c2;
SELECT c1, c2 FROM t1 WHERE c3 = const GROUP BY c1, c2;
```

The following queries cannot be executed with this quick select method, for the reasons given:

- There are aggregate functions other than `MIN()` or `MAX()`:

```
SELECT c1, SUM(c2) FROM t1 GROUP BY c1;
```

- The columns in the `GROUP BY` clause do not form a leftmost prefix of the index:

```
SELECT c1, c2 FROM t1 GROUP BY c2, c3;
```

- The query refers to a part of a key that comes after the `GROUP BY` part, and for which there is no equality with a constant:

```
SELECT c1, c3 FROM t1 GROUP BY c1, c2;
```

Were the query to include `WHERE c3 = const`, loose index scan could be used.

The loose index scan access method can be applied to other forms of aggregate function references in the select list, in addition to the `MIN()` and `MAX()` references already supported:

- `AVG(DISTINCT)`, `SUM(DISTINCT)`, and `COUNT(DISTINCT)` are supported. `AVG(DISTINCT)` and `SUM(DISTINCT)` take a single argument. `COUNT(DISTINCT)` can have more than one column argument.

- There must be no `GROUP BY` or `DISTINCT` clause in the query.
- The loose scan limitations described earlier still apply.

Assume that there is an index `idx(c1,c2,c3)` on table `t1(c1,c2,c3,c4)`. The loose index scan access method can be used for the following queries:

```
SELECT COUNT(DISTINCT c1), SUM(DISTINCT c1) FROM t1;

SELECT COUNT(DISTINCT c1, c2), COUNT(DISTINCT c2, c1) FROM t1;
```

## Tight Index Scan

A tight index scan may be either a full index scan or a range index scan, depending on the query conditions.

When the conditions for a loose index scan are not met, it still may be possible to avoid creation of temporary tables for `GROUP BY` queries. If there are range conditions in the `WHERE` clause, this method reads only the keys that satisfy these conditions. Otherwise, it performs an index scan. Because this method reads all keys in each range defined by the `WHERE` clause, or scans the whole index if there are no range conditions, we term it a *tight index scan*. With a tight index scan, the grouping operation is performed only after all keys that satisfy the range conditions have been found.

For this method to work, it is sufficient that there is a constant equality condition for all columns in a query referring to parts of the key coming before or in between parts of the `GROUP BY` key. The constants from the equality conditions fill in any “gaps” in the search keys so that it is possible to form complete prefixes of the index. These index prefixes then can be used for index lookups. If we require sorting of the `GROUP BY` result, and it is possible to form search keys that are prefixes of the index, MySQL also avoids extra sorting operations because searching with prefixes in an ordered index already retrieves all the keys in order.

Assume that there is an index `idx(c1,c2,c3)` on table `t1(c1,c2,c3,c4)`. The following queries do not work with the loose index scan access method described earlier, but still work with the tight index scan access method.

- There is a gap in the `GROUP BY`, but it is covered by the condition `c2 = 'a'`:

```
SELECT c1, c2, c3 FROM t1 WHERE c2 = 'a' GROUP BY c1, c3;
```

- The `GROUP BY` does not begin with the first part of the key, but there is a condition that provides a constant for that part:

```
SELECT c1, c2, c3 FROM t1 WHERE c1 = 'a' GROUP BY c2, c3;
```

### 9.2.1.17 DISTINCT Optimization

`DISTINCT` combined with `ORDER BY` needs a temporary table in many cases.

Because `DISTINCT` may use `GROUP BY`, learn how MySQL works with columns in `ORDER BY` or `HAVING` clauses that are not part of the selected columns. See [Section 13.19.3, “MySQL Handling of GROUP BY”](#).

In most cases, a `DISTINCT` clause can be considered as a special case of `GROUP BY`. For example, the following two queries are equivalent:

```
SELECT DISTINCT c1, c2, c3 FROM t1
WHERE c1 > const;

SELECT c1, c2, c3 FROM t1
```

```
WHERE c1 > const GROUP BY c1, c2, c3;
```

Due to this equivalence, the optimizations applicable to `GROUP BY` queries can be also applied to queries with a `DISTINCT` clause. Thus, for more details on the optimization possibilities for `DISTINCT` queries, see [Section 9.2.1.16, “GROUP BY Optimization”](#).

When combining `LIMIT row_count` with `DISTINCT`, MySQL stops as soon as it finds `row_count` unique rows.

If you do not use columns from all tables named in a query, MySQL stops scanning any unused tables as soon as it finds the first match. In the following case, assuming that `t1` is used before `t2` (which you can check with `EXPLAIN`), MySQL stops reading from `t2` (for any particular row in `t1`) when it finds the first row in `t2`:

```
SELECT DISTINCT t1.a FROM t1, t2 where t1.a=t2.a;
```

### 9.2.1.18 Subquery Optimization

The MySQL query optimizer has different strategies available to evaluate subqueries. For `IN` (or `=ANY`) subqueries, the optimizer has these choices:

- Semi-join
- Materialization
- `EXISTS` strategy

For `NOT IN` (or `<>ALL`) subqueries, the optimizer has these choices:

- Materialization
- `EXISTS` strategy

For derived tables (subqueries in the `FROM` clause) and view references, the optimizer has these choices:

- Merge the derived table or view into the outer query block
- Materialize the derived table or view to an internal temporary table

The following discussion provides more information about these optimization strategies.

#### Note

A limitation on `UPDATE` and `DELETE` statements that use a subquery to modify a single table is that the optimizer does not use semi-join or materialization subquery optimizations. As a workaround, try rewriting them as multiple-table `UPDATE` and `DELETE` statements that use a join rather than a subquery.

### Optimizing Subqueries with Semi-Join Transformations

The optimizer uses semi-join strategies to improve subquery execution, as described in this section.

For an inner join between two tables, the join returns a row from one table as many times as there are matches in the other table. But for some questions, the only information that matters is whether there is a match, not the number of matches. Suppose that there are tables named `class` and `roster` that list classes in a course curriculum and class rosters (students enrolled in each class), respectively. To list the classes that actually have students enrolled, you could use this join:

```
SELECT class.class_num, class.class_name
FROM class INNER JOIN roster
WHERE class.class_num = roster.class_num;
```

However, the result lists each class once for each enrolled student. For the question being asked, this is unnecessary duplication of information.

Assuming that `class_num` is a primary key in the `class` table, duplicate suppression could be achieved by using `SELECT DISTINCT`, but it is inefficient to generate all matching rows first only to eliminate duplicates later.

The same duplicate-free result can be obtained by using a subquery:

```
SELECT class_num, class_name
FROM class
WHERE class_num IN (SELECT class_num FROM roster);
```

Here, the optimizer can recognize that the `IN` clause requires the subquery to return only one instance of each class number from the `roster` table. In this case, the query can be executed as a *semi-join*—that is, an operation that returns only one instance of each row in `class` that is matched by rows in `roster`.

Outer join and inner join syntax is permitted in the outer query specification, and table references may be base tables or views.

In MySQL, a subquery must satisfy these criteria to be handled as a semi-join:

- It must be an `IN` (or `=ANY`) subquery that appears at the top level of the `WHERE` or `ON` clause, possibly as a term in an `AND` expression. For example:

```
SELECT ...
FROM ot1, ...
WHERE (oe1, ...) IN (SELECT ie1, ... FROM it1, ... WHERE ...);
```

Here, `oti` and `iti` represent tables in the outer and inner parts of the query, and `oei` and `iei` represent expressions that refer to columns in the outer and inner tables.

- It must be a single `SELECT` without `UNION` constructs.
- It must not contain a `GROUP BY` or `HAVING` clause.
- It must not be implicitly grouped (it must contain no aggregate functions).
- It must not have `ORDER BY` with `LIMIT`.
- It must not have `STRAIGHT_JOIN` in the outer query.
- The number of outer and inner tables together must be less than the maximum number of tables permitted in a join.
- The `STRAIGHT_JOIN` qualifier is not present.

The subquery may be correlated or uncorrelated. `DISTINCT` is permitted, as is `LIMIT` unless `ORDER BY` is also used.

If a subquery meets the preceding criteria, MySQL converts it to a semi-join and makes a cost-based choice from these strategies:

- Convert the subquery to a join, or use table pullout and run the query as an inner join between subquery tables and outer tables. Table pullout pulls a table out from the subquery to the outer query.

- Duplicate Weedout: Run the semi-join as if it was a join and remove duplicate records using a temporary table.
- FirstMatch: When scanning the inner tables for row combinations and there are multiple instances of a given value group, choose one rather than returning them all. This "shortcuts" scanning and eliminates production of unnecessary rows.
- LooseScan: Scan a subquery table using an index that enables a single value to be chosen from each subquery's value group.
- Materialize the subquery into a temporary table with an index and use the temporary table to perform a join. The index is used to remove duplicates. The index might also be used later for lookups when joining the temporary table with the outer tables; if not, the table is scanned.

Each of these strategies can be enabled or disabled using the `optimizer_switch` system variable. The `semi_join` flag controls whether semi-joins are used. If it is set to `on`, the `firstmatch`, `loosescan`, `duplicateweedout` (added in MySQL 5.7.8), and `materialization` flags enable finer control over the permitted semi-join strategies. These flags are `on` by default. See [Section 9.9.2, "Controlling Switchable Optimizations"](#).

If the `duplicateweedout` semi-join strategy is disabled, it is not used unless all other applicable strategies are also disabled.

If `duplicateweedout` is disabled, on occasion the optimizer may generate a query plan that is far from optimal. This occurs due to heuristic pruning during greedy search, which can be avoided by setting `optimizer_prune_level=0`.

As of MySQL 5.7.6, the optimizer minimizes differences in handling of views and subqueries in the `FROM` clause. This affects queries with the `STRAIGHT_JOIN` modifier and a view with an `IN` subquery that can be converted into a semi-join. The following query illustrates this because the change in processing causes a change in transformation, and thus a different execution strategy:

```
CREATE VIEW v AS
SELECT *
FROM t1
WHERE a IN (SELECT b
            FROM t2);

SELECT STRAIGHT_JOIN *
FROM t3 JOIN v ON t3.x = v.a;
```

Before 5.7.6, the optimizer first merges the view `v` into the outer query. When deciding whether to convert the `IN` subquery into a semi-join, it notices the `STRAIGHT_JOIN` and refuses the conversion.

As of 5.7.6, the optimizer first looks at the view and converts the `IN` subquery into a semi-join, then checks whether it is possible to merge the view into the outer query. Because the `STRAIGHT_JOIN` modifier in the outer query prevents semi-join, the optimizer refuses the merge, causing the derived table to be evaluated using a materialized table.

The use of semi-join strategies is indicated in `EXPLAIN` output as follows:

- Semi-joined tables show up in the outer select. `EXPLAIN EXTENDED` plus `SHOW WARNINGS` shows the rewritten query, which displays the semi-join structure. From this you can get an idea about which tables were pulled out of the semi-join. If a subquery was converted to a semi-join, you will see that the subquery predicate is gone and its tables and `WHERE` clause were merged into the outer query join list and `WHERE` clause.
- Temporary table use for Duplicate Weedout is indicated by `Start temporary` and `End temporary` in the `Extra` column. Tables that were not pulled out and are in the range of `EXPLAIN` output rows covered by `Start temporary` and `End temporary` will have their `rowid` in the temporary table.

- `FirstMatch(tbl_name)` in the `Extra` column indicates join shortcutting.
- `LooseScan(m..n)` in the `Extra` column indicates use of the LooseScan strategy. `m` and `n` are key part numbers.
- Temporary table use for materialization is indicated by rows with a `select_type` value of `MATERIALIZED` and rows with a `table` value of `<subqueryN>`.

## Optimizing Subqueries with Subquery Materialization

The optimizer uses subquery materialization as a strategy that enables more efficient subquery processing. Materialization speeds up query execution by generating a subquery result as a temporary table, normally in memory. The first time MySQL needs the subquery result, it materializes that result into a temporary table. Any subsequent time the result is needed, MySQL refers again to the temporary table. The table is indexed with a hash index to make lookups fast and inexpensive. The index is unique, which makes the table smaller because it has no duplicates.

Subquery materialization attempts to use an in-memory temporary table when possible, falling back to on-disk storage if the table becomes too large. See [Section 9.4.4, “Internal Temporary Table Use in MySQL”](#).

If materialization is not used, the optimizer sometimes rewrites a noncorrelated subquery as a correlated subquery. For example, the following `IN` subquery is noncorrelated (`where_condition` involves only columns from `t2` and not `t1`):

```
SELECT * FROM t1
WHERE t1.a IN (SELECT t2.b FROM t2 WHERE where_condition);
```

The optimizer might rewrite this as an `EXISTS` correlated subquery:

```
SELECT * FROM t1
WHERE EXISTS (SELECT t2.b FROM t2 WHERE where_condition AND t1.a=t2.b);
```

Subquery materialization using a temporary table avoids such rewrites and makes it possible to execute the subquery only once rather than once per row of the outer query.

For subquery materialization to be used in MySQL, the `materialization` flag of the `optimizer_switch` system variable must be `on`. Materialization then applies to subquery predicates that appear anywhere (in the select list, `WHERE`, `ON`, `GROUP BY`, `HAVING`, or `ORDER BY`), for predicates that fall into any of these use cases:

- The predicate has this form, when no outer expression `oe_i` or inner expression `ie_i` is nullable. `N` can be 1 or larger.

```
(oe_1, oe_2, ..., oe_N) [NOT] IN (SELECT ie_1, ie_2, ..., ie_N ...)
```

- The predicate has this form, when there is a single outer expression `oe` and inner expression `ie`. The expressions can be nullable.

```
oe [NOT] IN (SELECT ie ...)
```

- The predicate is `IN` or `NOT IN` and a result of `UNKNOWN` (`NULL`) has the same meaning as a result of `FALSE`.

The following examples illustrate how the requirement for equivalence of `UNKNOWN` and `FALSE` predicate evaluation affects whether subquery materialization can be used. Assume that `where_condition` involves columns only from `t2` and not `t1` so that the subquery is noncorrelated.

This query is subject to materialization:

```
SELECT * FROM t1
WHERE t1.a IN (SELECT t2.b FROM t2 WHERE where_condition);
```

Here, it does not matter whether the `IN` predicate returns `UNKNOWN` or `FALSE`. Either way, the row from `t1` is not included in the query result.

An example where subquery materialization will not be used is the following query, where `t2.b` is a nullable column.

```
SELECT * FROM t1
WHERE (t1.a,t1.b) NOT IN (SELECT t2.a,t2.b FROM t2
                        WHERE where_condition);
```

The following restrictions apply to the use of subquery materialization:

- The types of the inner and outer expressions must match. For example, the optimizer might be able to use materialization if both expressions are integer or both are decimal. The optimizer cannot use materialization if one expression is integer and the other is decimal.
- The inner expression cannot be a `BLOB`.

Use of `EXPLAIN` with a query can give some indication of whether the optimizer uses subquery materialization. Compared to query execution that does not use materialization, `select_type` may change from `DEPENDENT SUBQUERY` to `SUBQUERY`. This indicates that, for a subquery that would be executed once per outer row, materialization enables the subquery to be executed just once. In addition, for extended `EXPLAIN` output, the text displayed by a following `SHOW WARNINGS` includes `materialize materialize` and `materialized-subquery`.

## Optimizing Derived Tables and View References

The optimizer can handle derived tables (subqueries in the `FROM` clause) and view references using two strategies:

- Merge the derived table or view into the outer query block
- Materialize the derived table or view to an internal temporary table

Example 1:

```
SELECT * FROM (SELECT * FROM t1) AS derived_t1;
```

With merging, that query is executed similar to:

```
SELECT * FROM t1;
```

Example 2:

```
SELECT *
FROM t1 JOIN (SELECT t2.f1 FROM t2) AS derived_t2 ON t1.f2=derived_t2.f1
WHERE t1.f1 > 0;
```

With merging, that query is executed similar to:

```
SELECT t1.*, t2.f1
FROM t1 JOIN t2 ON t1.f2=t2.f1
WHERE t1.f1 > 0;
```

With materialization, `derived_t1` and `derived_t2` are treated as a separate table within their respective queries.

As of MySQL 5.7.6, the optimizer handles derived tables and view references the same way: It avoids unnecessary materialization whenever possible, which enables pushing down conditions from the outer query to derived tables and produces more efficient execution plans. (For an example, see [Optimizing Subqueries with Subquery Materialization](#).) Before MySQL 5.7.6, derived tables were always materialized, whereas equivalent view references were sometimes materialized and sometimes merged. This inconsistent treatment of equivalent queries could lead to performance problems: Unnecessary derived table materialization takes time and prevents the optimizer from pushing down conditions to derived tables.

If merging would result in an outer query block that references more than 61 base tables, the optimizer chooses materialization instead.

As of MySQL 5.7.6, the optimizer handles propagation of an `ORDER BY` clause in a derived table or view reference to the outer query block by propagating the `ORDER BY` clause if the following conditions apply: The outer query is not grouped or aggregated; does not specify `DISTINCT`, `HAVING`, or `ORDER BY`; and has this derived table or view reference as the only source in the `FROM` clause. Otherwise, the optimizer ignores the `ORDER BY` clause. Before MySQL 5.7.6, the optimizer always propagated `ORDER BY`, even if it was irrelevant or resulted in an invalid query.

The `derived_merge` flag of the `optimizer_switch` system variable controls whether the optimizer attempts to merge derived tables and views into the outer query block, assuming that no other rule prevents merging. By default, the flag is `on` to enable merging. Setting the flag to `off` prevents merging and avoids `ER_UPDATE_TABLE_USED` errors. It is also possible to disable merging by using in the subquery any constructs that prevent merging, although these are not as explicit in their effect on materialization. Constructs that prevent merging are the same as those that prevent merging in views. Examples are `SELECT DISTINCT` or `LIMIT` in the subquery. For details, see [Section 22.5.2, “View Processing Algorithms”](#).

The `derived_merge` flag also applies to views that contain no `ALGORITHM` clause. Thus, if an `ER_UPDATE_TABLE_USED` error occurs for a view reference that uses an expression equivalent to the subquery, adding `ALGORITHM=TEMPTABLE` to the view definition prevents merging and takes precedence over the current `derived_merge` value.

If the optimizer chooses the materialization strategy for a derived table, it handles the query as follows:

- The optimizer postpones materialization of subqueries in the `FROM` clause until their contents are needed during query execution. This improves performance because delay of materialization may result in not having to do it at all. Consider a query that joins the result of a subquery in the `FROM` clause to another table: If the optimizer processes that other table first and finds that it returns no rows, the join need not be carried out further and the optimizer can completely skip materializing the subquery.
- During query execution, the optimizer may add an index to a derived table to speed up row retrieval from it.

Consider the following `EXPLAIN` statement, for which a subquery appears in the `FROM` clause of a `SELECT` query:

```
EXPLAIN SELECT * FROM (SELECT * FROM t1) AS derived_t1;
```

The optimizer avoids materializing the subquery by delaying it until the result is needed during `SELECT` execution. In this case, the query is not executed, so the result is never needed.

Even for queries that are executed, delay of subquery materialization may enable the optimizer to avoid materialization entirely. When this happens, query execution is quicker by the time needed to perform materialization. Consider the following query, which joins the result of a subquery in the `FROM` clause to another table:

```
SELECT *
FROM t1 JOIN (SELECT t2.f1 FROM t2) AS derived_t2
      ON t1.f2=derived_t2.f1
WHERE t1.f1 > 0;
```

If the optimization processes `t1` first and the `WHERE` clause produces an empty result, the join must necessarily be empty and the subquery need not be materialized.

For cases when a derived table requires materialization, the optimizer may speed up access to the result by adding an index to the materialized table. If such an index enables `ref` access to the table, it can greatly reduce amount of data that must be read during query execution. Consider the following query:

```
SELECT *
FROM t1 JOIN (SELECT DISTINCT f1 FROM t2) AS derived_t2
      ON t1.f1=derived_t2.f1;
```

The optimizer constructs an index over column `f1` from `derived_t2` if doing so would enable use of `ref` access for the lowest cost execution plan. After adding the index, the optimizer can treat the materialized derived table the same as a regular table with an index, and it benefits similarly from the generated index. The overhead of index creation is negligible compared to the cost of query execution without the index. If `ref` access would result in higher cost than some other access method, the optimizer creates no index and loses nothing.

## Optimizing Subqueries with EXISTS Strategy

Certain optimizations are applicable to comparisons that use the `IN` operator to test subquery results (or that use `=ANY`, which is equivalent). This section discusses these optimizations, particularly with regard to the challenges that `NULL` values present. The last part of the discussion includes suggestions on what you can do to help the optimizer.

Consider the following subquery comparison:

```
outer_expr IN (SELECT inner_expr FROM ... WHERE subquery_where)
```

MySQL evaluates queries “from outside to inside.” That is, it first obtains the value of the outer expression `outer_expr`, and then runs the subquery and captures the rows that it produces.

A very useful optimization is to “inform” the subquery that the only rows of interest are those where the inner expression `inner_expr` is equal to `outer_expr`. This is done by pushing down an appropriate equality into the subquery's `WHERE` clause. That is, the comparison is converted to this:

```
EXISTS (SELECT 1 FROM ... WHERE subquery_where AND outer_expr=inner_expr)
```

After the conversion, MySQL can use the pushed-down equality to limit the number of rows that it must examine when evaluating the subquery.

More generally, a comparison of `N` values to a subquery that returns `N`-value rows is subject to the same conversion. If `oe_i` and `ie_i` represent corresponding outer and inner expression values, this subquery comparison:

```
(oe_1, ..., oe_N) IN
  (SELECT ie_1, ..., ie_N FROM ... WHERE subquery_where)
```

Becomes:

```
EXISTS (SELECT 1 FROM ... WHERE subquery_where
```

```
AND oe_1 = ie_1
AND ...
AND oe_N = ie_N)
```

For simplicity, the following discussion assumes a single pair of outer and inner expression values.

The conversion just described has its limitations. It is valid only if we ignore possible `NULL` values. That is, the “pushdown” strategy works as long as both of these two conditions are true:

- `outer_expr` and `inner_expr` cannot be `NULL`.
- You do not need to distinguish `NULL` from `FALSE` subquery results. If the subquery is a part of an `OR` or `AND` expression in the `WHERE` clause, MySQL assumes that you do not care. Another instance where the optimizer notices that `NULL` and `FALSE` subquery results need not be distinguished is this construct:

```
... WHERE outer_expr IN (subquery)
```

In this case, the `WHERE` clause rejects the row whether `IN (subquery)` returns `NULL` or `FALSE`.

When either or both of those conditions do not hold, optimization is more complex.

Suppose that `outer_expr` is known to be a non-`NULL` value but the subquery does not produce a row such that `outer_expr = inner_expr`. Then `outer_expr IN (SELECT ...)` evaluates as follows:

- `NULL`, if the `SELECT` produces any row where `inner_expr` is `NULL`
- `FALSE`, if the `SELECT` produces only non-`NULL` values or produces nothing

In this situation, the approach of looking for rows with `outer_expr = inner_expr` is no longer valid. It is necessary to look for such rows, but if none are found, also look for rows where `inner_expr` is `NULL`. Roughly speaking, the subquery can be converted to something like this:

```
EXISTS (SELECT 1 FROM ... WHERE subquery_where AND
        (outer_expr=inner_expr OR inner_expr IS NULL))
```

The need to evaluate the extra `IS NULL` condition is why MySQL has the `ref_or_null` access method:

```
mysql> EXPLAIN
-> SELECT outer_expr IN (SELECT t2.maybe_null_key
->                        FROM t2, t3 WHERE ...)
-> FROM t1;
***** 1. row *****
      id: 1
  select_type: PRIMARY
      table: t1
  ...
***** 2. row *****
      id: 2
  select_type: DEPENDENT SUBQUERY
      table: t2
      type: ref_or_null
possible_keys: maybe_null_key
      key: maybe_null_key
     key_len: 5
        ref: func
        rows: 2
      Extra: Using where; Using index
  ...
```

The `unique_subquery` and `index_subquery` subquery-specific access methods also have “or `NULL`” variants. However, prior to MySQL 5.7.3, they are not visible in `EXPLAIN` output, so you must

use `EXPLAIN EXTENDED` followed by `SHOW WARNINGS` (note the `checking NULL` in the warning message):

```
mysql> EXPLAIN EXTENDED
-> SELECT outer_expr IN (SELECT maybe_null_key FROM t2) FROM t1\G
***** 1. row *****
      id: 1
    select_type: PRIMARY
      table: t1
  ...
***** 2. row *****
      id: 2
    select_type: DEPENDENT SUBQUERY
      table: t2
        type: index_subquery
possible_keys: maybe_null_key
        key: maybe_null_key
      key_len: 5
        ref: func
        rows: 2
      Extra: Using index

mysql> SHOW WARNINGS\G
***** 1. row *****
    Level: Note
    Code: 1003
Message: select (`test`.`t1`.`outer_expr`,
  (((`test`.`t1`.`outer_expr`) in t2 on
  maybe_null_key checking NULL))) AS `outer_expr` IN (SELECT
  maybe_null_key FROM t2)` from `test`.`t1`
```

The additional `OR ... IS NULL` condition makes query execution slightly more complicated (and some optimizations within the subquery become inapplicable), but generally this is tolerable.

The situation is much worse when `outer_expr` can be `NULL`. According to the SQL interpretation of `NULL` as “unknown value,” `NULL IN (SELECT inner_expr ...)` should evaluate to:

- `NULL`, if the `SELECT` produces any rows
- `FALSE`, if the `SELECT` produces no rows

For proper evaluation, it is necessary to be able to check whether the `SELECT` has produced any rows at all, so `outer_expr = inner_expr` cannot be pushed down into the subquery. This is a problem, because many real world subqueries become very slow unless the equality can be pushed down.

Essentially, there must be different ways to execute the subquery depending on the value of `outer_expr`.

The optimizer chooses SQL compliance over speed, so it accounts for the possibility that `outer_expr` might be `NULL`.

If `outer_expr` is `NULL`, to evaluate the following expression, it is necessary to run the `SELECT` to determine whether it produces any rows:

```
NULL IN (SELECT inner_expr FROM ... WHERE subquery_where)
```

It is necessary to run the original `SELECT` here, without any pushed-down equalities of the kind mentioned earlier.

On the other hand, when `outer_expr` is not `NULL`, it is absolutely essential that this comparison:

```
outer_expr IN (SELECT inner_expr FROM ... WHERE subquery_where)
```

be converted to this expression that uses a pushed-down condition:

```
EXISTS (SELECT 1 FROM ... WHERE subquery_where AND outer_expr=inner_expr)
```

Without this conversion, subqueries will be slow. To solve the dilemma of whether to push down or not push down conditions into the subquery, the conditions are wrapped in “trigger” functions. Thus, an expression of the following form:

```
outer_expr IN (SELECT inner_expr FROM ... WHERE subquery_where)
```

is converted into:

```
EXISTS (SELECT 1 FROM ... WHERE subquery_where
      AND trigcond(outer_expr=inner_expr))
```

More generally, if the subquery comparison is based on several pairs of outer and inner expressions, the conversion takes this comparison:

```
(oe_1, ..., oe_N) IN (SELECT ie_1, ..., ie_N FROM ... WHERE subquery_where)
```

and converts it to this expression:

```
EXISTS (SELECT 1 FROM ... WHERE subquery_where
      AND trigcond(oe_1=ie_1)
      AND ...
      AND trigcond(oe_N=ie_N)
    )
```

Each `trigcond(X)` is a special function that evaluates to the following values:

- *X* when the “linked” outer expression *oe\_i* is not NULL
- TRUE when the “linked” outer expression *oe\_i* is NULL

#### Note

Trigger functions are *not* triggers of the kind that you create with `CREATE TRIGGER`.

Equalities that are wrapped into `trigcond()` functions are not first class predicates for the query optimizer. Most optimizations cannot deal with predicates that may be turned on and off at query execution time, so they assume any `trigcond(X)` to be an unknown function and ignore it. At the moment, triggered equalities can be used by those optimizations:

- Reference optimizations: `trigcond(X=Y [OR Y IS NULL])` can be used to construct `ref`, `eq_ref`, or `ref_or_null` table accesses.
- Index lookup-based subquery execution engines: `trigcond(X=Y)` can be used to construct `unique_subquery` or `index_subquery` accesses.
- Table-condition generator: If the subquery is a join of several tables, the triggered condition will be checked as soon as possible.

When the optimizer uses a triggered condition to create some kind of index lookup-based access (as for the first two items of the preceding list), it must have a fallback strategy for the case when the condition is turned off. This fallback strategy is always the same: Do a full table scan. In `EXPLAIN` output, the fallback shows up as `Full scan on NULL key` in the `Extra` column:

```
mysql> EXPLAIN SELECT t1.col1,
      -> t1.col1 IN (SELECT t2.key1 FROM t2 WHERE t2.col2=t1.col2) FROM t1\G
```

```
***** 1. row *****
      id: 1
      select_type: PRIMARY
      table: t1
      ...
***** 2. row *****
      id: 2
      select_type: DEPENDENT SUBQUERY
      table: t2
      type: index_subquery
possible_keys: key1
      key: key1
      key_len: 5
      ref: func
      rows: 2
      Extra: Using where; Full scan on NULL key
```

If you run `EXPLAIN EXTENDED` followed by `SHOW WARNINGS`, you can see the triggered condition:

```
***** 1. row *****
Level: Note
Code: 1003
Message: select `test`.`t1`.`col1` AS `col1`,
      <in_optimizer>(`test`.`t1`.`col1`,
      <exists>(<index_lookup>(<cache>(`test`.`t1`.`col1`) in t2
      on key1 checking NULL
      where (`test`.`t2`.`col2` = `test`.`t1`.`col2`) having
      trigcond(<is_not_null_test>(`test`.`t2`.`key1`)))) AS
      `t1.col1 IN (select t2.key1 from t2 where t2.col2=t1.col2)`
      from `test`.`t1`
```

The use of triggered conditions has some performance implications. A `NULL IN (SELECT ...)` expression now may cause a full table scan (which is slow) when it previously did not. This is the price paid for correct results (the goal of the trigger-condition strategy was to improve compliance and not speed).

For multiple-table subqueries, execution of `NULL IN (SELECT ...)` will be particularly slow because the join optimizer does not optimize for the case where the outer expression is `NULL`. It assumes that subquery evaluations with `NULL` on the left side are very rare, even if there are statistics that indicate otherwise. On the other hand, if the outer expression might be `NULL` but never actually is, there is no performance penalty.

To help the query optimizer better execute your queries, use these tips:

- Declare a column as `NOT NULL` if it really is. (This also helps other aspects of the optimizer by simplifying condition testing for the column.)
- If you do not need to distinguish a `NULL` from `FALSE` subquery result, you can easily avoid the slow execution path. Replace a comparison that looks like this:

```
outer_expr IN (SELECT inner_expr FROM ...)
```

with this expression:

```
(outer_expr IS NOT NULL) AND (outer_expr IN (SELECT inner_expr FROM ...))
```

Then `NULL IN (SELECT ...)` is never evaluated because MySQL stops evaluating `AND` parts as soon as the expression result is clear.

Another possible rewrite:

```
EXISTS (SELECT inner_expr FROM ...
      WHERE inner_expr=outer_expr)
```

This would apply when you need not distinguish `NULL` from `FALSE` subquery results, in which case you may actually want `EXISTS`.

The `subquery_materialization_cost_based` flag enables control over the choice between subquery materialization and `IN-to-EXISTS` subquery transformation. See [Section 9.9.2, “Controlling Switchable Optimizations”](#).

### 9.2.1.19 LIMIT Query Optimization

If you need only a specified number of rows from a result set, use a `LIMIT` clause in the query, rather than fetching the whole result set and throwing away the extra data.

MySQL sometimes optimizes a query that has a `LIMIT row_count` clause and no `HAVING` clause:

- If you select only a few rows with `LIMIT`, MySQL uses indexes in some cases when normally it would prefer to do a full table scan.
- If you combine `LIMIT row_count` with `ORDER BY`, MySQL ends the sorting as soon as it has found the first `row_count` rows of the sorted result, rather than sorting the entire result. If ordering is done by using an index, this is very fast. If a filesort must be done, all rows that match the query without the `LIMIT` clause are selected, and most or all of them are sorted, before the first `row_count` are found. After the initial rows have been found, MySQL does not sort any remainder of the result set.

One manifestation of this behavior is that an `ORDER BY` query with and without `LIMIT` may return rows in different order, as described later in this section.

- If you combine `LIMIT row_count` with `DISTINCT`, MySQL stops as soon as it finds `row_count` unique rows.
- In some cases, a `GROUP BY` can be resolved by reading the index in order (or doing a sort on the index) and then calculating summaries until the index value changes. In this case, `LIMIT row_count` does not calculate any unnecessary `GROUP BY` values.
- As soon as MySQL has sent the required number of rows to the client, it aborts the query unless you are using `SQL_CALC_FOUND_ROWS`. The number of rows can then be retrieved with `SELECT FOUND_ROWS()`. See [Section 13.14, “Information Functions”](#).
- `LIMIT 0` quickly returns an empty set. This can be useful for checking the validity of a query. It can also be employed to obtain the types of the result columns if you are using a MySQL API that makes result set metadata available. With the `mysql` client program, you can use the `--column-type-info` option to display result column types.
- If the server uses temporary tables to resolve the query, it uses the `LIMIT row_count` clause to calculate how much space is required.

If multiple rows have identical values in the `ORDER BY` columns, the server is free to return those rows in any order, and may do so differently depending on the overall execution plan. In other words, the sort order of those rows is nondeterministic with respect to the nonordered columns.

One factor that affects the execution plan is `LIMIT`, so an `ORDER BY` query with and without `LIMIT` may return rows in different orders. Consider this query, which is sorted by the `category` column but nondeterministic with respect to the `id` and `rating` columns:

```
mysql> SELECT * FROM ratings ORDER BY category;
```

| id | category | rating |
|----|----------|--------|
| 1  | 1        | 4.5    |
| 5  | 1        | 3.2    |

|   |   |     |
|---|---|-----|
| 3 | 2 | 3.7 |
| 4 | 2 | 3.5 |
| 6 | 2 | 3.5 |
| 2 | 3 | 5.0 |
| 7 | 3 | 2.7 |

Including `LIMIT` may affect order of rows within each `category` value. For example, this is a valid query result:

```
mysql> SELECT * FROM ratings ORDER BY category LIMIT 5;
```

| id | category | rating |
|----|----------|--------|
| 1  | 1        | 4.5    |
| 5  | 1        | 3.2    |
| 4  | 2        | 3.5    |
| 3  | 2        | 3.7    |
| 6  | 2        | 3.5    |

In each case, the rows are sorted by the `ORDER BY` column, which is all that is required by the SQL standard.

If it is important to ensure the same row order with and without `LIMIT`, include additional columns in the `ORDER BY` clause to make the order deterministic. For example, if `id` values are unique, you can make rows for a given `category` value appear in `id` order by sorting like this:

```
mysql> SELECT * FROM ratings ORDER BY category, id;
```

| id | category | rating |
|----|----------|--------|
| 1  | 1        | 4.5    |
| 5  | 1        | 3.2    |
| 3  | 2        | 3.7    |
| 4  | 2        | 3.5    |
| 6  | 2        | 3.5    |
| 2  | 3        | 5.0    |
| 7  | 3        | 2.7    |

```
mysql> SELECT * FROM ratings ORDER BY category, id LIMIT 5;
```

| id | category | rating |
|----|----------|--------|
| 1  | 1        | 4.5    |
| 5  | 1        | 3.2    |
| 3  | 2        | 3.7    |
| 4  | 2        | 3.5    |
| 6  | 2        | 3.5    |

The optimizer does handle queries (and subqueries) of the following form:

```
SELECT ... FROM single_table ... ORDER BY non_index_column [DESC] LIMIT [M,]N;
```

That type of query is common in web applications that display only a few rows from a larger result set. For example:

```
SELECT col1, ... FROM t1 ... ORDER BY name LIMIT 10;
SELECT col1, ... FROM t1 ... ORDER BY RAND() LIMIT 15;
```

The sort buffer has a size of `sort_buffer_size`. If the sort elements for `N` rows are small enough to fit in the sort buffer (`M+N` rows if `M` was specified), the server can avoid using a merge file and perform the sort entirely in memory by treating the sort buffer as a priority queue:

- Scan the table, inserting the select list columns from each selected row in sorted order in the queue. If the queue is full, bump out the last row in the sort order.
- Return the first  $N$  rows from the queue. (If  $M$  was specified, skip the first  $M$  rows and return the next  $N$  rows.)

Previously, the server performed this operation by using a merge file for the sort:

- Scan the table, repeating these steps through the end of the table:
  - Select rows until the sort buffer is filled.
  - Write the first  $N$  rows in the buffer ( $M+N$  rows if  $M$  was specified) to a merge file.
- Sort the merge file and return the first  $N$  rows. (If  $M$  was specified, skip the first  $M$  rows and return the next  $N$  rows.)

The cost of the table scan is the same for the queue and merge-file methods, so the optimizer chooses between methods based on other costs:

- The queue method involves more CPU for inserting rows into the queue in order
- The merge-file method has I/O costs to write and read the file and CPU cost to sort it

The optimizer considers the balance between these factors for particular values of  $N$  and the row size.

### 9.2.1.20 Row Constructor Expression Optimization

Row constructors permit simultaneous comparisons of multiple values. For example, these two statements are semantically equivalent:

```
SELECT * FROM t1 WHERE (column1,column2) = (1,1);
SELECT * FROM t1 WHERE column1 = 1 AND column2 = 1;
```

In addition, the optimizer handles both expressions the same way.

The optimizer is less likely to use available indexes if the row constructor columns do not cover the prefix of an index. Consider the following table, which has a primary key on ( $c1$ ,  $c2$ ,  $c3$ ):

```
CREATE TABLE t1 (
  c1 INT, c2 INT, c3 INT, c4 CHAR(100),
  PRIMARY KEY(c1,c2,c3)
);
```

In this query, the `WHERE` clause uses all columns in the index. However, the row constructor itself does not cover an index prefix, with the result that the optimizer uses only  $c1$  (`key_len=4`, the size of  $c1$ ):

```
mysql> EXPLAIN SELECT * FROM t1
-> WHERE c1=1 AND (c2,c3) > (1,1)\G
***** 1. row *****
      id: 1
    select_type: SIMPLE
      table: t1
    partitions: NULL
       type: ref
possible_keys: PRIMARY
        key: PRIMARY
       key_len: 4
         ref: const
        rows: 3
   filtered: 100.00
    Extra: Using where
```

In such cases, rewriting the row constructor expression using an equivalent nonconstructor expression may result in more complete index use. For the given query, the row constructor and equivalent nonconstructor expressions are:

```
(c2,c3) > (1,1)
c2 > 1 OR ((c2 = 1) AND (c3 > 1))
```

Rewriting the query to use the nonconstructor expression results in the optimizer using all three columns in the index (`key_len=12`):

```
mysql> EXPLAIN SELECT * FROM t1
-> WHERE c1 = 1 AND (c2 > 1 OR ((c2 = 1) AND (c3 > 1)))\G
***** 1. row *****
      id: 1
    select_type: SIMPLE
      table: t1
    partitions: NULL
      type: range
possible_keys: PRIMARY
      key: PRIMARY
     key_len: 12
       ref: NULL
      rows: 3
  filtered: 100.00
    Extra: Using where
```

Thus, for better results, avoid mixing row constructors with `AND/OR` expressions. Use one or the other.

Under certain conditions, the optimizer can apply the range access method to `IN( )` expressions that have row constructor arguments. See [Range Optimization of Row Constructor Expressions](#).

### 9.2.1.21 How to Avoid Full Table Scans

The output from `EXPLAIN` shows `ALL` in the `type` column when MySQL uses a [full table scan](#) to resolve a query. This usually happens under the following conditions:

- The table is so small that it is faster to perform a table scan than to bother with a key lookup. This is common for tables with fewer than 10 rows and a short row length.
- There are no usable restrictions in the `ON` or `WHERE` clause for indexed columns.
- You are comparing indexed columns with constant values and MySQL has calculated (based on the index tree) that the constants cover too large a part of the table and that a table scan would be faster. See [Section 9.2.1.2, “How MySQL Optimizes WHERE Clauses”](#).
- You are using a key with low cardinality (many rows match the key value) through another column. In this case, MySQL assumes that by using the key it probably will do many key lookups and that a table scan would be faster.

For small tables, a table scan often is appropriate and the performance impact is negligible. For large tables, try the following techniques to avoid having the optimizer incorrectly choose a table scan:

- Use `ANALYZE TABLE tbl_name` to update the key distributions for the scanned table. See [Section 14.7.2.1, “ANALYZE TABLE Syntax”](#).
- Use `FORCE INDEX` for the scanned table to tell MySQL that table scans are very expensive compared to using the given index:

```
SELECT * FROM t1, t2 FORCE INDEX (index_for_column)
WHERE t1.col_name=t2.col_name;
```

See [Section 9.9.4, “Index Hints”](#).

- Start `mysqld` with the `--max-seeks-for-key=1000` option or use `SET max_seeks_for_key=1000` to tell the optimizer to assume that no key scan causes more than 1,000 key seeks. See [Section 6.1.5, “Server System Variables”](#).

## 9.2.2 Optimizing Data Change Statements

This section explains how to speed up data change statements: `INSERT`, `UPDATE`, and `DELETE`. Traditional OLTP applications and modern web applications typically do many small data change operations, where concurrency is vital. Data analysis and reporting applications typically run data change operations that affect many rows at once, where the main considerations is the I/O to write large amounts of data and keep indexes up-to-date. For inserting and updating large volumes of data (known in the industry as ETL, for “extract-transform-load”), sometimes you use other SQL statements or external commands, that mimic the effects of `INSERT`, `UPDATE`, and `DELETE` statements.

### 9.2.2.1 Speed of INSERT Statements

To optimize insert speed, combine many small operations into a single large operation. Ideally, you make a single connection, send the data for many new rows at once, and delay all index updates and consistency checking until the very end.

The time required for inserting a row is determined by the following factors, where the numbers indicate approximate proportions:

- Connecting: (3)
- Sending query to server: (2)
- Parsing query: (2)
- Inserting row: (1 × size of row)
- Inserting indexes: (1 × number of indexes)
- Closing: (1)

This does not take into consideration the initial overhead to open tables, which is done once for each concurrently running query.

The size of the table slows down the insertion of indexes by  $\log N$ , assuming B-tree indexes.

You can use the following methods to speed up inserts:

- If you are inserting many rows from the same client at the same time, use `INSERT` statements with multiple `VALUES` lists to insert several rows at a time. This is considerably faster (many times faster in some cases) than using separate single-row `INSERT` statements. If you are adding data to a nonempty table, you can tune the `bulk_insert_buffer_size` variable to make data insertion even faster. See [Section 6.1.5, “Server System Variables”](#).
- When loading a table from a text file, use `LOAD DATA INFILE`. This is usually 20 times faster than using `INSERT` statements. See [Section 14.2.6, “LOAD DATA INFILE Syntax”](#).
- Take advantage of the fact that columns have default values. Insert values explicitly only when the value to be inserted differs from the default. This reduces the parsing that MySQL must do and improves the insert speed.
- See [Section 9.5.5, “Bulk Data Loading for InnoDB Tables”](#) for tips specific to `InnoDB` tables.
- See [Section 9.6.2, “Bulk Data Loading for MyISAM Tables”](#) for tips specific to `MyISAM` tables.

### 9.2.2.2 Speed of UPDATE Statements

An update statement is optimized like a [SELECT](#) query with the additional overhead of a write. The speed of the write depends on the amount of data being updated and the number of indexes that are updated. Indexes that are not changed do not get updated.

Another way to get fast updates is to delay updates and then do many updates in a row later. Performing multiple updates together is much quicker than doing one at a time if you lock the table.

For a [MyISAM](#) table that uses dynamic row format, updating a row to a longer total length may split the row. If you do this often, it is very important to use [OPTIMIZE TABLE](#) occasionally. See [Section 14.7.2.4, “OPTIMIZE TABLE Syntax”](#).

### 9.2.2.3 Speed of DELETE Statements

The time required to delete individual rows in a [MyISAM](#) table is exactly proportional to the number of indexes. To delete rows more quickly, you can increase the size of the key cache by increasing the [key\\_buffer\\_size](#) system variable. See [Section 6.1.1, “Configuring the Server”](#).

To delete all rows from a [MyISAM](#) table, [TRUNCATE TABLE tbl\\_name](#) is faster than [DELETE FROM tbl\\_name](#). Truncate operations are not transaction-safe; an error occurs when attempting one in the course of an active transaction or active table lock. See [Section 14.1.34, “TRUNCATE TABLE Syntax”](#).

## 9.2.3 Optimizing Database Privileges

The more complex your privilege setup, the more overhead applies to all SQL statements. Simplifying the privileges established by [GRANT](#) statements enables MySQL to reduce permission-checking overhead when clients execute statements. For example, if you do not grant any table-level or column-level privileges, the server need not ever check the contents of the [tables\\_priv](#) and [columns\\_priv](#) tables. Similarly, if you place no resource limits on any accounts, the server does not have to perform resource counting. If you have a very high statement-processing load, consider using a simplified grant structure to reduce permission-checking overhead.

### 9.2.4 Optimizing INFORMATION\_SCHEMA Queries

Applications that monitor databases may make frequent use of [INFORMATION\\_SCHEMA](#) tables. Certain types of queries for [INFORMATION\\_SCHEMA](#) tables can be optimized to execute more quickly. The goal is to minimize file operations (for example, scanning a directory or opening a table file) to collect the information that makes up these dynamic tables.

#### Note

Comparison behavior for database and table names in [INFORMATION\\_SCHEMA](#) queries might differ from what you expect. For details, see [Section 11.1.8.7, “Using Collation in INFORMATION\\_SCHEMA Searches”](#).

#### 1) Try to use constant lookup values for database and table names in the [WHERE](#) clause

You can take advantage of this principle as follows:

- To look up databases or tables, use expressions that evaluate to a constant, such as literal values, functions that return a constant, or scalar subqueries.
- Avoid queries that use a nonconstant database name lookup value (or no lookup value) because they require a scan of the data directory to find matching database directory names.
- Within a database, avoid queries that use a nonconstant table name lookup value (or no lookup value) because they require a scan of the database directory to find matching table files.

This principle applies to the [INFORMATION\\_SCHEMA](#) tables shown in the following table, which shows the columns for which a constant lookup value enables the server to avoid a directory scan. For

example, if you are selecting from `TABLES`, using a constant lookup value for `TABLE_SCHEMA` in the `WHERE` clause enables a data directory scan to be avoided.

| Table                                | Column to specify to avoid data directory scan | Column to specify to avoid database directory scan |
|--------------------------------------|--|--|
| <code>COLUMNS</code>                 | <code>TABLE_SCHEMA</code>                      | <code>TABLE_NAME</code>                            |
| <code>KEY_COLUMN_USAGE</code>        | <code>TABLE_SCHEMA</code>                      | <code>TABLE_NAME</code>                            |
| <code>PARTITIONS</code>              | <code>TABLE_SCHEMA</code>                      | <code>TABLE_NAME</code>                            |
| <code>REFERENTIAL_CONSTRAINTS</code> | <code>CONSTRAINT_SCHEMA</code>                 | <code>TABLE_NAME</code>                            |
| <code>STATISTICS</code>              | <code>TABLE_SCHEMA</code>                      | <code>TABLE_NAME</code>                            |
| <code>TABLES</code>                  | <code>TABLE_SCHEMA</code>                      | <code>TABLE_NAME</code>                            |
| <code>TABLE_CONSTRAINTS</code>       | <code>TABLE_SCHEMA</code>                      | <code>TABLE_NAME</code>                            |
| <code>TRIGGERS</code>                | <code>EVENT_OBJECT_SCHEMA</code>               | <code>EVENT_OBJECT_TABLE</code>                    |
| <code>VIEWS</code>                   | <code>TABLE_SCHEMA</code>                      | <code>TABLE_NAME</code>                            |

The benefit of a query that is limited to a specific constant database name is that checks need be made only for the named database directory. Example:

```
SELECT TABLE_NAME FROM INFORMATION_SCHEMA.TABLES
WHERE TABLE_SCHEMA = 'test';
```

Use of the literal database name `test` enables the server to check only the `test` database directory, regardless of how many databases there might be. By contrast, the following query is less efficient because it requires a scan of the data directory to determine which database names match the pattern `'test%'`:

```
SELECT TABLE_NAME FROM INFORMATION_SCHEMA.TABLES
WHERE TABLE_SCHEMA LIKE 'test%';
```

For a query that is limited to a specific constant table name, checks need be made only for the named table within the corresponding database directory. Example:

```
SELECT TABLE_NAME FROM INFORMATION_SCHEMA.TABLES
WHERE TABLE_SCHEMA = 'test' AND TABLE_NAME = 't1';
```

Use of the literal table name `t1` enables the server to check only the files for the `t1` table, regardless of how many tables there might be in the `test` database. By contrast, the following query requires a scan of the `test` database directory to determine which table names match the pattern `'t%'`:

```
SELECT TABLE_NAME FROM INFORMATION_SCHEMA.TABLES
WHERE TABLE_SCHEMA = 'test' AND TABLE_NAME LIKE 't%';
```

The following query requires a scan of the database directory to determine matching database names for the pattern `'test%'`, and for each matching database, it requires a scan of the database directory to determine matching table names for the pattern `'t%'`:

```
SELECT TABLE_NAME FROM INFORMATION_SCHEMA.TABLES
WHERE TABLE_SCHEMA = 'test%' AND TABLE_NAME LIKE 't%';
```

## 2) Write queries that minimize the number of table files that must be opened

For queries that refer to certain `INFORMATION_SCHEMA` table columns, several optimizations are available that minimize the number of table files that must be opened. Example:

```
SELECT TABLE_NAME, ENGINE FROM INFORMATION_SCHEMA.TABLES
WHERE TABLE_SCHEMA = 'test';
```

In this case, after the server has scanned the database directory to determine the names of the tables in the database, those names become available with no further file system lookups. Thus,

`TABLE_NAME` requires no files to be opened. The `ENGINE` (storage engine) value can be determined by opening the table's `.frm` file, without touching other table files such as the `.MYD` or `.MYI` file.

Some values, such as `INDEX_LENGTH` for `MyISAM` tables, require opening the `.MYD` or `.MYI` file as well.

The file-opening optimization types are denoted thus:

- `SKIP_OPEN_TABLE`: Table files do not need to be opened. The information has already become available within the query by scanning the database directory.
- `OPEN_FRM_ONLY`: Only the table's `.frm` file need be opened.
- `OPEN_TRIGGER_ONLY`: Only the table's `.TRG` file need be opened.
- `OPEN_FULL_TABLE`: The unoptimized information lookup. The `.frm`, `.MYD`, and `.MYI` files must be opened.

The following list indicates how the preceding optimization types apply to `INFORMATION_SCHEMA` table columns. For tables and columns not named, none of the optimizations apply.

- `COLUMNS`: `OPEN_FRM_ONLY` applies to all columns
- `KEY_COLUMN_USAGE`: `OPEN_FULL_TABLE` applies to all columns
- `PARTITIONS`: `OPEN_FULL_TABLE` applies to all columns
- `REFERENTIAL_CONSTRAINTS`: `OPEN_FULL_TABLE` applies to all columns
- `STATISTICS`:

| Column                     | Optimization type            |
|----------------------------|------------------------------|
| <code>TABLE_CATALOG</code> | <code>OPEN_FRM_ONLY</code>   |
| <code>TABLE_SCHEMA</code>  | <code>OPEN_FRM_ONLY</code>   |
| <code>TABLE_NAME</code>    | <code>OPEN_FRM_ONLY</code>   |
| <code>NON_UNIQUE</code>    | <code>OPEN_FRM_ONLY</code>   |
| <code>INDEX_SCHEMA</code>  | <code>OPEN_FRM_ONLY</code>   |
| <code>INDEX_NAME</code>    | <code>OPEN_FRM_ONLY</code>   |
| <code>SEQ_IN_INDEX</code>  | <code>OPEN_FRM_ONLY</code>   |
| <code>COLUMN_NAME</code>   | <code>OPEN_FRM_ONLY</code>   |
| <code>COLLATION</code>     | <code>OPEN_FRM_ONLY</code>   |
| <code>CARDINALITY</code>   | <code>OPEN_FULL_TABLE</code> |
| <code>SUB_PART</code>      | <code>OPEN_FRM_ONLY</code>   |
| <code>PACKED</code>        | <code>OPEN_FRM_ONLY</code>   |
| <code>NULLABLE</code>      | <code>OPEN_FRM_ONLY</code>   |
| <code>INDEX_TYPE</code>    | <code>OPEN_FULL_TABLE</code> |
| <code>COMMENT</code>       | <code>OPEN_FRM_ONLY</code>   |

- `TABLES`:

| Column                     | Optimization type            |
|----------------------------|------------------------------|
| <code>TABLE_CATALOG</code> | <code>SKIP_OPEN_TABLE</code> |
| <code>TABLE_SCHEMA</code>  | <code>SKIP_OPEN_TABLE</code> |
| <code>TABLE_NAME</code>    | <code>SKIP_OPEN_TABLE</code> |

| Column          | Optimization type |
|-----------------|-------------------|
| TABLE_TYPE      | OPEN_FRM_ONLY     |
| ENGINE          | OPEN_FRM_ONLY     |
| VERSION         | OPEN_FRM_ONLY     |
| ROW_FORMAT      | OPEN_FULL_TABLE   |
| TABLE_ROWS      | OPEN_FULL_TABLE   |
| AVG_ROW_LENGTH  | OPEN_FULL_TABLE   |
| DATA_LENGTH     | OPEN_FULL_TABLE   |
| MAX_DATA_LENGTH | OPEN_FULL_TABLE   |
| INDEX_LENGTH    | OPEN_FULL_TABLE   |
| DATA_FREE       | OPEN_FULL_TABLE   |
| AUTO_INCREMENT  | OPEN_FULL_TABLE   |
| CREATE_TIME     | OPEN_FULL_TABLE   |
| UPDATE_TIME     | OPEN_FULL_TABLE   |
| CHECK_TIME      | OPEN_FULL_TABLE   |
| TABLE_COLLATION | OPEN_FRM_ONLY     |
| CHECKSUM        | OPEN_FULL_TABLE   |
| CREATE_OPTIONS  | OPEN_FRM_ONLY     |
| TABLE_COMMENT   | OPEN_FRM_ONLY     |

- TABLE\_CONSTRAINTS: OPEN\_FULL\_TABLE applies to all columns
- TRIGGERS: OPEN\_TRIGGER\_ONLY applies to all columns
- VIEWS:

| Column               | Optimization type |
|----------------------|-------------------|
| TABLE_CATALOG        | OPEN_FRM_ONLY     |
| TABLE_SCHEMA         | OPEN_FRM_ONLY     |
| TABLE_NAME           | OPEN_FRM_ONLY     |
| VIEW_DEFINITION      | OPEN_FRM_ONLY     |
| CHECK_OPTION         | OPEN_FRM_ONLY     |
| IS_UPDATABLE         | OPEN_FULL_TABLE   |
| DEFINER              | OPEN_FRM_ONLY     |
| SECURITY_TYPE        | OPEN_FRM_ONLY     |
| CHARACTER_SET_CLIENT | OPEN_FRM_ONLY     |
| COLLATION_CONNECTION | OPEN_FRM_ONLY     |

### 3) Use **EXPLAIN** to determine whether the server can use **INFORMATION\_SCHEMA** optimizations for a query

This applies particularly for **INFORMATION\_SCHEMA** queries that search for information from more than one database, which might take a long time and impact performance. The **Extra** value in **EXPLAIN** output indicates which, if any, of the optimizations described earlier the server can use to evaluate **INFORMATION\_SCHEMA** queries. The following examples demonstrate the kinds of information you can expect to see in the **Extra** value.

```
mysql> EXPLAIN SELECT TABLE_NAME FROM INFORMATION_SCHEMA.VIEWS WHERE
-> TABLE_SCHEMA = 'test' AND TABLE_NAME = 'v1'\G
```

```

***** 1. row *****
      id: 1
      select_type: SIMPLE
      table: VIEWS
      type: ALL
possible_keys: NULL
      key: TABLE_SCHEMA, TABLE_NAME
      key_len: NULL
      ref: NULL
      rows: NULL
      Extra: Using where; Open_frm_only; Scanned 0 databases
    
```

Use of constant database and table lookup values enables the server to avoid directory scans. For references to `VIEWS.TABLE_NAME`, only the `.frm` file need be opened.

```

mysql> EXPLAIN SELECT TABLE_NAME, ROW_FORMAT FROM INFORMATION_SCHEMA.TABLES\G
***** 1. row *****
      id: 1
      select_type: SIMPLE
      table: TABLES
      type: ALL
possible_keys: NULL
      key: NULL
      key_len: NULL
      ref: NULL
      rows: NULL
      Extra: Open_full_table; Scanned all databases
    
```

No lookup values are provided (there is no `WHERE` clause), so the server must scan the data directory and each database directory. For each table thus identified, the table name and row format are selected. `TABLE_NAME` requires no further table files to be opened (the `SKIP_OPEN_TABLE` optimization applies). `ROW_FORMAT` requires all table files to be opened (`OPEN_FULL_TABLE` applies). `EXPLAIN` reports `OPEN_FULL_TABLE` because it is more expensive than `SKIP_OPEN_TABLE`.

```

mysql> EXPLAIN SELECT TABLE_NAME, TABLE_TYPE FROM INFORMATION_SCHEMA.TABLES
-> WHERE TABLE_SCHEMA = 'test'\G
***** 1. row *****
      id: 1
      select_type: SIMPLE
      table: TABLES
      type: ALL
possible_keys: NULL
      key: TABLE_SCHEMA
      key_len: NULL
      ref: NULL
      rows: NULL
      Extra: Using where; Open_frm_only; Scanned 1 database
    
```

No table name lookup value is provided, so the server must scan the `test` database directory. For the `TABLE_NAME` and `TABLE_TYPE` columns, the `SKIP_OPEN_TABLE` and `OPEN_FRM_ONLY` optimizations apply, respectively. `EXPLAIN` reports `OPEN_FRM_ONLY` because it is more expensive.

```

mysql> EXPLAIN SELECT B.TABLE_NAME
-> FROM INFORMATION_SCHEMA.TABLES AS A, INFORMATION_SCHEMA.COLUMNS AS B
-> WHERE A.TABLE_SCHEMA = 'test'
-> AND A.TABLE_NAME = 't1'
-> AND B.TABLE_NAME = A.TABLE_NAME\G
***** 1. row *****
      id: 1
      select_type: SIMPLE
      table: A
      type: ALL
possible_keys: NULL
      key: TABLE_SCHEMA, TABLE_NAME
      key_len: NULL
      ref: NULL
      rows: NULL
      Extra: Using where; Skip_open_table; Scanned 0 databases
***** 2. row *****
      id: 1
    
```

```

select_type: SIMPLE
table: B
type: ALL
possible_keys: NULL
key: NULL
key_len: NULL
ref: NULL
rows: NULL
Extra: Using where; Open_frm_only; Scanned all databases;
      Using join buffer

```

For the first `EXPLAIN` output row: Constant database and table lookup values enable the server to avoid directory scans for `TABLES` values. References to `TABLES.TABLE_NAME` require no further table files.

For the second `EXPLAIN` output row: All `COLUMNS` table values are `OPEN_FRM_ONLY` lookups, so `COLUMNS.TABLE_NAME` requires the `.frm` file to be opened.

```

mysql> EXPLAIN SELECT * FROM INFORMATION_SCHEMA.COLLATIONS\G
***** 1. row *****
      id: 1
select_type: SIMPLE
table: COLLATIONS
type: ALL
possible_keys: NULL
key: NULL
key_len: NULL
ref: NULL
rows: NULL
Extra:

```

In this case, no optimizations apply because `COLLATIONS` is not one of the `INFORMATION_SCHEMA` tables for which optimizations are available.

## 9.2.5 Other Optimization Tips

This section lists a number of miscellaneous tips for improving query processing speed:

- If your application makes several database requests to perform related updates, combining the statements into a stored routine can help performance. Similarly, if your application computes a single result based on several column values or large volumes of data, combining the computation into a UDF (user-defined function) can help performance. The resulting fast database operations are then available to be reused by other queries, applications, and even code written in different programming languages. See [Section 22.2, “Using Stored Routines \(Procedures and Functions\)”](#) and [Section 27.4, “Adding New Functions to MySQL”](#) for more information.
- To fix any compression issues that occur with `ARCHIVE` tables, use `OPTIMIZE TABLE`. See [Section 16.5, “The ARCHIVE Storage Engine”](#).
- If possible, classify reports as “live” or as “statistical”, where data needed for statistical reports is created only from summary tables that are generated periodically from the live data.
- If you have data that does not conform well to a rows-and-columns table structure, you can pack and store data into a `BLOB` column. In this case, you must provide code in your application to pack and unpack information, but this might save I/O operations to read and write the sets of related values.
- With Web servers, store images and other binary assets as files, with the path name stored in the database rather than the file itself. Most Web servers are better at caching files than database contents, so using files is generally faster. (Although you must handle backups and storage issues yourself in this case.)
- If you need really high speed, look at the low-level MySQL interfaces. For example, by accessing the MySQL `InnoDB` or `MyISAM` storage engine directly, you could get a substantial speed increase compared to using the SQL interface.

- Replication can provide a performance benefit for some operations. You can distribute client retrievals among replication servers to split up the load. To avoid slowing down the master while making backups, you can make backups using a slave server. See [Chapter 18, Replication](#).

## 9.3 Optimization and Indexes

The best way to improve the performance of [SELECT](#) operations is to create indexes on one or more of the columns that are tested in the query. The index entries act like pointers to the table rows, allowing the query to quickly determine which rows match a condition in the [WHERE](#) clause, and retrieve the other column values for those rows. All MySQL data types can be indexed.

Although it can be tempting to create an indexes for every possible column used in a query, unnecessary indexes waste space and waste time for MySQL to determine which indexes to use. Indexes also add to the cost of inserts, updates, and deletes because each index must be updated. You must find the right balance to achieve fast queries using the optimal set of indexes.

### 9.3.1 How MySQL Uses Indexes

Indexes are used to find rows with specific column values quickly. Without an index, MySQL must begin with the first row and then read through the entire table to find the relevant rows. The larger the table, the more this costs. If the table has an index for the columns in question, MySQL can quickly determine the position to seek to in the middle of the data file without having to look at all the data. This is much faster than reading every row sequentially.

Most MySQL indexes ([PRIMARY KEY](#), [UNIQUE](#), [INDEX](#), and [FULLTEXT](#)) are stored in [B-trees](#). Exceptions: Indexes on spatial data types use R-trees; [MEMORY](#) tables also support [hash indexes](#); [InnoDB](#) uses inverted lists for [FULLTEXT](#) indexes.

In general, indexes are used as described in the following discussion. Characteristics specific to hash indexes (as used in [MEMORY](#) tables) are described in [Section 9.3.8, “Comparison of B-Tree and Hash Indexes”](#).

MySQL uses indexes for these operations:

- To find the rows matching a [WHERE](#) clause quickly.
- To eliminate rows from consideration. If there is a choice between multiple indexes, MySQL normally uses the index that finds the smallest number of rows (the most [selective](#) index).
- If the table has a multiple-column index, any leftmost prefix of the index can be used by the optimizer to look up rows. For example, if you have a three-column index on ([col1](#), [col2](#), [col3](#)), you have indexed search capabilities on ([col1](#)), ([col1](#), [col2](#)), and ([col1](#), [col2](#), [col3](#)). For more information, see [Section 9.3.5, “Multiple-Column Indexes”](#).
- To retrieve rows from other tables when performing joins. MySQL can use indexes on columns more efficiently if they are declared as the same type and size. In this context, [VARCHAR](#) and [CHAR](#) are considered the same if they are declared as the same size. For example, [VARCHAR\(10\)](#) and [CHAR\(10\)](#) are the same size, but [VARCHAR\(10\)](#) and [CHAR\(15\)](#) are not.

For comparisons between nonbinary string columns, both columns should use the same character set. For example, comparing a [utf8](#) column with a [latin1](#) column precludes use of an index.

Comparison of dissimilar columns (comparing a string column to a temporal or numeric column, for example) may prevent use of indexes if values cannot be compared directly without conversion. For a given value such as [1](#) in the numeric column, it might compare equal to any number of values in the string column such as ['1'](#), [' 1'](#), ['00001'](#), or ['01.e1'](#). This rules out use of any indexes for the string column.

- To find the [MIN\(\)](#) or [MAX\(\)](#) value for a specific indexed column [key\\_col](#). This is optimized by a preprocessor that checks whether you are using [WHERE key\\_part\\_N = constant](#) on all key

parts that occur before *key\_col* in the index. In this case, MySQL does a single key lookup for each *MIN()* or *MAX()* expression and replaces it with a constant. If all expressions are replaced with constants, the query returns at once. For example:

```
SELECT MIN(key_part2),MAX(key_part2)
FROM tbl_name WHERE key_part1=10;
```

- To sort or group a table if the sorting or grouping is done on a leftmost prefix of a usable index (for example, *ORDER BY key\_part1, key\_part2*). If all key parts are followed by *DESC*, the key is read in reverse order. See [Section 9.2.1.15, “ORDER BY Optimization”](#), and [Section 9.2.1.16, “GROUP BY Optimization”](#).
- In some cases, a query can be optimized to retrieve values without consulting the data rows. (An index that provides all the necessary results for a query is called a [covering index](#).) If a query uses from a table only columns that are included in some index, the selected values can be retrieved from the index tree for greater speed:

```
SELECT key_part3 FROM tbl_name
WHERE key_part1=1
```

Indexes are less important for queries on small tables, or big tables where report queries process most or all of the rows. When a query needs to access most of the rows, reading sequentially is faster than working through an index. Sequential reads minimize disk seeks, even if not all the rows are needed for the query. See [Section 9.2.1.21, “How to Avoid Full Table Scans”](#) for details.

## 9.3.2 Using Primary Keys

The primary key for a table represents the column or set of columns that you use in your most vital queries. It has an associated index, for fast query performance. Query performance benefits from the *NOT NULL* optimization, because it cannot include any *NULL* values. With the *InnoDB* storage engine, the table data is physically organized to do ultra-fast lookups and sorts based on the primary key column or columns.

If your table is big and important, but does not have an obvious column or set of columns to use as a primary key, you might create a separate column with auto-increment values to use as the primary key. These unique IDs can serve as pointers to corresponding rows in other tables when you join tables using foreign keys.

## 9.3.3 Using Foreign Keys

If a table has many columns, and you query many different combinations of columns, it might be efficient to split the less-frequently used data into separate tables with a few columns each, and relate them back to the main table by duplicating the numeric ID column from the main table. That way, each small table can have a primary key for fast lookups of its data, and you can query just the set of columns that you need using a join operation. Depending on how the data is distributed, the queries might perform less I/O and take up less cache memory because the relevant columns are packed together on disk. (To maximize performance, queries try to read as few data blocks as possible from disk; tables with only a few columns can fit more rows in each data block.)

## 9.3.4 Column Indexes

The most common type of index involves a single column, storing copies of the values from that column in a data structure, allowing fast lookups for the rows with the corresponding column values. The B-tree data structure lets the index quickly find a specific value, a set of values, or a range of values, corresponding to operators such as *=*, *>*, *≤*, *BETWEEN*, *IN*, and so on, in a *WHERE* clause.

The maximum number of indexes per table and the maximum index length is defined per storage engine. See [Chapter 15, \*The InnoDB Storage Engine\*](#), and [Chapter 16, \*Alternative Storage Engines\*](#).

All storage engines support at least 16 indexes per table and a total index length of at least 256 bytes. Most storage engines have higher limits.

For additional information about column indexes, see [Section 14.1.14, “CREATE INDEX Syntax”](#).

## Prefix Indexes

With `col_name(N)` syntax in an index specification for a string column, you can create an index that uses only the first *N* characters of the column. Indexing only a prefix of column values in this way can make the index file much smaller. When you index a `BLOB` or `TEXT` column, you *must* specify a prefix length for the index. For example:

```
CREATE TABLE test (blob_col BLOB, INDEX(blob_col(10)));
```

Prefixes can be up to 1000 bytes long (767 bytes for `InnoDB` tables, unless you have `innodb_large_prefix` set).

### Note

Prefix limits are measured in bytes, whereas the prefix length in `CREATE TABLE`, `ALTER TABLE`, and `CREATE INDEX` statements is interpreted as number of characters for nonbinary string types (`CHAR`, `VARCHAR`, `TEXT`) and number of bytes for binary string types (`BINARY`, `VARBINARY`, `BLOB`). Take this into account when specifying a prefix length for a nonbinary string column that uses a multibyte character set.

For additional information about index prefixes, see [Section 14.1.14, “CREATE INDEX Syntax”](#).

## FULLTEXT Indexes

`FULLTEXT` indexes are used for full-text searches. Only the `InnoDB` and `MyISAM` storage engines support `FULLTEXT` indexes and only for `CHAR`, `VARCHAR`, and `TEXT` columns. Indexing always takes place over the entire column and column prefix indexing is not supported. For details, see [Section 13.9, “Full-Text Search Functions”](#).

Optimizations are applied to certain kinds of `FULLTEXT` queries against single `InnoDB` tables. Queries with these characteristics are particularly efficient:

- `FULLTEXT` queries that only return the document ID, or the document ID and the search rank.
- `FULLTEXT` queries that sort the matching rows in descending order of score and apply a `LIMIT` clause to take the top *N* matching rows. For this optimization to apply, there must be no `WHERE` clauses and only a single `ORDER BY` clause in descending order.
- `FULLTEXT` queries that retrieve only the `COUNT(*)` value of rows matching a search term, with no additional `WHERE` clauses. Code the `WHERE` clause as `WHERE MATCH(text) AGAINST ('other_text')`, without any `> 0` comparison operator.

## Spatial Indexes

You can create indexes on spatial data types. `MyISAM` and (as of MySQL 5.7.5) `InnoDB` support R-tree indexes on spatial types. Other storage engines use B-trees for indexing spatial types (except for `ARCHIVE`, which does not support spatial type indexing).

## Indexes in the MEMORY Storage Engine

The `MEMORY` storage engine uses `HASH` indexes by default, but also supports `BTREE` indexes.

## 9.3.5 Multiple-Column Indexes

MySQL can create composite indexes (that is, indexes on multiple columns). An index may consist of up to 16 columns. For certain data types, you can index a prefix of the column (see [Section 9.3.4, “Column Indexes”](#)).

MySQL can use multiple-column indexes for queries that test all the columns in the index, or queries that test just the first column, the first two columns, the first three columns, and so on. If you specify the columns in the right order in the index definition, a single composite index can speed up several kinds of queries on the same table.

A multiple-column index can be considered a sorted array, the rows of which contain values that are created by concatenating the values of the indexed columns.

#### Note

As an alternative to a composite index, you can introduce a column that is “hashed” based on information from other columns. If this column is short, reasonably unique, and indexed, it might be faster than a “wide” index on many columns. In MySQL, it is very easy to use this extra column:

```
SELECT * FROM tbl_name
WHERE hash_col=MD5(CONCAT(val1,val2))
AND col1=val1 AND col2=val2;
```

Suppose that a table has the following specification:

```
CREATE TABLE test (
  id          INT NOT NULL,
  last_name   CHAR(30) NOT NULL,
  first_name  CHAR(30) NOT NULL,
  PRIMARY KEY (id),
  INDEX name (last_name,first_name)
);
```

The `name` index is an index over the `last_name` and `first_name` columns. The index can be used for lookups in queries that specify values in a known range for combinations of `last_name` and `first_name` values. It can also be used for queries that specify just a `last_name` value because that column is a leftmost prefix of the index (as described later in this section). Therefore, the `name` index is used for lookups in the following queries:

```
SELECT * FROM test WHERE last_name='Widenius';

SELECT * FROM test
  WHERE last_name='Widenius' AND first_name='Michael';

SELECT * FROM test
  WHERE last_name='Widenius'
    AND (first_name='Michael' OR first_name='Monty');

SELECT * FROM test
  WHERE last_name='Widenius'
    AND first_name >='M' AND first_name < 'N';
```

However, the `name` index is *not* used for lookups in the following queries:

```
SELECT * FROM test WHERE first_name='Michael';

SELECT * FROM test
  WHERE last_name='Widenius' OR first_name='Michael';
```

Suppose that you issue the following `SELECT` statement:

```
SELECT * FROM tbl_name
```

```
WHERE col1=val1 AND col2=val2;
```

If a multiple-column index exists on `col1` and `col2`, the appropriate rows can be fetched directly. If separate single-column indexes exist on `col1` and `col2`, the optimizer attempts to use the Index Merge optimization (see [Section 9.2.1.4, “Index Merge Optimization”](#)), or attempts to find the most restrictive index by deciding which index excludes more rows and using that index to fetch the rows.

If the table has a multiple-column index, any leftmost prefix of the index can be used by the optimizer to look up rows. For example, if you have a three-column index on `(col1, col2, col3)`, you have indexed search capabilities on `(col1)`, `(col1, col2)`, and `(col1, col2, col3)`.

MySQL cannot use the index to perform lookups if the columns do not form a leftmost prefix of the index. Suppose that you have the `SELECT` statements shown here:

```
SELECT * FROM tbl_name WHERE col1=val1;
SELECT * FROM tbl_name WHERE col1=val1 AND col2=val2;

SELECT * FROM tbl_name WHERE col2=val2;
SELECT * FROM tbl_name WHERE col2=val2 AND col3=val3;
```

If an index exists on `(col1, col2, col3)`, only the first two queries use the index. The third and fourth queries do involve indexed columns, but `(col2)` and `(col2, col3)` are not leftmost prefixes of `(col1, col2, col3)`.

### 9.3.6 Verifying Index Usage

Always check whether all your queries really use the indexes that you have created in the tables. Use the `EXPLAIN` statement, as described in [Section 9.8.1, “Optimizing Queries with EXPLAIN”](#).

### 9.3.7 InnoDB and MyISAM Index Statistics Collection

Storage engines collect statistics about tables for use by the optimizer. Table statistics are based on value groups, where a value group is a set of rows with the same key prefix value. For optimizer purposes, an important statistic is the average value group size.

MySQL uses the average value group size in the following ways:

- To estimate how many rows must be read for each `ref` access
- To estimate how many row a partial join will produce; that is, the number of rows that an operation of this form will produce:

```
(...) JOIN tbl_name ON tbl_name.key = expr
```

As the average value group size for an index increases, the index is less useful for those two purposes because the average number of rows per lookup increases: For the index to be good for optimization purposes, it is best that each index value target a small number of rows in the table. When a given index value yields a large number of rows, the index is less useful and MySQL is less likely to use it.

The average value group size is related to table cardinality, which is the number of value groups. The `SHOW INDEX` statement displays a cardinality value based on  $N/S$ , where  $N$  is the number of rows in the table and  $S$  is the average value group size. That ratio yields an approximate number of value groups in the table.

For a join based on the `<=>` comparison operator, `NULL` is not treated differently from any other value: `NULL <=> NULL`, just as `N <=> N` for any other `N`.

However, for a join based on the `=` operator, `NULL` is different from non-`NULL` values: `expr1 = expr2` is not true when `expr1` or `expr2` (or both) are `NULL`. This affects `ref` accesses for comparisons of the form `tbl_name.key = expr`: MySQL will not access the table if the current value of `expr` is `NULL`, because the comparison cannot be true.

For `=` comparisons, it does not matter how many `NULL` values are in the table. For optimization purposes, the relevant value is the average size of the non-`NULL` value groups. However, MySQL does not currently enable that average size to be collected or used.

For `InnoDB` and `MyISAM` tables, you have some control over collection of table statistics by means of the `innodb_stats_method` and `myisam_stats_method` system variables, respectively. These variables have three possible values, which differ as follows:

- When the variable is set to `nulls_equal`, all `NULL` values are treated as identical (that is, they all form a single value group).

If the `NULL` value group size is much higher than the average non-`NULL` value group size, this method skews the average value group size upward. This makes index appear to the optimizer to be less useful than it really is for joins that look for non-`NULL` values. Consequently, the `nulls_equal` method may cause the optimizer not to use the index for `ref` accesses when it should.

- When the variable is set to `nulls_unequal`, `NULL` values are not considered the same. Instead, each `NULL` value forms a separate value group of size 1.

If you have many `NULL` values, this method skews the average value group size downward. If the average non-`NULL` value group size is large, counting `NULL` values each as a group of size 1 causes the optimizer to overestimate the value of the index for joins that look for non-`NULL` values. Consequently, the `nulls_unequal` method may cause the optimizer to use this index for `ref` lookups when other methods may be better.

- When the variable is set to `nulls_ignored`, `NULL` values are ignored.

If you tend to use many joins that use `<=>` rather than `=`, `NULL` values are not special in comparisons and one `NULL` is equal to another. In this case, `nulls_equal` is the appropriate statistics method.

The `innodb_stats_method` system variable has a global value; the `myisam_stats_method` system variable has both global and session values. Setting the global value affects statistics collection for tables from the corresponding storage engine. Setting the session value affects statistics collection only for the current client connection. This means that you can force a table's statistics to be regenerated with a given method without affecting other clients by setting the session value of `myisam_stats_method`.

To regenerate `MyISAM` table statistics, you can use any of the following methods:

- Execute `myisamchk --stats_method=method_name --analyze`
- Change the table to cause its statistics to go out of date (for example, insert a row and then delete it), and then set `myisam_stats_method` and issue an `ANALYZE TABLE` statement

Some caveats regarding the use of `innodb_stats_method` and `myisam_stats_method`:

- You can force table statistics to be collected explicitly, as just described. However, MySQL may also collect statistics automatically. For example, if during the course of executing statements for a table, some of those statements modify the table, MySQL may collect statistics. (This may occur for bulk inserts or deletes, or some `ALTER TABLE` statements, for example.) If this happens, the statistics are collected using whatever value `innodb_stats_method` or `myisam_stats_method` has at the time. Thus, if you collect statistics using one method, but the system variable is set to the other method when a table's statistics are collected automatically later, the other method will be used.
- There is no way to tell which method was used to generate statistics for a given table.
- These variables apply only to `InnoDB` and `MyISAM` tables. Other storage engines have only one method for collecting table statistics. Usually it is closer to the `nulls_equal` method.

### 9.3.8 Comparison of B-Tree and Hash Indexes

Understanding the B-tree and hash data structures can help predict how different queries perform on different storage engines that use these data structures in their indexes, particularly for the [MEMORY](#) storage engine that lets you choose B-tree or hash indexes.

## B-Tree Index Characteristics

A B-tree index can be used for column comparisons in expressions that use the `=`, `>`, `>=`, `<`, `<=`, or [BETWEEN](#) operators. The index also can be used for [LIKE](#) comparisons if the argument to [LIKE](#) is a constant string that does not start with a wildcard character. For example, the following [SELECT](#) statements use indexes:

```
SELECT * FROM tbl_name WHERE key_col LIKE 'Patrick%';
SELECT * FROM tbl_name WHERE key_col LIKE 'Pat%ck%';
```

In the first statement, only rows with `'Patrick' <= key_col < 'Patricl'` are considered. In the second statement, only rows with `'Pat' <= key_col < 'Pau'` are considered.

The following [SELECT](#) statements do not use indexes:

```
SELECT * FROM tbl_name WHERE key_col LIKE '%Patrick%';
SELECT * FROM tbl_name WHERE key_col LIKE other_col;
```

In the first statement, the [LIKE](#) value begins with a wildcard character. In the second statement, the [LIKE](#) value is not a constant.

If you use `... LIKE '%string%'` and *string* is longer than three characters, MySQL uses the *Turbo Boyer-Moore algorithm* to initialize the pattern for the string and then uses this pattern to perform the search more quickly.

A search using `col_name IS NULL` employs indexes if *col\_name* is indexed.

Any index that does not span all [AND](#) levels in the [WHERE](#) clause is not used to optimize the query. In other words, to be able to use an index, a prefix of the index must be used in every [AND](#) group.

The following [WHERE](#) clauses use indexes:

```
... WHERE index_part1=1 AND index_part2=2 AND other_column=3

/* index = 1 OR index = 2 */
... WHERE index=1 OR A=10 AND index=2

/* optimized like "index_part1='hello'" */
... WHERE index_part1='hello' AND index_part3=5

/* Can use index on index1 but not on index2 or index3 */
... WHERE index1=1 AND index2=2 OR index1=3 AND index3=3;
```

These [WHERE](#) clauses do *not* use indexes:

```
/* index_part1 is not used */
... WHERE index_part2=1 AND index_part3=2

/* Index is not used in both parts of the WHERE clause */
... WHERE index=1 OR A=10

/* No index spans all rows */
... WHERE index_part1=1 OR index_part2=10
```

Sometimes MySQL does not use an index, even if one is available. One circumstance under which this occurs is when the optimizer estimates that using the index would require MySQL to access a very large percentage of the rows in the table. (In this case, a table scan is likely to be much faster because it requires fewer seeks.) However, if such a query uses [LIMIT](#) to retrieve only some of the

rows, MySQL uses an index anyway, because it can much more quickly find the few rows to return in the result.

## Hash Index Characteristics

Hash indexes have somewhat different characteristics from those just discussed:

- They are used only for equality comparisons that use the `=` or `<=>` operators (but are *very* fast). They are not used for comparison operators such as `<` that find a range of values. Systems that rely on this type of single-value lookup are known as “key-value stores”; to use MySQL for such applications, use hash indexes wherever possible.
- The optimizer cannot use a hash index to speed up `ORDER BY` operations. (This type of index cannot be used to search for the next entry in order.)
- MySQL cannot determine approximately how many rows there are between two values (this is used by the range optimizer to decide which index to use). This may affect some queries if you change a `MyISAM` or `InnoDB` table to a hash-indexed `MEMORY` table.
- Only whole keys can be used to search for a row. (With a B-tree index, any leftmost prefix of the key can be used to find rows.)

### 9.3.9 Optimizer Use of Generated Column Indexes

MySQL supports indexes on generated columns. For example:

```
CREATE TABLE t1 (f1 INT, gc INT AS (f1 + 1) STORED, INDEX (gc));
```

The generated column, `gc`, is defined as the expression `f1 + 1`. The column is also indexed and the optimizer can take that index into account during execution plan construction. In the following query, the `WHERE` clause refers to `gc` and the optimizer considers whether the index on that column yields a more efficient plan:

```
SELECT * FROM t1 WHERE gc > 9;
```

As of MySQL 5.7.8, the optimizer can use indexes on generated columns to generate execution plans, even in the absence of direct references in queries to those columns by name. This occurs if the `WHERE`, `ORDER BY`, or `GROUP BY` clause refers to an expression that matches the definition of some indexed generated column. The following query does not refer directly to `gc` but does use an expression that matches the definition of `gc`:

```
SELECT * FROM t1 WHERE f1 + 1 > 9;
```

The optimizer recognizes that the expression `f1 + 1` matches the definition of `gc` and that `gc` is indexed, so it considers that index during execution plan construction. You can see this using `EXPLAIN`:

```
mysql> EXPLAIN SELECT * FROM t1 WHERE f1 + 1 > 9\G
***** 1. row *****
      id: 1
    select_type: SIMPLE
        table: t1
     partitions: NULL
         type: range
possible_keys: gc
          key: gc
        key_len: 5
         ref: NULL
         rows: 1
    filtered: 100.00
```

Extra: Using index condition

In effect, the optimizer has replaced the expression `f1 + 1` with the name of the generated column that matches the expression. That is also apparent in the rewritten query available in the extended [EXPLAIN](#) information displayed by [SHOW WARNINGS](#):

```
mysql> SHOW WARNINGS\G
***** 1. row *****
Level: Note
Code: 1003
Message: /* select#1 */ select `test`.`t1`.`f1` AS `f1`,`test`.`t1`.`gc`
        AS `gc` from `test`.`t1` where (`test`.`t1`.`gc` > 9)
```

The following restrictions and conditions apply to the optimizer's use of generated column indexes:

- For a query expression to match a generated column definition, the expression must be identical and it must have the same result type. For example, if the generated column expression is `f1 + 1`, the optimizer will not recognize a match if the query uses `1 + f1`, or if `f1 + 1` (an integer expression) is compared with a string.
- The optimization applies to these operators: `=`, `<`, `<=`, `>`, `>=`, [BETWEEN](#), and [IN\(\)](#).

For operators other than [BETWEEN](#) and [IN\(\)](#), either operand can be replaced by a matching generated column. For [BETWEEN](#) and [IN\(\)](#), only the first argument can be replaced by a matching generated column, and the other arguments must have the same result type. [BETWEEN](#) and [IN\(\)](#) are not yet supported for comparisons involving JSON values.

- The generated column must be defined as an expression that contains at least a function call or one of the operators mentioned in the preceding item. The expression cannot consist of a simple reference to another column. For example, `gc INT AS (f1) STORED` consists only of a column reference, so indexes on `gc` are not considered.
- For comparisons of strings to indexed generated columns that compute a value from a JSON function that returns a quoted string, [JSON\\_UNQUOTE\(\)](#) is needed in the column definition to remove the extra quotes from the function value. (For direct comparison of a string to the function result, the JSON comparator handles quote removal, but this does not occur for index lookups.) For example, instead of writing a column definition like this:

```
doc_name TEXT AS (JSON_EXTRACT(jdoc, '$.name')) STORED
```

Write it like this:

```
doc_name TEXT AS (JSON_UNQUOTE(JSON_EXTRACT(jdoc, '$.name'))) STORED
```

With the latter definition, the optimizer can detect a match for both of these comparisons:

```
... WHERE JSON_EXTRACT(jdoc, '$.name') = 'some_string' ...
... WHERE JSON_UNQUOTE(JSON_EXTRACT(jdoc, '$.name')) = 'some_string' ...
```

Without [JSON\\_UNQUOTE\(\)](#) in the column definition, the optimizer detects a match only for the first of those comparisons.

- If the optimizer fails to choose the desired index, an index hint can be used to force the optimizer to make a different choice.

## 9.4 Optimizing Database Structure

In your role as a database designer, look for the most efficient way to organize your schemas, tables, and columns. As when tuning application code, you minimize I/O, keep related items together, and plan ahead so that performance stays high as the data volume increases. Starting with an efficient database

design makes it easier for team members to write high-performing application code, and makes the database likely to endure as applications evolve and are rewritten.

### 9.4.1 Optimizing Data Size

Design your tables to minimize their space on the disk. This can result in huge improvements by reducing the amount of data written to and read from disk. Smaller tables normally require less main memory while their contents are being actively processed during query execution. Any space reduction for table data also results in smaller indexes that can be processed faster.

MySQL supports many different storage engines (table types) and row formats. For each table, you can decide which storage and indexing method to use. Choosing the proper table format for your application can give you a big performance gain. See [Chapter 15, The InnoDB Storage Engine](#), and [Chapter 16, Alternative Storage Engines](#).

You can get better performance for a table and minimize storage space by using the techniques listed here:

#### Table Columns

- Use the most efficient (smallest) data types possible. MySQL has many specialized types that save disk space and memory. For example, use the smaller integer types if possible to get smaller tables. `MEDIUMINT` is often a better choice than `INT` because a `MEDIUMINT` column uses 25% less space.
- Declare columns to be `NOT NULL` if possible. It makes SQL operations faster, by enabling better use of indexes and eliminating overhead for testing whether each value is `NULL`. You also save some storage space, one bit per column. If you really need `NULL` values in your tables, use them. Just avoid the default setting that allows `NULL` values in every column.

#### Row Format

- In MySQL 5.7.8 and earlier, `InnoDB` tables use the `COMPACT` row format by default. As of MySQL 5.7.9, the default row format is `DYNAMIC`.

To use a row format other than `DYNAMIC`, configure `innodb_default_row_format`, or specify the `ROW_FORMAT` option explicitly in a `CREATE TABLE` or `ALTER TABLE` statement.

The compact family of row formats, which includes `COMPACT`, `DYNAMIC`, and `COMPRESSED`, decreases row storage space at the cost of increasing CPU use for some operations. If your workload is a typical one that is limited by cache hit rates and disk speed it is likely to be faster. If it is a rare case that is limited by CPU speed, it might be slower.

The compact family of row formats also optimizes `CHAR` column storage when using a variable-length character set such as `utf8mb3` or `utf8mb4`. With `ROW_FORMAT=REDUNDANT`, `CHAR(N)` occupies  $N \times$  the maximum byte length of the character set. Many languages can be written primarily using single-byte `utf8` characters, so a fixed storage length often wastes space. With the compact family of rows formats, `InnoDB` allocates a variable amount of storage in the range of  $N$  to  $N \times$  the maximum byte length of the character set for these columns by stripping trailing spaces. The minimum storage length is  $N$  bytes to facilitate in-place updates in typical cases. For more information, see [Section 15.8.3, “Physical Row Structure of InnoDB Tables”](#).

- To minimize space even further by storing table data in compressed form, specify `ROW_FORMAT=COMPRESSED` when creating `InnoDB` tables, or run the `myisampack` command on an existing `MyISAM` table. (`InnoDB` tables compressed tables are readable and writable, while `MyISAM` compressed tables are read-only.)
- For `MyISAM` tables, if you do not have any variable-length columns (`VARCHAR`, `TEXT`, or `BLOB` columns), a fixed-size row format is used. This is faster but may waste some space. See [Section 16.2.3, “MyISAM Table Storage Formats”](#). You can hint that you want to have fixed length rows even if you have `VARCHAR` columns with the `CREATE TABLE` option `ROW_FORMAT=FIXED`.

## Indexes

- The primary index of a table should be as short as possible. This makes identification of each row easy and efficient. For [InnoDB](#) tables, the primary key columns are duplicated in each secondary index entry, so a short primary key saves considerable space if you have many secondary indexes.
- Create only the indexes that you need to improve query performance. Indexes are good for retrieval, but slow down insert and update operations. If you access a table mostly by searching on a combination of columns, create a single composite index on them rather than a separate index for each column. The first part of the index should be the column most used. If you *always* use many columns when selecting from the table, the first column in the index should be the one with the most duplicates, to obtain better compression of the index.
- If it is very likely that a long string column has a unique prefix on the first number of characters, it is better to index only this prefix, using MySQL's support for creating an index on the leftmost part of the column (see [Section 14.1.14, "CREATE INDEX Syntax"](#)). Shorter indexes are faster, not only because they require less disk space, but because they also give you more hits in the index cache, and thus fewer disk seeks. See [Section 6.1.1, "Configuring the Server"](#).

## Joins

- In some circumstances, it can be beneficial to split into two a table that is scanned very often. This is especially true if it is a dynamic-format table and it is possible to use a smaller static format table that can be used to find the relevant rows when scanning the table.
- Declare columns with identical information in different tables with identical data types, to speed up joins based on the corresponding columns.
- Keep column names simple, so that you can use the same name across different tables and simplify join queries. For example, in a table named `customer`, use a column name of `name` instead of `customer_name`. To make your names portable to other SQL servers, consider keeping them shorter than 18 characters.

## Normalization

- Normally, try to keep all data nonredundant (observing what is referred to in database theory as *third normal form*). Instead of repeating lengthy values such as names and addresses, assign them unique IDs, repeat these IDs as needed across multiple smaller tables, and join the tables in queries by referencing the IDs in the join clause.
- If speed is more important than disk space and the maintenance costs of keeping multiple copies of data, for example in a business intelligence scenario where you analyze all the data from large tables, you can relax the normalization rules, duplicating information or creating summary tables to gain more speed.

## 9.4.2 Optimizing MySQL Data Types

### 9.4.2.1 Optimizing for Numeric Data

- For unique IDs or other values that can be represented as either strings or numbers, prefer numeric columns to string columns. Since large numeric values can be stored in fewer bytes than the corresponding strings, it is faster and takes less memory to transfer and compare them.
- If you are using numeric data, it is faster in many cases to access information from a database (using a live connection) than to access a text file. Information in the database is likely to be stored in a more compact format than in the text file, so accessing it involves fewer disk accesses. You also save code in your application because you can avoid parsing the text file to find line and column boundaries.

### 9.4.2.2 Optimizing for Character and String Types

For character and string columns, follow these guidelines:

- Use binary collation order for fast comparison and sort operations, when you do not need language-specific collation features. You can use the `BINARY` operator to use binary collation within a particular query.
- When comparing values from different columns, declare those columns with the same character set and collation wherever possible, to avoid string conversions while running the query.
- For column values less than 8KB in size, use binary `VARCHAR` instead of `BLOB`. The `GROUP BY` and `ORDER BY` clauses can generate temporary tables, and these temporary tables can use the `MEMORY` storage engine if the original table does not contain any `BLOB` columns.
- If a table contains string columns such as name and address, but many queries do not retrieve those columns, consider splitting the string columns into a separate table and using join queries with a foreign key when necessary. When MySQL retrieves any value from a row, it reads a data block containing all the columns of that row (and possibly other adjacent rows). Keeping each row small, with only the most frequently used columns, allows more rows to fit in each data block. Such compact tables reduce disk I/O and memory usage for common queries.
- When you use a randomly generated value as a primary key in an `InnoDB` table, prefix it with an ascending value such as the current date and time if possible. When consecutive primary values are physically stored near each other, `InnoDB` can insert and retrieve them faster.
- See [Section 9.4.2.1, “Optimizing for Numeric Data”](#) for reasons why a numeric column is usually preferable to an equivalent string column.

### 9.4.2.3 Optimizing for BLOB Types

- When storing a large blob containing textual data, consider compressing it first. Do not use this technique when the entire table is compressed by `InnoDB` or `MyISAM`.
- For a table with several columns, to reduce memory requirements for queries that do not use the `BLOB` column, consider splitting the `BLOB` column into a separate table and referencing it with a join query when needed.
- Since the performance requirements to retrieve and display a `BLOB` value might be very different from other data types, you could put the `BLOB`-specific table on a different storage device or even a separate database instance. For example, to retrieve a `BLOB` might require a large sequential disk read that is better suited to a traditional hard drive than to an [SSD device](#).
- See [Section 9.4.2.2, “Optimizing for Character and String Types”](#) for reasons why a binary `VARCHAR` column is sometimes preferable to an equivalent `BLOB` column.
- Rather than testing for equality against a very long text string, you can store a hash of the column value in a separate column, index that column, and test the hashed value in queries. (Use the `MD5()` or `CRC32()` function to produce the hash value.) Since hash functions can produce duplicate results for different inputs, you still include a clause `AND blob_column = long_string_value` in the query to guard against false matches; the performance benefit comes from the smaller, easily scanned index for the hashed values.

### 9.4.2.4 Using PROCEDURE ANALYSE

```
ANALYSE([max_elements[,max_memory]])
```

`ANALYSE()` examines the result from a query and returns an analysis of the results that suggests optimal data types for each column that may help reduce table sizes. To obtain this analysis, append `PROCEDURE ANALYSE` to the end of a `SELECT` statement:

```
SELECT ... FROM ... WHERE ... PROCEDURE ANALYSE([max_elements[,max_memory]])
```

For example:

```
SELECT col1, col2 FROM table1 PROCEDURE ANALYSE(10, 2000);
```

The results show some statistics for the values returned by the query, and propose an optimal data type for the columns. This can be helpful for checking your existing tables, or after importing new data. You may need to try different settings for the arguments so that `PROCEDURE ANALYSE()` does not suggest the `ENUM` data type when it is not appropriate.

The arguments are optional and are used as follows:

- `max_elements` (default 256) is the maximum number of distinct values that `ANALYSE()` notices per column. This is used by `ANALYSE()` to check whether the optimal data type should be of type `ENUM`; if there are more than `max_elements` distinct values, then `ENUM` is not a suggested type.
- `max_memory` (default 8192) is the maximum amount of memory that `ANALYSE()` should allocate per column while trying to find all distinct values.

A `PROCEDURE` clause is not permitted in a `UNION` statement.

### 9.4.3 Optimizing for Many Tables

Some techniques for keeping individual queries fast involve splitting data across many tables. When the number of tables runs into the thousands or even millions, the overhead of dealing with all these tables becomes a new performance consideration.

#### 9.4.3.1 How MySQL Opens and Closes Tables

When you execute a `mysqladmin status` command, you should see something like this:

```
Uptime: 426 Running threads: 1 Questions: 11082
Reloads: 1 Open tables: 12
```

The `Open tables` value of 12 can be somewhat puzzling if you have only six tables.

MySQL is multi-threaded, so there may be many clients issuing queries for a given table simultaneously. To minimize the problem with multiple client sessions having different states on the same table, the table is opened independently by each concurrent session. This uses additional memory but normally increases performance. With `MyISAM` tables, one extra file descriptor is required for the data file for each client that has the table open. (By contrast, the index file descriptor is shared between all sessions.)

The `table_open_cache` and `max_connections` system variables affect the maximum number of files the server keeps open. If you increase one or both of these values, you may run up against a limit imposed by your operating system on the per-process number of open file descriptors. Many operating systems permit you to increase the open-files limit, although the method varies widely from system to system. Consult your operating system documentation to determine whether it is possible to increase the limit and how to do so.

`table_open_cache` is related to `max_connections`. For example, for 200 concurrent running connections, specify a table cache size of at least  $200 * N$ , where  $N$  is the maximum number of tables per join in any of the queries which you execute. You must also reserve some extra file descriptors for temporary tables and files.

Make sure that your operating system can handle the number of open file descriptors implied by the `table_open_cache` setting. If `table_open_cache` is set too high, MySQL may run out of file descriptors and refuse connections, fail to perform queries, and be very unreliable.

You should also take into account the fact that the `MyISAM` storage engine needs two file descriptors for each unique open table. For a partitioned `MyISAM` table, two file descriptors are required for each

partition of the opened table. (Note further that when [MyISAM](#) opens a partitioned table, it opens every partition of this table, whether or not a given partition is actually used. See [MyISAM and partition file descriptor usage](#).) You can increase the number of file descriptors available to MySQL using the `--open-files-limit` startup option to `mysqld`. See [Section B.5.2.18, “File Not Found and Similar Errors”](#).

The cache of open tables is kept at a level of `table_open_cache` entries. The server autosizes the cache size at startup. To set the size explicitly, set the `table_open_cache` system variable at startup. Note that MySQL may temporarily open more tables than this to execute queries.

MySQL closes an unused table and removes it from the table cache under the following circumstances:

- When the cache is full and a thread tries to open a table that is not in the cache.
- When the cache contains more than `table_open_cache` entries and a table in the cache is no longer being used by any threads.
- When a table flushing operation occurs. This happens when someone issues a `FLUSH TABLES` statement or executes a `mysqladmin flush-tables` or `mysqladmin refresh` command.

When the table cache fills up, the server uses the following procedure to locate a cache entry to use:

- Tables that are not currently in use are released, beginning with the table least recently used.
- If a new table needs to be opened, but the cache is full and no tables can be released, the cache is temporarily extended as necessary. When the cache is in a temporarily extended state and a table goes from a used to unused state, the table is closed and released from the cache.

A [MyISAM](#) table is opened for each concurrent access. This means the table needs to be opened twice if two threads access the same table or if a thread accesses the table twice in the same query (for example, by joining the table to itself). Each concurrent open requires an entry in the table cache. The first open of any [MyISAM](#) table takes two file descriptors: one for the data file and one for the index file. Each additional use of the table takes only one file descriptor for the data file. The index file descriptor is shared among all threads.

If you are opening a table with the `HANDLER tbl_name OPEN` statement, a dedicated table object is allocated for the thread. This table object is not shared by other threads and is not closed until the thread calls `HANDLER tbl_name CLOSE` or the thread terminates. When this happens, the table is put back in the table cache (if the cache is not full). See [Section 14.2.4, “HANDLER Syntax”](#).

You can determine whether your table cache is too small by checking the `mysqld` status variable `Opened_tables`, which indicates the number of table-opening operations since the server started:

```
mysql> SHOW GLOBAL STATUS LIKE 'Opened_tables';
+-----+-----+
| Variable_name | Value |
+-----+-----+
| Opened_tables | 2741  |
+-----+-----+
```

If the value is very large or increases rapidly, even when you have not issued many `FLUSH TABLES` statements, increase the table cache size. See [Section 6.1.5, “Server System Variables”](#), and [Section 6.1.7, “Server Status Variables”](#).

### 9.4.3.2 Disadvantages of Creating Many Tables in the Same Database

If you have many [MyISAM](#) tables in the same database directory, open, close, and create operations are slow. If you execute `SELECT` statements on many different tables, there is a little overhead when the table cache is full, because for every table that has to be opened, another must be closed. You can reduce this overhead by increasing the number of entries permitted in the table cache.

## 9.4.4 Internal Temporary Table Use in MySQL

In some cases, the server creates internal temporary tables while processing statements. Users have no direct control over when this occurs.

The server creates temporary tables under conditions such as these:

- Evaluation of [UNION](#) statements, with some exceptions described later.
- Evaluation of some views, such those that use the [TEMPTABLE](#) algorithm, [UNION](#), or aggregation.
- Evaluation of derived tables (subqueries in the [FROM](#) clause).
- Tables created for subquery or semi-join materialization (see [Section 9.2.1.18](#), “Subquery Optimization”).
- Evaluation of statements that contain an [ORDER BY](#) clause and a different [GROUP BY](#) clause, or for which the [ORDER BY](#) or [GROUP BY](#) contains columns from tables other than the first table in the join queue.
- Evaluation of [DISTINCT](#) combined with [ORDER BY](#) may require a temporary table.
- For queries that use the [SQL\\_SMALL\\_RESULT](#) option, MySQL uses an in-memory temporary table, unless the query also contains elements (described later) that require on-disk storage.
- Evaluation of multiple-table [UPDATE](#) statements.
- Evaluation of [GROUP\\_CONCAT\( \)](#) or [COUNT\(DISTINCT\)](#) expressions.

To determine whether a statement requires a temporary table, use [EXPLAIN](#) and check the [Extra](#) column to see whether it says [Using temporary](#) (see [Section 9.8.1](#), “Optimizing Queries with EXPLAIN”). [EXPLAIN](#) will not necessarily say [Using temporary](#) for derived or materialized temporary tables.

When the server creates an internal temporary table (either in memory or on disk), it increments the [Created\\_tmp\\_tables](#) status variable. If the server creates the table on disk (either initially or by converting an in-memory table) it increments the [Created\\_tmp\\_disk\\_tables](#) status variable.

Some query conditions prevent the use of an in-memory temporary table, in which case the server uses an on-disk table instead:

- Presence of a [BLOB](#) or [TEXT](#) column in the table
- Presence of any string column in a [GROUP BY](#) or [DISTINCT](#) clause larger than 512 bytes for binary strings or 512 characters for nonbinary strings. (This applies only before MySQL 5.7.5. In addition, before MySQL 5.7.3, the limit is 512 bytes regardless of string type.)
- Presence of any string column with a maximum length larger than 512 (bytes for binary strings, characters for nonbinary strings) in the [SELECT](#) list, if [UNION](#) or [UNION ALL](#) is used
- The [SHOW COLUMNS](#) and [DESCRIBE](#) statements use [BLOB](#) as the type for some columns, thus the temporary table used for the results is an on-disk table.

As of MySQL 5.7.3, the server does not use a temporary table for [UNION](#) statements that meet certain qualifications. Instead, it retains from temporary table creation only the data structures necessary to perform result column typecasting. The table is not fully instantiated and no rows are written to or read from it; rows are sent directly to the client. The result is reduced memory and disk requirements, and smaller delay before the first row is sent to the client because the server need not wait until the last query block is executed. [EXPLAIN](#) and optimizer trace output reflects this execution strategy: The [UNION RESULT](#) query block is not present because that block corresponds to the part that reads from the temporary table.

These conditions qualify a [UNION](#) for evaluation without a temporary table:

- The union is `UNION ALL`, not `UNION` or `UNION DISTINCT`.
- There is no global `ORDER BY` clause.
- The union is not the top-level query block of an `{INSERT | REPLACE} ... SELECT ...` statement.

## Storage Engines Used for Temporary Tables

An internal temporary table can be held in memory and processed by the `MEMORY` storage engine, or stored on disk by the `InnoDB` or `MyISAM` storage engine.

If an internal temporary table is created as an in-memory table but becomes too large, MySQL automatically converts it to an on-disk table. The maximum size for in-memory temporary tables is determined from whichever of the values of `tmp_table_size` and `max_heap_table_size` is smaller. This differs from `MEMORY` tables explicitly created with `CREATE TABLE`: For such tables, only the `max_heap_table_size` system variable determines how large the table is permitted to grow and there is no conversion to on-disk format.

As of MySQL 5.7.5, the `internal_tmp_disk_storage_engine` system variable determines which storage engine the server uses to manage on-disk internal temporary tables. The value can be `INNODB` or `MYISAM`. The default in MySQL 5.7.5 is `MYISAM`. As of MySQL 5.7.6, the default is `INNODB`. Before MySQL 5.7.5, the server always uses `MyISAM` for on-disk internal temporary tables.

### Note

Using `internal_tmp_disk_storage_engine=INNODB`, queries that generate temporary tables exceeding `InnoDB` row or column limits return `Row size too large` or `Too many columns` errors. The workaround is to set `internal_tmp_disk_storage_engine` to `MYISAM`.

## Temporary Table Storage Format

In-memory temporary tables are managed by the `MEMORY` storage engine, which uses fixed-length row format. `VARCHAR` and `VARBINARY` column values are padded to the maximum column length, in effect storing them as `CHAR` and `BINARY` columns.

On-disk temporary tables are managed by the `InnoDB` or `MyISAM` storage engine (depending on the `internal_tmp_disk_storage_engine` setting). Both engines store temporary tables using dynamic-width row format. Columns take only as much storage as needed, which reduces disk I/O and space requirements, and processing time compared to on-disk tables that use fixed-length rows.

For statements that initially create an internal temporary table in memory, then convert it to an on-disk table, better performance might be achieved by skipping the conversion step and creating the table on disk to begin with. The `big_tables` system variable can be used to force disk storage of internal temporary tables.

## 9.5 Optimizing for InnoDB Tables

`InnoDB` is the storage engine that MySQL customers typically use in production databases where reliability and concurrency are important. `InnoDB` is the default storage engine in MySQL. This section explains how to optimize database operations for `InnoDB` tables.

### 9.5.1 Optimizing Storage Layout for InnoDB Tables

- Once your data reaches a stable size, or a growing table has increased by tens or some hundreds of megabytes, consider using the `OPTIMIZE TABLE` statement to reorganize the table and compact any wasted space. The reorganized tables require less disk I/O to perform full table scans. This is a straightforward technique that can improve performance when other techniques such as improving index usage or tuning application code are not practical.

`OPTIMIZE TABLE` copies the data part of the table and rebuilds the indexes. The benefits come from improved packing of data within indexes, and reduced fragmentation within the tablespaces and on disk. The benefits vary depending on the data in each table. You may find that there are significant gains for some and not for others, or that the gains decrease over time until you next optimize the table. This operation can be slow if the table is large or if the indexes being rebuilt do not fit into the buffer pool. The first run after adding a lot of data to a table is often much slower than later runs.

- In `InnoDB`, having a long `PRIMARY KEY` (either a single column with a lengthy value, or several columns that form a long composite value) wastes a lot of disk space. The primary key value for a row is duplicated in all the secondary index records that point to the same row. (See [Section 15.8.9, “Clustered and Secondary Indexes”](#).) Create an `AUTO_INCREMENT` column as the primary key if your primary key is long, or index a prefix of a long `VARCHAR` column instead of the entire column.
- Use the `VARCHAR` data type instead of `CHAR` to store variable-length strings or for columns with many `NULL` values. A `CHAR(N)` column always takes `N` characters to store data, even if the string is shorter or its value is `NULL`. Smaller tables fit better in the buffer pool and reduce disk I/O.

When using `COMPACT` row format (the default `InnoDB` format) and variable-length character sets, such as `utf8` or `sjis`, `CHAR(N)` columns occupy a variable amount of space, but still at least `N` bytes.

- For tables that are big, or contain lots of repetitive text or numeric data, consider using `COMPRESSED` row format. Less disk I/O is required to bring data into the buffer pool, or to perform full table scans. Before making a permanent decision, measure the amount of compression you can achieve by using `COMPRESSED` versus `COMPACT` row format.

## 9.5.2 Optimizing InnoDB Transaction Management

To optimize `InnoDB` transaction processing, find the ideal balance between the performance overhead of transactional features and the workload of your server. For example, an application might encounter performance issues if it commits thousands of times per second, and different performance issues if it commits only every 2-3 hours.

- The default MySQL setting `AUTOCOMMIT=1` can impose performance limitations on a busy database server. Where practical, wrap several related data change operations into a single transaction, by issuing `SET AUTOCOMMIT=0` or a `START TRANSACTION` statement, followed by a `COMMIT` statement after making all the changes.

`InnoDB` must flush the log to disk at each transaction commit if that transaction made modifications to the database. When each change is followed by a commit (as with the default autocommit setting), the I/O throughput of the storage device puts a cap on the number of potential operations per second.

- Alternatively, for transactions that consist only of a single `SELECT` statement, turning on `AUTOCOMMIT` helps `InnoDB` to recognize read-only transactions and optimize them. See [Section 9.5.3, “Optimizing InnoDB Read-Only Transactions”](#) for requirements.
- Avoid performing rollbacks after inserting, updating, or deleting huge numbers of rows. If a big transaction is slowing down server performance, rolling it back can make the problem worse, potentially taking several times as long to perform as the original data change operations. Killing the database process does not help, because the rollback starts again on server startup.

To minimize the chance of this issue occurring:

- Increase the size of the `buffer pool` so that all the data change changes can be cached rather than immediately written to disk.
- Set `innodb_change_buffering=all` so that update and delete operations are buffered in addition to inserts.

- Consider issuing `COMMIT` statements periodically during the big data change operation, possibly breaking a single delete or update into multiple statements that operate on smaller numbers of rows.

To get rid of a runaway rollback once it occurs, increase the buffer pool so that the rollback becomes CPU-bound and runs fast, or kill the server and restart with `innodb_force_recovery=3`, as explained in [Section 15.18.1, “The InnoDB Recovery Process”](#).

This issue is expected to be less prominent in MySQL 5.5 and higher because the default setting `innodb_change_buffering=all` allows update and delete operations to be cached in memory, making them faster to perform in the first place, and also faster to roll back if needed. Make sure to use this parameter setting on servers that process long-running transactions with many inserts, updates, or deletes.

- If you can afford the loss of some of the latest committed transactions if a crash occurs, you can set the `innodb_flush_log_at_trx_commit` parameter to 0. InnoDB tries to flush the log once per second anyway, although the flush is not guaranteed. Also, set the value of `innodb_support_xa` to 0, which will reduce the number of disk flushes due to synchronizing on disk data and the binary log.

#### Note

`innodb_support_xa` is deprecated and will be removed in a future release. As of MySQL 5.7.10, InnoDB support for two-phase commit in XA transactions is always enabled and disabling `innodb_support_xa` is no longer permitted.

- When rows are modified or deleted, the rows and associated [undo logs](#) are not physically removed immediately, or even immediately after the transaction commits. The old data is preserved until transactions that started earlier or concurrently are finished, so that those transactions can access the previous state of modified or deleted rows. Thus, a long-running transaction can prevent InnoDB from purging data that was changed by a different transaction.
- When rows are modified or deleted within a long-running transaction, other transactions using the [READ COMMITTED](#) and [REPEATABLE READ](#) isolation levels have to do more work to reconstruct the older data if they read those same rows.
- When a long-running transaction modifies a table, queries against that table from other transactions do not make use of the [covering index](#) technique. Queries that normally could retrieve all the result columns from a secondary index, instead look up the appropriate values from the table data.

If secondary index pages are found to have a `PAGE_MAX_TRX_ID` that is too new, or if records in the secondary index are delete-marked, InnoDB may need to look up records using a clustered index.

### 9.5.3 Optimizing InnoDB Read-Only Transactions

InnoDB can avoid the overhead associated with setting up the [transaction ID](#) (`TRX_ID` field) for transactions that are known to be read-only. A transaction ID is only needed for a [transaction](#) that might perform write operations or [locking reads](#) such as `SELECT ... FOR UPDATE`. Eliminating unnecessary transaction IDs reduces the size of internal data structures that are consulted each time a query or data change statement constructs a [read view](#).

InnoDB detects read-only transactions when:

- The transaction is started with the `START TRANSACTION READ ONLY` statement. In this case, attempting to make changes to the database (for InnoDB, MyISAM, or other types of tables) causes an error, and the transaction continues in read-only state:

```
ERROR 1792 (25006): Cannot execute statement in a READ ONLY transaction.
```

You can still make changes to session-specific temporary tables in a read-only transaction, or issue locking queries for them, because those changes and locks are not visible to any other transaction.

- The `autocommit` setting is turned on, so that the transaction is guaranteed to be a single statement, and the single statement making up the transaction is a “non-locking” `SELECT` statement. That is, a `SELECT` that does not use a `FOR UPDATE` or `LOCK IN SHARED MODE` clause.
- The transaction is started without the `READ ONLY` option, but no updates or statements that explicitly lock rows have been executed yet. Until updates or explicit locks are required, a transaction stays in read-only mode.

Thus, for a read-intensive application such as a report generator, you can tune a sequence of `InnoDB` queries by grouping them inside `START TRANSACTION READ ONLY` and `COMMIT`, or by turning on the `autocommit` setting before running the `SELECT` statements, or simply by avoiding any data change statements interspersed with the queries.

For information about `START TRANSACTION` and `autocommit`, see [Section 14.3.1, “START TRANSACTION, COMMIT, and ROLLBACK Syntax”](#).

#### Note

Transactions that qualify as auto-commit, non-locking, and read-only (AC-NL-RO) are kept out of certain internal `InnoDB` data structures and are therefore not listed in `SHOW ENGINE INNODB STATUS` output.

## 9.5.4 Optimizing InnoDB Redo Logging

Consider the following guidelines for optimizing redo logging:

- Make your redo log files big, even as big as the `buffer pool`. When `InnoDB` has written the redo log files full, it must write the modified contents of the buffer pool to disk in a `checkpoint`. Small redo log files cause many unnecessary disk writes. Although historically big redo log files caused lengthy recovery times, recovery is now much faster and you can confidently use large redo log files.

The size and number of redo log files are configured using the `innodb_log_file_size` and `innodb_log_files_in_group` configuration options. For information about modifying an existing redo log file configuration, see [Section 15.7.2, “Changing the Number or Size of InnoDB Redo Log Files”](#).

- Consider increasing the size of the `log buffer`. A large log buffer enables large `transactions` to run without a need to write the log to disk before the transactions `commit`. Thus, if you have transactions that update, insert, or delete many rows, making the log buffer larger saves disk I/O. Log buffer size is configured using the `innodb_log_buffer_size` configuration option.

## 9.5.5 Bulk Data Loading for InnoDB Tables

These performance tips supplement the general guidelines for fast inserts in [Section 9.2.2.1, “Speed of INSERT Statements”](#).

- When importing data into `InnoDB`, turn off `autocommit` mode, because it performs a log flush to disk for every insert. To disable `autocommit` during your import operation, surround it with `SET autocommit` and `COMMIT` statements:

```
SET autocommit=0;
... SQL import statements ...
COMMIT;
```

The `mysqldump` option `--opt` creates dump files that are fast to import into an `InnoDB` table, even without wrapping them with the `SET autocommit` and `COMMIT` statements.

- If you have **UNIQUE** constraints on secondary keys, you can speed up table imports by temporarily turning off the uniqueness checks during the import session:

```
SET unique_checks=0;
... SQL import statements ...
SET unique_checks=1;
```

For big tables, this saves a lot of disk I/O because **InnoDB** can use its change buffer to write secondary index records in a batch. Be certain that the data contains no duplicate keys.

- If you have **FOREIGN KEY** constraints in your tables, you can speed up table imports by turning off the foreign key checks for the duration of the import session:

```
SET foreign_key_checks=0;
... SQL import statements ...
SET foreign_key_checks=1;
```

For big tables, this can save a lot of disk I/O.

- Use the multiple-row **INSERT** syntax to reduce communication overhead between the client and the server if you need to insert many rows:

```
INSERT INTO yourtable VALUES (1,2), (5,5), ...;
```

This tip is valid for inserts into any table, not just **InnoDB** tables.

- When doing bulk inserts into tables with auto-increment columns, set **innodb\_autoinc\_lock\_mode** to 2 instead of the default value 1. See [Section 15.8.6, “AUTO\\_INCREMENT Handling in InnoDB”](#) for details.
- When performing bulk inserts, it is faster to insert rows in **PRIMARY KEY** order. **InnoDB** tables use a **clustered index**, which makes it relatively fast to use data in the order of the **PRIMARY KEY**. Performing bulk inserts in **PRIMARY KEY** order is particularly important for tables that do not fit entirely within the buffer pool.
- For optimal performance when loading data into an **InnoDB FULLTEXT** index, follow this set of steps:
  1. Define a column **FTS\_DOC\_ID** at table creation time, of type **BIGINT UNSIGNED NOT NULL**, with a unique index named **FTS\_DOC\_ID\_INDEX**. For example:

```
CREATE TABLE t1 (
  FTS_DOC_ID BIGINT unsigned NOT NULL AUTO_INCREMENT,
  title varchar(255) NOT NULL DEFAULT "",
  text mediumtext NOT NULL,
  PRIMARY KEY (`FTS_DOC_ID`)
) ENGINE=InnoDB DEFAULT CHARSET=latin1;
CREATE UNIQUE INDEX FTS_DOC_ID_INDEX on t1(FTS_DOC_ID);
```

2. Load the data into the table.
3. Create the **FULLTEXT** index after the data is loaded.

#### Note

When adding **FTS\_DOC\_ID** column at table creation time, ensure that the **FTS\_DOC\_ID** column is updated when the **FULLTEXT** indexed column is updated, as the **FTS\_DOC\_ID** must increase monotonically with each **INSERT** or **UPDATE**. If you choose not to add the **FTS\_DOC\_ID** at table creation time and have **InnoDB** manage DOC IDs for you, **InnoDB** will add

the `FTS_DOC_ID` as a hidden column with the next `CREATE FULLTEXT INDEX` call. This approach, however, requires a table rebuild which will impact performance.

## 9.5.6 Optimizing InnoDB Queries

To tune queries for InnoDB tables, create an appropriate set of indexes on each table. See [Section 9.3.1, “How MySQL Uses Indexes”](#) for details. Follow these guidelines for InnoDB indexes:

- Because each InnoDB table has a **primary key** (whether you request one or not), specify a set of primary key columns for each table, columns that are used in the most important and time-critical queries.
- Do not specify too many or too long columns in the primary key, because these column values are duplicated in each secondary index. When an index contains unnecessary data, the I/O to read this data and memory to cache it reduce the performance and scalability of the server.
- Do not create a separate **secondary index** for each column, because each query can only make use of one index. Indexes on rarely tested columns or columns with only a few different values might not be helpful for any queries. If you have many queries for the same table, testing different combinations of columns, try to create a small number of **concatenated indexes** rather than a large number of single-column indexes. If an index contains all the columns needed for the result set (known as a **covering index**), the query might be able to avoid reading the table data at all.
- If an indexed column cannot contain any `NULL` values, declare it as `NOT NULL` when you create the table. The optimizer can better determine which index is most effective to use for a query, when it knows whether each column contains `NULL` values.
- You can optimize single-query transactions for InnoDB tables, using the technique in [Section 9.5.3, “Optimizing InnoDB Read-Only Transactions”](#).
- If you often have recurring queries for tables that are not updated frequently, enable the query cache:

```
[mysqld]
query_cache_type = 1
query_cache_size = 10M
```

## 9.5.7 Optimizing InnoDB DDL Operations

- For DDL operations on tables and indexes (`CREATE`, `ALTER`, and `DROP` statements), the most significant aspect for InnoDB tables is that creating and dropping secondary indexes is much faster in MySQL 5.5 and higher, than in MySQL 5.1 and before. See [Section 15.13.1, “Overview of Online DDL”](#) for details.
- “Fast index creation” makes it faster in some cases to drop an index before loading data into a table, then re-create the index after loading the data.
- Use `TRUNCATE TABLE` to empty a table, not `DELETE FROM tbl_name`. Foreign key constraints can make a `TRUNCATE` statement work like a regular `DELETE` statement, in which case a sequence of commands like `DROP TABLE` and `CREATE TABLE` might be fastest.
- Because the primary key is integral to the storage layout of each InnoDB table, and changing the definition of the primary key involves reorganizing the whole table, always set up the primary key as part of the `CREATE TABLE` statement, and plan ahead so that you do not need to `ALTER` or `DROP` the primary key afterward.

## 9.5.8 Optimizing InnoDB Disk I/O

If you follow the best practices for database design and the tuning techniques for SQL operations, but your database is still slowed by heavy disk I/O activity, explore these low-level techniques related to

disk I/O. If the Unix `top` tool or the Windows Task Manager shows that the CPU usage percentage with your workload is less than 70%, your workload is probably disk-bound.

- When table data is cached in the InnoDB buffer pool, it can be accessed repeatedly by queries without requiring any disk I/O. Specify the size of the buffer pool with the `innodb_buffer_pool_size` option. This memory area is important enough that it is typically recommended that `innodb_buffer_pool_size` is configured to 50 to 75 percent of system memory. For more information see, [Section 9.12.4.1, “How MySQL Uses Memory”](#).
- In some versions of GNU/Linux and Unix, flushing files to disk with the Unix `fsync()` call (which InnoDB uses by default) and similar methods is surprisingly slow. If database write performance is an issue, conduct benchmarks with the `innodb_flush_method` parameter set to `O_DSYNC`.
- When using the InnoDB storage engine on Solaris 10 for x86\_64 architecture (AMD Opteron), use direct I/O for InnoDB-related files, to avoid degradation of InnoDB performance. To use direct I/O for an entire UFS file system used for storing InnoDB-related files, mount it with the `forcedirectio` option; see `mount_ufs(1M)`. (The default on Solaris 10/x86\_64 is *not* to use this option.) To apply direct I/O only to InnoDB file operations rather than the whole file system, set `innodb_flush_method = O_DIRECT`. With this setting, InnoDB calls `directio()` instead of `fcntl()` for I/O to data files (not for I/O to log files).
- When using the InnoDB storage engine with a large `innodb_buffer_pool_size` value on any release of Solaris 2.6 and up and any platform (sparc/x86/x64/amd64), conduct benchmarks with InnoDB data files and log files on raw devices or on a separate direct I/O UFS file system, using the `forcedirectio` mount option as described earlier. (It is necessary to use the mount option rather than setting `innodb_flush_method` if you want direct I/O for the log files.) Users of the Veritas file system VxFS should use the `convosync=direct` mount option.

Do not place other MySQL data files, such as those for `MyISAM` tables, on a direct I/O file system. Executables or libraries *must not* be placed on a direct I/O file system.

- If you have additional storage devices available to set up a RAID configuration or symbolic links to different disks, [Section 9.12.2, “Optimizing Disk I/O”](#) for additional low-level I/O tips.
- If throughput drops periodically because of InnoDB [checkpoint](#) operations, consider increasing the value of the `innodb_io_capacity` configuration option. Higher values cause more frequent [flushing](#), avoiding the backlog of work that can cause dips in throughput.
- If the system is not falling behind with InnoDB [flushing](#) operations, consider lowering the value of the `innodb_io_capacity` configuration option. Typically, you keep this option value as low as practical, but not so low that it causes periodic drops in throughput as mentioned in the preceding bullet. In a typical scenario where you could lower the option value, you might see a combination like this in the output from `SHOW ENGINE INNODB STATUS`:
  - History list length low, below a few thousand.
  - Insert buffer merges close to rows inserted.
  - Modified pages in buffer pool consistently well below `innodb_max_dirty_pages_pct` of the buffer pool. (Measure at a time when the server is not doing bulk inserts; it is normal during bulk inserts for the modified pages percentage to rise significantly.)
  - `Log sequence number - Last checkpoint` is at less than 7/8 or ideally less than 6/8 of the total size of the InnoDB log files.
- As of MySQL 5.7.4, you can take advantage of a doublewrite buffer-related I/O optimization by storing system tablespace files (“ibdata files”) on Fusion-io devices that support atomic writes. In this case, doublewrite buffering (`innodb_doublewrite`) is automatically disabled and Fusion-io atomic writes are used for all data files. This feature is only supported on Fusion-io hardware and is only enabled for Fusion-io NVMFS on Linux. To take full advantage of this feature, an `innodb_flush_method` setting of `O_DIRECT` is recommended.

**Note**

Because the doublewrite buffer setting is global, doublewrite buffering is also disabled for data files residing on non-Fusion-io hardware.

- When using the InnoDB table [compression](#) feature, images of re-compressed [pages](#) are written to the [redo log](#) when changes are made to compressed data. This behavior is controlled by [innodb\\_log\\_compressed\\_pages](#), which is enabled by default to prevent corruption that can occur if a different version of the [zlib](#) compression algorithm is used during recovery. If you are certain that the [zlib](#) version will not change, disable [innodb\\_log\\_compressed\\_pages](#) to reduce redo log generation for workloads that modify compressed data.
- Other InnoDB configuration options to consider when tuning I/O-bound workloads include [innodb\\_adaptive\\_flushing](#), [innodb\\_change\\_buffer\\_max\\_size](#), [innodb\\_change\\_buffering](#), [innodb\\_flush\\_neighbors](#), [innodb\\_log\\_buffer\\_size](#), [innodb\\_log\\_file\\_size](#), [innodb\\_lru\\_scan\\_depth](#), [innodb\\_max\\_dirty\\_pages\\_pct](#), [innodb\\_max\\_purge\\_lag](#), [innodb\\_open\\_files](#), [innodb\\_page\\_size](#), [innodb\\_random\\_read\\_ahead](#), [innodb\\_read\\_ahead\\_threshold](#), [innodb\\_read\\_io\\_threads](#), [innodb\\_rollback\\_segments](#), [innodb\\_write\\_io\\_threads](#), and [sync\\_binlog](#).

## 9.5.9 Optimizing InnoDB Configuration Variables

Different settings work best for servers with light, predictable loads, versus servers that are running near full capacity all the time, or that experience spikes of high activity.

Because the InnoDB storage engine performs many of its optimizations automatically, many performance-tuning tasks involve monitoring to ensure that the database is performing well, and changing configuration options when performance drops. See [Section 15.16, “InnoDB Integration with MySQL Performance Schema”](#) for information about detailed InnoDB performance monitoring.

The main configuration steps you can perform include:

- Enabling InnoDB to use high-performance memory allocators on systems that include them. See [Section 15.6.4, “Configuring the Memory Allocator for InnoDB”](#).
- Controlling the types of data change operations for which InnoDB buffers the changed data, to avoid frequent small disk writes. See [Section 15.6.5, “Configuring InnoDB Change Buffering”](#). Because the default is to buffer all types of data change operations, only change this setting if you need to reduce the amount of buffering.
- Turning the adaptive hash indexing feature on and off using the [innodb\\_adaptive\\_hash\\_index](#) option. See [Section 15.4.3, “Adaptive Hash Index”](#) for more information. You might change this setting during periods of unusual activity, then restore it to its original setting.
- Setting a limit on the number of concurrent threads that InnoDB processes, if context switching is a bottleneck. See [Section 15.6.6, “Configuring Thread Concurrency for InnoDB”](#).
- Controlling the amount of prefetching that InnoDB does with its read-ahead operations. When the system has unused I/O capacity, more read-ahead can improve the performance of queries. Too much read-ahead can cause periodic drops in performance on a heavily loaded system. See [Section 15.6.3.5, “Configuring InnoDB Buffer Pool Prefetching \(Read-Ahead\)”](#).
- Increasing the number of background threads for read or write operations, if you have a high-end I/O subsystem that is not fully utilized by the default values. See [Section 15.6.7, “Configuring the Number of Background InnoDB I/O Threads”](#).
- Controlling how much I/O InnoDB performs in the background. See [Section 15.6.8, “Configuring the InnoDB Master Thread I/O Rate”](#). You might scale back this setting if you observe periodic drops in performance.

- Controlling the algorithm that determines when [InnoDB](#) performs certain types of background writes. See [Section 15.6.3.6, “Configuring InnoDB Buffer Pool Flushing”](#). The algorithm works for some types of workloads but not others, so might turn off this setting if you observe periodic drops in performance.
- Taking advantage of multicore processors and their cache memory configuration, to minimize delays in context switching. See [Section 15.6.9, “Configuring Spin Lock Polling”](#).
- Preventing one-time operations such as table scans from interfering with the frequently accessed data stored in the [InnoDB](#) buffer cache. See [Section 15.6.3.4, “Making the Buffer Pool Scan Resistant”](#).
- Adjusting log files to a size that makes sense for reliability and crash recovery. [InnoDB](#) log files have often been kept small to avoid long startup times after a crash. Optimizations introduced in MySQL 5.5.4 speed up certain steps of the crash [recovery](#) process. In particular, scanning the [redo log](#) and applying the redo log are faster due to improved algorithms for memory management. If you have kept your log files artificially small to avoid long startup times, you can now consider increasing log file size to reduce the I/O that occurs due recycling of redo log records.
- Configuring the size and number of instances for the [InnoDB](#) buffer pool, especially important for systems with multi-gigabyte buffer pools. See [Section 15.6.3.3, “Configuring Multiple Buffer Pool Instances”](#).
- Increasing the maximum number of concurrent transactions, which dramatically improves scalability for the busiest databases. See [Section 15.4.8, “Undo Logs”](#).
- Moving purge operations (a type of garbage collection) into a background thread. See [Section 15.6.10, “Configuring InnoDB Purge Scheduling”](#). To effectively measure the results of this setting, tune the other I/O-related and thread-related configuration settings first.
- Reducing the amount of switching that [InnoDB](#) does between concurrent threads, so that SQL operations on a busy server do not queue up and form a “traffic jam”. Set a value for the [innodb\\_thread\\_concurrency](#) option, up to approximately 32 for a high-powered modern system. Increase the value for the [innodb\\_concurrency\\_tickets](#) option, typically to 5000 or so. This combination of options sets a cap on the number of threads that [InnoDB](#) processes at any one time, and allows each thread to do substantial work before being swapped out, so that the number of waiting threads stays low and operations can complete without excessive context switching.

## 9.5.10 Optimizing InnoDB for Systems with Many Tables

- If you have configured [non-persistent optimizer statistics](#) (a non-default configuration), [InnoDB](#) computes index [cardinality](#) values for a table the first time that table is accessed after startup, instead of storing such values in the table. This step can take significant time on systems that partition the data into many tables. Since this overhead only applies to the initial table open operation, to “warm up” a table for later use, access it immediately after startup by issuing a statement such as `SELECT 1 FROM tbl_name LIMIT 1`.

Optimizer statistics are persisted to disk by default, enabled by the [innodb\\_stats\\_persistent](#) configuration option. For information about persistent optimizer statistics, see [Section 15.6.11.1, “Configuring Persistent Optimizer Statistics Parameters”](#).

## 9.6 Optimizing for MyISAM Tables

The [MyISAM](#) storage engine performs best with read-mostly data or with low-concurrency operations, because table locks limit the ability to perform simultaneous updates. In MySQL, [InnoDB](#) is the default storage engine rather than [MyISAM](#).

### 9.6.1 Optimizing MyISAM Queries

Some general tips for speeding up queries on [MyISAM](#) tables:

- To help MySQL better optimize queries, use `ANALYZE TABLE` or run `myisamchk --analyze` on a table after it has been loaded with data. This updates a value for each index part that indicates the average number of rows that have the same value. (For unique indexes, this is always 1.) MySQL uses this to decide which index to choose when you join two tables based on a nonconstant expression. You can check the result from the table analysis by using `SHOW INDEX FROM tbl_name` and examining the `Cardinality` value. `myisamchk --description --verbose` shows index distribution information.
- To sort an index and data according to an index, use `myisamchk --sort-index --sort-records=1` (assuming that you want to sort on index 1). This is a good way to make queries faster if you have a unique index from which you want to read all rows in order according to the index. The first time you sort a large table this way, it may take a long time.
- Try to avoid complex `SELECT` queries on `MyISAM` tables that are updated frequently, to avoid problems with table locking that occur due to contention between readers and writers.
- `MyISAM` supports concurrent inserts: If a table has no free blocks in the middle of the data file, you can `INSERT` new rows into it at the same time that other threads are reading from the table. If it is important to be able to do this, consider using the table in ways that avoid deleting rows. Another possibility is to run `OPTIMIZE TABLE` to defragment the table after you have deleted a lot of rows from it. This behavior is altered by setting the `concurrent_insert` variable. You can force new rows to be appended (and therefore permit concurrent inserts), even in tables that have deleted rows. See [Section 9.11.3, “Concurrent Inserts”](#).
- For `MyISAM` tables that change frequently, try to avoid all variable-length columns (`VARCHAR`, `BLOB`, and `TEXT`). The table uses dynamic row format if it includes even a single variable-length column. See [Chapter 16, Alternative Storage Engines](#).
- It is normally not useful to split a table into different tables just because the rows become large. In accessing a row, the biggest performance hit is the disk seek needed to find the first byte of the row. After finding the data, most modern disks can read the entire row fast enough for most applications. The only cases where splitting up a table makes an appreciable difference is if it is a `MyISAM` table using dynamic row format that you can change to a fixed row size, or if you very often need to scan the table but do not need most of the columns. See [Chapter 16, Alternative Storage Engines](#).
- Use `ALTER TABLE ... ORDER BY expr1, expr2, ...` if you usually retrieve rows in `expr1, expr2, ...` order. By using this option after extensive changes to the table, you may be able to get higher performance.
- If you often need to calculate results such as counts based on information from a lot of rows, it may be preferable to introduce a new table and update the counter in real time. An update of the following form is very fast:

```
UPDATE tbl_name SET count_col=count_col+1 WHERE key_col=constant;
```

This is very important when you use MySQL storage engines such as `MyISAM` that has only table-level locking (multiple readers with single writers). This also gives better performance with most database systems, because the row locking manager in this case has less to do.

- Use `OPTIMIZE TABLE` periodically to avoid fragmentation with dynamic-format `MyISAM` tables. See [Section 16.2.3, “MyISAM Table Storage Formats”](#).
- Declaring a `MyISAM` table with the `DELAY_KEY_WRITE=1` table option makes index updates faster because they are not flushed to disk until the table is closed. The downside is that if something kills the server while such a table is open, you must ensure that the table is okay by running the server with the `--myisam-recover-options` option, or by running `myisamchk` before restarting the server. (However, even in this case, you should not lose anything by using `DELAY_KEY_WRITE`, because the key information can always be generated from the data rows.)
- Strings are automatically prefix- and end-space compressed in `MyISAM` indexes. See [Section 14.1.14, “CREATE INDEX Syntax”](#).

- You can increase performance by caching queries or answers in your application and then executing many inserts or updates together. Locking the table during this operation ensures that the index cache is only flushed once after all updates. You can also take advantage of MySQL's query cache to achieve similar results; see [Section 9.10.3, “The MySQL Query Cache”](#).

## 9.6.2 Bulk Data Loading for MyISAM Tables

These performance tips supplement the general guidelines for fast inserts in [Section 9.2.2.1, “Speed of INSERT Statements”](#).

- For a [MyISAM](#) table, you can use concurrent inserts to add rows at the same time that [SELECT](#) statements are running, if there are no deleted rows in middle of the data file. See [Section 9.11.3, “Concurrent Inserts”](#).
- With some extra work, it is possible to make [LOAD DATA INFILE](#) run even faster for a [MyISAM](#) table when the table has many indexes. Use the following procedure:
  1. Execute a [FLUSH TABLES](#) statement or a `mysqladmin flush-tables` command.
  2. Use `myisamchk --keys-used=0 -rq /path/to/db/tbl_name` to remove all use of indexes for the table.
  3. Insert data into the table with [LOAD DATA INFILE](#). This does not update any indexes and therefore is very fast.
  4. If you intend only to read from the table in the future, use `myisampack` to compress it. See [Section 16.2.3.3, “Compressed Table Characteristics”](#).
  5. Re-create the indexes with `myisamchk -rq /path/to/db/tbl_name`. This creates the index tree in memory before writing it to disk, which is much faster than updating the index during [LOAD DATA INFILE](#) because it avoids lots of disk seeks. The resulting index tree is also perfectly balanced.
  6. Execute a [FLUSH TABLES](#) statement or a `mysqladmin flush-tables` command.

[LOAD DATA INFILE](#) performs the preceding optimization automatically if the [MyISAM](#) table into which you insert data is empty. The main difference between automatic optimization and using the procedure explicitly is that you can let `myisamchk` allocate much more temporary memory for the index creation than you might want the server to allocate for index re-creation when it executes the [LOAD DATA INFILE](#) statement.

You can also disable or enable the nonunique indexes for a [MyISAM](#) table by using the following statements rather than `myisamchk`. If you use these statements, you can skip the [FLUSH TABLE](#) operations:

```
ALTER TABLE tbl_name DISABLE KEYS;
ALTER TABLE tbl_name ENABLE KEYS;
```

- To speed up [INSERT](#) operations that are performed with multiple statements for nontransactional tables, lock your tables:

```
LOCK TABLES a WRITE;
INSERT INTO a VALUES (1,23),(2,34),(4,33);
INSERT INTO a VALUES (8,26),(6,29);
...
UNLOCK TABLES;
```

This benefits performance because the index buffer is flushed to disk only once, after all [INSERT](#) statements have completed. Normally, there would be as many index buffer flushes as there are [INSERT](#) statements. Explicit locking statements are not needed if you can insert all rows with a single [INSERT](#).

Locking also lowers the total time for multiple-connection tests, although the maximum wait time for individual connections might go up because they wait for locks. Suppose that five clients attempt to perform inserts simultaneously as follows:

- Connection 1 does 1000 inserts
- Connections 2, 3, and 4 do 1 insert
- Connection 5 does 1000 inserts

If you do not use locking, connections 2, 3, and 4 finish before 1 and 5. If you use locking, connections 2, 3, and 4 probably do not finish before 1 or 5, but the total time should be about 40% faster.

`INSERT`, `UPDATE`, and `DELETE` operations are very fast in MySQL, but you can obtain better overall performance by adding locks around everything that does more than about five successive inserts or updates. If you do very many successive inserts, you could do a `LOCK TABLES` followed by an `UNLOCK TABLES` once in a while (each 1,000 rows or so) to permit other threads to access table. This would still result in a nice performance gain.

`INSERT` is still much slower for loading data than `LOAD DATA INFILE`, even when using the strategies just outlined.

- To increase performance for `MyISAM` tables, for both `LOAD DATA INFILE` and `INSERT`, enlarge the key cache by increasing the `key_buffer_size` system variable. See [Section 6.1.1, “Configuring the Server”](#).

### 9.6.3 Speed of REPAIR TABLE Statements

`REPAIR TABLE` for `MyISAM` tables is similar to using `myisamchk` for repair operations, and some of the same performance optimizations apply:

- `myisamchk` has variables that control memory allocation. You may be able to improve its performance by setting these variables, as described in [Section 5.6.3.6, “myisamchk Memory Usage”](#).
- For `REPAIR TABLE`, the same principle applies, but because the repair is done by the server, you set server system variables instead of `myisamchk` variables. Also, in addition to setting memory-allocation variables, increasing the `myisam_max_sort_file_size` system variable increases the likelihood that the repair will use the faster filesort method and avoid the slower repair by key cache method. Set the variable to the maximum file size for your system, after checking to be sure that there is enough free space to hold a copy of the table files. The free space must be available in the file system containing the original table files.

Suppose that a `myisamchk` table-repair operation is done using the following options to set its memory-allocation variables:

```
--key_buffer_size=128M --myisam_sort_buffer_size=256M
--read_buffer_size=64M --write_buffer_size=64M
```

Some of those `myisamchk` variables correspond to server system variables:

| <code>myisamchk</code> Variable      | System Variable                      |
|--------------------------------------|--------------------------------------|
| <code>key_buffer_size</code>         | <code>key_buffer_size</code>         |
| <code>myisam_sort_buffer_size</code> | <code>myisam_sort_buffer_size</code> |
| <code>read_buffer_size</code>        | <code>read_buffer_size</code>        |
| <code>write_buffer_size</code>       | none                                 |

Each of the server system variables can be set at runtime, and some of them (`myisam_sort_buffer_size`, `read_buffer_size`) have a session value in addition to a global value. Setting a session value limits the effect of the change to your current session and does not affect other users. Changing a global-only variable (`key_buffer_size`, `myisam_max_sort_file_size`) affects other users as well. For `key_buffer_size`, you must take into account that the buffer is shared with those users. For example, if you set the `myisamchk key_buffer_size` variable to 128MB, you could set the corresponding `key_buffer_size` system variable larger than that (if it is not already set larger), to permit key buffer use by activity in other sessions. However, changing the global key buffer size invalidates the buffer, causing increased disk I/O and slowdown for other sessions. An alternative that avoids this problem is to use a separate key cache, assign to it the indexes from the table to be repaired, and deallocate it when the repair is complete. See [Section 9.10.2.2, “Multiple Key Caches”](#).

Based on the preceding remarks, a `REPAIR TABLE` operation can be done as follows to use settings similar to the `myisamchk` command. Here a separate 128MB key buffer is allocated and the file system is assumed to permit a file size of at least 100GB.

```
SET SESSION myisam_sort_buffer_size = 256*1024*1024;
SET SESSION read_buffer_size = 64*1024*1024;
SET GLOBAL myisam_max_sort_file_size = 100*1024*1024*1024;
SET GLOBAL repair_cache.key_buffer_size = 128*1024*1024;
CACHE INDEX tbl_name IN repair_cache;
LOAD INDEX INTO CACHE tbl_name;
REPAIR TABLE tbl_name ;
SET GLOBAL repair_cache.key_buffer_size = 0;
```

If you intend to change a global variable but want to do so only for the duration of a `REPAIR TABLE` operation to minimally affect other users, save its value in a user variable and restore it afterward. For example:

```
SET @old_myisam_sort_buffer_size = @@global.myisam_max_sort_file_size;
SET GLOBAL myisam_max_sort_file_size = 100*1024*1024*1024;
REPAIR TABLE tbl_name ;
SET GLOBAL myisam_max_sort_file_size = @old_myisam_max_sort_file_size;
```

The system variables that affect `REPAIR TABLE` can be set globally at server startup if you want the values to be in effect by default. For example, add these lines to the server `my.cnf` file:

```
[mysqld]
myisam_sort_buffer_size=256M
key_buffer_size=1G
myisam_max_sort_file_size=100G
```

These settings do not include `read_buffer_size`. Setting `read_buffer_size` globally to a large value does so for all sessions and can cause performance to suffer due to excessive memory allocation for a server with many simultaneous sessions.

## 9.7 Optimizing for MEMORY Tables

Consider using `MEMORY` tables for noncritical data that is accessed often, and is read-only or rarely updated. Benchmark your application against equivalent `InnoDB` or `MyISAM` tables under a realistic workload, to confirm that any additional performance is worth the risk of losing data, or the overhead of copying data from a disk-based table at application start.

For best performance with `MEMORY` tables, examine the kinds of queries against each table, and specify the type to use for each associated index, either a B-tree index or a hash index. On the `CREATE INDEX` statement, use the clause `USING BTREE` or `USING HASH`. B-tree indexes are fast for queries that do greater-than or less-than comparisons through operators such as `>` or `BETWEEN`. Hash indexes are only fast for queries that look up single values through the `=` operator, or a restricted set of values through the `IN` operator. For why `USING BTREE` is often a better choice than the default `USING HASH`,

see [Section 9.2.1.21, “How to Avoid Full Table Scans”](#). For implementation details of the different types of `MEMORY` indexes, see [Section 9.3.8, “Comparison of B-Tree and Hash Indexes”](#).

## 9.8 Understanding the Query Execution Plan

Depending on the details of your tables, columns, indexes, and the conditions in your `WHERE` clause, the MySQL optimizer considers many techniques to efficiently perform the lookups involved in an SQL query. A query on a huge table can be performed without reading all the rows; a join involving several tables can be performed without comparing every combination of rows. The set of operations that the optimizer chooses to perform the most efficient query is called the “query execution plan”, also known as the `EXPLAIN` plan. Your goals are to recognize the aspects of the `EXPLAIN` plan that indicate a query is optimized well, and to learn the SQL syntax and indexing techniques to improve the plan if you see some inefficient operations.

### 9.8.1 Optimizing Queries with EXPLAIN

The `EXPLAIN` statement provides information about how MySQL executes statements:

- Permitted explainable statements for `EXPLAIN` are `SELECT`, `DELETE`, `INSERT`, `REPLACE`, and `UPDATE`.
- When `EXPLAIN` is used with an explainable statement, MySQL displays information from the optimizer about the statement execution plan. That is, MySQL explains how it would process the statement, including information about how tables are joined and in which order. For information about using `EXPLAIN` to obtain execution plan information, see [Section 9.8.2, “EXPLAIN Output Format”](#).
- When `EXPLAIN` is used with `FOR CONNECTION connection_id` rather than an explainable statement, it displays the execution plan for the statement executing in the named connection. See [Section 9.8.4, “Obtaining Execution Plan Information for a Named Connection”](#).
- Before MySQL 5.7.3, `EXPLAIN EXTENDED` can be used to obtain additional execution plan information. See [Section 9.8.3, “EXPLAIN EXTENDED Output Format”](#). As of MySQL 5.7.3, extended output is enabled by default and the `EXTENDED` keyword is unnecessary.
- Before MySQL 5.7.3, `EXPLAIN PARTITIONS` is useful for examining queries involving partitioned tables. See [Section 21.3.5, “Obtaining Information About Partitions”](#). As of MySQL 5.7.3, partition information is enabled by default and the `PARTITIONS` keyword is unnecessary.
- The `FORMAT` option can be used to select the output format. `TRADITIONAL` presents the output in tabular format. This is the default if no `FORMAT` option is present. `JSON` format displays the information in JSON format. With `FORMAT = JSON`, the output includes extended and partition information.

With the help of `EXPLAIN`, you can see where you should add indexes to tables so that the statement executes faster by using indexes to find rows. You can also use `EXPLAIN` to check whether the optimizer joins the tables in an optimal order. To give a hint to the optimizer to use a join order corresponding to the order in which the tables are named in a `SELECT` statement, begin the statement with `SELECT STRAIGHT_JOIN` rather than just `SELECT`. (See [Section 14.2.9, “SELECT Syntax”](#).) However, `STRAIGHT_JOIN` may prevent indexes from being used because it disables semi-join transformations. See [Optimizing Subqueries with Semi-Join Transformations](#).

The optimizer trace may sometimes provide information complementary to that of `EXPLAIN`. However, the optimizer trace format and content are subject to change between versions. For details, see [MySQL Internals: Tracing the Optimizer](#).

If you have a problem with indexes not being used when you believe that they should be, run `ANALYZE TABLE` to update table statistics, such as cardinality of keys, that can affect the choices the optimizer makes. See [Section 14.7.2.1, “ANALYZE TABLE Syntax”](#).

**Note**

`EXPLAIN` can also be used to obtain information about the columns in a table. `EXPLAIN tbl_name` is synonymous with `DESCRIBE tbl_name` and `SHOW COLUMNS FROM tbl_name`. For more information, see [Section 14.8.1, “DESCRIBE Syntax”](#), and [Section 14.7.5.5, “SHOW COLUMNS Syntax”](#).

## 9.8.2 EXPLAIN Output Format

The `EXPLAIN` statement provides information about the execution plan for a `SELECT` statement.

`EXPLAIN` returns a row of information for each table used in the `SELECT` statement. It lists the tables in the output in the order that MySQL would read them while processing the statement. MySQL resolves all joins using a nested-loop join method. This means that MySQL reads a row from the first table, and then finds a matching row in the second table, the third table, and so on. When all tables are processed, MySQL outputs the selected columns and backtracks through the table list until a table is found for which there are more matching rows. The next row is read from this table and the process continues with the next table.

Before MySQL 5.7.3, when the `EXTENDED` keyword is used, `EXPLAIN` produces extra information that can be viewed by issuing a `SHOW WARNINGS` statement following the `EXPLAIN` statement. `EXPLAIN EXTENDED` also displays the `filtered` column. See [Section 9.8.3, “EXPLAIN EXTENDED Output Format”](#). As of MySQL 5.7.3, extended output is enabled by default and the `EXTENDED` keyword is unnecessary.

**Note**

You cannot use the `EXTENDED` and `PARTITIONS` keywords together in the same `EXPLAIN` statement. In addition, neither of these keywords can be used together with the `FORMAT` option. (`FORMAT=JSON` causes `EXPLAIN` to display extended and partition information automatically; using `FORMAT=TRADITIONAL` has no effect on `EXPLAIN` output.)

- [EXPLAIN Join Types](#)
- [EXPLAIN Extra Information](#)
- [EXPLAIN Output Interpretation](#)

### EXPLAIN Output Columns

This section describes the output columns produced by `EXPLAIN`. Later sections provide additional information about the `type` and `Extra` columns.

Each output row from `EXPLAIN` provides information about one table. Each row contains the values summarized in [Table 9.1, “EXPLAIN Output Columns”](#), and described in more detail following the table. Column names are shown in the table's first column; the second column provides the equivalent property name shown in the output when `FORMAT=JSON` is used.

**Table 9.1 EXPLAIN Output Columns**

| Column                   | JSON Name               | Meaning                            |
|--------------------------|-------------------------|------------------------------------|
| <code>id</code>          | <code>select_id</code>  | The <code>SELECT</code> identifier |
| <code>select_type</code> | None                    | The <code>SELECT</code> type       |
| <code>table</code>       | <code>table_name</code> | The table for the output row       |
| <code>partitions</code>  | <code>partitions</code> | The matching partitions            |

| Column                     | JSON Name                  | Meaning  |
|----------------------------|----------------------------|--|
| <code>type</code>          | <code>access_type</code>   | The join type                                  |
| <code>possible_keys</code> | <code>possible_keys</code> | The possible indexes to choose                 |
| <code>key</code>           | <code>key</code>           | The index actually chosen                      |
| <code>key_len</code>       | <code>key_length</code>    | The length of the chosen key                   |
| <code>ref</code>           | <code>ref</code>           | The columns compared to the index              |
| <code>rows</code>          | <code>rows</code>          | Estimate of rows to be examined                |
| <code>filtered</code>      | <code>filtered</code>      | Percentage of rows filtered by table condition |
| <code>Extra</code>         | None                       | Additional information                         |

**Note**

JSON properties which are `NULL` are not displayed in JSON-formatted `EXPLAIN` output.

- `id` (JSON name: `select_id`)

The `SELECT` identifier. This is the sequential number of the `SELECT` within the query. The value can be `NULL` if the row refers to the union result of other rows. In this case, the `table` column shows a value like `<unionM,N>` to indicate that the row refers to the union of the rows with `id` values of `M` and `N`.

- `select_type` (JSON name: none)

The type of `SELECT`, which can be any of those shown in the following table. A JSON-formatted `EXPLAIN` exposes the `SELECT` type as a property of a `query_block`, unless it is `SIMPLE` or `PRIMARY`. The JSON names (where applicable) are also shown in the table.

| <code>select_type</code> Value    | JSON Name                               | Meaning   |
|-----------------------------------|---|---|
| <code>SIMPLE</code>               | None                                    | Simple <code>SELECT</code> (not using <code>UNION</code> or subqueries)   |
| <code>PRIMARY</code>              | None                                    | Outermost <code>SELECT</code>   |
| <code>UNION</code>                | None                                    | Second or later <code>SELECT</code> statement in a <code>UNION</code>   |
| <code>DEPENDENT UNION</code>      | <code>dependent (true)</code>           | Second or later <code>SELECT</code> statement in a <code>UNION</code> , dependent on outer query                                    |
| <code>UNION RESULT</code>         | <code>union_result</code>               | Result of a <code>UNION</code> .  |
| <code>SUBQUERY</code>             | None                                    | First <code>SELECT</code> in subquery   |
| <code>DEPENDENT SUBQUERY</code>   | <code>dependent (true)</code>           | First <code>SELECT</code> in subquery, dependent on outer query   |
| <code>DERIVED</code>              | None                                    | Derived table <code>SELECT</code> (subquery in <code>FROM</code> clause)  |
| <code>MATERIALIZED</code>         | <code>materialized_from_subquery</code> | Materialized subquery   |
| <code>UNCACHEABLE SUBQUERY</code> | <code>cacheable (false)</code>          | A subquery for which the result cannot be cached and must be re-evaluated for each row of the outer query                           |
| <code>UNCACHEABLE UNION</code>    | <code>cacheable (false)</code>          | The second or later select in a <code>UNION</code> that belongs to an uncacheable subquery (see <code>UNCACHEABLE SUBQUERY</code> ) |

`DEPENDENT` typically signifies the use of a correlated subquery. See [Section 14.2.10.7, “Correlated Subqueries”](#).

`DEPENDENT SUBQUERY` evaluation differs from `UNCACHEABLE SUBQUERY` evaluation. For `DEPENDENT SUBQUERY`, the subquery is re-evaluated only once for each set of different values of

the variables from its outer context. For `UNCACHEABLE SUBQUERY`, the subquery is re-evaluated for each row of the outer context.

Cacheability of subqueries differs from caching of query results in the query cache (which is described in [Section 9.10.3.1, “How the Query Cache Operates”](#)). Subquery caching occurs during query execution, whereas the query cache is used to store results only after query execution finishes.

When you specify `FORMAT=JSON` with `EXPLAIN`, the output has no single property directly equivalent to `select_type`; the `query_block` property corresponds to a given `SELECT`. Properties equivalent to most of the `SELECT` subquery types just shown are available (an example being `materialized_from_subquery` for `MATERIALIZED`), and are displayed when appropriate. There are no JSON equivalents for `SIMPLE` or `PRIMARY`.

As of MySQL 5.7.2, the `select_type` value for non-`SELECT` statements displays the statement type for affected tables. For example, `select_type` is `DELETE` for `DELETE` statements.

- `table` (JSON name: `table_name`)

The name of the table to which the row of output refers. This can also be one of the following values:

- `<unionM,N>`: The row refers to the union of the rows with `id` values of `M` and `N`.
- `<derivedN>`: The row refers to the derived table result for the row with an `id` value of `N`. A derived table may result, for example, from a subquery in the `FROM` clause.
- `<subqueryN>`: The row refers to the result of a materialized subquery for the row with an `id` value of `N`. See [Optimizing Subqueries with Subquery Materialization](#).

- `partitions` (JSON name: `partitions`)

The partitions from which records would be matched by the query. This column is displayed only if the `PARTITIONS` keyword is used. The value is `NULL` for nonpartitioned tables. See [Section 21.3.5, “Obtaining Information About Partitions”](#).

- `type` (JSON name: `access_type`)

The join type. For descriptions of the different types, see [EXPLAIN Join Types](#).

- `possible_keys` (JSON name: `possible_keys`)

The `possible_keys` column indicates which indexes MySQL can choose from use to find the rows in this table. Note that this column is totally independent of the order of the tables as displayed in the output from `EXPLAIN`. That means that some of the keys in `possible_keys` might not be usable in practice with the generated table order.

If this column is `NULL` (or undefined in JSON-formatted output), there are no relevant indexes. In this case, you may be able to improve the performance of your query by examining the `WHERE` clause to check whether it refers to some column or columns that would be suitable for indexing. If so, create an appropriate index and check the query with `EXPLAIN` again. See [Section 14.1.8, “ALTER TABLE Syntax”](#).

To see what indexes a table has, use `SHOW INDEX FROM tbl_name`.

- `key` (JSON name: `key`)

The `key` column indicates the key (index) that MySQL actually decided to use. If MySQL decides to use one of the `possible_keys` indexes to look up rows, that index is listed as the key value.

It is possible that `key` will name an index that is not present in the `possible_keys` value. This can happen if none of the `possible_keys` indexes are suitable for looking up rows, but all the columns selected by the query are columns of some other index. That is, the named index covers

the selected columns, so although it is not used to determine which rows to retrieve, an index scan is more efficient than a data row scan.

For [InnoDB](#), a secondary index might cover the selected columns even if the query also selects the primary key because [InnoDB](#) stores the primary key value with each secondary index. If [key](#) is [NULL](#), MySQL found no index to use for executing the query more efficiently.

To force MySQL to use or ignore an index listed in the [possible\\_keys](#) column, use [FORCE INDEX](#), [USE INDEX](#), or [IGNORE INDEX](#) in your query. See [Section 9.9.4, “Index Hints”](#).

For [MyISAM](#) tables, running [ANALYZE TABLE](#) helps the optimizer choose better indexes. For [MyISAM](#) tables, [myisamchk --analyze](#) does the same. See [Section 14.7.2.1, “ANALYZE TABLE Syntax”](#), and [Section 8.6, “MyISAM Table Maintenance and Crash Recovery”](#).

- [key\\_len](#) (JSON name: [key\\_length](#))

The [key\\_len](#) column indicates the length of the key that MySQL decided to use. The value of [key\\_len](#) enables you to determine how many parts of a multiple-part key MySQL actually uses. If the [key](#) column says [NULL](#), the [len\\_len](#) column also says [NULL](#).

Due to the key storage format, the key length is one greater for a column that can be [NULL](#) than for a [NOT NULL](#) column.

- [ref](#) (JSON name: [ref](#))

The [ref](#) column shows which columns or constants are compared to the index named in the [key](#) column to select rows from the table.

If the value is [func](#), the value used is the result of some function. To see which function, use [EXPLAIN EXTENDED](#) followed by [SHOW WARNINGS](#). The function might actually be an operator such as an arithmetic operator.

- [rows](#) (JSON name: [rows](#))

The [rows](#) column indicates the number of rows MySQL believes it must examine to execute the query.

For [InnoDB](#) tables, this number is an estimate, and may not always be exact.

- [filtered](#) (JSON name: [filtered](#))

The [filtered](#) column indicates an estimated percentage of table rows that will be filtered by the table condition. That is, [rows](#) shows the estimated number of rows examined and  $\text{rows} \times \text{filtered} / 100$  shows the number of rows that will be joined with previous tables. Before MySQL 5.7.3, this column is displayed if you use [EXPLAIN EXTENDED](#). As of MySQL 5.7.3, extended output is enabled by default and the [EXTENDED](#) keyword is unnecessary.

- [Extra](#) (JSON name: none)

This column contains additional information about how MySQL resolves the query. For descriptions of the different values, see [EXPLAIN Extra Information](#).

There is no single JSON property corresponding to the [Extra](#) column; however, values that can occur in this column are exposed as JSON properties, or as the text of the [message](#) property.

## EXPLAIN Join Types

The [type](#) column of [EXPLAIN](#) output describes how tables are joined. In JSON-formatted output, these are found as values of the [access\\_type](#) property. The following list describes the join types, ordered from the best type to the worst:

- [system](#)

The table has only one row (= system table). This is a special case of the `const` join type.

- `const`

The table has at most one matching row, which is read at the start of the query. Because there is only one row, values from the column in this row can be regarded as constants by the rest of the optimizer. `const` tables are very fast because they are read only once.

`const` is used when you compare all parts of a `PRIMARY KEY` or `UNIQUE` index to constant values. In the following queries, `tbl_name` can be used as a `const` table:

```
SELECT * FROM tbl_name WHERE primary_key=1;

SELECT * FROM tbl_name
WHERE primary_key_part1=1 AND primary_key_part2=2;
```

- `eq_ref`

One row is read from this table for each combination of rows from the previous tables. Other than the `system` and `const` types, this is the best possible join type. It is used when all parts of an index are used by the join and the index is a `PRIMARY KEY` or `UNIQUE NOT NULL` index.

`eq_ref` can be used for indexed columns that are compared using the `=` operator. The comparison value can be a constant or an expression that uses columns from tables that are read before this table. In the following examples, MySQL can use an `eq_ref` join to process `ref_table`:

```
SELECT * FROM ref_table,other_table
WHERE ref_table.key_column=other_table.column;

SELECT * FROM ref_table,other_table
WHERE ref_table.key_column_part1=other_table.column
AND ref_table.key_column_part2=1;
```

- `ref`

All rows with matching index values are read from this table for each combination of rows from the previous tables. `ref` is used if the join uses only a leftmost prefix of the key or if the key is not a `PRIMARY KEY` or `UNIQUE` index (in other words, if the join cannot select a single row based on the key value). If the key that is used matches only a few rows, this is a good join type.

`ref` can be used for indexed columns that are compared using the `=` or `<=>` operator. In the following examples, MySQL can use a `ref` join to process `ref_table`:

```
SELECT * FROM ref_table WHERE key_column=expr;

SELECT * FROM ref_table,other_table
WHERE ref_table.key_column=other_table.column;

SELECT * FROM ref_table,other_table
WHERE ref_table.key_column_part1=other_table.column
AND ref_table.key_column_part2=1;
```

- `fulltext`

The join is performed using a `FULLTEXT` index.

- `ref_or_null`

This join type is like `ref`, but with the addition that MySQL does an extra search for rows that contain `NULL` values. This join type optimization is used most often in resolving subqueries. In the following examples, MySQL can use a `ref_or_null` join to process `ref_table`:

```
SELECT * FROM ref_table
WHERE key_column=expr OR key_column IS NULL;
```

See [Section 9.2.1.8, “IS NULL Optimization”](#).

- `index_merge`

This join type indicates that the Index Merge optimization is used. In this case, the `key` column in the output row contains a list of indexes used, and `key_len` contains a list of the longest key parts for the indexes used. For more information, see [Section 9.2.1.4, “Index Merge Optimization”](#).

- `unique_subquery`

This type replaces `eq_ref` for some `IN` subqueries of the following form:

```
value IN (SELECT primary_key FROM single_table WHERE some_expr)
```

`unique_subquery` is just an index lookup function that replaces the subquery completely for better efficiency.

- `index_subquery`

This join type is similar to `unique_subquery`. It replaces `IN` subqueries, but it works for nonunique indexes in subqueries of the following form:

```
value IN (SELECT key_column FROM single_table WHERE some_expr)
```

- `range`

Only rows that are in a given range are retrieved, using an index to select the rows. The `key` column in the output row indicates which index is used. The `key_len` contains the longest key part that was used. The `ref` column is `NULL` for this type.

`range` can be used when a key column is compared to a constant using any of the `=`, `<>`, `>`, `>=`, `<`, `<=`, `IS NULL`, `<=>`, `BETWEEN`, or `IN( )` operators:

```
SELECT * FROM tbl_name
WHERE key_column = 10;

SELECT * FROM tbl_name
WHERE key_column BETWEEN 10 and 20;

SELECT * FROM tbl_name
WHERE key_column IN (10,20,30);

SELECT * FROM tbl_name
WHERE key_part1 = 10 AND key_part2 IN (10,20,30);
```

- `index`

The `index` join type is the same as `ALL`, except that the index tree is scanned. This occurs two ways:

- If the index is a covering index for the queries and can be used to satisfy all data required from the table, only the index tree is scanned. In this case, the `Extra` column says `Using index`. An index-only scan usually is faster than `ALL` because the size of the index usually is smaller than the table data.
- A full table scan is performed using reads from the index to look up data rows in index order. `Uses index` does not appear in the `Extra` column.

MySQL can use this join type when the query uses only columns that are part of a single index.

- `ALL`

A full table scan is done for each combination of rows from the previous tables. This is normally not good if the table is the first table not marked `const`, and usually *very* bad in all other cases. Normally, you can avoid `ALL` by adding indexes that enable row retrieval from the table based on constant values or column values from earlier tables.

## EXPLAIN Extra Information

The `Extra` column of `EXPLAIN` output contains additional information about how MySQL resolves the query. The following list explains the values that can appear in this column. Each item also indicates for JSON-formatted output which property displays the `Extra` value. For some of these, there is a specific property. The others display as the text of the `message` property.

If you want to make your queries as fast as possible, look out for `Extra` column values of `Using filesort` and `Using temporary`, or, in JSON-formatted `EXPLAIN` output, for `using_filesort` and `using_temporary_table` properties equal to `true`.

- `Child of 'table' pushed join@1` (JSON: `message` text)

This table is referenced as the child of `table` in a join that can be pushed down to the NDB kernel. Applies only in MySQL Cluster, when pushed-down joins are enabled. See the description of the `ndb_join_pushdown` server system variable for more information and examples.

- `const row not found` (JSON property: `const_row_not_found`)

For a query such as `SELECT ... FROM tbl_name`, the table was empty.

- `Deleting all rows` (JSON property: `message`)

For `DELETE`, some storage engines (such as `MyISAM`) support a handler method that removes all table rows in a simple and fast way. This `Extra` value is displayed if the engine uses this optimization.

- `Distinct` (JSON property: `distinct`)

MySQL is looking for distinct values, so it stops searching for more rows for the current row combination after it has found the first matching row.

- `FirstMatch(tbl_name)` (JSON property: `first_match`)

The semi-join FirstMatch join shortcutting strategy is used for `tbl_name`.

- `Full scan on NULL key` (JSON property: `message`)

This occurs for subquery optimization as a fallback strategy when the optimizer cannot use an index-lookup access method.

- `Impossible HAVING` (JSON property: `message`)

The `HAVING` clause is always false and cannot select any rows.

- `Impossible WHERE` (JSON property: `message`)

The `WHERE` clause is always false and cannot select any rows.

- `Impossible WHERE noticed after reading const tables` (JSON property: `message`)

MySQL has read all `const` (and `system`) tables and notice that the `WHERE` clause is always false.

- `LooseScan(m..n)` (JSON property: `message`)

The semi-join LooseScan strategy is used. *m* and *n* are key part numbers.

- `No matching min/max row` (JSON property: `message`)

No row satisfies the condition for a query such as `SELECT MIN(...) FROM ... WHERE condition`.

- `no matching row in const table` (JSON property: `message`)

For a query with a join, there was an empty table or a table with no rows satisfying a unique index condition.

- `No matching rows after partition pruning` (JSON property: `message`)

For `DELETE` or `UPDATE`, the optimizer found nothing to delete or update after partition pruning. It is similar in meaning to `Impossible WHERE` for `SELECT` statements.

- `No tables used` (JSON property: `message`)

The query has no `FROM` clause, or has a `FROM DUAL` clause.

For `INSERT` or `REPLACE` statements, `EXPLAIN` displays this value when there is no `SELECT` part. For example, it appears for `EXPLAIN INSERT INTO t VALUES(10)` because that is equivalent to `EXPLAIN INSERT INTO t SELECT 10 FROM DUAL`.

- `Not exists` (JSON property: `message`)

MySQL was able to do a `LEFT JOIN` optimization on the query and does not examine more rows in this table for the previous row combination after it finds one row that matches the `LEFT JOIN` criteria. Here is an example of the type of query that can be optimized this way:

```
SELECT * FROM t1 LEFT JOIN t2 ON t1.id=t2.id
WHERE t2.id IS NULL;
```

Assume that `t2.id` is defined as `NOT NULL`. In this case, MySQL scans `t1` and looks up the rows in `t2` using the values of `t1.id`. If MySQL finds a matching row in `t2`, it knows that `t2.id` can never be `NULL`, and does not scan through the rest of the rows in `t2` that have the same `id` value. In other words, for each row in `t1`, MySQL needs to do only a single lookup in `t2`, regardless of how many rows actually match in `t2`.

- `Plan isn't ready yet` (JSON property: `none`)

This value occurs with `EXPLAIN FOR CONNECTION` when the optimizer has not finished creating the execution plan for the statement executing in the named connection. If execution plan output comprises multiple lines, any or all of them could have this `Extra` value, depending on the progress of the optimizer in determining the full execution plan.

- `Range checked for each record (index map: N)` (JSON property: `message`)

MySQL found no good index to use, but found that some of indexes might be used after column values from preceding tables are known. For each row combination in the preceding tables, MySQL checks whether it is possible to use a `range` or `index_merge` access method to retrieve rows. This is not very fast, but is faster than performing a join with no index at all. The applicability criteria are as described in [Section 9.2.1.3, “Range Optimization”](#), and [Section 9.2.1.4, “Index Merge Optimization”](#), with the exception that all column values for the preceding table are known and considered to be constants.

Indexes are numbered beginning with 1, in the same order as shown by `SHOW INDEX` for the table. The index map value *N* is a bitmask value that indicates which indexes are candidates. For example, a value of `0x19` (binary 11001) means that indexes 1, 4, and 5 will be considered.

- `Scanned N databases` (JSON property: `message`)

This indicates how many directory scans the server performs when processing a query for `INFORMATION_SCHEMA` tables, as described in [Section 9.2.4, “Optimizing INFORMATION\\_SCHEMA Queries”](#). The value of *N* can be 0, 1, or `all`.

- `Select tables optimized away` (JSON property: `message`)

The optimizer determined 1) that at most one row should be returned, and 2) that to produce this row, a deterministic set of rows must be read. When the rows to be read can be read during the optimization phase (for example, by reading index rows), there is no need to read any tables during query execution.

The first condition is fulfilled when the query is implicitly grouped (contains an aggregate function but no `GROUP BY` clause). The second condition is fulfilled when one row lookup is performed per index used. The number of indexes read determines the number of rows to read.

Consider the following implicitly grouped query:

```
SELECT MIN(c1), MIN(c2) FROM t1;
```

Suppose that `MIN(c1)` can be retrieved by reading one index row and `MIN(c2)` can be retrieved by reading one row from a different index. That is, for each column `c1` and `c2`, there exists an index where the column is the first column of the index. In this case, one row is returned, produced by reading two deterministic rows.

This `Extra` value does not occur if the rows to read are not deterministic. Consider this query:

```
SELECT MIN(c2) FROM t1 WHERE c1 <= 10;
```

Suppose that `(c1, c2)` is a covering index. Using this index, all rows with `c1 <= 10` must be scanned to find the minimum `c2` value. By contrast, consider this query:

```
SELECT MIN(c2) FROM t1 WHERE c1 = 10;
```

In this case, the first index row with `c1 = 10` contains the minimum `c2` value. Only one row must be read to produce the returned row.

For storage engines that maintain an exact row count per table (such as `MyISAM`, but not `InnoDB`), this `Extra` value can occur for `COUNT(*)` queries for which the `WHERE` clause is missing or always true and there is no `GROUP BY` clause. (This is an instance of an implicitly grouped query where the storage engine influences whether a deterministic number of rows can be read.)

- `Skip_open_table`, `Open_frm_only`, `Open_full_table` (JSON property: `message`)

These values indicate file-opening optimizations that apply to queries for `INFORMATION_SCHEMA` tables, as described in [Section 9.2.4, “Optimizing INFORMATION\\_SCHEMA Queries”](#).

- `Skip_open_table`: Table files do not need to be opened. The information has already become available within the query by scanning the database directory.
- `Open_frm_only`: Only the table's `.frm` file need be opened.
- `Open_full_table`: The unoptimized information lookup. The `.frm`, `.MYD`, and `.MYI` files must be opened.

- `Start temporary`, `End temporary` (JSON property: `message`)

This indicates temporary table use for the semi-join Duplicate Weedout strategy.

- `unique row not found` (JSON property: `message`)

For a query such as `SELECT ... FROM tbl_name`, no rows satisfy the condition for a `UNIQUE` index or `PRIMARY KEY` on the table.

- `Using filesort` (JSON property: `using_filesort`)

MySQL must do an extra pass to find out how to retrieve the rows in sorted order. The sort is done by going through all rows according to the join type and storing the sort key and pointer to the row for all rows that match the `WHERE` clause. The keys then are sorted and the rows are retrieved in sorted order. See [Section 9.2.1.15, “ORDER BY Optimization”](#).

- `Using index` (JSON property: `using_index`)

The column information is retrieved from the table using only information in the index tree without having to do an additional seek to read the actual row. This strategy can be used when the query uses only columns that are part of a single index.

For `InnoDB` tables that have a user-defined clustered index, that index can be used even when `Using index` is absent from the `Extra` column. This is the case if `type` is `index` and `key` is `PRIMARY`.

- `Using index condition` (JSON property: `using_index_condition`)

Tables are read by accessing index tuples and testing them first to determine whether to read full table rows. In this way, index information is used to defer (“push down”) reading full table rows unless it is necessary. See [Section 9.2.1.6, “Index Condition Pushdown Optimization”](#).

- `Using index for group-by` (JSON property: `using_index_for_group_by`)

Similar to the `Using index` table access method, `Using index for group-by` indicates that MySQL found an index that can be used to retrieve all columns of a `GROUP BY` or `DISTINCT` query without any extra disk access to the actual table. Additionally, the index is used in the most efficient way so that for each group, only a few index entries are read. For details, see [Section 9.2.1.16, “GROUP BY Optimization”](#).

- `Using join buffer (Block Nested Loop)`, `Using join buffer (Batched Key Access)` (JSON property: `using_join_buffer`)

Tables from earlier joins are read in portions into the join buffer, and then their rows are used from the buffer to perform the join with the current table. `(Block Nested Loop)` indicates use of the Block Nested-Loop algorithm and `(Batched Key Access)` indicates use of the Batched Key Access algorithm. That is, the keys from the table on the preceding line of the `EXPLAIN` output will be buffered, and the matching rows will be fetched in batches from the table represented by the line in which `Using join buffer` appears.

In JSON-formatted output, the value of `using_join_buffer` is always either one of `Block Nested Loop` or `Batched Key Access`.

- `Using MRR` (JSON property: `message`)

Tables are read using the Multi-Range Read optimization strategy. See [Section 9.2.1.13, “Multi-Range Read Optimization”](#).

- `Using sort_union(...)`, `Using union(...)`, `Using intersect(...)` (JSON property: `message`)

These indicate how index scans are merged for the `index_merge` join type. See [Section 9.2.1.4, “Index Merge Optimization”](#).

- `Using temporary` (JSON property: `using_temporary_table`)

To resolve the query, MySQL needs to create a temporary table to hold the result. This typically happens if the query contains `GROUP BY` and `ORDER BY` clauses that list columns differently.

- `Using where` (JSON property: `attached_condition`)

A `WHERE` clause is used to restrict which rows to match against the next table or send to the client. Unless you specifically intend to fetch or examine all rows from the table, you may have something wrong in your query if the `Extra` value is not `Using where` and the table join type is `ALL` or `index`.

`Using where` has no direct counterpart in JSON-formatted output; the `attached_condition` property contains any `WHERE` condition used.

- `Using where with pushed condition` (JSON property: `message`)

This item applies to `NDB` tables *only*. It means that MySQL Cluster is using the Condition Pushdown optimization to improve the efficiency of a direct comparison between a nonindexed column and a constant. In such cases, the condition is “pushed down” to the cluster's data nodes and is evaluated on all data nodes simultaneously. This eliminates the need to send nonmatching rows over the network, and can speed up such queries by a factor of 5 to 10 times over cases where Condition Pushdown could be but is not used. For more information, see [Section 9.2.1.5, “Engine Condition Pushdown Optimization”](#).

- `Zero limit` (JSON property: `message`)

The query had a `LIMIT 0` clause and cannot select any rows.

## EXPLAIN Output Interpretation

You can get a good indication of how good a join is by taking the product of the values in the `rows` column of the `EXPLAIN` output. This should tell you roughly how many rows MySQL must examine to execute the query. If you restrict queries with the `max_join_size` system variable, this row product also is used to determine which multiple-table `SELECT` statements to execute and which to abort. See [Section 6.1.1, “Configuring the Server”](#).

The following example shows how a multiple-table join can be optimized progressively based on the information provided by `EXPLAIN`.

Suppose that you have the `SELECT` statement shown here and that you plan to examine it using `EXPLAIN`:

```
EXPLAIN SELECT tt.TicketNumber, tt.TimeIn,
              tt.ProjectReference, tt.EstimatedShipDate,
              tt.ActualShipDate, tt.ClientID,
              tt.ServiceCodes, tt.RepetitiveID,
              tt.CurrentProcess, tt.CurrentDPPerson,
              tt.RecordVolume, tt.DPPrinted, et.COUNTRY,
              et_1.COUNTRY, do.CUSTNAME
FROM tt, et, et AS et_1, do
WHERE tt.SubmitTime IS NULL
      AND tt.ActualPC = et.EMPLOYID
      AND tt.AssignedPC = et_1.EMPLOYID
      AND tt.ClientID = do.CUSTNMBR;
```

For this example, make the following assumptions:

- The columns being compared have been declared as follows.

| Table | Column     | Data Type |
|-------|------------|-----------|
| tt    | ActualPC   | CHAR(10)  |
| tt    | AssignedPC | CHAR(10)  |
| tt    | ClientID   | CHAR(10)  |

| Table | Column   | Data Type |
|-------|----------|-----------|
| et    | EMPLOYID | CHAR(15)  |
| do    | CUSTNMBR | CHAR(15)  |

- The tables have the following indexes.

| Table | Index                  |
|-------|------------------------|
| tt    | ActualPC               |
| tt    | AssignedPC             |
| tt    | ClientID               |
| et    | EMPLOYID (primary key) |
| do    | CUSTNMBR (primary key) |

- The `tt.ActualPC` values are not evenly distributed.

Initially, before any optimizations have been performed, the `EXPLAIN` statement produces the following information:

```
table type possible_keys key key_len ref rows Extra
et ALL PRIMARY NULL NULL NULL 74
do ALL PRIMARY NULL NULL NULL 2135
et_1 ALL PRIMARY NULL NULL NULL 74
tt ALL AssignedPC, NULL NULL NULL 3872
    ClientID,
    ActualPC
    Range checked for each record (index map: 0x23)
```

Because `type` is `ALL` for each table, this output indicates that MySQL is generating a Cartesian product of all the tables; that is, every combination of rows. This takes quite a long time, because the product of the number of rows in each table must be examined. For the case at hand, this product is  $74 \times 2135 \times 74 \times 3872 = 45,268,558,720$  rows. If the tables were bigger, you can only imagine how long it would take.

One problem here is that MySQL can use indexes on columns more efficiently if they are declared as the same type and size. In this context, `VARCHAR` and `CHAR` are considered the same if they are declared as the same size. `tt.ActualPC` is declared as `CHAR(10)` and `et.EMPLOYID` is `CHAR(15)`, so there is a length mismatch.

To fix this disparity between column lengths, use `ALTER TABLE` to lengthen `ActualPC` from 10 characters to 15 characters:

```
mysql> ALTER TABLE tt MODIFY ActualPC VARCHAR(15);
```

Now `tt.ActualPC` and `et.EMPLOYID` are both `VARCHAR(15)`. Executing the `EXPLAIN` statement again produces this result:

```
table type possible_keys key key_len ref rows Extra
tt ALL AssignedPC, NULL NULL NULL 3872 Using
    ClientID, where
    ActualPC
do ALL PRIMARY NULL NULL NULL 2135
    Range checked for each record (index map: 0x1)
et_1 ALL PRIMARY NULL NULL NULL 74
    Range checked for each record (index map: 0x1)
et eq_ref PRIMARY PRIMARY 15 tt.ActualPC 1
```

This is not perfect, but is much better: The product of the `rows` values is less by a factor of 74. This version executes in a couple of seconds.

A second alteration can be made to eliminate the column length mismatches for the `tt.AssignedPC = et_1.EMPLOYID` and `tt.ClientID = do.CUSTNMBR` comparisons:

```
mysql> ALTER TABLE tt MODIFY AssignedPC VARCHAR(15),
->          MODIFY ClientID VARCHAR(15);
```

After that modification, `EXPLAIN` produces the output shown here:

| table | type   | possible_keys                        | key      | key_len | ref           | rows | Extra          |
|-------|--------|--------------------------------------|----------|---------|---------------|------|----------------|
| et    | ALL    | PRIMARY                              | NULL     | NULL    | NULL          | 74   |                |
| tt    | ref    | AssignedPC,<br>ClientID,<br>ActualPC | ActualPC | 15      | et.EMPLOYID   | 52   | Using<br>where |
| et_1  | eq_ref | PRIMARY                              | PRIMARY  | 15      | tt.AssignedPC | 1    |                |
| do    | eq_ref | PRIMARY                              | PRIMARY  | 15      | tt.ClientID   | 1    |                |

At this point, the query is optimized almost as well as possible. The remaining problem is that, by default, MySQL assumes that values in the `tt.ActualPC` column are evenly distributed, and that is not the case for the `tt` table. Fortunately, it is easy to tell MySQL to analyze the key distribution:

```
mysql> ANALYZE TABLE tt;
```

With the additional index information, the join is perfect and `EXPLAIN` produces this result:

| table | type   | possible_keys                        | key     | key_len | ref           | rows | Extra          |
|-------|--------|--------------------------------------|---------|---------|---------------|------|----------------|
| tt    | ALL    | AssignedPC,<br>ClientID,<br>ActualPC | NULL    | NULL    | NULL          | 3872 | Using<br>where |
| et    | eq_ref | PRIMARY                              | PRIMARY | 15      | tt.ActualPC   | 1    |                |
| et_1  | eq_ref | PRIMARY                              | PRIMARY | 15      | tt.AssignedPC | 1    |                |
| do    | eq_ref | PRIMARY                              | PRIMARY | 15      | tt.ClientID   | 1    |                |

The `rows` column in the output from `EXPLAIN` is an educated guess from the MySQL join optimizer. Check whether the numbers are even close to the truth by comparing the `rows` product with the actual number of rows that the query returns. If the numbers are quite different, you might get better performance by using `STRAIGHT_JOIN` in your `SELECT` statement and trying to list the tables in a different order in the `FROM` clause. (However, `STRAIGHT_JOIN` may prevent indexes from being used because it disables semi-join transformations. See [Optimizing Subqueries with Semi-Join Transformations](#).)

It is possible in some cases to execute statements that modify data when `EXPLAIN SELECT` is used with a subquery; for more information, see [Section 14.2.10.8, “Subqueries in the FROM Clause”](#).

### 9.8.3 EXPLAIN EXTENDED Output Format

When `EXPLAIN` is used with the `EXTENDED` keyword, the output includes a `filtered` column not otherwise displayed. This column indicates the estimated percentage of table rows that will be filtered by the table condition. In addition, the statement produces extra (“extended”) information that is not part of `EXPLAIN` output but can be viewed by issuing a `SHOW WARNINGS` statement following the `EXPLAIN` statement. The `Message` value in `SHOW WARNINGS` output displays how the optimizer qualifies table and column names in the `SELECT` statement, what the `SELECT` looks like after the application of rewriting and optimization rules, and possibly other notes about the optimization process.

#### Note

As of MySQL 5.7.3, the `EXPLAIN` statement is changed so that the effect of the `EXTENDED` keyword is always enabled. `EXTENDED` is still recognized, but is superfluous and is deprecated. It will be removed from `EXPLAIN` syntax in a future MySQL release.

Here is an example of extended output:

```
mysql> EXPLAIN EXTENDED
-> SELECT t1.a, t1.a IN (SELECT t2.a FROM t2) FROM t1\G
***** 1. row *****
      id: 1
    select_type: PRIMARY
      table: t1
      type: index
possible_keys: NULL
      key: PRIMARY
     key_len: 4
       ref: NULL
      rows: 4
  filtered: 100.00
    Extra: Using index
***** 2. row *****
      id: 2
    select_type: SUBQUERY
      table: t2
      type: index
possible_keys: a
      key: a
     key_len: 5
       ref: NULL
      rows: 3
  filtered: 100.00
    Extra: Using index
2 rows in set, 1 warning (0.00 sec)

mysql> SHOW WARNINGS\G
***** 1. row *****
      Level: Note
      Code: 1003
Message: /* select#1 */ select `test`.`t1`.`a` AS `a`,
      <in_optimizer>(`test`.`t1`.`a`,`test`.`t1`.`a` in
      ( <materialize> (/* select#2 */ select `test`.`t2`.`a`
      from `test`.`t2` where 1 having 1 ),
      <primary_index_lookup>(`test`.`t1`.`a` in
      <temporary table> on <auto_key>
      where ((`test`.`t1`.`a` = `materialized-subquery`.`a`)))) AS `t1.a
      IN (SELECT t2.a FROM t2)` from `test`.`t1`
1 row in set (0.00 sec)
```

`EXPLAIN EXTENDED` can be used with `SELECT`, `DELETE`, `INSERT`, `REPLACE`, and `UPDATE` statements. However, a `SHOW WARNINGS` statement following `EXPLAIN` displays a nonempty result only for `SELECT` statements.

Because the statement displayed by `SHOW WARNINGS` may contain special markers to provide information about query rewriting or optimizer actions, the statement is not necessarily valid SQL and is not intended to be executed. The output may also include rows with `Message` values that provide additional non-SQL explanatory notes about actions taken by the optimizer.

The following list describes special markers that can appear in the extended output displayed by `SHOW WARNINGS`:

- `<auto_key>`

An automatically generated key for a temporary table.

- `<cache>(expr)`

The expression (such as a scalar subquery) is executed once and the resulting value is saved in memory for later use. For results consisting of multiple values, a temporary table may be created and you will see `<temporary table>` instead.

- `<exists>(query fragment)`

The subquery predicate is converted to an [EXISTS](#) predicate and the subquery is transformed so that it can be used together with the [EXISTS](#) predicate.

- `<in_optimizer>(query fragment)`

This is an internal optimizer object with no user significance.

- `<index_lookup>(query fragment)`

The query fragment is processed using an index lookup to find qualifying rows.

- `<if>(condition, expr1, expr2)`

If the condition is true, evaluate to `expr1`, otherwise `expr2`.

- `<is_not_null_test>(expr)`

A test to verify that the expression does not evaluate to [NULL](#).

- `<materialize>(query fragment)`

Subquery materialization is used.

- ``materialized-subquery`.col_name`

A reference to the column `col_name` in an internal temporary table materialized to hold the result from evaluating a subquery.

- `<primary_index_lookup>(query fragment)`

The query fragment is processed using a primary key lookup to find qualifying rows.

- `<ref_null_helper>(expr)`

This is an internal optimizer object with no user significance.

- `/* select#N */ select_stmt`

The [SELECT](#) is associated with the row in non-extended [EXPLAIN](#) output that has an `id` value of `N`.

- `outer_tables semi join (inner_tables)`

A semi-join operation. `inner_tables` shows the tables that were not pulled out. See [Optimizing Subqueries with Semi-Join Transformations](#).

- `<temporary table>`

This represents an internal temporary table created to cache an intermediate result.

When some tables are of [const](#) or [system](#) type, expressions involving columns from these tables are evaluated early by the optimizer and are not part of the displayed statement. However, with [FORMAT=JSON](#), some [const](#) table accesses are displayed as a [ref](#) access that uses a const value.

## 9.8.4 Obtaining Execution Plan Information for a Named Connection

To obtain the execution plan for an explainable statement executing in a named connection, use this statement:

```
EXPLAIN [options] FOR CONNECTION connection_id;
```

[EXPLAIN FOR CONNECTION](#) returns the [EXPLAIN](#) information that is currently being used to execute a query in a given connection. Because of changes to data (and supporting statistics) it may produce a different result from running [EXPLAIN](#) on the equivalent query text. This difference in behavior can be

useful in diagnosing more transient performance problems. For example, if you are running a statement in one session that is taking a long time to complete, using `EXPLAIN FOR CONNECTION` in another session may yield useful information about the cause of the delay.

`connection_id` is the connection identifier, as obtained from the `INFORMATION_SCHEMA.PROCESSLIST` table or the `SHOW PROCESSLIST` statement. If you have the `PROCESS` privilege, you can specify the identifier for any connection. Otherwise, you can specify the identifier only for your own connections.

If the named connection is not executing a statement, the result is empty. Otherwise, `EXPLAIN FOR CONNECTION` applies only if the statement being executed in the named connection is explainable. This includes `SELECT`, `DELETE`, `INSERT`, `REPLACE`, and `UPDATE`. (However, `EXPLAIN FOR CONNECTION` does not work for prepared statements, even prepared statements of those types.)

If the named connection is executing an explainable statement, the output is what you would obtain by using `EXPLAIN` on the statement itself.

If the named connection is executing a statement that is not explainable, an error occurs. For example, you cannot name the connection identifier for your current session because `EXPLAIN` is not explainable:

```
mysql> SELECT CONNECTION_ID();
+-----+
| CONNECTION_ID() |
+-----+
|          373   |
+-----+
1 row in set (0.00 sec)

mysql> EXPLAIN FOR CONNECTION 373;
ERROR 1889 (HY000): EXPLAIN FOR CONNECTION command is supported
only for SELECT/UPDATE/INSERT/DELETE/REPLACE
```

The `Com_explain_other` status variable indicates the number of `EXPLAIN FOR CONNECTION` statements executed.

## 9.8.5 Estimating Query Performance

In most cases, you can estimate query performance by counting disk seeks. For small tables, you can usually find a row in one disk seek (because the index is probably cached). For bigger tables, you can estimate that, using B-tree indexes, you need this many seeks to find a row:  $\log(\text{row\_count}) / \log(\text{index\_block\_length} / 3 * 2 / (\text{index\_length} + \text{data\_pointer\_length})) + 1$ .

In MySQL, an index block is usually 1,024 bytes and the data pointer is usually four bytes. For a 500,000-row table with a key value length of three bytes (the size of `MEDIUMINT`), the formula indicates  $\log(500,000) / \log(1024 / 3 * 2 / (3 + 4)) + 1 = 4$  seeks.

This index would require storage of about  $500,000 * 7 * 3/2 = 5.2\text{MB}$  (assuming a typical index buffer fill ratio of 2/3), so you probably have much of the index in memory and so need only one or two calls to read data to find the row.

For writes, however, you need four seek requests to find where to place a new index value and normally two seeks to update the index and write the row.

The preceding discussion does not mean that your application performance slowly degenerates by  $\log N$ . As long as everything is cached by the OS or the MySQL server, things become only marginally slower as the table gets bigger. After the data gets too big to be cached, things start to go much slower until your applications are bound only by disk seeks (which increase by  $\log N$ ). To avoid this, increase the key cache size as the data grows. For `MyISAM` tables, the key cache size is controlled by the `key_buffer_size` system variable. See [Section 6.1.1, “Configuring the Server”](#).

## 9.9 Controlling the Query Optimizer

MySQL provides optimizer control through system variables that affect how query plans are evaluated, switchable optimizations, optimizer and index hints, and the optimizer cost model.

### 9.9.1 Controlling Query Plan Evaluation

The task of the query optimizer is to find an optimal plan for executing an SQL query. Because the difference in performance between “good” and “bad” plans can be orders of magnitude (that is, seconds versus hours or even days), most query optimizers, including that of MySQL, perform a more or less exhaustive search for an optimal plan among all possible query evaluation plans. For join queries, the number of possible plans investigated by the MySQL optimizer grows exponentially with the number of tables referenced in a query. For small numbers of tables (typically less than 7 to 10) this is not a problem. However, when larger queries are submitted, the time spent in query optimization may easily become the major bottleneck in the server's performance.

A more flexible method for query optimization enables the user to control how exhaustive the optimizer is in its search for an optimal query evaluation plan. The general idea is that the fewer plans that are investigated by the optimizer, the less time it spends in compiling a query. On the other hand, because the optimizer skips some plans, it may miss finding an optimal plan.

The behavior of the optimizer with respect to the number of plans it evaluates can be controlled using two system variables:

- The `optimizer_prune_level` variable tells the optimizer to skip certain plans based on estimates of the number of rows accessed for each table. Our experience shows that this kind of “educated guess” rarely misses optimal plans, and may dramatically reduce query compilation times. That is why this option is on (`optimizer_prune_level=1`) by default. However, if you believe that the optimizer missed a better query plan, this option can be switched off (`optimizer_prune_level=0`) with the risk that query compilation may take much longer. Note that, even with the use of this heuristic, the optimizer still explores a roughly exponential number of plans.
- The `optimizer_search_depth` variable tells how far into the “future” of each incomplete plan the optimizer should look to evaluate whether it should be expanded further. Smaller values of `optimizer_search_depth` may result in orders of magnitude smaller query compilation times. For example, queries with 12, 13, or more tables may easily require hours and even days to compile if `optimizer_search_depth` is close to the number of tables in the query. At the same time, if compiled with `optimizer_search_depth` equal to 3 or 4, the optimizer may compile in less than a minute for the same query. If you are unsure of what a reasonable value is for `optimizer_search_depth`, this variable can be set to 0 to tell the optimizer to determine the value automatically.

### 9.9.2 Controlling Switchable Optimizations

The `optimizer_switch` system variable enables control over optimizer behavior. Its value is a set of flags, each of which has a value of `on` or `off` to indicate whether the corresponding optimizer behavior is enabled or disabled. This variable has global and session values and can be changed at runtime. The global default can be set at server startup.

To see the current set of optimizer flags, select the variable value:

```
mysql> SELECT @@optimizer_switch\G
***** 1. row *****
@@optimizer_switch: index_merge=on,index_merge_union=on,
                    index_merge_sort_union=on,
                    index_merge_intersection=on,
                    engine_condition_pushdown=on,
                    index_condition_pushdown=on,
                    mrr=on,mrr_cost_based=on,
                    block_nested_loop=on,batched_key_access=off,
                    materialization=on,semijoin=on,loosescan=on,
                    firstmatch=on,duplicateweedout=on,
                    subquery_materialization_cost_based=on,
```

```
use_index_extensions=on,
condition_fanout_filter=on,derived_merge=on
```

To change the value of `optimizer_switch`, assign a value consisting of a comma-separated list of one or more commands:

```
SET [GLOBAL|SESSION] optimizer_switch='command[,command]...';
```

Each `command` value should have one of the forms shown in the following table.

| Command Syntax                | Meaning   |
|-------------------------------|---|
| <code>default</code>          | Reset every optimization to its default value   |
| <code>opt_name=default</code> | Set the named optimization to its default value |
| <code>opt_name=off</code>     | Disable the named optimization                  |
| <code>opt_name=on</code>      | Enable the named optimization                   |

The order of the commands in the value does not matter, although the `default` command is executed first if present. Setting an `opt_name` flag to `default` sets it to whichever of `on` or `off` is its default value. Specifying any given `opt_name` more than once in the value is not permitted and causes an error. Any errors in the value cause the assignment to fail with an error, leaving the value of `optimizer_switch` unchanged.

The following table lists the permissible `opt_name` flag names, grouped by optimization strategy.

| Optimization              | Flag Name                              | Meaning  | Default |
|---------------------------|--|--|---------|
| Batched Key Access        | <code>batched_key_access</code>        | Controls use of BKA join algorithm   | OFF     |
| Block Nested-Loop         | <code>block_nested_loop</code>         | Controls use of BNL join algorithm   | ON      |
| Condition Filtering       | <code>condition_fanout_filter</code>   | Controls use of condition filtering  | ON      |
| Engine Condition Pushdown | <code>engine_condition_pushdown</code> | Controls engine condition pushdown   | ON      |
| Index Condition Pushdown  | <code>index_condition_pushdown</code>  | Controls index condition pushdown  | ON      |
| Index Extensions          | <code>use_index_extensions</code>      | Controls use of index extensions   | ON      |
| Index Merge               | <code>index_merge</code>               | Controls all Index Merge optimizations   | ON      |
|                           | <code>index_merge_intersection</code>  | Controls the Index Merge Intersection Access optimization  | ON      |
|                           | <code>index_merge_sort_union</code>    | Controls the Index Merge Sort-Union Access optimization  | ON      |
|                           | <code>index_merge_union</code>         | Controls the Index Merge Union Access optimization   | ON      |
| Multi-Range Read          | <code>mrr</code>                       | Controls the Multi-Range Read strategy   | ON      |
|                           | <code>mrr_cost_based</code>            | Controls use of cost-based MRR if <code>mrr=on</code>  | ON      |
| Semi-join                 | <code>semijoin</code>                  | Controls all semi-join strategies  | ON      |
|                           | <code>firstmatch</code>                | Controls the semi-join FirstMatch strategy   | ON      |
|                           | <code>loosescan</code>                 | Controls the semi-join LooseScan strategy (not to be confused with LooseScan for <code>GROUP BY</code> ) | ON      |

| Optimization             | Flag Name  | Meaning   | Default |
|--------------------------|--|---|---------|
|                          | <code>duplicateweedout</code>                    | Controls the semi-join Duplicate Weedout strategy                   | ON      |
| Subquery materialization | <code>materialization</code>                     | Controls materialization (including semi-join materialization)      | ON      |
|                          | <code>subquery_materialization_cost_based</code> | Used cost-based materialization choice                              | ON      |
| Derived table merging    | <code>derived_merge</code>                       | Controls merging of derived tables and views into outer query block | ON      |

For `batched_key_access` to have any effect when set to `on`, the `mrr` flag must also be `on`. Currently, the cost estimation for MRR is too pessimistic. Hence, it is also necessary for `mrr_cost_based` to be `off` for BKA to be used.

The `semijoin`, `firstmatch`, `loosescan`, `duplicateweedout` (added in MySQL 5.7.8), and `materialization` flags enable control over semi-join and subquery materialization strategies. The `semijoin` flag controls whether semi-joins are used. If it is set to `on`, the `firstmatch` and `loosescan` flags enable finer control over the permitted semi-join strategies. The `materialization` flag controls whether subquery materialization is used. If `semijoin` and `materialization` are both `on`, semi-joins also use materialization where applicable. These flags are `on` by default.

If the `duplicateweedout` semi-join strategy is disabled, it is not used unless all other applicable strategies are also disabled.

The `subquery_materialization_cost_based` flag enables control over the choice between subquery materialization and `IN-to-EXISTS` subquery transformation. If the flag is `on` (the default), the optimizer performs a cost-based choice between subquery materialization and `IN-to-EXISTS` subquery transformation if either method could be used. If the flag is `off`, the optimizer chooses subquery materialization over `IN -> EXISTS` subquery transformation.

The `derived_merge` flag (added in MySQL 5.7.6) controls whether the optimizer attempts to merge derived tables and view references into the outer query block, assuming that no other rule prevents merging; for example, an `ALGORITHM` directive for a view takes precedence over the `derived_merge` setting. By default, the flag is `on` to enable merging. For more information, see [Optimizing Derived Tables and View References](#).

For more information about individual optimization strategies, see the following sections:

- [Section 9.2.1.14, “Block Nested-Loop and Batched Key Access Joins”](#)
- [Section 9.2.1.5, “Engine Condition Pushdown Optimization”](#)
- [Section 9.2.1.7, “Use of Index Extensions”](#)
- [Section 9.2.1.6, “Index Condition Pushdown Optimization”](#)
- [Section 9.2.1.4, “Index Merge Optimization”](#)
- [Section 9.2.1.13, “Multi-Range Read Optimization”](#)
- [Section 9.2.1.18, “Subquery Optimization”](#)

When you assign a value to `optimizer_switch`, flags that are not mentioned keep their current values. This makes it possible to enable or disable specific optimizer behaviors in a single statement without affecting other behaviors. The statement does not depend on what other optimizer flags exist and what their values are. Suppose that all Index Merge optimizations are enabled:

```
mysql> SELECT @@optimizer_switch\G
***** 1. row *****
```

```
@@optimizer_switch: index_merge=on,index_merge_union=on,
                    index_merge_sort_union=on,
                    index_merge_intersection=on,
                    engine_condition_pushdown=on,
                    index_condition_pushdown=on,
                    mrr=on,mrr_cost_based=on,
                    block_nested_loop=on,batched_key_access=off,
                    materialization=on,semijoin=on,loosescan=on,
                    firstmatch=on,
                    subquery_materialization_cost_based=on,
                    use_index_extensions=on,
                    condition_fanout_filter=on
```

If the server is using the Index Merge Union or Index Merge Sort-Union access methods for certain queries and you want to check whether the optimizer will perform better without them, set the variable value like this:

```
mysql> SET optimizer_switch='index_merge_union=off,index_merge_sort_union=off';

mysql> SELECT @@optimizer_switch\G
***** 1. row *****
@@optimizer_switch: index_merge=on,index_merge_union=off,
                    index_merge_sort_union=off,
                    index_merge_intersection=on,
                    engine_condition_pushdown=on,
                    index_condition_pushdown=on,
                    mrr=on,mrr_cost_based=on,
                    block_nested_loop=on,batched_key_access=off,
                    materialization=on,semijoin=on,loosescan=on,
                    firstmatch=on,
                    subquery_materialization_cost_based=on,
                    use_index_extensions=on,
                    condition_fanout_filter=on
```

### 9.9.3 Optimizer Hints

One means of control over optimizer strategies is to set the `optimizer_switch` system variable (see [Section 9.9.2, “Controlling Switchable Optimizations”](#)). Changes to this variable affect execution of all subsequent queries; to affect one query differently from another, it's necessary to change `optimizer_switch` before each one.

As of MySQL 5.7.7, another way to control the optimizer is by using optimizer hints, which can be specified within individual statements. Because optimizer hints apply on a per-statement basis, they provide finer control over statement execution plans than can be achieved using `optimizer_switch`. For example, you can enable an optimization for one table in a statement and disable the optimization for a different table. Hints within a statement take precedence over `optimizer_switch` flags.

Examples:

```
SELECT /*+ NO_RANGE_OPTIMIZATION(t3 PRIMARY, f2_idx) */ f1
  FROM t3 WHERE f1 > 30 AND f1 < 33;
SELECT /*+ BKA(t1) NO_BKA(t2) */ * FROM t1 INNER JOIN t2 WHERE ...;
SELECT /*+ NO_ICP(t1, t2) */ * FROM t1 INNER JOIN t2 WHERE ...;
SELECT /*+ SEMIJOIN(FIRSTMATCH, LOOSECAN) */ * FROM t1 ...;
EXPLAIN SELECT /*+ NO_ICP(t1) */ * FROM t1 WHERE ...;
```

#### Note

As of MySQL 5.7.7, the `mysql` client always passes optimizer hints to the server. Prior to 5.7.7, `mysql` by default strips comments from SQL statements sent to the server (including optimizer hints). To ensure that optimizer hints are not stripped if you are using an older version of the `mysql` client with a version of the server that understands optimizer hints, invoke `mysql` with the `--comments` option.

Optimizer hints, described here, differ from index hints, described in [Section 9.9.4, “Index Hints”](#). Optimizer and index hints may be used separately or together.

- [Optimizer Hint Overview](#)
- [Optimizer Hint Syntax](#)
- [Table-Level Optimizer Hints](#)
- [Index-Level Optimizer Hints](#)
- [Subquery Optimizer Hints](#)
- [Statement Execution Time Optimizer Hints](#)
- [Optimizer Hints for Naming Query Blocks](#)

## Optimizer Hint Overview

Optimizer hints apply at different scope levels:

- Global: The hint affects the entire statement
- Query block: The hint affects a particular query block within a statement
- Table-level: The hint affects a particular table within a query block
- Index-level: The hint affects a particular index within a table

The following table summarizes the available optimizer hints, the optimizer strategies they affect, and the scope or scopes at which they apply. More details are given later.

**Table 9.2 Optimizer Hints Available**

| Hint Name  | Description   | Applicable Scopes  |
|--|---|--------------------|
| <a href="#">BKA</a> , <a href="#">NO_BKA</a>           | Affects Batched Key Access join processing                                | Query block, table |
| <a href="#">BNL</a> , <a href="#">NO_BNL</a>           | Affects Block Nested-Loop join processing                                 | Query block, table |
| <a href="#">MAX_EXECUTION_TIME</a>                     | Limits statement execution time   | Global             |
| <a href="#">MRR</a> , <a href="#">NO_MRR</a>           | Affects Multi-Range Read optimization                                     | Table, index       |
| <a href="#">NO_ICP</a>                                 | Affects Index Condition Pushdown optimization                             | Table, index       |
| <a href="#">NO_RANGE_OPTIMIZATION</a>                  | Affects range optimization  | Table, index       |
| <a href="#">QB_NAME</a>                                | Assigns name to query block   | Query block        |
| <a href="#">SEMIJOIN</a> , <a href="#">NO_SEMIJOIN</a> | Affects semi-join strategies  | Query block        |
| <a href="#">SUBQUERY</a>                               | Affects materialization, <a href="#">IN-to-EXISTS</a> subquery strategies | Query block        |

Disabling an optimization prevents the optimizer from using it. Enabling an optimization means the optimizer is free to use the strategy if it applies to statement execution, not that the optimizer necessarily will use it.

## Optimizer Hint Syntax

MySQL supports comments in SQL statements as described in [Section 10.6, “Comment Syntax”](#). Optimizer hints must be specified within `/*+ ... */` comments. That is, optimizer hints use a variant of `/* ... */` C-style comment syntax, with a `+` character following the `/*` comment opening sequence. Examples:

```
/*+ BKA(t1) */
/*+ BNL(t1, t2) */
/*+ NO_RANGE_OPTIMIZATION(t4 PRIMARY) */
/*+ QB_NAME(qb2) */
```

Whitespace is permitted after the + character.

The parser recognizes optimizer hint comments after the initial keyword of [SELECT](#), [UPDATE](#), [INSERT](#), [REPLACE](#), and [DELETE](#) statements. Hints are permitted in these contexts:

- At the beginning of query and data change statements:

```
SELECT /*+ ... */ ...
INSERT /*+ ... */ ...
REPLACE /*+ ... */ ...
UPDATE /*+ ... */ ...
DELETE /*+ ... */ ...
```

- At the beginning of query blocks:

```
(SELECT /*+ ... */ ... )
(SELECT ... ) UNION (SELECT /*+ ... */ ... )
(SELECT /*+ ... */ ... ) UNION (SELECT /*+ ... */ ... )
UPDATE ... WHERE x IN (SELECT /*+ ... */ ...)
INSERT ... SELECT /*+ ... */ ...
```

- In hintable statements prefaced by [EXPLAIN](#). For example:

```
EXPLAIN SELECT /*+ ... */ ...
EXPLAIN UPDATE ... WHERE x IN (SELECT /*+ ... */ ...)
```

The implication is that you can use [EXPLAIN](#) to see how optimizer hints affect execution plans. Use [SHOW WARNINGS](#) immediately after [EXPLAIN](#) to see how hints are used. The extended [EXPLAIN](#) output displayed by [SHOW WARNINGS](#) indicates which hints were used. Ignored hints are not displayed.

A hint comment may contain multiple hints, but a query block cannot contain multiple hint comments. This is valid:

```
SELECT /*+ BNL(t1) BKA(t2) */ ...
```

But this is invalid:

```
SELECT /*+ BNL(t1) */ /* BKA(t2) */ ...
```

When a hint comment contains multiple hints, the possibility of duplicates and conflicts exists. The following general guidelines apply. For specific hint types, additional rules may apply, as indicated in the hint descriptions.

- Duplicate hints: For a hint such as `/*+ MRR(idx1) MRR(idx1) */`, MySQL uses the first hint and issues a warning about the duplicate hint.
- Conflicting hints: For a hint such as `/*+ MRR(idx1) NO_MRR(idx1) */`, MySQL uses the first hint and issues a warning about the second conflicting hint.

Query block names are identifiers and follow the usual rules about what names are valid and how to quote them (see [Section 10.2, “Schema Object Names”](#)).

Hint names, query block names, and strategy names are not case sensitive. References to table and index names follow the usual identifier case sensitivity rules (see [Section 10.2.2, “Identifier Case Sensitivity”](#)), except that table name comparisons do not use the `lower_case_table_names` value until MySQL 5.7.8.

## Table-Level Optimizer Hints

Table-level hints affect use of the Block Nested-Loop (BNL) and Batched Key Access (BKA) join-processing algorithms (see [Section 9.2.1.14, “Block Nested-Loop and Batched Key Access Joins”](#)). These hint types apply to specific tables, or all tables in a query block.

Syntax of table-level hints:

```
hint_name([@query_block_name] [tbl_name [, tbl_name] ...])
hint_name([tbl_name@query_block_name [, tbl_name@query_block_name] ...])
```

The syntax refers to these terms:

- *hint\_name*: These hint names are permitted:
  - *BKA*, *NO\_BKA*: Enable or disable BKA for the specified tables.
  - *BNL*, *NO\_BNL*: Enable or disable BNL for the specified tables.
- *tbl\_name*: The name of a table used in the statement. The hint applies to all tables that it names. If the hint names no tables, it applies to all tables of the query block in which it occurs.

If a table has an alias, hints must refer to the alias, not the table name.

Table names in hints cannot be qualified with schema names.

- *query\_block\_name*: The query block to which the hint applies. If the hint includes no leading *@query\_block\_name*, the hint applies to the query block in which it occurs. For *tbl\_name@query\_block\_name* syntax, the hint applies to the named table in the named query block. To assign a name to a query block, see [Optimizer Hints for Naming Query Blocks](#).

Examples:

```
SELECT /*+ NO_BKA(t1, t2) */ t1.* FROM t1 INNER JOIN t2 INNER JOIN t3;
SELECT /*+ NO_BNL() BKA(t1) */ t1.* FROM t1 INNER JOIN t2 INNER JOIN t3;
```

A table-level hint applies to tables that receive records from previous tables, not sender tables. Consider this statement:

```
SELECT /*+ BNL(t2) */ FROM t1, t2;
```

If the optimizer chooses to process *t1* first, it applies a Block Nested-Loop join to *t2* by buffering the rows from *t1* before starting to read from *t2*. If the optimizer instead chooses to process *t2* first, the hint has no effect because *t2* is a sender table.

## Index-Level Optimizer Hints

Index-level hints affect which index-processing strategies the optimizer uses for particular tables or indexes. These hint types affect use of Index Condition Pushdown (ICP), Multi-Range Read (MRR), and range optimizations (see [Section 9.2.1, “Optimizing SELECT Statements”](#)).

Syntax of index-level hints:

```
hint_name([@query_block_name] tbl_name [index_name [, index_name] ...])
hint_name(tbl_name@query_block_name [index_name [, index_name] ...])
```

The syntax refers to these terms:

- *hint\_name*: These hint names are permitted:
  - *MRR*, *NO\_MRR*: Enable or disable MRR for the specified tables or indexes. MRR hints apply only to InnoDB and MyISAM tables.

- **NO\_ICP**: Disable ICP for the specified tables or indexes. By default, ICP is a candidate optimization strategy, so there is no hint for enabling it.
- **NO\_RANGE\_OPTIMIZATION**: Disable index range access for the specified tables or indexes. This hint also disables Index Merge and Loose Index Scan for the tables or indexes. By default, range access is a candidate optimization strategy, so there is no hint for enabling it.

This hint may be useful when the number of ranges may be high and range optimization would require many resources.

- **tbl\_name**: The table to which the hint applies.
- **index\_name**: The name of an index in the named table. The hint applies to all indexes that it names. If the hint names no indexes, it applies to all indexes in the table.

To refer to a primary key, use the name **PRIMARY**. To see the index names for a table, use **SHOW INDEX**.

- **query\_block\_name**: The query block to which the hint applies. If the hint includes no leading **@query\_block\_name**, the hint applies to the query block in which it occurs. For **tbl\_name@query\_block\_name** syntax, the hint applies to the named table in the named query block. To assign a name to a query block, see [Optimizer Hints for Naming Query Blocks](#).

Examples:

```
SELECT /*+ MRR(t1) */ * FROM t1 WHERE f2 <= 3 AND 3 <= f3;
SELECT /*+ NO_RANGE_OPTIMIZATION(t3 PRIMARY, f2_idx) */ f1
  FROM t3 WHERE f1 > 30 AND f1 < 33;
INSERT INTO t3(f1, f2, f3)
  (SELECT /*+ NO_ICP(t2) */ t2.f1, t2.f2, t2.f3 FROM t1,t2
   WHERE t1.f1=t2.f1 AND t2.f2 BETWEEN t1.f1
   AND t1.f2 AND t2.f2 + 1 >= t1.f1 + 1);
```

## Subquery Optimizer Hints

Subquery hints (added in MySQL 5.7.8) affect whether to use semi-join transformations and which semi-join strategies to permit, and, when semi-joins are not used, whether to use subquery materialization or **IN-to-EXISTS** transformations. For more information about these optimizations, see [Section 9.2.1.18, “Subquery Optimization”](#).

Syntax of hints that affect semi-join strategies:

```
hint_name([@query_block_name] [strategy [, strategy] ...])
```

The syntax refers to these terms:

- **hint\_name**: These hint names are permitted:
  - **SEMIJOIN**, **NO\_SEMIJOIN**: Enable or disable the named semi-join strategies.
- **strategy**: A semi-join strategy to be enabled or disabled. These strategy names are permitted: **DUPSWEEDOUT**, **FIRSTMATCH**, **LOOESCAN**, **MATERIALIZATION**.

For **SEMIJOIN( )** hints, if no strategies are named, semi-join is used if possible based on the strategies enabled according to the **optimizer\_switch** system variable. If strategies are named but inapplicable for the statement, **DUPSWEEDOUT** is used.

For **NO\_SEMIJOIN( )** hints, if no strategies are named, semi-join is not used. If strategies are named that rule out all applicable strategies for the statement, **DUPSWEEDOUT** is used.

If one subquery is nested within another and both are merged into a semi-join of an outer query, any specification of semi-join strategies for the innermost query are ignored. **SEMIJOIN( )** and

`NO_SEMIJOIN()` hints can still be used to enable or disable semi-join transformations for such nested subqueries.

If `DUPSWEEP` is disabled, on occasion the optimizer may generate a query plan that is far from optimal. This occurs due to heuristic pruning during greedy search, which can be avoided by setting `optimizer_prune_level=0`.

Examples:

```
SELECT /*+ NO_SEMIJOIN(@subq1 FIRSTMATCH, LOOPESCAN) */ * FROM t2
  WHERE t2.a IN (SELECT /*+ QB_NAME(subq1) */ a FROM t3);
SELECT /*+ SEMIJOIN(@subq1 MATERIALIZATION, DUPSWEEP) */ * FROM t2
  WHERE t2.a IN (SELECT /*+ QB_NAME(subq1) */ a FROM t3);
```

Syntax of hints that affect whether to use subquery materialization or `IN-to-EXISTS` transformations:

```
SUBQUERY([@query_block_name] strategy)
```

The hint name is always `SUBQUERY`.

For `SUBQUERY()` hints, these *strategy* values are permitted: `INTOEXISTS`, `MATERIALIZATION`.

Examples:

```
SELECT id, a IN (SELECT /*+ SUBQUERY(MATERIALIZATION) */ a FROM t1) FROM t2;
SELECT * FROM t2 WHERE t2.a IN (SELECT /*+ SUBQUERY(INTOEXISTS) */ a FROM t1);
```

For semi-join and `SUBQUERY()` hints, a leading `@query_block_name` specifies the query block to which the hint applies. If the hint includes no leading `@query_block_name`, the hint applies to the query block in which it occurs. To assign a name to a query block, see [Optimizer Hints for Naming Query Blocks](#).

If a hint comment contains multiple subquery hints, the first is used. If there are other following hints of that type, they produce a warning. Following hints of other types are silently ignored.

## Statement Execution Time Optimizer Hints

The `MAX_EXECUTION_TIME()` hint is permitted only for `SELECT` statements. It places a limit *N* (a timeout value in milliseconds) on how long a statement is permitted to execute before the server terminates it:

```
MAX_EXECUTION_TIME(N)
```

Example with a timeout of 1 second (1000 milliseconds):

```
SELECT /*+ MAX_EXECUTION_TIME(1000) */ * FROM t1 INNER JOIN t2 WHERE ...
```

The `MAX_EXECUTION_TIME(N)` hint sets a statement execution timeout of *N* milliseconds. If this option is absent or *N* is 0, the statement timeout established by the `max_execution_time` system variable applies. (Prior to MySQL 5.7.8, this variable was named `max_statement_time`.)

The `MAX_EXECUTION_TIME()` hint is applicable as follows:

- For statements with multiple `SELECT` keywords, such as unions or statements with subqueries, `MAX_EXECUTION_TIME()` applies to the entire statement and must appear after the first `SELECT`.
- It applies to read-only `SELECT` statements. Statements that are not read only are those that invoke a stored function that modifies data as a side effect.
- It does not apply to `SELECT` statements in stored programs and is ignored.

## Optimizer Hints for Naming Query Blocks

Table-level, index-level, and subquery optimizer hints permit specific query blocks to be named as part of their argument syntax. To create these names, use the `QB_NAME ( )` hint, which assigns a name to the query block in which it occurs:

```
QB_NAME (name)
```

`QB_NAME ( )` hints can be used to make explicit in a clear way which query blocks other hints apply to. They also permit all non-query block name hints to be specified within a single hint comment for easier understanding of complex statements. Consider the following statement:

```
SELECT ...
  FROM (SELECT ...
        FROM (SELECT ... FROM ...)) ...
```

`QB_NAME ( )` hints assign names to query blocks in the statement:

```
SELECT /*+ QB_NAME(qb1) */ ...
  FROM (SELECT /*+ QB_NAME(qb2) */ ...
        FROM (SELECT /*+ QB_NAME(qb3) */ ... FROM ...)) ...
```

Then other hints can use those names to refer to the appropriate query blocks:

```
SELECT /*+ QB_NAME(qb1) MRR(@qb1 t1) BKA(@qb2) NO_MRR(@qb3t1 idx1, id2) */ ...
  FROM (SELECT /*+ QB_NAME(qb2) */ ...
        FROM (SELECT /*+ QB_NAME(qb3) */ ... FROM ...)) ...
```

The resulting effect is as follows:

- `MRR(@qb1 t1)` applies to table `t1` in query block `qb1`.
- `BKA(@qb2)` applies to query block `qb2`.
- `NO_MRR(@qb3 t1 idx1, id2)` applies to indexes `idx1` and `idx2` in table `t1` in query block `qb3`.

Query block names are identifiers and follow the usual rules about what names are valid and how to quote them (see [Section 10.2, “Schema Object Names”](#)). For example, a query block name that contains spaces must be quoted, which can be done using backticks:

```
SELECT /*+ BKA(@`my hint name`) */ ...
  FROM (SELECT /*+ QB_NAME(`my hint name`) */ ...) ...
```

If the `ANSI_QUOTES` SQL mode is enabled, it is also possible to quote query block names within double quotation marks:

```
SELECT /*+ BKA(@"my hint name") */ ...
  FROM (SELECT /*+ QB_NAME("my hint name") */ ...) ...
```

### 9.9.4 Index Hints

Index hints give the optimizer information about how to choose indexes during query processing. Index hints, described here, differ from optimizer hints, described in [Section 9.9.3, “Optimizer Hints”](#). Index and optimizer hints may be used separately or together.

Index hints are specified following a table name. (For the general syntax for specifying tables in a `SELECT` statement, see [Section 14.2.9.2, “JOIN Syntax”](#).) The syntax for referring to an individual table, including index hints, looks like this:

```
tbl_name [[AS] alias] [index_hint_list]
```

```

index_hint_list:
    index_hint [, index_hint] ...

index_hint:
    USE {INDEX|KEY}
        [FOR {JOIN|ORDER BY|GROUP BY}] ([index_list])
    | IGNORE {INDEX|KEY}
        [FOR {JOIN|ORDER BY|GROUP BY}] (index_list)
    | FORCE {INDEX|KEY}
        [FOR {JOIN|ORDER BY|GROUP BY}] (index_list)

index_list:
    index_name [, index_name] ...

```

The `USE INDEX (index_list)` hint tells MySQL to use only one of the named indexes to find rows in the table. The alternative syntax `IGNORE INDEX (index_list)` tells MySQL to not use some particular index or indexes. These hints are useful if `EXPLAIN` shows that MySQL is using the wrong index from the list of possible indexes.

The `FORCE INDEX` hint acts like `USE INDEX (index_list)`, with the addition that a table scan is assumed to be *very* expensive. In other words, a table scan is used only if there is no way to use one of the named indexes to find rows in the table.

Each hint requires the names of *indexes*, not the names of columns. To refer to a primary key, use the name `PRIMARY`. To see the index names for a table, use `SHOW INDEX`.

An *index\_name* value need not be a full index name. It can be an unambiguous prefix of an index name. If a prefix is ambiguous, an error occurs.

Examples:

```

SELECT * FROM table1 USE INDEX (col1_index,col2_index)
    WHERE col1=1 AND col2=2 AND col3=3;

SELECT * FROM table1 IGNORE INDEX (col3_index)
    WHERE col1=1 AND col2=2 AND col3=3;

```

The syntax for index hints has the following characteristics:

- It is syntactically valid to omit *index\_list* for `USE INDEX`, which means “use no indexes.” Omitting *index\_list* for `FORCE INDEX` or `IGNORE INDEX` is a syntax error.
- You can specify the scope of an index hint by adding a `FOR` clause to the hint. This provides more fine-grained control over the optimizer's selection of an execution plan for various phases of query processing. To affect only the indexes used when MySQL decides how to find rows in the table and how to process joins, use `FOR JOIN`. To influence index usage for sorting or grouping rows, use `FOR ORDER BY` or `FOR GROUP BY`.
- You can specify multiple index hints:

```
SELECT * FROM t1 USE INDEX (i1) IGNORE INDEX FOR ORDER BY (i2) ORDER BY a;
```

It is not an error to name the same index in several hints (even within the same hint):

```
SELECT * FROM t1 USE INDEX (i1) USE INDEX (i1,i1);
```

However, it is an error to mix `USE INDEX` and `FORCE INDEX` for the same table:

```
SELECT * FROM t1 USE INDEX FOR JOIN (i1) FORCE INDEX FOR JOIN (i2);
```

If an index hint includes no `FOR` clause, the scope of the hint is to apply to all parts of the statement. For example, this hint:

```
IGNORE INDEX (i1)
```

is equivalent to this combination of hints:

```
IGNORE INDEX FOR JOIN (i1)
IGNORE INDEX FOR ORDER BY (i1)
IGNORE INDEX FOR GROUP BY (i1)
```

In MySQL 5.0, hint scope with no **FOR** clause was to apply only to row retrieval. To cause the server to use this older behavior when no **FOR** clause is present, enable the `old` system variable at server startup. Take care about enabling this variable in a replication setup. With statement-based binary logging, having different modes for the master and slaves might lead to replication errors.

When index hints are processed, they are collected in a single list by type (**USE**, **FORCE**, **IGNORE**) and by scope (**FOR JOIN**, **FOR ORDER BY**, **FOR GROUP BY**). For example:

```
SELECT * FROM t1
  USE INDEX () IGNORE INDEX (i2) USE INDEX (i1) USE INDEX (i2);
```

is equivalent to:

```
SELECT * FROM t1
  USE INDEX (i1,i2) IGNORE INDEX (i2);
```

The index hints then are applied for each scope in the following order:

1. **{USE|FORCE} INDEX** is applied if present. (If not, the optimizer-determined set of indexes is used.)
2. **IGNORE INDEX** is applied over the result of the previous step. For example, the following two queries are equivalent:

```
SELECT * FROM t1 USE INDEX (i1) IGNORE INDEX (i2) USE INDEX (i2);

SELECT * FROM t1 USE INDEX (i1);
```

For **FULLTEXT** searches, index hints work as follows:

- For natural language mode searches, index hints are silently ignored. For example, **IGNORE INDEX(i1)** is ignored with no warning and the index is still used.
- For boolean mode searches, index hints with **FOR ORDER BY** or **FOR GROUP BY** are silently ignored. Index hints with **FOR JOIN** or no **FOR** modifier are honored. In contrast to how hints apply for non-**FULLTEXT** searches, the hint is used for all phases of query execution (finding rows and retrieval, grouping, and ordering). This is true even if the hint is given for a non-**FULLTEXT** index.

For example, the following two queries are equivalent:

```
SELECT * FROM t
  USE INDEX (index1)
  IGNORE INDEX (index1) FOR ORDER BY
  IGNORE INDEX (index1) FOR GROUP BY
  WHERE ... IN BOOLEAN MODE ... ;

SELECT * FROM t
  USE INDEX (index1)
  WHERE ... IN BOOLEAN MODE ... ;
```

## 9.9.5 The Optimizer Cost Model

To generate execution plans, the optimizer uses a cost model that is based on estimates of the cost of various operations that occur during query execution. The optimizer has a set of compiled-in default “cost constants” available to it to make decisions regarding execution plans.

As of MySQL 5.7.5, the optimizer has in addition a database of cost estimates to use during execution plan construction. These estimates are stored in the `server_cost` and `engine_cost` tables in the `mysql` system database and are configurable at any time. The intent of these tables is to make it possible to easily adjust the cost estimates that the optimizer uses when it attempts to arrive at query execution plans.

## Cost Model General Operation

The configurable optimizer cost model works like this:

- The server reads the cost model tables into memory at startup and uses the in-memory values at runtime. Any non-`NULL` cost estimate specified in the tables takes precedence over the corresponding compiled-in default cost constant. Any `NULL` estimate indicates to the optimizer to use the compiled-in default.
- At runtime, the server may reread the cost tables. This occurs when a storage engine is dynamically loaded or when a `FLUSH OPTIMIZER_COSTS` statement is executed.
- Cost tables enable server administrators to easily adjust cost estimates by changing entries in the tables. It is also easy to revert to a default by setting an entry's cost to `NULL`. The optimizer uses the in-memory cost values, so changes to the tables should be followed by `FLUSH OPTIMIZER_COSTS` to take effect.
- The in-memory cost estimates that are current when a client session begins apply throughout that session until it ends. In particular, if the server rereads the cost tables, any changed estimates apply only to subsequently started sessions. Existing sessions are unaffected.
- Cost tables are specific to a given server instance. The server does not replicate cost table changes to replication slaves.

## The Cost Model Database

The optimizer cost model database consists of two tables in the `mysql` system database that contain cost estimate information for operations that occur during query execution:

- `server_cost`: Optimizer cost estimates for general server operations
- `engine_cost`: Optimizer cost estimates for operations specific to particular storage engines

The `server_cost` table contains these columns:

- `cost_name`

The name of a cost estimate used in the cost model. The name is not case sensitive. If the server does not recognize the cost name when it reads this table, it writes a warning to the error log.

- `cost_value`

The cost estimate value. If the value is non-`NULL`, the server uses it as the cost. Otherwise, it uses the default estimate (the compiled-in value). DBAs can change a cost estimate by updating this column. If the server finds that the cost value is invalid (nonpositive) when it reads this table, it writes a warning to the error log.

To override a default cost estimate (for an entry that specifies `NULL`), set the cost to a non-`NULL` value. To revert to the default, set the value to `NULL`. Then execute `FLUSH OPTIMIZER_COSTS` to tell the server to reread the cost tables.

- `last_update`

The time of the last row update.

- `comment`

A descriptive comment associated with the cost estimate. DBAs can use this column to provide information about why a cost estimate row stores a particular value.

The primary key for the `server_cost` table is the `cost_name` column, so it is not possible to create multiple entries for any cost estimate.

The server recognizes these `cost_name` values for the `server_cost` table:

- `disk temptable_create_cost` (default 40.0), `disk temptable_row_cost` (default 1.0)

The cost estimates for internally created temporary tables stored in a disk-based storage engine (either `InnoDB` or `MyISAM`). Increasing these values increases the cost estimate of using internal temporary tables and makes the optimizer prefer query plans with less use of them. For information about such tables, see [Section 9.4.4, “Internal Temporary Table Use in MySQL”](#).

The larger default values for these disk parameters compared to the default values for the corresponding memory parameters (`memory temptable_create_cost`, `memory temptable_row_cost`) reflects the greater cost of processing disk-based tables.

- `key_compare_cost` (default 0.1)

The cost of comparing record keys. Increasing this value causes a query plan that compares many keys to become more expensive. For example, a query plan that performs a `filesort` becomes relatively more expensive compared to a query plan that avoids sorting by using an index.

- `memory temptable_create_cost` (default 2.0), `memory temptable_row_cost` (default 0.2)

The cost estimates for internally created temporary tables stored in the `MEMORY` storage engine. Increasing these values increases the cost estimate of using internal temporary tables and makes the optimizer prefer query plans with less use of them. For information about such tables, see [Section 9.4.4, “Internal Temporary Table Use in MySQL”](#).

The smaller default values for these memory parameters compared to the default values for the corresponding disk parameters (`disk temptable_create_cost`, `disk temptable_row_cost`) reflects the lesser cost of processing memory-based tables.

- `row_evaluate_cost` (default 0.2)

The cost of evaluating record conditions. Increasing this value causes a query plan that examines many rows to become more expensive compared to a query plan that examines fewer rows. For example, a table scan becomes relatively more expensive compared to a range scan that reads fewer rows.

The `engine_cost` table contains these columns:

- `engine_name`

The name of the storage engine to which this cost estimate applies. The name is not case sensitive. If the value is `default`, it applies to all storage engines that have no named entry of their own. If the server does not recognize the engine name when it reads this table, it writes a warning to the error log.

- `device_type`

The device type to which this cost estimate applies. The column is intended for specifying different cost estimates for different storage device types, such as hard disk drives versus solid state drives. Currently, this information is not used and 0 is the only permitted value.

- `cost_name`

Same as in the `server_cost` table.

- `cost_value`

Same as in the `server_cost` table.

- `last_update`

Same as in the `server_cost` table.

- `comment`

Same as in the `server_cost` table.

The primary key for the `engine_cost` table is a tuple comprising the (`cost_name`, `engine_name`, `device_type`) columns, so it is not possible to create multiple entries for any combination of values in those columns.

The server recognizes these `cost_name` values for the `engine_cost` table:

- `io_block_read_cost` (default 1.0)

The cost of reading an index or data block from disk. Increasing this value causes a query plan that reads many disk blocks to become more expensive compared to a query plan that reads fewer disk blocks. For example, a table scan becomes relatively more expensive compared to a range scan that reads fewer blocks.

- `memory_block_read_cost` (default 1.0)

Similar to `io_block_read_cost`, but represents the cost of reading an index or data block from an in-memory database buffer. This cost parameter was added in MySQL 5.7.8.

## Making Changes to the Cost Model Database

For DBAs who wish to change the cost model parameters from their defaults, try doubling or halving the value and measuring the effect.

Changes to the `io_block_read_cost` and `memory_block_read_cost` parameters are most likely to yield worthwhile results. These parameter values enable cost models for data access methods to take into account the costs of reading information from different sources; that is, the cost of reading information from disk versus reading information already in a memory buffer. For example, all other things being equal, setting `io_block_read_cost` to a value larger than `memory_block_read_cost` causes the optimizer to prefer query plans that read information already held in memory to plans that must read from disk.

This example shows how to change the default value for `io_block_read_cost`:

```
UPDATE mysql.engine_cost
  SET cost_value = 2.0
  WHERE cost_name = 'io_block_read_cost';
FLUSH OPTIMIZER_COSTS;
```

This example shows how to change the value of `io_block_read_cost` only for the `InnoDB` storage engine:

```
INSERT INTO mysql.engine_cost
  VALUES ('InnoDB', 0, 'io_block_read_cost', 3.0,
    CURRENT_TIMESTAMP, 'Using a slower disk for InnoDB');
FLUSH OPTIMIZER_COSTS;
```

## 9.10 Buffering and Caching

MySQL uses several strategies that cache information in memory buffers to increase performance.

## 9.10.1 InnoDB Buffer Pool Optimization

[InnoDB](#) maintains a storage area called the [buffer pool](#) for caching data and indexes in memory. Knowing how the [InnoDB](#) buffer pool works, and taking advantage of it to keep frequently accessed data in memory, is an important aspect of MySQL tuning.

For an explanation of the inner workings of the [InnoDB](#) buffer pool, an overview of its LRU replacement algorithm, and general configuration information, see [Section 15.6.3.1, “The InnoDB Buffer Pool”](#).

For additional [InnoDB](#) buffer pool configuration and tuning information, see these sections:

- [Section 15.6.3.5, “Configuring InnoDB Buffer Pool Prefetching \(Read-Ahead\)”](#)
- [Section 15.6.3.6, “Configuring InnoDB Buffer Pool Flushing”](#)
- [Section 15.6.3.4, “Making the Buffer Pool Scan Resistant”](#)
- [Section 15.6.3.3, “Configuring Multiple Buffer Pool Instances”](#)
- [Section 15.6.3.8, “Saving and Restoring the Buffer Pool State”](#)
- [Section 15.6.3.7, “Fine-tuning InnoDB Buffer Pool Flushing”](#)
- [Section 15.6.3.2, “Configuring InnoDB Buffer Pool Size”](#)

## 9.10.2 The MyISAM Key Cache

To minimize disk I/O, the [MyISAM](#) storage engine exploits a strategy that is used by many database management systems. It employs a cache mechanism to keep the most frequently accessed table blocks in memory:

- For index blocks, a special structure called the *key cache* (or *key buffer*) is maintained. The structure contains a number of block buffers where the most-used index blocks are placed.
- For data blocks, MySQL uses no special cache. Instead it relies on the native operating system file system cache.

This section first describes the basic operation of the [MyISAM](#) key cache. Then it discusses features that improve key cache performance and that enable you to better control cache operation:

- Multiple sessions can access the cache concurrently.
- You can set up multiple key caches and assign table indexes to specific caches.

To control the size of the key cache, use the [key\\_buffer\\_size](#) system variable. If this variable is set equal to zero, no key cache is used. The key cache also is not used if the [key\\_buffer\\_size](#) value is too small to allocate the minimal number of block buffers (8).

When the key cache is not operational, index files are accessed using only the native file system buffering provided by the operating system. (In other words, table index blocks are accessed using the same strategy as that employed for table data blocks.)

An index block is a contiguous unit of access to the [MyISAM](#) index files. Usually the size of an index block is equal to the size of nodes of the index B-tree. (Indexes are represented on disk using a B-tree data structure. Nodes at the bottom of the tree are leaf nodes. Nodes above the leaf nodes are nonleaf nodes.)

All block buffers in a key cache structure are the same size. This size can be equal to, greater than, or less than the size of a table index block. Usually one of these two values is a multiple of the other.

When data from any table index block must be accessed, the server first checks whether it is available in some block buffer of the key cache. If it is, the server accesses data in the key cache rather than on disk. That is, it reads from the cache or writes into it rather than reading from or writing to disk.

Otherwise, the server chooses a cache block buffer containing a different table index block (or blocks) and replaces the data there by a copy of required table index block. As soon as the new index block is in the cache, the index data can be accessed.

If it happens that a block selected for replacement has been modified, the block is considered “dirty.” In this case, prior to being replaced, its contents are flushed to the table index from which it came.

Usually the server follows an *LRU (Least Recently Used)* strategy: When choosing a block for replacement, it selects the least recently used index block. To make this choice easier, the key cache module maintains all used blocks in a special list (*LRU chain*) ordered by time of use. When a block is accessed, it is the most recently used and is placed at the end of the list. When blocks need to be replaced, blocks at the beginning of the list are the least recently used and become the first candidates for eviction.

The [InnoDB](#) storage engine also uses an LRU algorithm, to manage its buffer pool. See [Section 15.6.3.1, “The InnoDB Buffer Pool”](#).

### 9.10.2.1 Shared Key Cache Access

Threads can access key cache buffers simultaneously, subject to the following conditions:

- A buffer that is not being updated can be accessed by multiple sessions.
- A buffer that is being updated causes sessions that need to use it to wait until the update is complete.
- Multiple sessions can initiate requests that result in cache block replacements, as long as they do not interfere with each other (that is, as long as they need different index blocks, and thus cause different cache blocks to be replaced).

Shared access to the key cache enables the server to improve throughput significantly.

### 9.10.2.2 Multiple Key Caches

Shared access to the key cache improves performance but does not eliminate contention among sessions entirely. They still compete for control structures that manage access to the key cache buffers. To reduce key cache access contention further, MySQL also provides multiple key caches. This feature enables you to assign different table indexes to different key caches.

Where there are multiple key caches, the server must know which cache to use when processing queries for a given [MyISAM](#) table. By default, all [MyISAM](#) table indexes are cached in the default key cache. To assign table indexes to a specific key cache, use the [CACHE INDEX](#) statement (see [Section 14.7.6.2, “CACHE INDEX Syntax”](#)). For example, the following statement assigns indexes from the tables `t1`, `t2`, and `t3` to the key cache named `hot_cache`:

```
mysql> CACHE INDEX t1, t2, t3 IN hot_cache;
```

| Table   | Op                 | Msg_type | Msg_text |
|---------|--------------------|----------|----------|
| test.t1 | assign_to_keycache | status   | OK       |
| test.t2 | assign_to_keycache | status   | OK       |
| test.t3 | assign_to_keycache | status   | OK       |

The key cache referred to in a [CACHE INDEX](#) statement can be created by setting its size with a [SET GLOBAL](#) parameter setting statement or by using server startup options. For example:

```
mysql> SET GLOBAL keycache1.key_buffer_size=128*1024;
```

To destroy a key cache, set its size to zero:

```
mysql> SET GLOBAL keycache1.key_buffer_size=0;
```

You cannot destroy the default key cache. Any attempt to do this is ignored:

```
mysql> SET GLOBAL key_buffer_size = 0;

mysql> SHOW VARIABLES LIKE 'key_buffer_size';
+-----+-----+
| Variable_name | Value |
+-----+-----+
| key_buffer_size | 8384512 |
+-----+-----+
```

Key cache variables are structured system variables that have a name and components. For `keycachel.key_buffer_size`, `keycachel` is the cache variable name and `key_buffer_size` is the cache component. See [Section 6.1.6.1, “Structured System Variables”](#), for a description of the syntax used for referring to structured key cache system variables.

By default, table indexes are assigned to the main (default) key cache created at the server startup. When a key cache is destroyed, all indexes assigned to it are reassigned to the default key cache.

For a busy server, you can use a strategy that involves three key caches:

- A “hot” key cache that takes up 20% of the space allocated for all key caches. Use this for tables that are heavily used for searches but that are not updated.
- A “cold” key cache that takes up 20% of the space allocated for all key caches. Use this cache for medium-sized, intensively modified tables, such as temporary tables.
- A “warm” key cache that takes up 60% of the key cache space. Employ this as the default key cache, to be used by default for all other tables.

One reason the use of three key caches is beneficial is that access to one key cache structure does not block access to the others. Statements that access tables assigned to one cache do not compete with statements that access tables assigned to another cache. Performance gains occur for other reasons as well:

- The hot cache is used only for retrieval queries, so its contents are never modified. Consequently, whenever an index block needs to be pulled in from disk, the contents of the cache block chosen for replacement need not be flushed first.
- For an index assigned to the hot cache, if there are no queries requiring an index scan, there is a high probability that the index blocks corresponding to nonleaf nodes of the index B-tree remain in the cache.
- An update operation most frequently executed for temporary tables is performed much faster when the updated node is in the cache and need not be read in from disk first. If the size of the indexes of the temporary tables are comparable with the size of cold key cache, the probability is very high that the updated node is in the cache.

The `CACHE INDEX` statement sets up an association between a table and a key cache, but the association is lost each time the server restarts. If you want the association to take effect each time the server starts, one way to accomplish this is to use an option file: Include variable settings that configure your key caches, and an `init-file` option that names a file containing `CACHE INDEX` statements to be executed. For example:

```
key_buffer_size = 4G
hot_cache.key_buffer_size = 2G
cold_cache.key_buffer_size = 2G
init_file=/path/to/data-directory/mysqld_init.sql
```

The statements in `mysqld_init.sql` are executed each time the server starts. The file should contain one SQL statement per line. The following example assigns several tables each to `hot_cache` and `cold_cache`:

```
CACHE INDEX db1.t1, db1.t2, db2.t3 IN hot_cache
CACHE INDEX db1.t4, db2.t5, db2.t6 IN cold_cache
```

### 9.10.2.3 Midpoint Insertion Strategy

By default, the key cache management system uses a simple LRU strategy for choosing key cache blocks to be evicted, but it also supports a more sophisticated method called the *midpoint insertion strategy*.

When using the midpoint insertion strategy, the LRU chain is divided into two parts: a hot sublist and a warm sublist. The division point between two parts is not fixed, but the key cache management system takes care that the warm part is not “too short,” always containing at least `key_cache_division_limit` percent of the key cache blocks. `key_cache_division_limit` is a component of structured key cache variables, so its value is a parameter that can be set per cache.

When an index block is read from a table into the key cache, it is placed at the end of the warm sublist. After a certain number of hits (accesses of the block), it is promoted to the hot sublist. At present, the number of hits required to promote a block (3) is the same for all index blocks.

A block promoted into the hot sublist is placed at the end of the list. The block then circulates within this sublist. If the block stays at the beginning of the sublist for a long enough time, it is demoted to the warm sublist. This time is determined by the value of the `key_cache_age_threshold` component of the key cache.

The threshold value prescribes that, for a key cache containing  $N$  blocks, the block at the beginning of the hot sublist not accessed within the last  $N * \text{key\_cache\_age\_threshold} / 100$  hits is to be moved to the beginning of the warm sublist. It then becomes the first candidate for eviction, because blocks for replacement always are taken from the beginning of the warm sublist.

The midpoint insertion strategy enables you to keep more-valued blocks always in the cache. If you prefer to use the plain LRU strategy, leave the `key_cache_division_limit` value set to its default of 100.

The midpoint insertion strategy helps to improve performance when execution of a query that requires an index scan effectively pushes out of the cache all the index blocks corresponding to valuable high-level B-tree nodes. To avoid this, you must use a midpoint insertion strategy with the `key_cache_division_limit` set to much less than 100. Then valuable frequently hit nodes are preserved in the hot sublist during an index scan operation as well.

### 9.10.2.4 Index Preloading

If there are enough blocks in a key cache to hold blocks of an entire index, or at least the blocks corresponding to its nonleaf nodes, it makes sense to preload the key cache with index blocks before starting to use it. Preloading enables you to put the table index blocks into a key cache buffer in the most efficient way: by reading the index blocks from disk sequentially.

Without preloading, the blocks are still placed into the key cache as needed by queries. Although the blocks will stay in the cache, because there are enough buffers for all of them, they are fetched from disk in random order, and not sequentially.

To preload an index into a cache, use the `LOAD INDEX INTO CACHE` statement. For example, the following statement preloads nodes (index blocks) of indexes of the tables `t1` and `t2`:

```
mysql> LOAD INDEX INTO CACHE t1, t2 IGNORE LEAVES;
+-----+-----+-----+-----+
| Table | Op          | Msg_type | Msg_text |
+-----+-----+-----+-----+
| test.t1 | preload_keys | status   | OK       |
| test.t2 | preload_keys | status   | OK       |
+-----+-----+-----+-----+
```

The `IGNORE LEAVES` modifier causes only blocks for the nonleaf nodes of the index to be preloaded. Thus, the statement shown preloads all index blocks from `t1`, but only blocks for the nonleaf nodes from `t2`.

If an index has been assigned to a key cache using a `CACHE INDEX` statement, preloading places index blocks into that cache. Otherwise, the index is loaded into the default key cache.

### 9.10.2.5 Key Cache Block Size

It is possible to specify the size of the block buffers for an individual key cache using the `key_cache_block_size` variable. This permits tuning of the performance of I/O operations for index files.

The best performance for I/O operations is achieved when the size of read buffers is equal to the size of the native operating system I/O buffers. But setting the size of key nodes equal to the size of the I/O buffer does not always ensure the best overall performance. When reading the big leaf nodes, the server pulls in a lot of unnecessary data, effectively preventing reading other leaf nodes.

To control the size of blocks in the `.MYI` index file of `MyISAM` tables, use the `--myisam-block-size` option at server startup.

### 9.10.2.6 Restructuring a Key Cache

A key cache can be restructured at any time by updating its parameter values. For example:

```
mysql> SET GLOBAL cold_cache.key_buffer_size=4*1024*1024;
```

If you assign to either the `key_buffer_size` or `key_cache_block_size` key cache component a value that differs from the component's current value, the server destroys the cache's old structure and creates a new one based on the new values. If the cache contains any dirty blocks, the server saves them to disk before destroying and re-creating the cache. Restructuring does not occur if you change other key cache parameters.

When restructuring a key cache, the server first flushes the contents of any dirty buffers to disk. After that, the cache contents become unavailable. However, restructuring does not block queries that need to use indexes assigned to the cache. Instead, the server directly accesses the table indexes using native file system caching. File system caching is not as efficient as using a key cache, so although queries execute, a slowdown can be anticipated. After the cache has been restructured, it becomes available again for caching indexes assigned to it, and the use of file system caching for the indexes ceases.

## 9.10.3 The MySQL Query Cache

The query cache stores the text of a `SELECT` statement together with the corresponding result that was sent to the client. If an identical statement is received later, the server retrieves the results from the query cache rather than parsing and executing the statement again. The query cache is shared among sessions, so a result set generated by one client can be sent in response to the same query issued by another client.

The query cache can be useful in an environment where you have tables that do not change very often and for which the server receives many identical queries. This is a typical situation for many Web servers that generate many dynamic pages based on database content.

The query cache does not return stale data. When tables are modified, any relevant entries in the query cache are flushed.

#### Note

The query cache does not work in an environment where you have multiple `mysqld` servers updating the same `MyISAM` tables.

The query cache is used for prepared statements under the conditions described in [Section 9.10.3.1, “How the Query Cache Operates”](#).

**Note**

The query cache is not supported for partitioned tables, and is automatically disabled for queries involving partitioned tables. The query cache cannot be enabled for such queries.

Some performance data for the query cache follows. These results were generated by running the MySQL benchmark suite on a Linux Alpha 2×500MHz system with 2GB RAM and a 64MB query cache.

- If all the queries you are performing are simple (such as selecting a row from a table with one row), but still differ so that the queries cannot be cached, the overhead for having the query cache active is 13%. This could be regarded as the worst case scenario. In real life, queries tend to be much more complicated, so the overhead normally is significantly lower.
- Searches for a single row in a single-row table are 238% faster with the query cache than without it. This can be regarded as close to the minimum speedup to be expected for a query that is cached.

To disable the query cache at server startup, set the `query_cache_size` system variable to 0. By disabling the query cache code, there is no noticeable overhead.

The query cache offers the potential for substantial performance improvement, but do not assume that it will do so under all circumstances. With some query cache configurations or server workloads, you might actually see a performance decrease:

- Be cautious about sizing the query cache excessively large, which increases the overhead required to maintain the cache, possibly beyond the benefit of enabling it. Sizes in tens of megabytes are usually beneficial. Sizes in the hundreds of megabytes might not be.
- Server workload has a significant effect on query cache efficiency. A query mix consisting almost entirely of a fixed set of `SELECT` statements is much more likely to benefit from enabling the cache than a mix in which frequent `INSERT` statements cause continual invalidation of results in the cache. In some cases, a workaround is to use the `SQL_NO_CACHE` option to prevent results from even entering the cache for `SELECT` statements that use frequently modified tables. (See [Section 9.10.3.2, “Query Cache SELECT Options”](#).)

To verify that enabling the query cache is beneficial, test the operation of your MySQL server with the cache enabled and disabled. Then retest periodically because query cache efficiency may change as server workload changes.

### 9.10.3.1 How the Query Cache Operates

This section describes how the query cache works when it is operational. [Section 9.10.3.3, “Query Cache Configuration”](#), describes how to control whether it is operational.

Incoming queries are compared to those in the query cache before parsing, so the following two queries are regarded as different by the query cache:

```
SELECT * FROM tbl_name
Select * from tbl_name
```

Queries must be *exactly* the same (byte for byte) to be seen as identical. In addition, query strings that are identical may be treated as different for other reasons. Queries that use different databases, different protocol versions, or different default character sets are considered different queries and are cached separately.

The cache is not used for queries of the following types:

- Queries that are a subquery of an outer query

- Queries executed within the body of a stored function, trigger, or event

Before a query result is fetched from the query cache, MySQL checks whether the user has `SELECT` privilege for all databases and tables involved. If this is not the case, the cached result is not used.

If a query result is returned from query cache, the server increments the `Qcache_hits` status variable, not `Com_select`. See [Section 9.10.3.4, “Query Cache Status and Maintenance”](#).

If a table changes, all cached queries that use the table become invalid and are removed from the cache. This includes queries that use `MERGE` tables that map to the changed table. A table can be changed by many types of statements, such as `INSERT`, `UPDATE`, `DELETE`, `TRUNCATE TABLE`, `ALTER TABLE`, `DROP TABLE`, or `DROP DATABASE`.

The query cache also works within transactions when using `InnoDB` tables.

The result from a `SELECT` query on a view is cached.

The query cache works for `SELECT SQL_CALC_FOUND_ROWS . . .` queries and stores a value that is returned by a following `SELECT FOUND_ROWS()` query. `FOUND_ROWS()` returns the correct value even if the preceding query was fetched from the cache because the number of found rows is also stored in the cache. The `SELECT FOUND_ROWS()` query itself cannot be cached.

Prepared statements that are issued using the binary protocol using `mysql_stmt_prepare()` and `mysql_stmt_execute()` (see [Section 26.8.8, “C API Prepared Statements”](#)), are subject to limitations on caching. Comparison with statements in the query cache is based on the text of the statement after expansion of `?` parameter markers. The statement is compared only with other cached statements that were executed using the binary protocol. That is, for query cache purposes, prepared statements issued using the binary protocol are distinct from prepared statements issued using the text protocol (see [Section 14.5, “Prepared SQL Statement Syntax”](#)).

A query cannot be cached if it contains any of the functions shown in the following table.

|   |  |                                  |
|---|--|----------------------------------|
| <code>AES_DECRYPT()</code> (as of 5.7.4)  | <code>AES_ENCRYPT()</code> (as of 5.7.4)         | <code>BENCHMARK()</code>         |
| <code>CONNECTION_ID()</code>              | <code>CONVERT_TZ()</code>                        | <code>CURDATE()</code>           |
| <code>CURRENT_DATE()</code>               | <code>CURRENT_TIME()</code>                      | <code>CURRENT_TIMESTAMP()</code> |
| <code>CURRENT_USER()</code>               | <code>CURTIME()</code>                           | <code>DATABASE()</code>          |
| <code>ENCRYPT()</code> with one parameter | <code>FOUND_ROWS()</code>                        | <code>GET_LOCK()</code>          |
| <code>IS_FREE_LOCK()</code>               | <code>IS_USED_LOCK()</code>                      | <code>LAST_INSERT_ID()</code>    |
| <code>LOAD_FILE()</code>                  | <code>MASTER_POS_WAIT()</code>                   | <code>NOW()</code>               |
| <code>PASSWORD()</code>                   | <code>RAND()</code>                              | <code>RANDOM_BYTES()</code>      |
| <code>RELEASE_ALL_LOCKS()</code>          | <code>RELEASE_LOCK()</code>                      | <code>SLEEP()</code>             |
| <code>SYSDATE()</code>                    | <code>UNIX_TIMESTAMP()</code> with no parameters | <code>USER()</code>              |
| <code>UUID()</code>                       | <code>UUID_SHORT()</code>                        |                                  |

A query also is not cached under these conditions:

- It refers to user-defined functions (UDFs) or stored functions.
- It refers to user variables or local stored program variables.
- It refers to tables in the `mysql`, `INFORMATION_SCHEMA`, or `performance_schema` database.
- It refers to any partitioned tables.
- It is of any of the following forms:

```
SELECT ... LOCK IN SHARE MODE
SELECT ... FOR UPDATE
SELECT ... INTO OUTFILE ...
SELECT ... INTO DUMPFILE ...
SELECT * FROM ... WHERE autoincrement_col IS NULL
```

The last form is not cached because it is used as the ODBC workaround for obtaining the last insert ID value. See the Connector/ODBC section of [Chapter 26, Connectors and APIs](#).

Statements within transactions that use [SERIALIZABLE](#) isolation level also cannot be cached because they use [LOCK IN SHARE MODE](#) locking.

- It uses [TEMPORARY](#) tables.
- It does not use any tables.
- It generates warnings.
- The user has a column-level privilege for any of the involved tables.

### 9.10.3.2 Query Cache SELECT Options

Two query cache-related options may be specified in [SELECT](#) statements:

- [SQL\\_CACHE](#)

The query result is cached if it is cacheable and the value of the [query\\_cache\\_type](#) system variable is [ON](#) or [DEMAND](#).

- [SQL\\_NO\\_CACHE](#)

The server does not use the query cache. It neither checks the query cache to see whether the result is already cached, nor does it cache the query result.

Examples:

```
SELECT SQL_CACHE id, name FROM customer;
SELECT SQL_NO_CACHE id, name FROM customer;
```

### 9.10.3.3 Query Cache Configuration

The [have\\_query\\_cache](#) server system variable indicates whether the query cache is available:

```
mysql> SHOW VARIABLES LIKE 'have_query_cache';
+-----+-----+
| Variable_name | Value |
+-----+-----+
| have_query_cache | YES   |
+-----+-----+
```

When using a standard MySQL binary, this value is always [YES](#), even if query caching is disabled.

Several other system variables control query cache operation. These can be set in an option file or on the command line when starting [mysqld](#). The query cache system variables all have names that begin with [query\\_cache\\_](#). They are described briefly in [Section 6.1.5, “Server System Variables”](#), with additional configuration information given here.

To set the size of the query cache, set the [query\\_cache\\_size](#) system variable. Setting it to 0 disables the query cache, as does setting [query\\_cache\\_type=0](#). By default, the query cache is disabled. This is achieved using a default size of 1M, with a default for [query\\_cache\\_type](#) of 0.

To reduce overhead significantly, also start the server with [query\\_cache\\_type=0](#) if you will not be using the query cache.

**Note**

When using the Windows Configuration Wizard to install or configure MySQL, the default value for `query_cache_size` will be configured automatically for you based on the different configuration types available. When using the Windows Configuration Wizard, the query cache may be enabled (that is, set to a nonzero value) due to the selected configuration. The query cache is also controlled by the setting of the `query_cache_type` variable. Check the values of these variables as set in your `my.ini` file after configuration has taken place.

When you set `query_cache_size` to a nonzero value, keep in mind that the query cache needs a minimum size of about 40KB to allocate its structures. (The exact size depends on system architecture.) If you set the value too small, you'll get a warning, as in this example:

```
mysql> SET GLOBAL query_cache_size = 40000;
Query OK, 0 rows affected, 1 warning (0.00 sec)

mysql> SHOW WARNINGS\G
***** 1. row *****
      Level: Warning
      Code: 1282
Message: Query cache failed to set size 39936;
         new query cache size is 0

mysql> SET GLOBAL query_cache_size = 41984;
Query OK, 0 rows affected (0.00 sec)

mysql> SHOW VARIABLES LIKE 'query_cache_size';
+-----+-----+
| Variable_name | Value |
+-----+-----+
| query_cache_size | 41984 |
+-----+-----+
```

For the query cache to actually be able to hold any query results, its size must be set larger:

```
mysql> SET GLOBAL query_cache_size = 1000000;
Query OK, 0 rows affected (0.04 sec)

mysql> SHOW VARIABLES LIKE 'query_cache_size';
+-----+-----+
| Variable_name | Value |
+-----+-----+
| query_cache_size | 999424 |
+-----+-----+
1 row in set (0.00 sec)
```

The `query_cache_size` value is aligned to the nearest 1024 byte block. The value reported may therefore be different from the value that you assign.

If the query cache size is greater than 0, the `query_cache_type` variable influences how it works. This variable can be set to the following values:

- A value of `0` or `OFF` prevents caching or retrieval of cached results.
- A value of `1` or `ON` enables caching except of those statements that begin with `SELECT SQL_NO_CACHE`.
- A value of `2` or `DEMAND` causes caching of only those statements that begin with `SELECT SQL_CACHE`.

If `query_cache_size` is 0, you should also set `query_cache_type` variable to 0. In this case, the server does not acquire the query cache mutex at all, which means that the query cache cannot be enabled at runtime and there is reduced overhead in query execution.

Setting the `GLOBAL query_cache_type` value determines query cache behavior for all clients that connect after the change is made. Individual clients can control cache behavior for their own connection by setting the `SESSION query_cache_type` value. For example, a client can disable use of the query cache for its own queries like this:

```
mysql> SET SESSION query_cache_type = OFF;
```

If you set `query_cache_type` at server startup (rather than at runtime with a `SET` statement), only the numeric values are permitted.

To control the maximum size of individual query results that can be cached, set the `query_cache_limit` system variable. The default value is 1MB.

Be careful not to set the size of the cache too large. Due to the need for threads to lock the cache during updates, you may see lock contention issues with a very large cache.

#### Note

You can set the maximum size that can be specified for the query cache at runtime with the `SET` statement by using the `--maximum-query_cache_size=32M` option on the command line or in the configuration file.

When a query is to be cached, its result (the data sent to the client) is stored in the query cache during result retrieval. Therefore the data usually is not handled in one big chunk. The query cache allocates blocks for storing this data on demand, so when one block is filled, a new block is allocated. Because memory allocation operation is costly (timewise), the query cache allocates blocks with a minimum size given by the `query_cache_min_res_unit` system variable. When a query is executed, the last result block is trimmed to the actual data size so that unused memory is freed. Depending on the types of queries your server executes, you might find it helpful to tune the value of `query_cache_min_res_unit`:

- The default value of `query_cache_min_res_unit` is 4KB. This should be adequate for most cases.
- If you have a lot of queries with small results, the default block size may lead to memory fragmentation, as indicated by a large number of free blocks. Fragmentation can force the query cache to prune (delete) queries from the cache due to lack of memory. In this case, decrease the value of `query_cache_min_res_unit`. The number of free blocks and queries removed due to pruning are given by the values of the `Qcache_free_blocks` and `Qcache_lowmem_prunes` status variables.
- If most of your queries have large results (check the `Qcache_total_blocks` and `Qcache_queries_in_cache` status variables), you can increase performance by increasing `query_cache_min_res_unit`. However, be careful to not make it too large (see the previous item).

### 9.10.3.4 Query Cache Status and Maintenance

To check whether the query cache is present in your MySQL server, use the following statement:

```
mysql> SHOW VARIABLES LIKE 'have_query_cache';
+-----+-----+
| Variable_name | Value |
+-----+-----+
| have_query_cache | YES  |
+-----+-----+
```

You can defragment the query cache to better utilize its memory with the `FLUSH QUERY CACHE` statement. The statement does not remove any queries from the cache.

The `RESET QUERY CACHE` statement removes all query results from the query cache. The `FLUSH TABLES` statement also does this.

To monitor query cache performance, use `SHOW STATUS` to view the cache status variables:

```
mysql> SHOW STATUS LIKE 'Qcache%';
```

| Variable_name           | Value  |
|-------------------------|--------|
| Qcache_free_blocks      | 36     |
| Qcache_free_memory      | 138488 |
| Qcache_hits             | 79570  |
| Qcache_inserts          | 27087  |
| Qcache_lowmem_prunes    | 3114   |
| Qcache_not_cached       | 22989  |
| Qcache_queries_in_cache | 415    |
| Qcache_total_blocks     | 912    |

Descriptions of each of these variables are given in [Section 6.1.7, “Server Status Variables”](#). Some uses for them are described here.

The total number of `SELECT` queries is given by this formula:

```
Com_select
+ Qcache_hits
+ queries with errors found by parser
```

The `Com_select` value is given by this formula:

```
Qcache_inserts
+ Qcache_not_cached
+ queries with errors found during the column-privileges check
```

The query cache uses variable-length blocks, so `Qcache_total_blocks` and `Qcache_free_blocks` may indicate query cache memory fragmentation. After `FLUSH QUERY CACHE`, only a single free block remains.

Every cached query requires a minimum of two blocks (one for the query text and one or more for the query results). Also, every table that is used by a query requires one block. However, if two or more queries use the same table, only one table block needs to be allocated.

The information provided by the `Qcache_lowmem_prunes` status variable can help you tune the query cache size. It counts the number of queries that have been removed from the cache to free up memory for caching new queries. The query cache uses a least recently used (LRU) strategy to decide which queries to remove from the cache. Tuning information is given in [Section 9.10.3.3, “Query Cache Configuration”](#).

## 9.10.4 Caching of Prepared Statements and Stored Programs

For certain statements that a client might execute multiple times during a session, the server converts the statement to an internal structure and caches that structure to be used during execution. Caching enables the server to perform more efficiently because it avoids the overhead of reconverting the statement should it be needed again during the session. Conversion and caching occurs for these statements:

- Prepared statements, both those processed at the SQL level (using the `PREPARE` statement) and those processed using the binary client/server protocol (using the `mysql_stmt_prepare()` C API function). The `max_prepared_stmt_count` system variable controls the total number of statements the server caches. (The sum of the number of prepared statements across all sessions.)

- Stored programs (stored procedures and functions, triggers, and events). In this case, the server converts and caches the entire program body. The `stored_program_cache` system variable indicates the approximate number of stored programs the server caches per session.

The server maintains caches for prepared statements and stored programs on a per-session basis. Statements cached for one session are not accessible to other sessions. When a session ends, the server discards any statements cached for it.

When the server uses a cached internal statement structure, it must take care that the structure does not go out of date. Metadata changes can occur for an object used by the statement, causing a mismatch between the current object definition and the definition as represented in the internal statement structure. Metadata changes occur for DDL statements such as those that create, drop, alter, rename, or truncate tables, or that analyze, optimize, or repair tables. Table content changes (for example, with `INSERT` or `UPDATE`) do not change metadata, nor do `SELECT` statements.

Here is an illustration of the problem. Suppose that a client prepares this statement:

```
PREPARE s1 FROM 'SELECT * FROM t1';
```

The `SELECT *` expands in the internal structure to the list of columns in the table. If the set of columns in the table is modified with `ALTER TABLE`, the prepared statement goes out of date. If the server does not detect this change the next time the client executes `s1`, the prepared statement will return incorrect results.

To avoid problems caused by metadata changes to tables or views referred to by the prepared statement, the server detects these changes and automatically reprepares the statement when it is next executed. That is, the server reparses the statement and rebuilds the internal structure. Reparsing also occurs after referenced tables or views are flushed from the table definition cache, either implicitly to make room for new entries in the cache, or explicitly due to `FLUSH TABLES`.

Similarly, if changes occur to objects used by a stored program, the server reparses affected statements within the program.

The server also detects metadata changes for objects in expressions. These might be used in statements specific to stored programs, such as `DECLARE CURSOR` or flow-control statements such as `IF`, `CASE`, and `RETURN`.

To avoid reparsing entire stored programs, the server reparses affected statements or expressions within a program only as needed. Examples:

- Suppose that metadata for a table or view is changed. Reparsing occurs for a `SELECT *` within the program that accesses the table or view, but not for a `SELECT *` that does not access the table or view.
- When a statement is affected, the server reparses it only partially if possible. Consider this `CASE` statement:

```
CASE case_expr
  WHEN when_expr1 ...
  WHEN when_expr2 ...
  WHEN when_expr3 ...
  ...
END CASE
```

If a metadata change affects only `WHEN when_expr3`, that expression is reparsed. `case_expr` and the other `WHEN` expressions are not reparsed.

Reparsing uses the default database and SQL mode that were in effect for the original conversion to internal form.

The server attempts reparsing up to three times. An error occurs if all attempts fail.

Reparsing is automatic, but to the extent that it occurs, diminishes prepared statement and stored program performance.

For prepared statements, the `Com_stmt_reprepare` status variable tracks the number of re Preparations.

## 9.11 Optimizing Locking Operations

MySQL manages contention for table contents using [locking](#):

- Internal locking is performed within the MySQL server itself to manage contention for table contents by multiple threads. This type of locking is internal because it is performed entirely by the server and involves no other programs. See [Section 9.11.1, “Internal Locking Methods”](#).
- External locking occurs when the server and other programs lock [MyISAM](#) table files to coordinate among themselves which program can access the tables at which time. See [Section 9.11.5, “External Locking”](#).

### 9.11.1 Internal Locking Methods

This section discusses internal locking; that is, locking performed within the MySQL server itself to manage contention for table contents by multiple sessions. This type of locking is internal because it is performed entirely by the server and involves no other programs. For locking performed on MySQL files by other programs, see [Section 9.11.5, “External Locking”](#).

#### Row-Level Locking

MySQL uses [row-level locking](#) for [InnoDB](#) tables to support simultaneous write access by multiple sessions, making them suitable for multi-user, highly concurrent, and OLTP applications.

To avoid [deadlocks](#) when performing multiple concurrent write operations on a single [InnoDB](#) table, acquire necessary locks at the start of the transaction by issuing a `SELECT ... FOR UPDATE` statement for each group of rows expected to be modified, even if the data change statements come later in the transaction. If transactions modify or lock more than one table, issue the applicable statements in the same order within each transaction. Deadlocks affect performance rather than representing a serious error, because [InnoDB](#) automatically [detects](#) deadlock conditions and rolls back one of the affected transactions.

On high concurrency systems, deadlock detection can cause a slowdown when numerous threads wait for the same lock. At times, it may be more efficient to disable deadlock detection and rely on the `innodb_lock_wait_timeout` setting for transaction rollback when a deadlock occurs. Deadlock detection can be disabled using the `innodb_deadlock_detect` configuration option.

Advantages of row-level locking:

- Fewer lock conflicts when different sessions access different rows.
- Fewer changes for rollbacks.
- Possible to lock a single row for a long time.

#### Table-Level Locking

MySQL uses [table-level locking](#) for [MyISAM](#), [MEMORY](#), and [MERGE](#) tables, permitting only one session to update those tables at a time. This locking level makes these storage engines more suitable for read-only, read-mostly, or single-user applications.

These storage engines avoid [deadlocks](#) by always requesting all needed locks at once at the beginning of a query and always locking the tables in the same order. The tradeoff is that this strategy reduces concurrency; other sessions that want to modify the table must wait until the current data change statement finishes.

Advantages of table-level locking:

- Relatively little memory required (row locking requires memory per row or group of rows locked)
- Fast when used on a large part of the table because only a single lock is involved.
- Fast if you often do `GROUP BY` operations on a large part of the data or must scan the entire table frequently.

MySQL grants table write locks as follows:

1. If there are no locks on the table, put a write lock on it.
2. Otherwise, put the lock request in the write lock queue.

MySQL grants table read locks as follows:

1. If there are no write locks on the table, put a read lock on it.
2. Otherwise, put the lock request in the read lock queue.

Table updates are given higher priority than table retrievals. Therefore, when a lock is released, the lock is made available to the requests in the write lock queue and then to the requests in the read lock queue. This ensures that updates to a table are not “starved” even when there is heavy `SELECT` activity for the table. However, if there are many updates for a table, `SELECT` statements wait until there are no more updates.

For information on altering the priority of reads and writes, see [Section 9.11.2, “Table Locking Issues”](#).

You can analyze the table lock contention on your system by checking the `Table_locks_immediate` and `Table_locks_waited` status variables, which indicate the number of times that requests for table locks could be granted immediately and the number that had to wait, respectively:

```
mysql> SHOW STATUS LIKE 'Table%';
+-----+-----+
| Variable_name | Value |
+-----+-----+
| Table_locks_immediate | 1151552 |
| Table_locks_waited   | 15324  |
+-----+-----+
```

The Performance Schema lock tables also provide locking information. See [Section 24.10.12, “Performance Schema Lock Tables”](#).

The `MyISAM` storage engine supports concurrent inserts to reduce contention between readers and writers for a given table: If a `MyISAM` table has no free blocks in the middle of the data file, rows are always inserted at the end of the data file. In this case, you can freely mix concurrent `INSERT` and `SELECT` statements for a `MyISAM` table without locks. That is, you can insert rows into a `MyISAM` table at the same time other clients are reading from it. Holes can result from rows having been deleted from or updated in the middle of the table. If there are holes, concurrent inserts are disabled but are enabled again automatically when all holes have been filled with new data. To control this behavior, use the `concurrent_insert` system variable. See [Section 9.11.3, “Concurrent Inserts”](#).

If you acquire a table lock explicitly with `LOCK TABLES`, you can request a `READ LOCAL` lock rather than a `READ` lock to enable other sessions to perform concurrent inserts while you have the table locked.

To perform many `INSERT` and `SELECT` operations on a table `t1` when concurrent inserts are not possible, you can insert rows into a temporary table `temp_t1` and update the real table with the rows from the temporary table:

```
mysql> LOCK TABLES t1 WRITE, temp_t1 WRITE;
mysql> INSERT INTO t1 SELECT * FROM temp_t1;
mysql> DELETE FROM temp_t1;
mysql> UNLOCK TABLES;
```

## Choosing the Type of Locking

Generally, table locks are superior to row-level locks in the following cases:

- Most statements for the table are reads.
- Statements for the table are a mix of reads and writes, where writes are updates or deletes for a single row that can be fetched with one key read:

```
UPDATE tbl_name SET column=value WHERE unique_key_col=key_value;  
DELETE FROM tbl_name WHERE unique_key_col=key_value;
```

- **SELECT** combined with concurrent **INSERT** statements, and very few **UPDATE** or **DELETE** statements.
- Many scans or **GROUP BY** operations on the entire table without any writers.

With higher-level locks, you can more easily tune applications by supporting locks of different types, because the lock overhead is less than for row-level locks.

Options other than row-level locking:

- Versioning (such as that used in MySQL for concurrent inserts) where it is possible to have one writer at the same time as many readers. This means that the database or table supports different views for the data depending on when access begins. Other common terms for this are “time travel,” “copy on write,” or “copy on demand.”
- Copy on demand is in many cases superior to row-level locking. However, in the worst case, it can use much more memory than using normal locks.
- Instead of using row-level locks, you can employ application-level locks, such as those provided by **GET\_LOCK()** and **RELEASE\_LOCK()** in MySQL. These are advisory locks, so they work only with applications that cooperate with each other. See [Section 13.20, “Miscellaneous Functions”](#).

### 9.11.2 Table Locking Issues

**InnoDB** tables use row-level locking so that multiple sessions and applications can read from and write to the same table simultaneously, without making each other wait or producing inconsistent results. For this storage engine, avoid using the **LOCK TABLES** statement, because it does not offer any extra protection, but instead reduces concurrency. The automatic row-level locking makes these tables suitable for your busiest databases with your most important data, while also simplifying application logic since you do not need to lock and unlock tables. Consequently, the **InnoDB** storage engine is the default in MySQL.

MySQL uses table locking (instead of page, row, or column locking) for all storage engines except **InnoDB**. The locking operations themselves do not have much overhead. But because only one session can write to a table at any one time, for best performance with these other storage engines, use them primarily for tables that are queried often and rarely inserted into or updated.

## Performance Considerations Favoring InnoDB

When choosing whether to create a table using **InnoDB** or a different storage engine, keep in mind the following disadvantages of table locking:

- Table locking enables many sessions to read from a table at the same time, but if a session wants to write to a table, it must first get exclusive access, meaning it might have to wait for other sessions to finish with the table first. During the update, all other sessions that want to access this particular table must wait until the update is done.
- Table locking causes problems when a session is waiting because the disk is full and free space needs to become available before the session can proceed. In this case, all sessions that want to access the problem table are also put in a waiting state until more disk space is made available.

- A `SELECT` statement that takes a long time to run prevents other sessions from updating the table in the meantime, making the other sessions appear slow or unresponsive. While a session is waiting to get exclusive access to the table for updates, other sessions that issue `SELECT` statements will queue up behind it, reducing concurrency even for read-only sessions.

## Workarounds for Locking Performance Issues

The following items describe some ways to avoid or reduce contention caused by table locking:

- Consider switching the table to the `InnoDB` storage engine, either using `CREATE TABLE ... ENGINE=INNODB` during setup, or using `ALTER TABLE ... ENGINE=INNODB` for an existing table. See [Chapter 15, The InnoDB Storage Engine](#) for more details about this storage engine.
- Optimize `SELECT` statements to run faster so that they lock tables for a shorter time. You might have to create some summary tables to do this.
- Start `mysqld` with `--low-priority-updates`. For storage engines that use only table-level locking (such as `MyISAM`, `MEMORY`, and `MERGE`), this gives all statements that update (modify) a table lower priority than `SELECT` statements. In this case, the second `SELECT` statement in the preceding scenario would execute before the `UPDATE` statement, and would not wait for the first `SELECT` to finish.
- To specify that all updates issued in a specific connection should be done with low priority, set the `low_priority_updates` server system variable equal to 1.
- To give a specific `INSERT`, `UPDATE`, or `DELETE` statement lower priority, use the `LOW_PRIORITY` attribute.
- To give a specific `SELECT` statement higher priority, use the `HIGH_PRIORITY` attribute. See [Section 14.2.9, “SELECT Syntax”](#).
- Start `mysqld` with a low value for the `max_write_lock_count` system variable to force MySQL to temporarily elevate the priority of all `SELECT` statements that are waiting for a table after a specific number of inserts to the table occur. This permits `READ` locks after a certain number of `WRITE` locks.
- If you have problems with `INSERT` combined with `SELECT`, consider switching to `MyISAM` tables, which support concurrent `SELECT` and `INSERT` statements. (See [Section 9.11.3, “Concurrent Inserts”](#).)
- If you have problems with mixed `SELECT` and `DELETE` statements, the `LIMIT` option to `DELETE` may help. See [Section 14.2.2, “DELETE Syntax”](#).
- Using `SQL_BUFFER_RESULT` with `SELECT` statements can help to make the duration of table locks shorter. See [Section 14.2.9, “SELECT Syntax”](#).
- Splitting table contents into separate tables may help, by allowing queries to run against columns in one table, while updates are confined to columns in a different table.
- You could change the locking code in `mysys/thr_lock.c` to use a single queue. In this case, write locks and read locks would have the same priority, which might help some applications.

### 9.11.3 Concurrent Inserts

The `MyISAM` storage engine supports concurrent inserts to reduce contention between readers and writers for a given table: If a `MyISAM` table has no holes in the data file (deleted rows in the middle), an `INSERT` statement can be executed to add rows to the end of the table at the same time that `SELECT` statements are reading rows from the table. If there are multiple `INSERT` statements, they are queued and performed in sequence, concurrently with the `SELECT` statements. The results of a concurrent `INSERT` may not be visible immediately.

The `concurrent_insert` system variable can be set to modify the concurrent-insert processing. By default, the variable is set to `AUTO` (or 1) and concurrent inserts are handled as just described. If

`concurrent_insert` is set to `NEVER` (or 0), concurrent inserts are disabled. If the variable is set to `ALWAYS` (or 2), concurrent inserts at the end of the table are permitted even for tables that have deleted rows. See also the description of the `concurrent_insert` system variable.

If you are using the binary log, concurrent inserts are converted to normal inserts for `CREATE ... SELECT` or `INSERT ... SELECT` statements. This is done to ensure that you can re-create an exact copy of your tables by applying the log during a backup operation. See [Section 6.4.4, “The Binary Log”](#). In addition, for those statements a read lock is placed on the selected-from table such that inserts into that table are blocked. The effect is that concurrent inserts for that table must wait as well.

With `LOAD DATA INFILE`, if you specify `CONCURRENT` with a `MyISAM` table that satisfies the condition for concurrent inserts (that is, it contains no free blocks in the middle), other sessions can retrieve data from the table while `LOAD DATA` is executing. Use of the `CONCURRENT` option affects the performance of `LOAD DATA` a bit, even if no other session is using the table at the same time.

If you specify `HIGH_PRIORITY`, it overrides the effect of the `--low-priority-updates` option if the server was started with that option. It also causes concurrent inserts not to be used.

For `LOCK TABLE`, the difference between `READ LOCAL` and `READ` is that `READ LOCAL` permits nonconflicting `INSERT` statements (concurrent inserts) to execute while the lock is held. However, this cannot be used if you are going to manipulate the database using processes external to the server while you hold the lock.

## 9.11.4 Metadata Locking

MySQL uses metadata locking to manage concurrent access to database objects and to ensure data consistency. Metadata locking applies not just to tables, but also to schemas, stored programs (procedures, functions, triggers, and scheduled events), and (as of MySQL 5.7.6) tablespaces.

Metadata locking does involve some overhead, which increases as query volume increases. Metadata contention increases the more that multiple queries attempt to access the same objects.

Metadata locking is not a replacement for the table definition cache, and its mutexes and locks differ from the `LOCK_open` mutex. The following discussion provides some information about how metadata locking works.

To ensure transaction serializability, the server must not permit one session to perform a data definition language (DDL) statement on a table that is used in an uncompleted explicitly or implicitly started transaction in another session. The server achieves this by acquiring metadata locks on tables used within a transaction and deferring release of those locks until the transaction ends. A metadata lock on a table prevents changes to the table's structure. This locking approach has the implication that a table that is being used by a transaction within one session cannot be used in DDL statements by other sessions until the transaction ends.

This principle applies not only to transactional tables, but also to nontransactional tables. Suppose that a session begins a transaction that uses transactional table `t` and nontransactional table `nt` as follows:

```
START TRANSACTION;
SELECT * FROM t;
SELECT * FROM nt;
```

The server holds metadata locks on both `t` and `nt` until the transaction ends. If another session attempts a DDL or write lock operation on either table, it blocks until metadata lock release at transaction end. For example, a second session blocks if it attempts any of these operations:

```
DROP TABLE t;
ALTER TABLE t ...;
DROP TABLE nt;
ALTER TABLE nt ...;
LOCK TABLE t ... WRITE;
```

As of MySQL 5.7.5, the same behavior applies for The `LOCK TABLES ... READ`. That is, explicitly or implicitly started transactions that update any table (transactional or nontransactional) will block and be blocked by `LOCK TABLES ... READ` for that table.

If the server acquires metadata locks for a statement that is syntactically valid but fails during execution, it does not release the locks early. Lock release is still deferred to the end of the transaction because the failed statement is written to the binary log and the locks protect log consistency.

In autocommit mode, each statement is in effect a complete transaction, so metadata locks acquired for the statement are held only to the end of the statement.

Metadata locks acquired during a `PREPARE` statement are released once the statement has been prepared, even if preparation occurs within a multiple-statement transaction.

## 9.11.5 External Locking

External locking is the use of file system locking to manage contention for `MyISAM` database tables by multiple processes. External locking is used in situations where a single process such as the MySQL server cannot be assumed to be the only process that requires access to tables. Here are some examples:

- If you run multiple servers that use the same database directory (not recommended), each server must have external locking enabled.
- If you use `myisamchk` to perform table maintenance operations on `MyISAM` tables, you must either ensure that the server is not running, or that the server has external locking enabled so that it locks table files as necessary to coordinate with `myisamchk` for access to the tables. The same is true for use of `mysampack` to pack `MyISAM` tables.

If the server is run with external locking enabled, you can use `myisamchk` at any time for read operations such as checking tables. In this case, if the server tries to update a table that `myisamchk` is using, the server will wait for `myisamchk` to finish before it continues.

If you use `myisamchk` for write operations such as repairing or optimizing tables, or if you use `mysampack` to pack tables, you *must* always ensure that the `mysqld` server is not using the table. If you do not stop `mysqld`, at least do a `mysqladmin flush-tables` before you run `myisamchk`. Your tables *may become corrupted* if the server and `myisamchk` access the tables simultaneously.

With external locking in effect, each process that requires access to a table acquires a file system lock for the table files before proceeding to access the table. If all necessary locks cannot be acquired, the process is blocked from accessing the table until the locks can be obtained (after the process that currently holds the locks releases them).

External locking affects server performance because the server must sometimes wait for other processes before it can access tables.

External locking is unnecessary if you run a single server to access a given data directory (which is the usual case) and if no other programs such as `myisamchk` need to modify tables while the server is running. If you only *read* tables with other programs, external locking is not required, although `myisamchk` might report warnings if the server changes tables while `myisamchk` is reading them.

With external locking disabled, to use `myisamchk`, you must either stop the server while `myisamchk` executes or else lock and flush the tables before running `myisamchk`. (See [Section 9.12.1, “System Factors”](#).) To avoid this requirement, use the `CHECK TABLE` and `REPAIR TABLE` statements to check and repair `MyISAM` tables.

For `mysqld`, external locking is controlled by the value of the `skip_external_locking` system variable. When this variable is enabled, external locking is disabled, and vice versa. External locking is disabled by default.

Use of external locking can be controlled at server startup by using the `--external-locking` or `--skip-external-locking` option.

If you do use external locking option to enable updates to [MyISAM](#) tables from many MySQL processes, you must ensure that the following conditions are satisfied:

- Do not use the query cache for queries that use tables that are updated by another process.
- Do not start the server with the `--delay-key-write=ALL` option or use the `DELAY_KEY_WRITE=1` table option for any shared tables. Otherwise, index corruption can occur.

The easiest way to satisfy these conditions is to always use `--external-locking` together with `--delay-key-write=OFF` and `--query-cache-size=0`. (This is not done by default because in many setups it is useful to have a mixture of the preceding options.)

## 9.12 Optimizing the MySQL Server

This section discusses optimization techniques for the database server, primarily dealing with system configuration rather than tuning SQL statements. The information in this section is appropriate for DBAs who want to ensure performance and scalability across the servers they manage; for developers constructing installation scripts that include setting up the database; and people running MySQL themselves for development, testing, and so on who want to maximize their own productivity.

### 9.12.1 System Factors

Some system-level factors can affect performance in a major way:

- If you have enough RAM, you could remove all swap devices. Some operating systems use a swap device in some contexts even if you have free memory.
- Avoid external locking for [MyISAM](#) tables. The default is for external locking to be disabled. The `--external-locking` and `--skip-external-locking` options explicitly enable and disable external locking.

Disabling external locking does not affect MySQL's functionality as long as you run only one server. Just remember to take down the server (or lock and flush the relevant tables) before you run [myisamchk](#). On some systems it is mandatory to disable external locking because it does not work, anyway.

The only case in which you cannot disable external locking is when you run multiple MySQL *servers* (not clients) on the same data, or if you run [myisamchk](#) to check (not repair) a table without telling the server to flush and lock the tables first. Note that using multiple MySQL servers to access the same data concurrently is generally *not* recommended, except when using MySQL Cluster.

The [LOCK TABLES](#) and [UNLOCK TABLES](#) statements use internal locking, so you can use them even if external locking is disabled.

### 9.12.2 Optimizing Disk I/O

This section describes ways to configure storage devices when you can devote more and faster storage hardware to the database server. For information about optimizing an [InnoDB](#) configuration to improve I/O performance, see [Section 9.5.8, “Optimizing InnoDB Disk I/O”](#).

- Disk seeks are a huge performance bottleneck. This problem becomes more apparent when the amount of data starts to grow so large that effective caching becomes impossible. For large databases where you access data more or less randomly, you can be sure that you need at least one disk seek to read and a couple of disk seeks to write things. To minimize this problem, use disks with low seek times.
- Increase the number of available disk spindles (and thereby reduce the seek overhead) by either symlinking files to different disks or striping the disks:
  - Using symbolic links

This means that, for `MyISAM` tables, you symlink the index file and data files from their usual location in the data directory to another disk (that may also be striped). This makes both the seek and read times better, assuming that the disk is not used for other purposes as well. See [Section 9.12.3, “Using Symbolic Links”](#).

Symbolic links are not supported for use with `InnoDB` tables. However, you can create an `InnoDB file-per-table` tablespace in a location outside of the MySQL data directory using the `DATA DIRECTORY = absolute_path_to_directory` clause of the `CREATE TABLE` statement. For more information, see [Section 15.7.5, “Creating a File-Per-Table Tablespace Outside the Data Directory”](#). General tablespaces can also be created in a location outside of the MySQL data directory. For more information, see [Section 15.7.9, “InnoDB General Tablespaces”](#).

- **Striping**

Striping means that you have many disks and put the first block on the first disk, the second block on the second disk, and the  $N$ -th block on the  $(N \bmod \text{number\_of\_disks})$  disk, and so on. This means if your normal data size is less than the stripe size (or perfectly aligned), you get much better performance. Striping is very dependent on the operating system and the stripe size, so benchmark your application with different stripe sizes. See [Section 9.13.2, “Using Your Own Benchmarks”](#).

The speed difference for striping is very dependent on the parameters. Depending on how you set the striping parameters and number of disks, you may get differences measured in orders of magnitude. You have to choose to optimize for random or sequential access.

- For reliability, you may want to use RAID 0+1 (striping plus mirroring), but in this case, you need  $2 \times N$  drives to hold  $N$  drives of data. This is probably the best option if you have the money for it. However, you may also have to invest in some volume-management software to handle it efficiently.
- A good option is to vary the RAID level according to how critical a type of data is. For example, store semi-important data that can be regenerated on a RAID 0 disk, but store really important data such as host information and logs on a RAID 0+1 or RAID  $N$  disk. RAID  $N$  can be a problem if you have many writes, due to the time required to update the parity bits.
- You can also set the parameters for the file system that the database uses:

If you do not need to know when files were last accessed (which is not really useful on a database server), you can mount your file systems with the `-o noatime` option. That skips updates to the last access time in inodes on the file system, which avoids some disk seeks.

On many operating systems, you can set a file system to be updated asynchronously by mounting it with the `-o async` option. If your computer is reasonably stable, this should give you better performance without sacrificing too much reliability. (This flag is on by default on Linux.)

### 9.12.3 Using Symbolic Links

You can move databases or tables from the database directory to other locations and replace them with symbolic links to the new locations. You might want to do this, for example, to move a database to a file system with more free space or increase the speed of your system by spreading your tables to different disks.

For `InnoDB` tables, use the `DATA DIRECTORY` clause on the `CREATE TABLE` statement instead of symbolic links, as explained in [Section 15.7.5, “Creating a File-Per-Table Tablespace Outside the Data Directory”](#). This new feature is a supported, cross-platform technique.

The recommended way to do this is to symlink entire database directories to a different disk. Symlink `MyISAM` tables only as a last resort.

To determine the location of your data directory, use this statement:

```
SHOW VARIABLES LIKE 'datadir';
```

### 9.12.3.1 Using Symbolic Links for Databases on Unix

On Unix, the way to symlink a database is first to create a directory on some disk where you have free space and then to create a soft link to it from the MySQL data directory.

```
shell> mkdir /dr1/databases/test
shell> ln -s /dr1/databases/test /path/to/datadir
```

MySQL does not support linking one directory to multiple databases. Replacing a database directory with a symbolic link works as long as you do not make a symbolic link between databases. Suppose that you have a database `db1` under the MySQL data directory, and then make a symlink `db2` that points to `db1`:

```
shell> cd /path/to/datadir
shell> ln -s db1 db2
```

The result is that, or any table `tbl_a` in `db1`, there also appears to be a table `tbl_a` in `db2`. If one client updates `db1.tbl_a` and another client updates `db2.tbl_a`, problems are likely to occur.

### 9.12.3.2 Using Symbolic Links for MyISAM Tables on Unix

Symlinks are fully supported only for `MyISAM` tables. For files used by tables for other storage engines, you may get strange problems if you try to use symbolic links. For `InnoDB` tables, use the alternative technique explained in [Section 15.7.5, “Creating a File-Per-Table Tablespace Outside the Data Directory”](#) instead.

Do not symlink tables on systems that do not have a fully operational `realpath()` call. (Linux and Solaris support `realpath()`). To determine whether your system supports symbolic links, check the value of the `have_symlink` system variable using this statement:

```
SHOW VARIABLES LIKE 'have_symlink';
```

The handling of symbolic links for `MyISAM` tables works as follows:

- In the data directory, you always have the table format (`.frm`) file, the data (`.MYD`) file, and the index (`.MYI`) file. The data file and index file can be moved elsewhere and replaced in the data directory by symlinks. The format file cannot.
- You can symlink the data file and the index file independently to different directories.
- To instruct a running MySQL server to perform the symlinking, use the `DATA DIRECTORY` and `INDEX DIRECTORY` options to `CREATE TABLE`. See [Section 14.1.18, “CREATE TABLE Syntax”](#). Alternatively, if `mysqld` is not running, symlinking can be accomplished manually using `ln -s` from the command line.

#### Note

The path used with either or both of the `DATA DIRECTORY` and `INDEX DIRECTORY` options may not include the MySQL `data` directory. (Bug #32167)

- `myisamchk` does not replace a symlink with the data file or index file. It works directly on the file to which the symlink points. Any temporary files are created in the directory where the data file or index file is located. The same is true for the `ALTER TABLE`, `OPTIMIZE TABLE`, and `REPAIR TABLE` statements.

#### Note

When you drop a table that is using symlinks, *both the symlink and the file to which the symlink points are dropped*. This is an extremely good reason

*not* to run `mysqld` as the system `root` or permit system users to have write access to MySQL database directories.

- If you rename a table with `ALTER TABLE ... RENAME` or `RENAME TABLE` and you do not move the table to another database, the symlinks in the database directory are renamed to the new names and the data file and index file are renamed accordingly.
- If you use `ALTER TABLE ... RENAME` or `RENAME TABLE` to move a table to another database, the table is moved to the other database directory. If the table name changed, the symlinks in the new database directory are renamed to the new names and the data file and index file are renamed accordingly.
- If you are not using symlinks, start `mysqld` with the `--skip-symbolic-links` option to ensure that no one can use `mysqld` to drop or rename a file outside of the data directory.

These table symlink operations are not supported:

- `ALTER TABLE` ignores the `DATA DIRECTORY` and `INDEX DIRECTORY` table options.
- As indicated previously, only the data and index files can be symbolic links. The `.frm` file must *never* be a symbolic link. Attempting to do this (for example, to make one table name a synonym for another) produces incorrect results. Suppose that you have a database `db1` under the MySQL data directory, a table `tbl1` in this database, and in the `db1` directory you make a symlink `tbl2` that points to `tbl1`:

```
shell> cd /path/to/datadir/db1
shell> ln -s tbl1.frm tbl2.frm
shell> ln -s tbl1.MYD tbl2.MYD
shell> ln -s tbl1.MYI tbl2.MYI
```

Problems result if one thread reads `db1.tbl1` and another thread updates `db1.tbl2`:

- The query cache is “fooled” (it has no way of knowing that `tbl1` has not been updated, so it returns outdated results).
- `ALTER` statements on `tbl2` fail.

### 9.12.3.3 Using Symbolic Links for Databases on Windows

On Windows, symbolic links can be used for database directories. This enables you to put a database directory at a different location (for example, on a different disk) by setting up a symbolic link to it. Use of database symlinks on Windows is similar to their use on Unix, although the procedure for setting up the link differs.

Suppose that you want to place the database directory for a database named `mydb` at `D:\data\mydb`. To do this, create a symbolic link in the MySQL data directory that points to `D:\data\mydb`. However, before creating the symbolic link, make sure that the `D:\data\mydb` directory exists by creating it if necessary. If you already have a database directory named `mydb` in the data directory, move it to `D:\data`. Otherwise, the symbolic link will be ineffective. To avoid problems, make sure that the server is not running when you move the database directory.

Windows Vista, Windows Server 2008, or newer have native symbolic link support, so you can create a symlink using the `mklink` command. This command requires administrative privileges.

1. Change location into the data directory:

```
C:\> cd \path\to\datadir
```

2. In the data directory, create a symlink named `mydb` that points to the location of the database directory:

```
C:\> mklink /d mydb D:\data\mydb
```

After this, all tables created in the database `mydb` are created in `D:\data\mydb`.

## 9.12.4 Optimizing Memory Use

### 9.12.4.1 How MySQL Uses Memory

MySQL allocates buffers and caches to improve performance of database operations. The default configuration is designed to allow a MySQL Server to start on a virtual machine that has approximately 512MB of RAM. You can improve MySQL performance by increasing the values of certain cache and buffer-related system variables. You can also modify the default configuration to run MySQL on systems with limited memory.

The following list describes some of the ways that MySQL uses memory. Where applicable, relevant system variables are referenced. Some items are storage engine or feature specific.

- The `InnoDB` buffer pool is a memory area that holds cached `InnoDB` data for tables, indexes, and other auxiliary buffers. For efficiency of high-volume read operations, the buffer pool is divided into `pages` that can potentially hold multiple rows. For efficiency of cache management, the buffer pool is implemented as a linked list of pages; data that is rarely used is aged out of the cache, using a variation of the `LRU` algorithm. For more information, see [Section 15.6.3.1, “The InnoDB Buffer Pool”](#).

The size of the buffer pool is important for system performance.

- Typically, it is recommended that `innodb_buffer_pool_size` is configured to 50 to 75 percent of system memory.
- `InnoDB` allocates memory for the entire buffer pool at server startup. Memory allocation is performed by `malloc()` operations. Buffer pool size is defined by the `innodb_buffer_pool_size` configuration option. As of MySQL 5.7, `innodb_buffer_pool_size` can be configured dynamically, while the server is running. For more information, see [Section 15.6.3.2, “Configuring InnoDB Buffer Pool Size”](#).
- On systems with a large amount of memory, you can improve concurrency by dividing the buffer pool into multiple `buffer pool instances`. The number of buffer pool instances is defined by `innodb_buffer_pool_instances`.
- A buffer pool that is too small may cause excessive churning as pages are flushed from the buffer pool only to be required again a short time later.
- A buffer pool that is too large may cause swapping due to competition for memory.
- The [MySQL Performance Schema](#) is a feature for monitoring MySQL server execution at a low level. As of MySQL 5.7, the Performance Schema dynamically allocates memory incrementally, scaling its memory use to actual server load, instead of allocating required memory during server startup. Once memory is allocated, it is not freed until the server is restarted. For more information, see [Section 24.15, “The Performance Schema Memory-Allocation Model”](#).
- All threads share the `MyISAM` key buffer; its size is determined by the `key_buffer_size` variable. Other buffers used by the server are allocated as needed. See [Section 6.1.1, “Configuring the Server”](#).

For each `MyISAM` table that is opened, the index file is opened once; the data file is opened once for each concurrently running thread. For each concurrent thread, a table structure, column structures for each column, and a buffer of size `3 * N` are allocated (where `N` is the maximum row length, not counting `BLOB` columns). A `BLOB` column requires five to eight bytes plus the length of the `BLOB` data. The `MyISAM` storage engine maintains one extra row buffer for internal use.

- Each thread that is used to manage client connections uses some thread-specific space. The following list indicates these and which variables control their size:

- A stack (variable `thread_stack`)
- A connection buffer (variable `net_buffer_length`)
- A result buffer (variable `net_buffer_length`)

The connection buffer and result buffer each begin with a size equal to `net_buffer_length` bytes, but are dynamically enlarged up to `max_allowed_packet` bytes as needed. The result buffer shrinks to `net_buffer_length` bytes after each SQL statement. While a statement is running, a copy of the current statement string is also allocated.

Each connection thread uses memory for computing statement digests (see [Section 24.8, “Performance Schema Statement Digests”](#)): Before MySQL 5.7.4, 1024 bytes per session if the Performance Schema is compiled in with statement instrumentation. In 5.7.4 and 5.7.5, 1024 bytes per session. In 5.7.6 and higher, `max_digest_length` bytes per session.

- All threads share the same base memory.
- When a thread is no longer needed, the memory allocated to it is released and returned to the system unless the thread goes back into the thread cache. In that case, the memory remains allocated.
- The `myisam_use_mmap` system variable can be set to 1 to enable memory-mapping for all `MyISAM` tables.
- Each request that performs a sequential scan of a table allocates a *read buffer* (variable `read_buffer_size`).
- When reading rows in an arbitrary sequence (for example, following a sort), a *random-read buffer* (variable `read_rnd_buffer_size`) may be allocated to avoid disk seeks.
- All joins are executed in a single pass, and most joins can be done without even using a temporary table. Most temporary tables are memory-based hash tables. Temporary tables with a large row length (calculated as the sum of all column lengths) or that contain `BLOB` columns are stored on disk.
