- Standard SQL privileges are structured in a hierarchical manner. If you remove a user, all privileges the user has been granted are revoked. This is also true in MySQL if you use `DROP USER`. See [Section 14.7.1.3, “DROP USER Syntax”](#).
- In standard SQL, when you drop a table, all privileges for the table are revoked. In standard SQL, when you revoke a privilege, all privileges that were granted based on that privilege are also revoked. In MySQL, privileges can be dropped with `DROP USER` or `REVOKE` statements.
- In MySQL, it is possible to have the `INSERT` privilege for only some of the columns in a table. In this case, you can still execute `INSERT` statements on the table, provided that you insert values only for those columns for which you have the `INSERT` privilege. The omitted columns are set to their implicit default values if strict SQL mode is not enabled. In strict mode, the statement is rejected if any of the omitted columns have no default value. (Standard SQL requires you to have the `INSERT` privilege on all columns.) For information about strict SQL mode and implicit default values, see [Section 6.1.8, “Server SQL Modes”](#), and [Section 12.7, “Data Type Default Values”](#).

### 14.7.1.5 RENAME USER Syntax

```
RENAME USER old_user TO new_user
[, old_user TO new_user] ...
```

The `RENAME USER` statement renames existing MySQL accounts. An error occurs for old accounts that do not exist or new accounts that already exist.

To use `RENAME USER`, you must have the global `CREATE USER` privilege, or the `UPDATE` privilege for the `mysql` database. When the `read_only` system variable is enabled, `RENAME USER` additionally requires the `SUPER` privilege.

Each account name uses the format described in [Section 7.2.3, “Specifying Account Names”](#). For example:

```
RENAME USER 'jeffrey'@'localhost' TO 'jeff'@'127.0.0.1';
```

The host name part of the account name, if omitted, defaults to `'%'`.

`RENAME USER` causes the privileges held by the old user to be those held by the new user. However, `RENAME USER` does not automatically drop or invalidate databases or objects within them that the old user created. This includes stored programs or views for which the `DEFINER` attribute names the old user. Attempts to access such objects may produce an error if they execute in definer security context. (For information about security context, see [Section 22.6, “Access Control for Stored Programs and Views”](#).)

The privilege changes take effect as indicated in [Section 7.2.6, “When Privilege Changes Take Effect”](#).

### 14.7.1.6 REVOKE Syntax

```
REVOKE
  priv_type [(column_list)]
  [, priv_type [(column_list)] ...
  ON [object_type] priv_level
  FROM user [, user] ...

REVOKE ALL PRIVILEGES, GRANT OPTION
  FROM user [, user] ...

REVOKE PROXY ON user
  FROM user [, user] ...
```

The `REVOKE` statement enables system administrators to revoke privileges from MySQL accounts.

When the `read_only` system variable is enabled, `REVOKE` requires the `SUPER` privilege in addition to any other required privileges described in the following discussion.

Each account name uses the format described in [Section 7.2.3, “Specifying Account Names”](#). For example:

```
REVOKE INSERT ON *.* FROM 'jeffrey'@'localhost';
```

The host name part of the account name, if omitted, defaults to `'%'`.

For details on the levels at which privileges exist, the permissible *priv\_type*, *priv\_level*, and *object\_type* values, and the syntax for specifying users and passwords, see [Section 14.7.1.4, “GRANT Syntax”](#)

To use the first `REVOKE` syntax, you must have the `GRANT OPTION` privilege, and you must have the privileges that you are revoking.

To revoke all privileges, use the second syntax, which drops all global, database, table, column, and routine privileges for the named user or users:

```
REVOKE ALL PRIVILEGES, GRANT OPTION FROM user [, user] ...
```

To use this `REVOKE` syntax, you must have the global `CREATE USER` privilege, or the `UPDATE` privilege for the `mysql` database.

`REVOKE` removes privileges, but does not drop `mysql.user` table entries. To remove a user account entirely, use `DROP USER` (see [Section 14.7.1.3, “DROP USER Syntax”](#)) or `DELETE`.

If the grant tables hold privilege rows that contain mixed-case database or table names and the `lower_case_table_names` system variable is set to a nonzero value, `REVOKE` cannot be used to revoke these privileges. It will be necessary to manipulate the grant tables directly. (`GRANT` will not create such rows when `lower_case_table_names` is set, but such rows might have been created prior to setting the variable.)

When successfully executed from the `mysql` program, `REVOKE` responds with `Query OK, 0 rows affected`. To determine what privileges result from the operation, use `SHOW GRANTS`. See [Section 14.7.5.21, “SHOW GRANTS Syntax”](#).

### 14.7.1.7 SET PASSWORD Syntax

`SET PASSWORD` syntax for MySQL 5.7.6 and higher:

```
SET PASSWORD [FOR user] = password_option

password_option: {
    PASSWORD('auth_string')
  | 'auth_string'
}
```

`SET PASSWORD` syntax before MySQL 5.7.6:

```
SET PASSWORD [FOR user] = password_option

password_option: {
    PASSWORD('auth_string')
  | OLD_PASSWORD('auth_string')
  | 'hash_string'
}
```

The `SET PASSWORD` statement assigns a password to a MySQL user account, specified as either a cleartext (unencrypted) or encrypted value:

- `'auth_string'` represents a cleartext password.
- `'hash_string'` represents an encrypted password.

**Note**

- `SET PASSWORD ... = PASSWORD('auth_string')` syntax is deprecated as of MySQL 5.7.6 and will be removed in a future MySQL release.
- `SET PASSWORD ... = 'auth_string'` syntax is not deprecated, but `ALTER USER` is now the preferred statement for assigning passwords. For example:

```
ALTER USER user IDENTIFIED BY 'auth_string';
```

`SET PASSWORD` can be used with or without an explicitly named user account:

- With a `FOR user` clause, the statement sets the password for the named account, which must exist:

```
SET PASSWORD FOR 'jeffrey'@'localhost' = password_option;
```

In this case, you must have the `UPDATE` privilege for the `mysql` database.

- With no `FOR user` clause, the statement sets the password for the current user:

```
SET PASSWORD = password_option;
```

Any client who connects to the server using a nonanonymous account can change the password for that account. To see which account the server authenticated you as, invoke the `CURRENT_USER()` function:

```
SELECT CURRENT_USER();
```

When the `read_only` system variable is enabled, `SET PASSWORD` requires the `SUPER` privilege in addition to any other required privileges.

If a `FOR user` clause is given, the account name uses the format described in [Section 7.2.3, “Specifying Account Names”](#). The `user` value should be given as `'user_name'@'host_name'`, where `'user_name'` and `'host_name'` are exactly as listed in the `User` and `Host` columns of the account's `mysql.user` table row. The host name part of the account name, if omitted, defaults to `'%'`. For example, to set the password for an account with `User` and `Host` column values of `'bob'` and `'%.example.org'`, write the statement like this:

```
SET PASSWORD FOR 'bob'@'%.example.org' = PASSWORD('auth_string');
```

The password can be specified in these ways:

- Using the `PASSWORD()` function (deprecated as of MySQL 5.7.6)

The `'auth_string'` function argument is the cleartext (unencrypted) password. `PASSWORD()` hashes the password and returns the encrypted password string for storage in the `mysql.user` account row.

The `PASSWORD()` function hashes the password using the hashing method determined by the value of the `old_passwords` system variable value. If `SET PASSWORD` rejects the hashed password value returned by `PASSWORD()` as not being in the correct format, it may be necessary to change `old_passwords` to change the hashing method. For example, if the account uses the `mysql_native_password` plugin, the `old_passwords` value must be 0:

```
SET old_passwords = 0;
SET PASSWORD FOR 'jeffrey'@'localhost' = PASSWORD('mypass');
```

If the `old_passwords` value differs from that required by the authentication plugin, the hashed password value returned by `PASSWORD()` is not acceptable for that plugin, and attempts to set the password produce an error. For example:

```
mysql> SET old_passwords = 1;
mysql> SET PASSWORD FOR 'jeffrey'@'localhost' = PASSWORD('mypass');
ERROR 1372 (HY000): Password hash should be a 41-digit hexadecimal number
```

Permitted `old_passwords` values are described later in this section.

- Using the `OLD_PASSWORD()` function (permitted before MySQL 5.7.5 only):

The '`auth_string`' function argument is the cleartext (unencrypted) password. `OLD_PASSWORD()` hashes the password using pre-4.1 hashing and returns the encrypted password string for storage in the `mysql.user` account row. This hashing method is appropriate only for accounts that use the `mysql_old_password` authentication plugin.

#### Note

Passwords that use the pre-4.1 hashing method are less secure than passwords that use the native password hashing method and should be avoided. Pre-4.1 passwords are deprecated and support for them is removed in MySQL 5.7.5. Consequently, `OLD_PASSWORD()` is deprecated and is removed in MySQL 5.7.5. For account upgrade instructions, see [Section 7.5.1.3, “Migrating Away from Pre-4.1 Password Hashing and the mysql\\_old\\_password Plugin”](#).

- Using a string without `PASSWORD()` or `OLD_PASSWORD()`

For this syntax, the meaning *differs in MySQL 5.7.6 and higher from earlier versions*:

- As of MySQL 5.7.6, `SET PASSWORD` interprets the string as a cleartext string and hashes it appropriately for the account authentication plugin before storing it in the `mysql.user` account row.
- Before MySQL 5.7.6, `SET PASSWORD` interprets the string as a hashed password value to be stored directly. The string must be hashed in the format required by the account authentication plugin. A string not hashed appropriately causes client connections for the account to fail with an `Access denied` error.

For more information about setting passwords, see [Section 7.3.5, “Assigning Account Passwords”](#).

The following table shows the permitted values of `old_passwords`, the password hashing method for each value, and which authentication plugins use passwords hashed with each method.

| Value | Password Hashing Method  | Associated Authentication Plugin   |
|-------|--------------------------|------------------------------------|
| 0     | MySQL 4.1 native hashing | <code>mysql_native_password</code> |
| 1     | Pre-4.1 (“old”) hashing  | <code>mysql_old_password</code>    |
| 2     | SHA-256 hashing          | <code>sha256_password</code>       |

#### Note

Passwords that use the pre-4.1 hashing method are less secure than passwords that use the native password hashing method and should be avoided. Pre-4.1 passwords are deprecated and support for them is removed in MySQL 5.7.5. Consequently, `old_passwords=1`, which causes `PASSWORD()` to generate pre-4.1 password hashes, is not permitted as of 5.7.5. For account upgrade instructions, see [Section 7.5.1.3, “Migrating Away from Pre-4.1 Password Hashing and the mysql\\_old\\_password Plugin”](#).

### Important

Under some circumstances, `SET PASSWORD` may be recorded in server logs or on the client side in a history file such as `~/.mysql_history`, which means that cleartext passwords may be read by anyone having read access to that information. For information about the conditions under which this occurs for the server logs and how to control it, see [Section 7.1.2.3, “Passwords and Logging”](#). For similar information about client-side logging, see [Section 5.5.1.3, “mysql Logging”](#).

If you are using MySQL Replication, be aware that, currently, a password used by a replication slave as part of a `CHANGE MASTER TO` statement is effectively limited to 32 characters in length; if the password is longer, any excess characters are truncated. This is not due to any limit imposed by the MySQL Server generally, but rather is an issue specific to MySQL Replication. (For more information, see Bug #43439.)

## 14.7.2 Table Maintenance Statements

### 14.7.2.1 ANALYZE TABLE Syntax

```
ANALYZE [NO_WRITE_TO_BINLOG | LOCAL] TABLE
      tbl_name [, tbl_name] ...
```

`ANALYZE TABLE` analyzes and stores the key distribution for a table. During the analysis, the table is locked with a read lock for `InnoDB` and `MyISAM`. This statement works with `InnoDB`, `NDB`, and `MyISAM` tables. For `MyISAM` tables, this statement is equivalent to using `myisamchk --analyze`. This statement does not work with views.

For more information on how the analysis works within `InnoDB`, see [Section 15.6.11.1, “Configuring Persistent Optimizer Statistics Parameters”](#) and [Section 15.6.11.3, “Estimating ANALYZE TABLE Complexity for InnoDB Tables”](#). Also see [Section 15.8.8, “Limits on InnoDB Tables”](#). In particular, when you enable the `innodb_stats_persistent` option, you must run `ANALYZE TABLE` after loading substantial data into an `InnoDB` table, or creating a new index for one.

MySQL uses the stored key distribution to decide the order in which tables should be joined when you perform a join on something other than a constant. In addition, key distributions can be used when deciding which indexes to use for a specific table within a query.

This statement requires `SELECT` and `INSERT` privileges for the table.

`ANALYZE TABLE` is supported for partitioned tables, and you can use `ALTER TABLE ... ANALYZE PARTITION` to analyze one or more partitions; for more information, see [Section 14.1.8, “ALTER TABLE Syntax”](#), and [Section 21.3.4, “Maintenance of Partitions”](#).

In MySQL 5.7.1, `gtid_next` must be set to `AUTOMATIC` before issuing this statement. This restriction does not apply in MySQL 5.7.2 or later. (Bug #16062608, Bug #16715809, Bug #69045)

`ANALYZE TABLE` returns a result set with the following columns.

| Column   | Value  |
|----------|--|
| Table    | The table name   |
| Op       | Always <code>analyze</code>  |
| Msg_type | <code>status</code> , <code>error</code> , <code>info</code> , <code>note</code> , or <code>warning</code> |
| Msg_text | An informational message   |

You can check the stored key distribution with the `SHOW INDEX` statement. See [Section 14.7.5.22, “SHOW INDEX Syntax”](#).

If the table has not changed since the last `ANALYZE TABLE` statement, the table is not analyzed again.

By default, the server writes `ANALYZE TABLE` statements to the binary log so that they replicate to replication slaves. To suppress logging, specify the optional `NO_WRITE_TO_BINLOG` keyword or its alias `LOCAL`.

### 14.7.2.2 CHECK TABLE Syntax

```
CHECK TABLE tbl_name [, tbl_name] ... [option] ...
```

```
option = {
    FOR UPGRADE
    | QUICK
    | FAST
    | MEDIUM
    | EXTENDED
    | CHANGED
}
```

`CHECK TABLE` checks a table or tables for errors. `CHECK TABLE` works for InnoDB, MyISAM, ARCHIVE, and CSV tables. For MyISAM tables, the key statistics are updated as well.

Before running `CHECK TABLE` on InnoDB tables, see [CHECK TABLE Usage Notes for InnoDB Tables](#).

To check a table, you must have some privilege for it.

`CHECK TABLE` can also check views for problems, such as tables that are referenced in the view definition that no longer exist.

`CHECK TABLE` is supported for partitioned tables, and you can use `ALTER TABLE ... CHECK PARTITION` to check one or more partitions; for more information, see [Section 14.1.8, “ALTER TABLE Syntax”](#), and [Section 21.3.4, “Maintenance of Partitions”](#).

In MySQL 5.7.1, `gtid_next` must be set to `AUTOMATIC` before issuing this statement. This restriction does not apply in MySQL 5.7.2 or later. (Bug #16062608, Bug #16715809, Bug #69045)

`CHECK TABLE` ignores generated virtual columns that are not indexed.

### Output

`CHECK TABLE` returns a result set with the following columns.

| Column   | Value  |
|----------|--|
| Table    | The table name   |
| Op       | Always <code>check</code>  |
| Msg_type | <code>status</code> , <code>error</code> , <code>info</code> , <code>note</code> , or <code>warning</code> |
| Msg_text | An informational message   |

The statement might produce many rows of information for each checked table. The last row has a `Msg_type` value of `status` and the `Msg_text` normally should be `OK`. If you don't get `OK`, or `Table is already up to date` for a MyISAM table, you should normally run a repair of the table. See [Section 8.6, “MyISAM Table Maintenance and Crash Recovery”](#). `Table is already up to date` means that the storage engine for the table indicated that there was no need to check the table.

### Checking Version Compatibility

The `FOR UPGRADE` option checks whether the named tables are compatible with the current version of MySQL. With `FOR UPGRADE`, the server checks each table to determine whether there have been any incompatible changes in any of the table's data types or indexes since the table was created. If not, the check succeeds. Otherwise, if there is a possible incompatibility, the server runs a full check on the

table (which might take some time). If the full check succeeds, the server marks the table's `.frm` file with the current MySQL version number. Marking the `.frm` file ensures that further checks for the table with the same version of the server will be fast.

Incompatibilities might occur because the storage format for a data type has changed or because its sort order has changed. Our aim is to avoid these changes, but occasionally they are necessary to correct problems that would be worse than an incompatibility between releases.

`FOR UPGRADE` discovers these incompatibilities:

- The indexing order for end-space in `TEXT` columns for `InnoDB` and `MyISAM` tables changed between MySQL 4.1 and 5.0.
- The storage method of the new `DECIMAL` data type changed between MySQL 5.0.3 and 5.0.5.
- If your table was created by a different version of the MySQL server than the one you are currently running, `FOR UPGRADE` indicates that the table has an `.frm` file with an incompatible version. In this case, the result set returned by `CHECK TABLE` contains a line with a `Msg_type` value of `error` and a `Msg_text` value of `Table upgrade required. Please do "REPAIR TABLE `tbl_name`" to fix it!`
- Changes are sometimes made to character sets or collations that require table indexes to be rebuilt. For details about these changes and when `FOR UPGRADE` detects them, see [Section 2.11.3, “Checking Whether Tables or Indexes Must Be Rebuilt”](#).
- The `YEAR(2)` data type is deprecated and support for it is removed in MySQL 5.7.5. For tables containing `YEAR(2)` columns, `CHECK TABLE` recommends `REPAIR TABLE`, which converts `YEAR(2)` to `YEAR(4)`.
- As of MySQL 5.7.2, trigger creation time is maintained. If run against a table that has triggers, `CHECK TABLE ... FOR UPGRADE` displays this warning for each trigger created before MySQL 5.7.2:

```
Trigger db_name.tbl_name.trigger_name does not have CREATED attribute.
```

The warning is informational only. No change is made to the trigger.

## Checking Data Consistency

The following table shows the other check options that can be given. These options are passed to the storage engine, which may use them or not.

| Type                  | Meaning   |
|-----------------------|---|
| <code>QUICK</code>    | Do not scan the rows to check for incorrect links. Applies to <code>InnoDB</code> and <code>MyISAM</code> tables and views.   |
| <code>FAST</code>     | Check only tables that have not been closed properly. Applies only to <code>MyISAM</code> tables and views; ignored for <code>InnoDB</code> .   |
| <code>CHANGED</code>  | Check only tables that have been changed since the last check or that have not been closed properly. Applies only to <code>MyISAM</code> tables and views; ignored for <code>InnoDB</code> .  |
| <code>MEDIUM</code>   | Scan rows to verify that deleted links are valid. This also calculates a key checksum for the rows and verifies this with a calculated checksum for the keys. Applies only to <code>MyISAM</code> tables and views; ignored for <code>InnoDB</code> . |
| <code>EXTENDED</code> | Do a full key lookup for all keys for each row. This ensures that the table is 100% consistent, but takes a long time. Applies only to <code>MyISAM</code> tables and views; ignored for <code>InnoDB</code> .  |

If none of the options `QUICK`, `MEDIUM`, or `EXTENDED` are specified, the default check type for dynamic-format `MyISAM` tables is `MEDIUM`. This has the same result as running `myisamchk --medium-check tbl_name` on the table. The default check type also is `MEDIUM` for static-format `MyISAM` tables, unless

`CHANGED` or `FAST` is specified. In that case, the default is `QUICK`. The row scan is skipped for `CHANGED` and `FAST` because the rows are very seldom corrupted.

You can combine check options, as in the following example that does a quick check on the table to determine whether it was closed properly:

```
CHECK TABLE test_table FAST QUICK;
```

#### Note

If `CHECK TABLE` finds no problems with a table that is marked as “corrupted” or “not closed properly”, `CHECK TABLE` may remove the mark.

If a table is corrupted, the problem is most likely in the indexes and not in the data part. All of the preceding check types check the indexes thoroughly and should thus find most errors.

If you just want to check a table that you assume is okay, you should use no check options or the `QUICK` option. The latter should be used when you are in a hurry and can take the very small risk that `QUICK` does not find an error in the data file. (In most cases, under normal usage, MySQL should find any error in the data file. If this happens, the table is marked as “corrupted” and cannot be used until it is repaired.)

`FAST` and `CHANGED` are mostly intended to be used from a script (for example, to be executed from `cron`) if you want to check tables from time to time. In most cases, `FAST` is to be preferred over `CHANGED`. (The only case when it is not preferred is when you suspect that you have found a bug in the `MyISAM` code.)

`EXTENDED` is to be used only after you have run a normal check but still get strange errors from a table when MySQL tries to update a row or find a row by key. This is very unlikely if a normal check has succeeded.

Use of `CHECK TABLE ... EXTENDED` might influence the execution plan generated by the query optimizer.

Some problems reported by `CHECK TABLE` cannot be corrected automatically:

- Found row where the `auto_increment` column has the value 0.

This means that you have a row in the table where the `AUTO_INCREMENT` index column contains the value 0. (It is possible to create a row where the `AUTO_INCREMENT` column is 0 by explicitly setting the column to 0 with an `UPDATE` statement.)

This is not an error in itself, but could cause trouble if you decide to dump the table and restore it or do an `ALTER TABLE` on the table. In this case, the `AUTO_INCREMENT` column changes value according to the rules of `AUTO_INCREMENT` columns, which could cause problems such as a duplicate-key error.

To get rid of the warning, execute an `UPDATE` statement to set the column to some value other than 0.

## CHECK TABLE Usage Notes for InnoDB Tables

The following notes apply to `InnoDB` tables:

- If `CHECK TABLE` encounters a corrupt page, the server exits to prevent error propagation (Bug #10132). If the corruption occurs in a secondary index but table data is readable, running `CHECK TABLE` can still cause a server exit.
- If `CHECK TABLE` encounters a corrupted `DB_TRX_ID` or `DB_ROLL_PTR` field in a clustered index, `CHECK TABLE` can cause `InnoDB` to access an invalid undo log record, resulting in an `MVCC`-related server exit.

- If `CHECK TABLE` encounters errors in `InnoDB` tables or indexes, it reports an error, and usually marks the index and sometimes marks the table as corrupted, preventing further use of the index or table. Such errors include an incorrect number of entries in a secondary index or incorrect links.
- If `CHECK TABLE` finds an incorrect number of entries in a secondary index, it reports an error but does not cause a server exit or prevent access to the file.
- `CHECK TABLE` surveys the index page structure, then surveys each key entry. It does not validate the key pointer to a clustered record or follow the path for `BLOB` pointers.
- When an `InnoDB` table is stored in its own `.ibd` file, the first 3 pages of the `.ibd` file contain header information rather than table or index data. The `CHECK TABLE` statement does not detect inconsistencies that affect only the header data. To verify the entire contents of an `InnoDB .ibd` file, use the `innochecksum` command.
- When running `CHECK TABLE` on large `InnoDB` tables, other threads may be blocked during `CHECK TABLE` execution. To avoid timeouts, the semaphore wait threshold (600 seconds) is extended by 2 hours (7200 seconds) for `CHECK TABLE` operations. If `InnoDB` detects semaphore waits of 240 seconds or more it starts printing `InnoDB` monitor output to the error log. If a lock request extends beyond the semaphore wait threshold, `InnoDB` aborts the process. To avoid the possibility of a semaphore wait timeout entirely, you can run `CHECK TABLE QUICK` instead of `CHECK TABLE`.
- `CHECK TABLE` functionality for `InnoDB SPATIAL` indexes is enhanced in MySQL 5.7.6. Enhancements include an R-tree validity check and a check to ensure that the R-tree row count matches the clustered index. Prior to these enhancements, minimal checks were performed on `InnoDB SPATIAL` indexes (introduced in MySQL 5.7.5).
- `CHECK TABLE` supports secondary indexes on generated virtual columns. `InnoDB` added supported for secondary indexes on generated virtual columns in MySQL 5.7.8.

### 14.7.2.3 CHECKSUM TABLE Syntax

```
CHECKSUM TABLE tbl_name [, tbl_name] ... [QUICK | EXTENDED]
```

`CHECKSUM TABLE` reports a `checksum` for the contents of a table. During the checksum operation, the table is locked with a read lock for `InnoDB` and `MyISAM`. You can use this statement to verify that the contents are the same before and after a backup, rollback, or other operation that is intended to put the data back to a known state. This statement requires the `SELECT` privilege for the table.

This statement is not supported for views. If you run `CHECKSUM TABLE` against a view, the `Checksum` value is always `NULL`, and a warning is returned.

### Performance Considerations

By default, the entire table is read row by row and the checksum is calculated. For large tables, this could take a long time, thus you would only perform this operation occasionally. This row-by-row calculation is what you get with the `EXTENDED` clause, with `InnoDB` and all other storage engines other than `MyISAM`, and with `MyISAM` tables not created with the `CHECKSUM=1` clause.

For `MyISAM` tables created with the `CHECKSUM=1` clause, `CHECKSUM TABLE` or `CHECKSUM TABLE ... QUICK` returns the “live” table checksum that can be returned very fast. If the table does not meet all these conditions, the `QUICK` method returns `NULL`. See [Section 14.1.18, “CREATE TABLE Syntax”](#) for the syntax of the `CHECKSUM` clause.

For a nonexistent table, `CHECKSUM TABLE` returns `NULL` and generates a warning.

The checksum value depends on the table row format. If the row format changes, the checksum also changes. For example, the storage format for temporal types such as `TIME`, `DATETIME`, and `TIMESTAMP` changed in MySQL 5.6 prior to MySQL 5.6.5, so if a 5.5 table is upgraded to MySQL 5.6, the checksum value may change.

### Important

If the checksums for two tables are different, then it is almost certain that the tables are different in some way. However, because the hashing function used by `CHECKSUM TABLE` is not guaranteed to be collision-free, there is a slight chance that two tables which are not identical can produce the same checksum.

## 14.7.2.4 OPTIMIZE TABLE Syntax

```
OPTIMIZE [NO_WRITE_TO_BINLOG | LOCAL] TABLE
    tbl_name [, tbl_name] ...
```

Reorganizes the physical storage of table data and associated index data, to reduce storage space and improve I/O efficiency when accessing the table. The exact changes made to each table depend on the [storage engine](#) used by that table. This statement does not work with views.

Use `OPTIMIZE TABLE` in these cases, depending on the type of table:

- After doing substantial insert, update, or delete operations on an [InnoDB](#) table that has its own [.ibd file](#) because it was created with the `innodb_file_per_table` option enabled. The table and indexes are reorganized, and disk space can be reclaimed for use by the operating system.
- After doing substantial insert, update, or delete operations on columns that are part of a [FULLTEXT](#) index in an [InnoDB](#) table. Set the configuration option `innodb_optimize_fulltext_only=1` first. To keep the index maintenance period to a reasonable time, set the `innodb_ft_num_word_optimize` option to specify how many words to update in the search index, and run a sequence of `OPTIMIZE TABLE` statements until the search index is fully updated.
- After deleting a large part of a [MyISAM](#) or [ARCHIVE](#) table, or making many changes to a [MyISAM](#) or [ARCHIVE](#) table with variable-length rows (tables that have [VARCHAR](#), [VARBINARY](#), [BLOB](#), or [TEXT](#) columns). Deleted rows are maintained in a linked list and subsequent [INSERT](#) operations reuse old row positions. You can use `OPTIMIZE TABLE` to reclaim the unused space and to defragment the data file. After extensive changes to a table, this statement may also improve performance of statements that use the table, sometimes significantly.

This statement requires [SELECT](#) and [INSERT](#) privileges for the table.

`OPTIMIZE TABLE` is also supported for partitioned tables. For information about using this statement with partitioned tables and table partitions, see [Section 21.3.4, “Maintenance of Partitions”](#).

In MySQL 5.7.1, `gtid_next` must be set to [AUTOMATIC](#) before issuing this statement. This restriction does not apply in MySQL 5.7.2 or later. (Bug #16062608, Bug #16715809, Bug #69045)

`OPTIMIZE TABLE` works for [InnoDB](#), [MyISAM](#), and [ARCHIVE](#) tables.

By default, `OPTIMIZE TABLE` does *not* work for tables created using any other storage engine and returns a result indicating this lack of support. You can make `OPTIMIZE TABLE` work for other storage engines by starting `mysqld` with the `--skip-new` option. In this case, `OPTIMIZE TABLE` is just mapped to `ALTER TABLE`.

## InnoDB Details

For [InnoDB](#) tables, `OPTIMIZE TABLE` is mapped to `ALTER TABLE ... FORCE`, which rebuilds the table to update index statistics and free unused space in the clustered index. This is displayed in the output of `OPTIMIZE TABLE` when you run it on an [InnoDB](#) table, as shown here:

```
mysql> OPTIMIZE TABLE foo;
+-----+-----+-----+-----+
| Table | Op    | Msg_type | Msg_text |
+-----+-----+-----+-----+
```

|          |          |        |   |
|----------|----------|--------|---|
| test.foo | optimize | note   | Table does not support optimize, doing recreate + analyze instead |
| test.foo | optimize | status | OK  |

Prior to MySQL 5.7.4, `OPTIMIZE TABLE` does not use [online DDL \(ALGORITHM=INPLACE\)](#). Consequently, concurrent DML (`INSERT`, `UPDATE`, `DELETE`) is not permitted on a table while `OPTIMIZE TABLE` is running, i.e. the table is locked. Also, secondary indexes are not created as efficiently because keys are inserted in the order they appeared in the primary key.

As of 5.7.4, `OPTIMIZE TABLE` uses [online DDL \(ALGORITHM=INPLACE\)](#) for both regular and partitioned [InnoDB](#) tables. The table rebuild, triggered by `OPTIMIZE TABLE` and performed under the cover by `ALTER TABLE ... FORCE`, is now performed using [online DDL \(ALGORITHM=INPLACE\)](#) and only locks the table for a brief interval, which reduces downtime for concurrent DML operations.

`OPTIMIZE TABLE` continues to use [ALGORITHM=COPY](#) under the following conditions:

- When the `old_alter_table` system variable is turned ON.
- When the `mysqld --skip-new` option is enabled.

`OPTIMIZE TABLE` using [online DDL \(ALGORITHM=INPLACE\)](#) is not supported for [InnoDB](#) tables that contain `FULLTEXT` indexes. [ALGORITHM=COPY](#) must be used instead.

[InnoDB](#) stores data using a page-allocation method and does not suffer from fragmentation in the same way that legacy storage engines (such as [MyISAM](#)) will. When considering whether or not to run `optimize`, consider the workload of transactions that your server will process:

- Some level of fragmentation is expected. [InnoDB](#) only fills [pages](#) 93% full, to leave room for updates without having to split pages.
- Delete operations might leave gaps that leave pages less filled than desired, which could make it worthwhile to optimize the table.
- Updates to rows usually rewrite the data within the same page, depending on the data type and row format, when sufficient space is available. See [Section 15.9.1.5, “How Compression Works for InnoDB Tables”](#) and [Section 15.11.1, “Overview of InnoDB Row Storage”](#).
- High-concurrency workloads might leave gaps in indexes over time, as [InnoDB](#) retains multiple versions of the same data due through its [MVCC](#) mechanism. See [Section 15.3, “InnoDB Multi-Versioning”](#).

## MyISAM Details

For [MyISAM](#) tables, `OPTIMIZE TABLE` works as follows:

1. If the table has deleted or split rows, repair the table.
2. If the index pages are not sorted, sort them.
3. If the table's statistics are not up to date (and the repair could not be accomplished by sorting the index), update them.

## Other Considerations

`OPTIMIZE TABLE` returns a result set with the following columns.

| Column   | Value  |
|----------|--|
| Table    | The table name   |
| Op       | Always <code>optimize</code>   |
| Msg_type | <code>status</code> , <code>error</code> , <code>info</code> , <code>note</code> , or <code>warning</code> |

| Column                | Value                    |
|-----------------------|--------------------------|
| <code>Msg_text</code> | An informational message |

For `InnoDB` tables prior to 5.7.4 and other table types, MySQL [locks the table](#) during the time `OPTIMIZE TABLE` is running. As of MySQL 5.7.4, `OPTIMIZE TABLE` is performed online for regular and partitioned `InnoDB` tables.

By default, the server writes `OPTIMIZE TABLE` statements to the binary log so that they replicate to replication slaves. To suppress logging, specify the optional `NO_WRITE_TO_BINLOG` keyword or its alias `LOCAL`.

`OPTIMIZE TABLE` does not sort R-tree indexes, such as spatial indexes on `POINT` columns. (Bug #23578)

`OPTIMIZE TABLE` catches and throws any errors that occur while copying table statistics from the old file to the newly created file. For example, if the user ID of the owner of the `.frm`, `.MYD`, or `.MYI` file is different from the user ID of the `mysqld` process, `OPTIMIZE TABLE` generates a "cannot change ownership of the file" error unless `mysqld` is started by the `root` user.

### 14.7.2.5 REPAIR TABLE Syntax

```
REPAIR [NO_WRITE_TO_BINLOG | LOCAL] TABLE
      tbl_name [, tbl_name] ...
      [QUICK] [EXTENDED] [USE_FRM]
```

`REPAIR TABLE` repairs a possibly corrupted table, for certain storage engines only. By default, it has the same effect as `myisamchk --recover tbl_name`. `REPAIR TABLE` works for `MyISAM`, `ARCHIVE`, and `CSV` tables. See [Section 16.2, “The MyISAM Storage Engine”](#), [Section 16.5, “The ARCHIVE Storage Engine”](#), and [Section 16.4, “The CSV Storage Engine”](#). This statement does not work with views.

This statement requires `SELECT` and `INSERT` privileges for the table.

`REPAIR TABLE` is supported for partitioned tables. However, the `USE_FRM` option cannot be used with this statement on a partitioned table.

In MySQL 5.7.1, `gtid_next` must be set to `AUTOMATIC` before issuing this statement. This restriction does not apply in MySQL 5.7.2 or later. (Bug #16062608, Bug #16715809, Bug #69045)

You can use `ALTER TABLE ... REPAIR PARTITION` to repair one or more partitions; for more information, see [Section 14.1.8, “ALTER TABLE Syntax”](#), and [Section 21.3.4, “Maintenance of Partitions”](#).

Although normally you should never have to run `REPAIR TABLE`, if disaster strikes, this statement is very likely to get back all your data from a `MyISAM` table. If your tables become corrupted often, try to find the reason for it, to eliminate the need to use `REPAIR TABLE`. See [Section B.5.3.3, “What to Do If MySQL Keeps Crashing”](#), and [Section 16.2.4, “MyISAM Table Problems”](#).

#### Caution

Make a backup of a table before performing a table repair operation; under some circumstances the operation might cause data loss. Possible causes include but are not limited to file system errors. See [Chapter 8, Backup and Recovery](#).

#### Warning

If the server crashes during a `REPAIR TABLE` operation, it is essential after restarting it that you immediately execute another `REPAIR TABLE` statement for the table before performing any other operations on it. In the worst case,

you might have a new clean index file without information about the data file, and then the next operation you perform could overwrite the data file. This is an unlikely but possible scenario that underscores the value of making a backup first.

`REPAIR TABLE` returns a result set with the following columns.

| Column   | Value  |
|----------|--|
| Table    | The table name   |
| Op       | Always <code>repair</code>   |
| Msg_type | <code>status</code> , <code>error</code> , <code>info</code> , <code>note</code> , or <code>warning</code> |
| Msg_text | An informational message   |

The `REPAIR TABLE` statement might produce many rows of information for each repaired table. The last row has a `Msg_type` value of `status` and `Msg_text` normally should be `OK`. If you do not get `OK` for a `MyISAM` table, you should try repairing it with `myisamchk --safe-recover`. (`REPAIR TABLE` does not implement all the options of `myisamchk`.) With `myisamchk --safe-recover`, you can also use options that `REPAIR TABLE` does not support, such as `--max-record-length`.

If you use the `QUICK` option, `REPAIR TABLE` tries to repair only the index file, and not the data file. This type of repair is like that done by `myisamchk --recover --quick`.

If you use the `EXTENDED` option, MySQL creates the index row by row instead of creating one index at a time with sorting. This type of repair is like that done by `myisamchk --safe-recover`.

The `USE_FRM` option is available for use if the `.MYI` index file is missing or if its header is corrupted. This option tells MySQL not to trust the information in the `.MYI` file header and to re-create it using information from the `.frm` file. This kind of repair cannot be done with `myisamchk`.

#### Caution

Use the `USE_FRM` option *only* if you cannot use regular `REPAIR` modes. Telling the server to ignore the `.MYI` file makes important table metadata stored in the `.MYI` unavailable to the repair process, which can have deleterious consequences:

- The current `AUTO_INCREMENT` value is lost.
- The link to deleted records in the table is lost, which means that free space for deleted records will remain unoccupied thereafter.
- The `.MYI` header indicates whether the table is compressed. If the server ignores this information, it cannot tell that a table is compressed and repair can cause change or loss of table contents. This means that `USE_FRM` should not be used with compressed tables. That should not be necessary, anyway: Compressed tables are read only, so they should not become corrupt.

#### Caution

If you use `USE_FRM` for a table that was created by a different version of the MySQL server than the one you are currently running, `REPAIR TABLE` will not attempt to repair the table. In this case, the result set returned by `REPAIR TABLE` contains a line with a `Msg_type` value of `error` and a `Msg_text` value of `Failed repairing incompatible .FRM file`.

If `USE_FRM` is *not* used, `REPAIR TABLE` checks the table to see whether an upgrade is required. If so, it performs the upgrade, following the same rules as `CHECK TABLE ... FOR UPGRADE`. See [Section 14.7.2.2, “CHECK TABLE Syntax”](#), for more information. `REPAIR TABLE` without `USE_FRM` upgrades the `.frm` file to the current version.

By default, the server writes `REPAIR TABLE` statements to the binary log so that they replicate to replication slaves. To suppress logging, specify the optional `NO_WRITE_TO_BINLOG` keyword or its alias `LOCAL`.

### Important

In the event that a table on the master becomes corrupted and you run `REPAIR TABLE` on it, any resulting changes to the original table are *not* propagated to slaves.

You may be able to increase `REPAIR TABLE` performance by setting certain system variables. See [Section 9.6.3, “Speed of REPAIR TABLE Statements”](#).

`REPAIR TABLE` catches and throws any errors that occur while copying table statistics from the old corrupted file to the newly created file. For example, if the user ID of the owner of the `.frm`, `.MYD`, or `.MYI` file is different from the user ID of the `mysqld` process, `REPAIR TABLE` generates a "cannot change ownership of the file" error unless `mysqld` is started by the `root` user.

## 14.7.3 Plugin and User-Defined Function Statements

### 14.7.3.1 CREATE FUNCTION Syntax for User-Defined Functions

```
CREATE [AGGREGATE] FUNCTION function_name RETURNS {STRING|INTEGER|REAL|DECIMAL}
      SONAME shared_library_name
```

A user-defined function (UDF) is a way to extend MySQL with a new function that works like a native (built-in) MySQL function such as `ABS()` or `CONCAT()`.

*function\_name* is the name that should be used in SQL statements to invoke the function. The `RETURNS` clause indicates the type of the function's return value. `DECIMAL` is a legal value after `RETURNS`, but currently `DECIMAL` functions return string values and should be written like `STRING` functions.

*shared\_library\_name* is the base name of the shared library file that contains the code that implements the function. The file must be located in the plugin directory. This directory is given by the value of the `plugin_dir` system variable. For more information, see [Section 27.4.2.5, “UDF Compiling and Installing”](#).

To create a function, you must have the `INSERT` privilege for the `mysql` database. This is necessary because `CREATE FUNCTION` adds a row to the `mysql.func` system table that records the function's name, type, and shared library name. If you do not have this table, you should run the `mysql_upgrade` command to create it. See [Section 5.4.7, “mysql\\_upgrade — Check and Upgrade MySQL Tables”](#).

An active function is one that has been loaded with `CREATE FUNCTION` and not removed with `DROP FUNCTION`. All active functions are reloaded each time the server starts, unless you start `mysqld` with the `--skip-grant-tables` option. In this case, UDF initialization is skipped and UDFs are unavailable.

For instructions on writing user-defined functions, see [Section 27.4.2, “Adding a New User-Defined Function”](#). For the UDF mechanism to work, functions must be written in C or C++ (or another language that can use C calling conventions), your operating system must support dynamic loading and you must have compiled `mysqld` dynamically (not statically).

An `AGGREGATE` function works exactly like a native MySQL aggregate (summary) function such as `SUM` or `COUNT()`. For `AGGREGATE` to work, your `mysql.func` table must contain a `type` column. If your `mysql.func` table does not have this column, you should run the `mysql_upgrade` program to create it (see [Section 5.4.7, “mysql\\_upgrade — Check and Upgrade MySQL Tables”](#)).

**Note**

To upgrade the shared library associated with a UDF, issue a `DROP FUNCTION` statement, upgrade the shared library, and then issue a `CREATE FUNCTION` statement. If you upgrade the shared library first and then use `DROP FUNCTION`, the server may crash.

### 14.7.3.2 DROP FUNCTION Syntax

```
DROP FUNCTION function_name
```

This statement drops the user-defined function (UDF) named *function\_name*.

To drop a function, you must have the `DELETE` privilege for the `mysql` database. This is because `DROP FUNCTION` removes a row from the `mysql.func` system table that records the function's name, type, and shared library name.

**Note**

To upgrade the shared library associated with a UDF, issue a `DROP FUNCTION` statement, upgrade the shared library, and then issue a `CREATE FUNCTION` statement. If you upgrade the shared library first and then use `DROP FUNCTION`, the server may crash.

`DROP FUNCTION` is also used to drop stored functions (see [Section 14.1.27, “DROP PROCEDURE and DROP FUNCTION Syntax”](#)).

### 14.7.3.3 INSTALL PLUGIN Syntax

```
INSTALL PLUGIN plugin_name SONAME 'shared_library_name'
```

This statement installs a server plugin. It requires the `INSERT` privilege for the `mysql.plugin` system table.

*plugin\_name* is the name of the plugin as defined in the plugin descriptor structure contained in the library file (see [Section 27.2.4.2, “Plugin Data Structures”](#)). Plugin names are not case sensitive. For maximal compatibility, plugin names should be limited to ASCII letters, digits, and underscore because they are used in C source files, shell command lines, M4 and Bourne shell scripts, and SQL environments.

*shared\_library\_name* is the name of the shared library that contains the plugin code. The name includes the file name extension (for example, `libmyplugin.so`, `libmyplugin.dll`, or `libmyplugin.dylib`).

The shared library must be located in the plugin directory (the directory named by the `plugin_dir` system variable). The library must be in the plugin directory itself, not in a subdirectory. By default, `plugin_dir` is the `plugin` directory under the directory named by the `pkglibdir` configuration variable, but it can be changed by setting the value of `plugin_dir` at server startup. For example, set its value in a `my.cnf` file:

```
[mysqld]
plugin_dir=/path/to/plugin/directory
```

If the value of `plugin_dir` is a relative path name, it is taken to be relative to the MySQL base directory (the value of the `basedir` system variable).

`INSTALL PLUGIN` loads and initializes the plugin code to make the plugin available for use. A plugin is initialized by executing its initialization function, which handles any setup that the plugin must perform before it can be used. When the server shuts down, it executes the deinitialization function for each plugin that is loaded so that the plugin has a chance to perform any final cleanup.

`INSTALL PLUGIN` also registers the plugin by adding a line that indicates the plugin name and library file name to the `mysql.plugin` table. At server startup, the server loads and initializes any plugin that is listed in the `mysql.plugin` table. This means that a plugin is installed with `INSTALL PLUGIN` only once, not every time the server starts. Plugin loading at startup does not occur if the server is started with the `--skip-grant-tables` option.

A plugin library can contain multiple plugins. For each of them to be installed, use a separate `INSTALL PLUGIN` statement. Each statement names a different plugin, but all of them specify the same library name.

`INSTALL PLUGIN` causes the server to read option (`my.cnf`) files just as during server startup. This enables the plugin to pick up any relevant options from those files. It is possible to add plugin options to an option file even before loading a plugin (if the `loose` prefix is used). It is also possible to uninstall a plugin, edit `my.cnf`, and install the plugin again. Restarting the plugin this way enables it to the new option values without a server restart.

For options that control individual plugin loading at server startup, see [Section 6.5.2, “Installing and Uninstalling Plugins”](#). If you need to load plugins for a single server startup when the `--skip-grant-tables` option is given (which tells the server not to read system tables), use the `--plugin-load` option. See [Section 6.1.4, “Server Command Options”](#).

To remove a plugin, use the `UNINSTALL PLUGIN` statement.

For additional information about plugin loading, see [Section 6.5.2, “Installing and Uninstalling Plugins”](#).

To see what plugins are installed, use the `SHOW PLUGINS` statement or query the `INFORMATION_SCHEMA.PLUGINS` table.

If you recompile a plugin library and need to reinstall it, you can use either of the following methods:

- Use `UNINSTALL PLUGIN` to uninstall all plugins in the library, install the new plugin library file in the plugin directory, and then use `INSTALL PLUGIN` to install all plugins in the library. This procedure has the advantage that it can be used without stopping the server. However, if the plugin library contains many plugins, you must issue many `INSTALL PLUGIN` and `UNINSTALL PLUGIN` statements.
- Stop the server, install the new plugin library file in the plugin directory, and restart the server.

#### 14.7.3.4 UNINSTALL PLUGIN Syntax

```
UNINSTALL PLUGIN plugin_name
```

This statement removes an installed server plugin. It requires the `DELETE` privilege for the `mysql.plugin` system table. `UNINSTALL PLUGIN` is the complement of `INSTALL PLUGIN`.

*plugin\_name* must be the name of some plugin that is listed in the `mysql.plugin` table. The server executes the plugin's deinitialization function and removes the row for the plugin from the `mysql.plugin` table, so that subsequent server restarts will not load and initialize the plugin. `UNINSTALL PLUGIN` does not remove the plugin's shared library file.

You cannot uninstall a plugin if any table that uses it is open.

Plugin removal has implications for the use of associated tables. For example, if a full-text parser plugin is associated with a `FULLTEXT` index on the table, uninstalling the plugin makes the table unusable. Any attempt to access the table results in an error. The table cannot even be opened, so you cannot drop an index for which the plugin is used. This means that uninstalling a plugin is something to do with care unless you do not care about the table contents. If you are uninstalling a plugin with no intention of reinstalling it later and you care about the table contents, you should dump the table with `mysqldump` and remove the `WITH PARSE` clause from the dumped `CREATE TABLE` statement so that you can

reload the table later. If you do not care about the table, `DROP TABLE` can be used even if any plugins associated with the table are missing.

For additional information about plugin loading, see [Section 6.5.2, “Installing and Uninstalling Plugins”](#).

## 14.7.4 SET Syntax

The `SET` statement has several forms:

- `SET var_name = value` enables you to assign values to variables that affect the operation of the server or clients. See [Section 14.7.4.1, “SET Syntax for Variable Assignment”](#).
- `SET CHARACTER SET` and `SET NAMES` assign values to character set and collation variables associated with the current connection to the server. See [Section 14.7.4.2, “SET CHARACTER SET Syntax”](#), and [Section 14.7.4.3, “SET NAMES Syntax”](#).
- `SET PASSWORD` assigns account passwords. See [Section 14.7.1.7, “SET PASSWORD Syntax”](#).
- `SET TRANSACTION ISOLATION LEVEL` sets the isolation level for transaction processing. See [Section 14.3.6, “SET TRANSACTION Syntax”](#).

### 14.7.4.1 SET Syntax for Variable Assignment

```
SET variable_assignment [, variable_assignment] ...

variable_assignment:
    user_var_name = expr
  | param_name = expr
  | local_var_name = expr
  | [GLOBAL | SESSION]
    system_var_name = expr
  | [@@global. | @@session. | @@]
    system_var_name = expr
```

`SET` syntax for variable assignment enables you to assign values to different types of variables that affect the operation of the server or clients:

- System variables. See [Section 6.1.5, “Server System Variables”](#). System variables also can be set at server startup, as described in [Section 6.1.6, “Using System Variables”](#). (To *display* system variable names and values, use the `SHOW VARIABLES` statement; see [Section 14.7.5.39, “SHOW VARIABLES Syntax”](#).)
- User-defined variables. See [Section 10.4, “User-Defined Variables”](#).
- Stored procedure and function parameters, and stored program local variables. See [Section 14.6.4, “Variables in Stored Programs”](#).

A `SET` statement that assigns variable values is not written to the binary log, so in replication scenarios it affects only the host on which you execute it. To affect all replication hosts, execute the statement on each one.

The following examples illustrate `SET` syntax for setting variables. They use the `=` assignment operator, but the `:=` assignment operator is also permitted for this purpose.

A user variable is written as `@var_name` and is assigned an expression value as follows:

```
SET @var_name = expr;
```

Examples:

```
SET @name = 43;
```

```
SET @total_tax = (SELECT SUM(tax) FROM taxable_transactions);
```

The *expr* can range from simple (a literal value) to more complex (the value returned by a scalar subquery).

**SET** applies to parameters and local variables in the context of the stored object within which they are defined. The following procedure uses the *counter* local variable as a loop counter:

```
CREATE PROCEDURE p()
BEGIN
  DECLARE counter INT DEFAULT 0;
  WHILE counter < 10 DO
    -- ... do work ...
    SET counter = counter + 1;
  END WHILE;
END;
```

Many system variables are dynamic and can be changed at runtime by using the **SET** statement. For a list, see [Section 6.1.6.2, “Dynamic System Variables”](#). To change a system variable with **SET**, refer to it by name, optionally preceded by a modifier:

- To indicate that a variable is a global variable, precede its name by the **GLOBAL** keyword or the *@@global.* qualifier:

```
SET GLOBAL max_connections = 1000;
SET @@global.max_connections = 1000;
```

The **SUPER** privilege is required to set global variables.

- To indicate that a variable is a session variable, precede its name by the **SESSION** keyword or either the *@@session.* or *@@* qualifier:

```
SET SESSION sql_mode = 'TRADITIONAL';
SET @@session.sql_mode = 'TRADITIONAL';
SET @@sql_mode = 'TRADITIONAL';
```

Setting a session variable normally requires no special privilege, although there are exceptions that require the **SUPER** privilege (such as *sql\_log\_bin*). A client can change its own session variables, but not those of any other client.

- **LOCAL** and *@@local.* are synonyms for **SESSION** and *@@session..*
- If no modifier is present, **SET** changes the session variable. If the variable has no session value, an error occurs.

```
mysql> SET max_connections = 1000;
ERROR 1229 (HY000): Variable 'max_connections' is a
GLOBAL variable and should be set with SET GLOBAL
```

- An error occurs under these circumstances:
  - Use of **SET GLOBAL** (or *@@global.*) when setting a variable that has only a session value
  - Omission of **GLOBAL** (or *@@global.*) when setting a variable that has only a global value
  - Use of **SET SESSION** (or *@@SESSION.*) when setting a variable that has only a global value

The preceding modifiers apply only to system variables. An error occurs for attempts to apply them to user-defined variables, stored procedure or function parameters, or stored program local variables.

A **SET** statement can contain multiple variable assignments, separated by commas. This statement assigns values to a user-defined variable and a system variable:

```
SET @x = 1, SESSION sql_mode = '';
```

If you set multiple system variables, the most recent [GLOBAL](#) or [SESSION](#) modifier in the statement is used for following assignments that have no modifier specified.

Examples of multiple-variable assignment:

```
SET GLOBAL sort_buffer_size = 1000000, SESSION sort_buffer_size = 1000000;
SET @@global.sort_buffer_size = 1000000, @@local.sort_buffer_size = 1000000;
SET GLOBAL max_connections = 1000, sort_buffer_size = 1000000;
```

If any variable assignment in a [SET](#) statement fails, the entire statement fails and no variables are changed.

If you change a session system variable, the value remains in effect within your session until you change the variable to a different value or the session ends. The change has no effect on other sessions.

If you change a global system variable, the value is remembered and used for new sessions until you change the variable to a different value or the server exits. The change is visible to any client that accesses the global variable. However, the change affects the corresponding session variable only for clients that connect after the change. The global variable change does not affect the session variable for any current client sessions (not even the session within which the [SET GLOBAL](#) statement occurred).

To make a global system variable setting permanent so that it applies across server restarts, you should also set it in an option file.

To set a [GLOBAL](#) value to the compiled-in MySQL default value or a [SESSION](#) variable to the current corresponding [GLOBAL](#) value, set the variable to the value [DEFAULT](#). For example, the following two statements are identical in setting the session value of [max\\_join\\_size](#) to the current global value:

```
SET @@session.max_join_size=DEFAULT;
SET @@session.max_join_size=@@global.max_join_size;
```

Not all system variables can be set to [DEFAULT](#). In such cases, assigning [DEFAULT](#) results in an error.

An error occurs for attempts to assign [DEFAULT](#) to user-defined variables, stored procedure or function parameters, or stored program local variables.

To refer to the value of a system variable in expressions, use one of the @@-modifiers. For example, you can retrieve values in a [SELECT](#) statement like this:

```
SELECT @@global.sql_mode, @@session.sql_mode, @@sql_mode;
```

For a reference to a system variable in an expression as @@*var\_name* (rather than with @@[global.](#) or @@[session.](#)), MySQL returns the session value if it exists and the global value otherwise. This differs from [SET @@var\\_name = expr](#), which always refers to the session value.

#### 14.7.4.2 SET CHARACTER SET Syntax

```
SET {CHARACTER SET | CHARSET}
    {charset_name | DEFAULT}
```

This statement maps all strings sent between the server and the current client with the given mapping. [SET CHARACTER SET](#) sets three session system variables: [character\\_set\\_client](#) and [character\\_set\\_results](#) are set to the given character set, and [character\\_set\\_connection](#)

to the value of `character_set_database`. See [Section 11.1.4, “Connection Character Sets and Collations”](#).

The default character set mapping can be restored by using the value `DEFAULT`. The default depends on the server configuration.

`ucs2`, `utf16`, and `utf32` cannot be used as a client character set, which means that they do not work for `SET CHARACTER SET`.

### 14.7.4.3 SET NAMES Syntax

```
SET NAMES { 'charset_name'
           [COLLATE 'collation_name'] | DEFAULT }
```

This statement sets the three session system variables `character_set_client`, `character_set_connection`, and `character_set_results` to the given character set. Setting `character_set_connection` to `charset_name` also sets `collation_connection` to the default collation for `charset_name`. See [Section 11.1.4, “Connection Character Sets and Collations”](#).

The optional `COLLATE` clause may be used to specify a collation explicitly. If given, the collation must one of the permitted collations for `charset_name`.

The default mapping can be restored by using a value of `DEFAULT`. The default depends on the server configuration.

`ucs2`, `utf16`, and `utf32` cannot be used as a client character set, which means that they do not work for `SET NAMES`.

## 14.7.5 SHOW Syntax

`SHOW` has many forms that provide information about databases, tables, columns, or status information about the server. This section describes those following:

```
SHOW {BINARY | MASTER} LOGS
SHOW BINLOG EVENTS [IN 'log_name'] [FROM pos] [LIMIT [offset,] row_count]
SHOW CHARACTER SET [like_or_where]
SHOW COLLATION [like_or_where]
SHOW [FULL] COLUMNS FROM tbl_name [FROM db_name] [like_or_where]
SHOW CREATE DATABASE db_name
SHOW CREATE EVENT event_name
SHOW CREATE FUNCTION func_name
SHOW CREATE PROCEDURE proc_name
SHOW CREATE TABLE tbl_name
SHOW CREATE TRIGGER trigger_name
SHOW CREATE VIEW view_name
SHOW DATABASES [like_or_where]
SHOW ENGINE engine_name {STATUS | MUTEX}
SHOW [STORAGE] ENGINES
SHOW ERRORS [LIMIT [offset,] row_count]
SHOW EVENTS
SHOW FUNCTION CODE func_name
SHOW FUNCTION STATUS [like_or_where]
SHOW GRANTS FOR user
SHOW INDEX FROM tbl_name [FROM db_name]
SHOW MASTER STATUS
SHOW OPEN TABLES [FROM db_name] [like_or_where]
SHOW PLUGINS
SHOW PROCEDURE CODE proc_name
SHOW PROCEDURE STATUS [like_or_where]
SHOW PRIVILEGES
SHOW [FULL] PROCESSLIST
SHOW PROFILE [types] [FOR QUERY n] [OFFSET n] [LIMIT n]
SHOW PROFILES
SHOW RELAYLOG EVENTS [IN 'log_name'] [FROM pos] [LIMIT [offset,] row_count]
SHOW SLAVE HOSTS
```

```
SHOW SLAVE STATUS [NONBLOCKING]
SHOW [GLOBAL | SESSION] STATUS [like_or_where]
SHOW TABLE STATUS [FROM db_name] [like_or_where]
SHOW [FULL] TABLES [FROM db_name] [like_or_where]
SHOW TRIGGERS [FROM db_name] [like_or_where]
SHOW [GLOBAL | SESSION] VARIABLES [like_or_where]
SHOW WARNINGS [LIMIT [offset,] row_count]
```

```
like_or_where:
    LIKE 'pattern'
    | WHERE expr
```

If the syntax for a given `SHOW` statement includes a `LIKE 'pattern'` part, '*pattern*' is a string that can contain the SQL `%` and `_` wildcard characters. The pattern is useful for restricting statement output to matching values.

Several `SHOW` statements also accept a `WHERE` clause that provides more flexibility in specifying which rows to display. See [Section 23.34, “Extensions to SHOW Statements”](#).

Many MySQL APIs (such as PHP) enable you to treat the result returned from a `SHOW` statement as you would a result set from a `SELECT`; see [Chapter 26, Connectors and APIs](#), or your API documentation for more information. In addition, you can work in SQL with results from queries on tables in the `INFORMATION_SCHEMA` database, which you cannot easily do with results from `SHOW` statements. See [Chapter 23, INFORMATION\\_SCHEMA Tables](#).

### 14.7.5.1 SHOW BINARY LOGS Syntax

```
SHOW BINARY LOGS
SHOW MASTER LOGS
```

Lists the binary log files on the server. This statement is used as part of the procedure described in [Section 14.4.1.1, “PURGE BINARY LOGS Syntax”](#), that shows how to determine which logs can be purged.

```
mysql> SHOW BINARY LOGS;
+-----+-----+
| Log_name          | File_size |
+-----+-----+
| binlog.000015     | 724935    |
| binlog.000016     | 733481    |
+-----+-----+
```

`SHOW MASTER LOGS` is equivalent to `SHOW BINARY LOGS`.

A user with the `SUPER` or `REPLICATION CLIENT` privilege may execute this statement.

### 14.7.5.2 SHOW BINLOG EVENTS Syntax

```
SHOW BINLOG EVENTS
    [IN 'log_name'] [FROM pos] [LIMIT [offset,] row_count]
```

Shows the events in the binary log. If you do not specify '*log\_name*', the first binary log is displayed.

The `LIMIT` clause has the same syntax as for the `SELECT` statement. See [Section 14.2.9, “SELECT Syntax”](#).

#### Note

Issuing a `SHOW BINLOG EVENTS` with no `LIMIT` clause could start a very time- and resource-consuming process because the server returns to the client the complete contents of the binary log (which includes all statements executed by the server that modify data). As an alternative to `SHOW BINLOG EVENTS`, use

the `mysqlbinlog` utility to save the binary log to a text file for later examination and analysis. See [Section 5.6.7, “mysqlbinlog — Utility for Processing Binary Log Files”](#).

#### Note

Some events relating to the setting of user and system variables are not included in the output from `SHOW BINLOG EVENTS`. To get complete coverage of events within a binary log, use `mysqlbinlog`.

#### Note

`SHOW BINLOG EVENTS` does *not* work with relay log files. You can use `SHOW RELAYLOG EVENTS` for this purpose.

### 14.7.5.3 SHOW CHARACTER SET Syntax

```
SHOW CHARACTER SET
[LIKE 'pattern' | WHERE expr]
```

The `SHOW CHARACTER SET` statement shows all available character sets. The `LIKE` clause, if present, indicates which character set names to match. The `WHERE` clause can be given to select rows using more general conditions, as discussed in [Section 23.34, “Extensions to SHOW Statements”](#). For example:

```
mysql> SHOW CHARACTER SET LIKE 'latin%';
+-----+-----+-----+-----+
| Charset | Description | Default collation | Maxlen |
+-----+-----+-----+-----+
| latin1  | cp1252 West European | latin1_swedish_ci | 1 |
| latin2  | ISO 8859-2 Central European | latin2_general_ci | 1 |
| latin5  | ISO 8859-9 Turkish | latin5_turkish_ci | 1 |
| latin7  | ISO 8859-13 Baltic | latin7_general_ci | 1 |
+-----+-----+-----+-----+
```

The `Maxlen` column shows the maximum number of bytes required to store one character.

The `filename` character set is for internal use only; consequently, `SHOW CHARACTER SET` does not display it.

You can also obtain information about character sets from `INFORMATION_SCHEMA`, which contains a `CHARACTER_SETS` table. See [Section 23.1, “The INFORMATION\\_SCHEMA CHARACTER\\_SETS Table”](#).

### 14.7.5.4 SHOW COLLATION Syntax

```
SHOW COLLATION
[LIKE 'pattern' | WHERE expr]
```

This statement lists collations supported by the server. By default, the output from `SHOW COLLATION` includes all available collations. The `LIKE` clause, if present, indicates which collation names to match. The `WHERE` clause can be given to select rows using more general conditions, as discussed in [Section 23.34, “Extensions to SHOW Statements”](#). For example:

```
mysql> SHOW COLLATION WHERE Charset = 'latin1';
+-----+-----+-----+-----+-----+-----+
| Collation | Charset | Id | Default | Compiled | Sortlen |
+-----+-----+-----+-----+-----+-----+
| latin1_german1_ci | latin1 | 5 | | Yes | 1 |
| latin1_swedish_ci | latin1 | 8 | Yes | Yes | 1 |
| latin1_danish_ci | latin1 | 15 | | Yes | 1 |
+-----+-----+-----+-----+-----+-----+
```

|                   |        |    |  |     |   |
|-------------------|--------|----|--|-----|---|
| latin1_german2_ci | latin1 | 31 |  | Yes | 2 |
| latin1_bin        | latin1 | 47 |  | Yes | 1 |
| latin1_general_ci | latin1 | 48 |  | Yes | 1 |
| latin1_general_cs | latin1 | 49 |  | Yes | 1 |
| latin1_spanish_ci | latin1 | 94 |  | Yes | 1 |

The [Collation](#) and [Charset](#) columns indicate the names of the collation and the character set with which it is associated. [Id](#) is the collation ID. [Default](#) indicates whether the collation is the default for its character set. [Compiled](#) indicates whether the character set is compiled into the server. [Sortlen](#) is related to the amount of memory required to sort strings expressed in the character set.

To see the default collation for each character set, use the following statement. [Default](#) is a reserved word, so to use it as an identifier, it must be quoted as such:

```
mysql> SHOW COLLATION WHERE `Default` = 'Yes';
```

| Collation         | Charset | Id | Default | Compiled | Sortlen |
|-------------------|---------|----|---------|----------|---------|
| big5_chinese_ci   | big5    | 1  | Yes     | Yes      | 1       |
| dec8_swedish_ci   | dec8    | 3  | Yes     | Yes      | 1       |
| cp850_general_ci  | cp850   | 4  | Yes     | Yes      | 1       |
| hp8_english_ci    | hp8     | 6  | Yes     | Yes      | 1       |
| koi8r_general_ci  | koi8r   | 7  | Yes     | Yes      | 1       |
| latin1_swedish_ci | latin1  | 8  | Yes     | Yes      | 1       |

...

You can also obtain information about collations from [INFORMATION\\_SCHEMA](#), which contains a [COLLATIONS](#) table. See [Section 23.2, “The INFORMATION\\_SCHEMA COLLATIONS Table”](#).

### 14.7.5.5 SHOW COLUMNS Syntax

```
SHOW [FULL] COLUMNS {FROM | IN} tbl_name [{FROM | IN} db_name]
[LIKE 'pattern' | WHERE expr]
```

[SHOW COLUMNS](#) displays information about the columns in a given table. It also works for views. The [LIKE](#) clause, if present, indicates which column names to match. The [WHERE](#) clause can be given to select rows using more general conditions, as discussed in [Section 23.34, “Extensions to SHOW Statements”](#).

[SHOW COLUMNS](#) displays information only for those columns for which you have some privilege.

```
mysql> SHOW COLUMNS FROM City;
```

| Field      | Type     | Null | Key | Default | Extra          |
|------------|----------|------|-----|---------|----------------|
| Id         | int(11)  | NO   | PRI | NULL    | auto_increment |
| Name       | char(35) | NO   |     |         |                |
| Country    | char(3)  | NO   | UNI |         |                |
| District   | char(20) | YES  | MUL |         |                |
| Population | int(11)  | NO   |     | 0       |                |

5 rows in set (0.00 sec)

If the data types differ from what you expect them to be based on a [CREATE TABLE](#) statement, note that MySQL sometimes changes data types when you create or alter a table. The conditions under which this occurs are described in [Section 14.1.18.6, “Silent Column Specification Changes”](#).

The [FULL](#) keyword causes the output to include the column collation and comments, as well as the privileges you have for each column.

You can use [db\\_name.tbl\\_name](#) as an alternative to the [tbl\\_name FROM db\\_name](#) syntax. In other words, these two statements are equivalent:

```
mysql> SHOW COLUMNS FROM mytable FROM mydb;  
mysql> SHOW COLUMNS FROM mydb.mytable;
```

`SHOW COLUMNS` displays the following values for each table column:

`Field` indicates the column name.

`Type` indicates the column data type.

`Collation` indicates the collation for nonbinary string columns, or `NULL` for other columns. This value is displayed only if you use the `FULL` keyword.

The `Null` field contains `YES` if `NULL` values can be stored in the column, `NO` if not.

The `Key` field indicates whether the column is indexed:

- If `Key` is empty, the column either is not indexed or is indexed only as a secondary column in a multiple-column, nonunique index.
- If `Key` is `PRI`, the column is a `PRIMARY KEY` or is one of the columns in a multiple-column `PRIMARY KEY`.
- If `Key` is `UNI`, the column is the first column of a `UNIQUE` index. (A `UNIQUE` index permits multiple `NULL` values, but you can tell whether the column permits `NULL` by checking the `Null` field.)
- If `Key` is `MUL`, the column is the first column of a nonunique index in which multiple occurrences of a given value are permitted within the column.

If more than one of the `Key` values applies to a given column of a table, `Key` displays the one with the highest priority, in the order `PRI`, `UNI`, `MUL`.

A `UNIQUE` index may be displayed as `PRI` if it cannot contain `NULL` values and there is no `PRIMARY KEY` in the table. A `UNIQUE` index may display as `MUL` if several columns form a composite `UNIQUE` index; although the combination of the columns is unique, each column can still hold multiple occurrences of a given value.

The `Default` field indicates the default value that is assigned to the column. This is `NULL` if the column has an explicit default of `NULL`, or if the column definition has no `DEFAULT` clause.

The `Extra` field contains any additional information that is available about a given column. The value is nonempty in these cases:

- `auto_increment` for columns that have the `AUTO_INCREMENT` attribute
- `on update CURRENT_TIMESTAMP` for `TIMESTAMP` or `DATETIME` columns that have the `ON UPDATE CURRENT_TIMESTAMP` attribute
- `VIRTUAL GENERATED` or `VIRTUAL STORED` for generated columns

`Privileges` indicates the privileges you have for the column. This value is displayed only if you use the `FULL` keyword.

`Comment` indicates any comment the column has. This value is displayed only if you use the `FULL` keyword.

`SHOW FIELDS` is a synonym for `SHOW COLUMNS`. You can also list a table's columns with the `mysqlshow db_name tbl_name` command.

The `DESCRIBE` statement provides information similar to `SHOW COLUMNS`. See [Section 14.8.1, “DESCRIBE Syntax”](#).

The `SHOW CREATE TABLE`, `SHOW TABLE STATUS`, and `SHOW INDEX` statements also provide information about tables. See [Section 14.7.5, “SHOW Syntax”](#).

### 14.7.5.6 SHOW CREATE DATABASE Syntax

```
SHOW CREATE {DATABASE | SCHEMA} [IF NOT EXISTS] db_name
```

Shows the `CREATE DATABASE` statement that creates the named database. If the `SHOW` statement includes an `IF NOT EXISTS` clause, the output too includes such a clause. `SHOW CREATE SCHEMA` is a synonym for `SHOW CREATE DATABASE`.

```
mysql> SHOW CREATE DATABASE test\G
***** 1. row *****
      Database: test
Create Database: CREATE DATABASE `test`
                  /*!40100 DEFAULT CHARACTER SET latin1 */

mysql> SHOW CREATE SCHEMA test\G
***** 1. row *****
      Database: test
Create Database: CREATE DATABASE `test`
                  /*!40100 DEFAULT CHARACTER SET latin1 */
```

`SHOW CREATE DATABASE` quotes table and column names according to the value of the `sql_quote_show_create` option. See [Section 6.1.5, “Server System Variables”](#).

### 14.7.5.7 SHOW CREATE EVENT Syntax

```
SHOW CREATE EVENT event_name
```

This statement displays the `CREATE EVENT` statement needed to re-create a given event. It requires the `EVENT` privilege for the database from which the event is to be shown. For example (using the same event `e_daily` defined and then altered in [Section 14.7.5.18, “SHOW EVENTS Syntax”](#)):

```
mysql> SHOW CREATE EVENT test.e_daily\G
***** 1. row *****
      Event: e_daily
      sql_mode:
      time_zone: SYSTEM
Create Event: CREATE EVENT `e_daily`
              ON SCHEDULE EVERY 1 DAY
              STARTS CURRENT_TIMESTAMP + INTERVAL 6 HOUR
              ON COMPLETION NOT PRESERVE
              ENABLE
              COMMENT 'Saves total number of sessions then
                      clears the table each day'
              DO BEGIN
                INSERT INTO site_activity.totals (time, total)
                  SELECT CURRENT_TIMESTAMP, COUNT(*)
                    FROM site_activity.sessions;
                DELETE FROM site_activity.sessions;
              END
character_set_client: latin1
collation_connection: latin1_swedish_ci
Database Collation: latin1_swedish_ci
```

`character_set_client` is the session value of the `character_set_client` system variable when the event was created. `collation_connection` is the session value of the `collation_connection` system variable when the event was created. `Database Collation` is the collation of the database with which the event is associated.

The output reflects the current status of the event (`ENABLE`) rather than the status with which it was created.

### 14.7.5.8 SHOW CREATE FUNCTION Syntax

```
SHOW CREATE FUNCTION func_name
```

This statement is similar to `SHOW CREATE PROCEDURE` but for stored functions. See [Section 14.7.5.9, “SHOW CREATE PROCEDURE Syntax”](#).

### 14.7.5.9 SHOW CREATE PROCEDURE Syntax

```
SHOW CREATE PROCEDURE proc_name
```

This statement is a MySQL extension. It returns the exact string that can be used to re-create the named stored procedure. A similar statement, `SHOW CREATE FUNCTION`, displays information about stored functions (see [Section 14.7.5.8, “SHOW CREATE FUNCTION Syntax”](#)).

To use either statement, you must be the user named in the routine `DEFINER` clause or have `SELECT` access to the `mysql.proc` table. If you do not have privileges for the routine itself, the value displayed for the `Create Procedure` or `Create Function` field will be `NULL`.

```
mysql> SHOW CREATE PROCEDURE test.simpleproc\G
***** 1. row *****
      Procedure: simpleproc
      sql_mode:
  Create Procedure: CREATE PROCEDURE `simpleproc` (OUT param1 INT)
                    BEGIN
                    SELECT COUNT(*) INTO param1 FROM t;
                    END
character_set_client: latin1
collation_connection: latin1_swedish_ci
  Database Collation: latin1_swedish_ci

mysql> SHOW CREATE FUNCTION test.hello\G
***** 1. row *****
      Function: hello
      sql_mode:
  Create Function: CREATE FUNCTION `hello` (s CHAR(20))
                    RETURNS CHAR(50)
                    RETURN CONCAT('Hello, ',s, '!')
character_set_client: latin1
collation_connection: latin1_swedish_ci
  Database Collation: latin1_swedish_ci
```

`character_set_client` is the session value of the `character_set_client` system variable when the routine was created. `collation_connection` is the session value of the `collation_connection` system variable when the routine was created. `Database Collation` is the collation of the database with which the routine is associated.

### 14.7.5.10 SHOW CREATE TABLE Syntax

```
SHOW CREATE TABLE tbl_name
```

Shows the `CREATE TABLE` statement that creates the named table. To use this statement, you must have some privilege for the table. This statement also works with views.

```
mysql> SHOW CREATE TABLE t\G
***** 1. row *****
      Table: t
  Create Table: CREATE TABLE `t` (
    `id` int(11) NOT NULL AUTO_INCREMENT,
    `s` char(60) DEFAULT NULL,
    PRIMARY KEY (`id`)
  ) ENGINE=InnoDB DEFAULT CHARSET=latin1
```

`SHOW CREATE TABLE` quotes table and column names according to the value of the `sql_quote_show_create` option. See [Section 6.1.5, “Server System Variables”](#).

### 14.7.5.11 SHOW CREATE TRIGGER Syntax

```
SHOW CREATE TRIGGER trigger_name
```

This statement shows the `CREATE TRIGGER` statement that creates the named trigger. This statement requires the `TRIGGER` privilege for the table associated with the trigger.

```
mysql> SHOW CREATE TRIGGER ins_sum\G
***** 1. row *****
      Trigger: ins_sum
      sql_mode: STRICT_TRANS_TABLES,NO_ENGINE_SUBSTITUTION
SQL Original Statement: CREATE DEFINER=`me`@`localhost` TRIGGER ins_sum
                        BEFORE INSERT ON account
                        FOR EACH ROW SET @sum = @sum + NEW.amount
      character_set_client: utf8
      collation_connection: utf8_general_ci
      Database Collation: latin1_swedish_ci
      Created: 2013-07-09 10:39:34.96
```

`SHOW CREATE TRIGGER` output has the following columns:

- `Trigger`: The trigger name.
- `sql_mode`: The SQL mode in effect when the trigger executes.
- `SQL Original Statement`: The `CREATE TRIGGER` statement that defines the trigger.
- `character_set_client`: The session value of the `character_set_client` system variable when the trigger was created.
- `collation_connection`: The session value of the `collation_connection` system variable when the trigger was created.
- `Database Collation`: The collation of the database with which the trigger is associated.
- `Created`: The date and time when the trigger was created. This is a `TIMESTAMP(2)` value (with a fractional part in hundredths of seconds) for triggers created in MySQL 5.7.2 or later, `NULL` for triggers created prior to 5.7.2. This column was added in MySQL 5.7.2.

You can also obtain information about trigger objects from `INFORMATION_SCHEMA`, which contains a `TRIGGERS` table. See [Section 23.28, “The INFORMATION\\_SCHEMA TRIGGERS Table”](#).

### 14.7.5.12 SHOW CREATE USER Syntax

```
SHOW CREATE USER user
```

This statement shows the `CREATE USER` statement that creates the named user. An error occurs if the user does not exist. The statement requires the `SELECT` privilege for the `mysql` database, except to see the privileges for the current user.

To name the account, use the format described in [Section 7.2.3, “Specifying Account Names”](#). The host name part of the account name, if omitted, defaults to `'%'`. It is also possible to specify `CURRENT_USER` or `CURRENT_USER()` to refer to the account associated with the current session.

```
mysql> SHOW CREATE USER 'root'@'localhost'\G
***** 1. row *****
CREATE USER for root@localhost: CREATE USER 'root'@'localhost'
IDENTIFIED WITH 'mysql_native_password'
```

```
AS '*2470C0C06DEE42FD1618BB99005ADCA2EC9D1E19'
REQUIRE NONE PASSWORD EXPIRE DEFAULT ACCOUNT UNLOCK
```

The output format is affected by the setting of the `log_built_in_as_identified_by_password` system variable (`log_backward_compatible_user_definitions` before MySQL 5.7.9).

This statement was added in MySQL 5.7.6.

To display the privileges granted to an account, use the `SHOW GRANTS` statement. See [Section 14.7.5.21, “SHOW GRANTS Syntax”](#).

### 14.7.5.13 SHOW CREATE VIEW Syntax

```
SHOW CREATE VIEW view_name
```

This statement shows the `CREATE VIEW` statement that creates the named view.

```
mysql> SHOW CREATE VIEW v\G
***** 1. row *****
      View: v
      Create View: CREATE ALGORITHM=UNDEFINED
                   DEFINER=`bob`@`localhost`
                   SQL SECURITY DEFINER VIEW
                   `v` AS select 1 AS `a`,2 AS `b`
character_set_client: latin1
collation_connection: latin1_swedish_ci
```

`character_set_client` is the session value of the `character_set_client` system variable when the view was created. `collation_connection` is the session value of the `collation_connection` system variable when the view was created.

Use of `SHOW CREATE VIEW` requires the `SHOW VIEW` privilege, and the `SELECT` privilege for the view in question.

You can also obtain information about view objects from `INFORMATION_SCHEMA`, which contains a `VIEWS` table. See [Section 23.30, “The INFORMATION\\_SCHEMA VIEWS Table”](#).

MySQL lets you use different `sql_mode` settings to tell the server the type of SQL syntax to support. For example, you might use the `ANSI` SQL mode to ensure MySQL correctly interprets the standard SQL concatenation operator, the double bar (`||`), in your queries. If you then create a view that concatenates items, you might worry that changing the `sql_mode` setting to a value different from `ANSI` could cause the view to become invalid. But this is not the case. No matter how you write out a view definition, MySQL always stores it the same way, in a canonical form. Here is an example that shows how the server changes a double bar concatenation operator to a `CONCAT()` function:

```
mysql> SET sql_mode = 'ANSI';
Query OK, 0 rows affected (0.00 sec)

mysql> CREATE VIEW test.v AS SELECT 'a' || 'b' as coll;
Query OK, 0 rows affected (0.01 sec)

mysql> SHOW CREATE VIEW test.v\G
***** 1. row *****
      View: v
      Create View: CREATE VIEW "v" AS select concat('a','b') AS "coll"
...
1 row in set (0.00 sec)
```

The advantage of storing a view definition in canonical form is that changes made later to the value of `sql_mode` will not affect the results from the view. However an additional consequence is that comments prior to `SELECT` are stripped from the definition by the server.

### 14.7.5.14 SHOW DATABASES Syntax

```
SHOW {DATABASES | SCHEMAS}
    [LIKE 'pattern' | WHERE expr]
```

`SHOW DATABASES` lists the databases on the MySQL server host. `SHOW SCHEMAS` is a synonym for `SHOW DATABASES`. The `LIKE` clause, if present, indicates which database names to match. The `WHERE` clause can be given to select rows using more general conditions, as discussed in [Section 23.34, “Extensions to SHOW Statements”](#).

You see only those databases for which you have some kind of privilege, unless you have the global `SHOW DATABASES` privilege. You can also get this list using the `mysqlshow` command.

If the server was started with the `--skip-show-database` option, you cannot use this statement at all unless you have the `SHOW DATABASES` privilege.

MySQL implements databases as directories in the data directory, so this statement simply lists directories in that location. However, the output may include names of directories that do not correspond to actual databases.

### 14.7.5.15 SHOW ENGINE Syntax

```
SHOW ENGINE engine_name {STATUS | MUTEX}
```

`SHOW ENGINE` displays operational information about a storage engine. It requires the `PROCESS` privilege. The statement has these variants:

```
SHOW ENGINE INNODB STATUS
SHOW ENGINE INNODB MUTEX
SHOW ENGINE PERFORMANCE_SCHEMA STATUS
```

`SHOW ENGINE INNODB STATUS` displays extensive information from the standard `InnoDB` Monitor about the state of the `InnoDB` storage engine. For information about the standard monitor and other `InnoDB` Monitors that provide information about `InnoDB` processing, see [Section 15.17, “InnoDB Monitors”](#).

`SHOW ENGINE INNODB MUTEX` displays `InnoDB mutex` and `rw-lock` statistics.

#### Note

`InnoDB` mutexes and rwlocks can also be monitored using [Performance Schema](#) tables. See [Section 15.16.2, “Monitoring InnoDB Mutex Waits Using Performance Schema”](#).

`SHOW ENGINE INNODB MUTEX` output was removed in MySQL 5.7.2. It was revised and reintroduced in MySQL 5.7.8.

In MySQL 5.7.8, mutex statistics collection is configured dynamically using the following options:

- To enable the collection of mutex statistics, run:

```
SET GLOBAL innodb_monitor_enable='latch';
```

- To reset mutex statistics, run:

```
SET GLOBAL innodb_monitor_reset='latch';
```

- To disable the collection of mutex statistics, run:

```
SET GLOBAL innodb_monitor_disable='latch';
```

Collection of mutex statistics for `SHOW ENGINE INNODB MUTEX` can also be enabled by setting `innodb_monitor_enable='all'`, or disabled by setting `innodb_monitor_disable='all'`.

`SHOW ENGINE INNODB MUTEX` output has the following columns:

- `Type`

Always `InnoDB`.

- `Name`

Prior to MySQL 5.7.8, the `Name` field reports the source file where the mutex is implemented, and the line number in the file where the mutex is created. The line number is specific to your version of MySQL. As of MySQL 5.7.8, only the mutex name is reported. File name and line number are still reported for rwlocks.

- `Status`

The mutex status.

Prior to MySQL 5.7.8, the `Status` field displays several values if `WITH_DEBUG` was defined at MySQL compilation time. If `WITH_DEBUG` was not defined, the statement displays only the `os_waits` value. In the latter case (without `WITH_DEBUG`), the information on which the output is based is insufficient to distinguish regular mutexes and mutexes that protect rwlocks (which permit multiple readers or a single writer). Consequently, the output may appear to contain multiple rows for the same mutex. Pre-MySQL 5.7.8 `Status` field values include:

- `count` indicates how many times the mutex was requested.
- `spin_waits` indicates how many times the spinlock had to run.
- `spin_rounds` indicates the number of spinlock rounds. (`spin_rounds` divided by `spin_waits` provides the average round count.)
- `os_waits` indicates the number of operating system waits. This occurs when the spinlock did not work (the mutex was not locked during the spinlock and it was necessary to yield to the operating system and wait).
- `os_yields` indicates the number of times a thread trying to lock a mutex gave up its timeslice and yielded to the operating system (on the presumption that permitting other threads to run will free the mutex so that it can be locked).
- `os_wait_times` indicates the amount of time (in ms) spent in operating system waits. In MySQL 5.7 timing is disabled and this value is always 0.

As of MySQL 5.7.8, the `Status` field reports the number of spins, waits, and calls. Statistics for low-level operating system mutexes, which are implemented outside of `InnoDB`, are not reported.

- `spins` indicates the number of spins.
- `waits` indicates the number of mutex waits.
- `calls` indicates how many times the mutex was requested.

`SHOW ENGINE INNODB MUTEX` skips the `mutexes` and `rw-locks` of `buffer pool` blocks, as the amount of output can be overwhelming on systems with a large buffer pool. (There is one mutex and one rw-lock in each 16K buffer pool block, and there are 65,536 blocks per gigabyte.) `SHOW ENGINE INNODB MUTEX` also does not list any mutexes or rw-locks that have never been waited on (`os_waits=0`). Thus, `SHOW ENGINE INNODB MUTEX` only displays information about mutexes and rw-locks outside of the buffer pool that have caused at least one OS-level `wait`.

Use `SHOW ENGINE PERFORMANCE_SCHEMA STATUS` to inspect the internal operation of the Performance Schema code:

```
mysql> SHOW ENGINE PERFORMANCE_SCHEMA STATUS\G
...
***** 3. row *****
  Type: performance_schema
  Name: events_waits_history.size
Status: 76
***** 4. row *****
  Type: performance_schema
  Name: events_waits_history.count
Status: 10000
***** 5. row *****
  Type: performance_schema
  Name: events_waits_history.memory
Status: 760000
...
***** 57. row *****
  Type: performance_schema
  Name: performance_schema.memory
Status: 26459600
...
```

This statement is intended to help the DBA understand the effects that different Performance Schema options have on memory requirements.

**Name** values consist of two parts, which name an internal buffer and a buffer attribute, respectively. Interpret buffer names as follows:

- An internal buffer that is not exposed as a table is named within parentheses. Examples: `(pfs_cond_class).size`, `(pfs_mutex_class).memory`.
- An internal buffer that is exposed as a table in the `performance_schema` database is named after the table, without parentheses. Examples: `events_waits_history.size`, `mutex_instances.count`.
- A value that applies to the Performance Schema as a whole begins with `performance_schema`. Example: `performance_schema.memory`.

Buffer attributes have these meanings:

- **size** is the size of the internal record used by the implementation, such as the size of a row in a table. **size** values cannot be changed.
- **count** is the number of internal records, such as the number of rows in a table. **count** values can be changed using Performance Schema configuration options.
- For a table, `tbl_name.memory` is the product of **size** and **count**. For the Performance Schema as a whole, `performance_schema.memory` is the sum of all the memory used (the sum of all other **memory** values).

Some **size** and **count** attributes were named **row\_size** and **row\_count** before MySQL 5.7.1.

In some cases, there is a direct relationship between a Performance Schema configuration parameter and a `SHOW ENGINE` value. For example, `events_waits_history_long.count` corresponds to `performance_schema_events_waits_history_long.size`. In other cases, the relationship is more complex. For example, `events_waits_history.count` corresponds to `performance_schema_events_waits_history_size` (the number of rows per thread) multiplied by `performance_schema_max_thread_instances` (the number of threads).

**SHOW ENGINE NDB STATUS.** If the server has the **NDB** storage engine enabled, `SHOW ENGINE NDB STATUS` displays cluster status information such as the number of connected data nodes, the cluster connectstring, and cluster binary log epochs, as well as counts of various Cluster API objects created by the MySQL Server when connected to the cluster. Sample output from this statement is shown here:

```
mysql> SHOW ENGINE NDB STATUS;
```

| Type       | Name                  | Status   |
|------------|-----------------------|--|
| ndbcluster | connection            | cluster_node_id=7,<br>connected_host=192.168.0.103, connected_port=1186, number_of_data_nodes=4,<br>number_of_ready_data_nodes=3, connect_count=0  |
| ndbcluster | NdbTransaction        | created=6, free=0, sizeof=212  |
| ndbcluster | NdbOperation          | created=8, free=8, sizeof=660  |
| ndbcluster | NdbIndexScanOperation | created=1, free=1, sizeof=744  |
| ndbcluster | NdbIndexOperation     | created=0, free=0, sizeof=664  |
| ndbcluster | NdbRecAttr            | created=1285, free=1285, sizeof=60   |
| ndbcluster | NdbApiSignal          | created=16, free=16, sizeof=136  |
| ndbcluster | NdbLabel              | created=0, free=0, sizeof=196  |
| ndbcluster | NdbBranch             | created=0, free=0, sizeof=24   |
| ndbcluster | NdbSubroutine         | created=0, free=0, sizeof=68   |
| ndbcluster | NdbCall               | created=0, free=0, sizeof=16   |
| ndbcluster | NdbBlob               | created=1, free=1, sizeof=264  |
| ndbcluster | NdbReceiver           | created=4, free=0, sizeof=68   |
| ndbcluster | binlog                | latest_epoch=155467, latest_trans_epoch=148126,<br>latest_received_binlog_epoch=0, latest_handled_binlog_epoch=0,<br>latest_applied_binlog_epoch=0 |

The **Status** column in each of these rows provides information about the MySQL server's connection to the cluster and about the cluster binary log's status, respectively. The **Status** information is in the form of comma-delimited set of name/value pairs.

The **connection** row's **Status** column contains the name/value pairs described in the following table.

| Name                                    | Value   |
|---|---|
| <code>cluster_node_id</code>            | The node ID of the MySQL server in the cluster  |
| <code>connected_host</code>             | The host name or IP address of the cluster management server to which the MySQL server is connected   |
| <code>connected_port</code>             | The port used by the MySQL server to connect to the management server ( <code>connected_host</code> )   |
| <code>number_of_data_nodes</code>       | The number of data nodes configured for the cluster (that is, the number of <code>[ndbd]</code> sections in the cluster <code>config.ini</code> file) |
| <code>number_of_ready_data_nodes</code> | The number of data nodes in the cluster that are actually running   |
| <code>connect_count</code>              | The number of times this <code>mysqld</code> has connected or reconnected to cluster data nodes   |

The **binlog** row's **Status** column contains information relating to MySQL Cluster Replication. The name/value pairs it contains are described in the following table.

| Name                                      | Value  |
|---|--|
| <code>latest_epoch</code>                 | The most recent epoch most recently run on this MySQL server (that is, the sequence number of the most recent transaction run on the server) |
| <code>latest_trans_epoch</code>           | The most recent epoch processed by the cluster's data nodes  |
| <code>latest_received_binlog_epoch</code> | The most recent epoch received by the binary log thread  |
| <code>latest_handled_binlog_epoch</code>  | The most recent epoch processed by the binary log thread (for writing to the binary log)   |
| <code>latest_applied_binlog_epoch</code>  | The most recent epoch actually written to the binary log   |

See [Section 20.6, “NDB Cluster Replication”](#), for more information.

The remaining rows from the output of `SHOW ENGINE NDB STATUS` which are most likely to prove useful in monitoring the cluster are listed here by *Name*:

- **NdbTransaction**: The number and size of **NdbTransaction** objects that have been created. An **NdbTransaction** is created each time a table schema operation (such as `CREATE TABLE` or `ALTER TABLE`) is performed on an **NDB** table.
- **NdbOperation**: The number and size of **NdbOperation** objects that have been created.
- **NdbIndexScanOperation**: The number and size of **NdbIndexScanOperation** objects that have been created.
- **NdbIndexOperation**: The number and size of **NdbIndexOperation** objects that have been created.
- **NdbRecAttr**: The number and size of **NdbRecAttr** objects that have been created. In general, one of these is created each time a data manipulation statement is performed by an SQL node.
- **NdbBlob**: The number and size of **NdbBlob** objects that have been created. An **NdbBlob** is created for each new operation involving a **BLOB** column in an **NDB** table.
- **NdbReceiver**: The number and size of any **NdbReceiver** object that have been created. The number in the *created* column is the same as the number of data nodes in the cluster to which the MySQL server has connected.

#### Note

`SHOW ENGINE NDB STATUS` returns an empty result if no operations involving **NDB** tables have been performed during the current session by the MySQL client accessing the SQL node on which this statement is run.

### 14.7.5.16 SHOW ENGINES Syntax

```
SHOW [STORAGE] ENGINES
```

`SHOW ENGINES` displays status information about the server's storage engines. This is particularly useful for checking whether a storage engine is supported, or to see what the default engine is. This information can also be obtained from the `INFORMATION_SCHEMA.ENGINES` table. See [Section 23.6, “The INFORMATION\\_SCHEMA.ENGINES Table”](#).

```
mysql> SHOW ENGINES\G
***** 1. row *****
      Engine: InnoDB
      Support: DEFAULT
      Comment: Supports transactions, row-level locking, and foreign keys
Transactions: YES
          XA: YES
      Savepoints: YES
***** 2. row *****
      Engine: MRG_MYISAM
      Support: YES
      Comment: Collection of identical MyISAM tables
Transactions: NO
          XA: NO
      Savepoints: NO
***** 3. row *****
      Engine: MEMORY
      Support: YES
      Comment: Hash based, stored in memory, useful for temporary tables
Transactions: NO
          XA: NO
```

```

Savepoints: NO
***** 4. row *****
  Engine: BLACKHOLE
  Support: YES
  Comment: /dev/null storage engine (anything you write to it disappears)
Transactions: NO
  XA: NO
  Savepoints: NO
***** 5. row *****
  Engine: MyISAM
  Support: YES
  Comment: MyISAM storage engine
Transactions: NO
  XA: NO
  Savepoints: NO
***** 6. row *****
  Engine: CSV
  Support: YES
  Comment: CSV storage engine
Transactions: NO
  XA: NO
  Savepoints: NO
***** 7. row *****
  Engine: ARCHIVE
  Support: YES
  Comment: Archive storage engine
Transactions: NO
  XA: NO
  Savepoints: NO
***** 8. row *****
  Engine: PERFORMANCE_SCHEMA
  Support: YES
  Comment: Performance Schema
Transactions: NO
  XA: NO
  Savepoints: NO
***** 9. row *****
  Engine: FEDERATED
  Support: YES
  Comment: Federated MySQL storage engine
Transactions: NO
  XA: NO
  Savepoints: NO

```

The output from `SHOW ENGINES` may vary according to the MySQL version used and other factors. The values shown in the `Support` column indicate the server's level of support for the storage engine, as shown in the following table.

| Value                 | Meaning   |
|-----------------------|---|
| <code>YES</code>      | The engine is supported and is active                   |
| <code>DEFAULT</code>  | Like <code>YES</code> , plus this is the default engine |
| <code>NO</code>       | The engine is not supported                             |
| <code>DISABLED</code> | The engine is supported but has been disabled           |

A value of `NO` means that the server was compiled without support for the engine, so it cannot be enabled at runtime.

A value of `DISABLED` occurs either because the server was started with an option that disables the engine, or because not all options required to enable it were given. In the latter case, the error log file should contain a reason indicating why the option is disabled. See [Section 6.4.2, “The Error Log”](#).

You might also see `DISABLED` for a storage engine if the server was compiled to support it, but was started with a `--skip-engine_name` option.

All MySQL servers support `MyISAM` tables. It is not possible to disable `MyISAM`.

The [Transactions](#), [XA](#), and [Savepoints](#) columns indicate whether the storage engine supports transactions, XA transactions, and savepoints, respectively.

### 14.7.5.17 SHOW ERRORS Syntax

```
SHOW ERRORS [LIMIT [offset,] row_count]
SHOW COUNT(*) ERRORS
```

**SHOW ERRORS** is a diagnostic statement that is similar to **SHOW WARNINGS**, except that it displays information only for errors, rather than for errors, warnings, and notes.

The **LIMIT** clause has the same syntax as for the **SELECT** statement. See [Section 14.2.9, “SELECT Syntax”](#).

The **SHOW COUNT(\*) ERRORS** statement displays the number of errors. You can also retrieve this number from the `error_count` variable:

```
SHOW COUNT(*) ERRORS;
SELECT @@error_count;
```

**SHOW ERRORS** and `error_count` apply only to errors, not warnings or notes. In other respects, they are similar to **SHOW WARNINGS** and `warning_count`. In particular, **SHOW ERRORS** cannot display information for more than `max_error_count` messages, and `error_count` can exceed the value of `max_error_count` if the number of errors exceeds `max_error_count`.

For more information, see [Section 14.7.5.40, “SHOW WARNINGS Syntax”](#).

### 14.7.5.18 SHOW EVENTS Syntax

```
SHOW EVENTS [{FROM | IN} schema_name]
           [LIKE 'pattern' | WHERE expr]
```

This statement displays information about Event Manager events. It requires the [EVENT](#) privilege for the database from which the events are to be shown.

In its simplest form, **SHOW EVENTS** lists all of the events in the current schema:

```
mysql> SELECT CURRENT_USER(), SCHEMA();
+-----+-----+
| CURRENT_USER() | SCHEMA() |
+-----+-----+
| jon@ghidora   | myschema |
+-----+-----+
1 row in set (0.00 sec)

mysql> SHOW EVENTS\G
***** 1. row *****
      Db: myschema
      Name: e_daily
      Definer: jon@ghidora
      Time zone: SYSTEM
      Type: RECURRING
      Execute at: NULL
      Interval value: 10
      Interval field: SECOND
      Starts: 2006-02-09 10:41:23
      Ends: NULL
      Status: ENABLED
      Originator: 0
character_set_client: latin1
collation_connection: latin1_swedish_ci
Database Collation: latin1_swedish_ci
```

To see events for a specific schema, use the `FROM` clause. For example, to see events for the `test` schema, use the following statement:

```
SHOW EVENTS FROM test;
```

The `LIKE` clause, if present, indicates which event names to match. The `WHERE` clause can be given to select rows using more general conditions, as discussed in [Section 23.34](#), “Extensions to `SHOW Statements`”.

`SHOW EVENTS` output has the following columns:

- **Db**: The schema (database) on which the event is defined.
- **Name**: The name of the event.
- **Time zone**: The event time zone, which is the time zone used for scheduling the event and that is in effect within the event as it executes. The default value is `SYSTEM`.
- **Definer**: The account of the user who created the event, in `'user_name'@'host_name'` format.
- **Type**: The event repetition type, either `ONE TIME` (transient) or `RECURRING` (repeating).
- **Execute At**: The date and time when a transient event is set to execute. Shown as a `DATETIME` value.

For a recurring event, the value of this column is always `NULL`.

- **Interval Value**: For a recurring event, the number of intervals to wait between event executions.

For a transient event, the value of this column is always `NULL`.

- **Interval Field**: The time units used for the interval which a recurring event waits before repeating.

For a transient event, the value of this column is always `NULL`.

- **Starts**: The start date and time for a recurring event. This is displayed as a `DATETIME` value, and is `NULL` if no start date and time are defined for the event.

For a transient event, this column is always `NULL`.

- **Ends**: The end date and time for a recurring event. This is displayed as a `DATETIME` value, and defaults to `NULL` if no end date and time is defined for the event.

For a transient event, this column is always `NULL`.

- **Status**: The event status. One of `ENABLED`, `DISABLED`, or `SLAVESIDE_DISABLED`.

`SLAVESIDE_DISABLED` indicates that the creation of the event occurred on another MySQL server acting as a replication master and replicated to the current MySQL server which is acting as a slave, but the event is not presently being executed on the slave.

- **Originator**: The server ID of the MySQL server on which the event was created. Defaults to 0.
- `character_set_client` is the session value of the `character_set_client` system variable when the routine was created. `collation_connection` is the session value of the `collation_connection` system variable when the routine was created. `Database Collation` is the collation of the database with which the routine is associated.

For more information about `SLAVE_DISABLED` and the `Originator` column, see [Section 18.4.1.12](#), “Replication of Invoked Features”.

The event action statement is not shown in the output of `SHOW EVENTS`. Use `SHOW CREATE EVENT` or the `INFORMATION_SCHEMA.EVENTS` table.

Times displayed by `SHOW EVENTS` are given in the event time zone, as discussed in [Section 22.4.4, “Event Metadata”](#).

The columns in the output of `SHOW EVENTS` are similar to, but not identical to the columns in the `INFORMATION_SCHEMA.EVENTS` table. See [Section 23.7, “The INFORMATION\\_SCHEMA EVENTS Table”](#).

#### 14.7.5.19 SHOW FUNCTION CODE Syntax

```
SHOW FUNCTION CODE func_name
```

This statement is similar to `SHOW PROCEDURE CODE` but for stored functions. See [Section 14.7.5.27, “SHOW PROCEDURE CODE Syntax”](#).

#### 14.7.5.20 SHOW FUNCTION STATUS Syntax

```
SHOW FUNCTION STATUS
  [LIKE 'pattern' | WHERE expr]
```

This statement is similar to `SHOW PROCEDURE STATUS` but for stored functions. See [Section 14.7.5.28, “SHOW PROCEDURE STATUS Syntax”](#).

#### 14.7.5.21 SHOW GRANTS Syntax

```
SHOW GRANTS [FOR user]
```

This statement displays the privileges that are assigned to a MySQL user account, in the form of `GRANT` statements that must be executed to duplicate the privilege assignments. `SHOW GRANTS` requires the `SELECT` privilege for the `mysql` database, except to see the privileges for the current user.

For output that includes an `IDENTIFIED BY PASSWORD` clause displaying an account password hash value, the `SUPER` privilege is required to see the actual hash value. Otherwise, the value displays as `<secret>`.

To name the account, use the same format as for the `GRANT` statement; for example, `'jeffrey'@'localhost'`. If you specify only the user name part of the account name, a host name part of `'%'` is used. For additional information about specifying account names, see [Section 14.7.1.4, “GRANT Syntax”](#).

```
mysql> SHOW GRANTS FOR 'root'@'localhost';
+-----+
| Grants for root@localhost |
+-----+
| GRANT ALL PRIVILEGES ON *.* TO 'root'@'localhost' WITH GRANT OPTION |
+-----+
```

To display the privileges granted to the account that you are using to connect to the server, you can use any of the following statements:

```
SHOW GRANTS;
SHOW GRANTS FOR CURRENT_USER;
SHOW GRANTS FOR CURRENT_USER();
```

If `SHOW GRANTS FOR CURRENT_USER` (or any of the equivalent syntaxes) is used in `DEFINER` context, such as within a stored procedure that is defined with `SQL SECURITY DEFINER`, the grants displayed are those of the definer and not the invoker.

`SHOW GRANTS` displays only the privileges granted explicitly to the named account. Other privileges that might be available to the account are not displayed. For example, if an anonymous account exists, the named account might be able to use its privileges, but `SHOW GRANTS` will not display them.

As of MySQL 5.7.6, `SHOW GRANTS` output does not include `IDENTIFIED BY PASSWORD` clauses. Use the `SHOW CREATE USER` statement instead. See [Section 14.7.5.12, “SHOW CREATE USER Syntax”](#).

To display nonprivilege information for MySQL accounts, use the `SHOW CREATE USER` statement.

## 14.7.5.22 SHOW INDEX Syntax

```
SHOW {INDEX | INDEXES | KEYS}
    {FROM | IN} tbl_name
    [{FROM | IN} db_name]
    [WHERE expr]
```

`SHOW INDEX` returns table index information. The format resembles that of the `SQLStatistics` call in ODBC. This statement requires some privilege for any column in the table.

`SHOW INDEX` returns the following fields:

- `Table`

The name of the table.

- `Non_unique`

0 if the index cannot contain duplicates, 1 if it can.

- `Key_name`

The name of the index. If the index is the primary key, the name is always `PRIMARY`.

- `Seq_in_index`

The column sequence number in the index, starting with 1.

- `Column_name`

The column name.

- `Collation`

How the column is sorted in the index. This can have values `A` (ascending) or `NULL` (not sorted).

- `Cardinality`

An estimate of the number of unique values in the index. This is updated by running `ANALYZE TABLE` or `myisamchk -a`. `Cardinality` is counted based on statistics stored as integers, so the value is not necessarily exact even for small tables. The higher the cardinality, the greater the chance that MySQL uses the index when doing joins.

- `Sub_part`

The index prefix. That is, the number of indexed characters if the column is only partly indexed, `NULL` if the entire column is indexed.

### Note

Prefix limits are measured in bytes, whereas the prefix length in `CREATE TABLE`, `ALTER TABLE`, and `CREATE INDEX` statements is interpreted as number of characters for nonbinary string types (`CHAR`, `VARCHAR`, `TEXT`) and

number of bytes for binary string types ([BINARY](#), [VARBINARY](#), [BLOB](#)). Take this into account when specifying a prefix length for a nonbinary string column that uses a multibyte character set.

For additional information about index prefixes, see [Section 14.1.14, “CREATE INDEX Syntax”](#).

- [Packed](#)

Indicates how the key is packed. [NULL](#) if it is not.

- [Null](#)

Contains [YES](#) if the column may contain [NULL](#) values and [''](#) if not.

- [Index\\_type](#)

The index method used ([BTREE](#), [FULLTEXT](#), [HASH](#), [RTREE](#)).

- [Comment](#)

Information about the index not described in its own column, such as [disabled](#) if the index is disabled.

- [Index\\_comment](#)

Any comment provided for the index with a [COMMENT](#) attribute when the index was created.

You can use [db\\_name.tbl\\_name](#) as an alternative to the [tbl\\_name FROM db\\_name](#) syntax. These two statements are equivalent:

```
SHOW INDEX FROM mytable FROM mydb;
SHOW INDEX FROM mydb.mytable;
```

The [WHERE](#) clause can be given to select rows using more general conditions, as discussed in [Section 23.34, “Extensions to SHOW Statements”](#).

You can also list a table's indexes with the [mysqlshow -k db\\_name tbl\\_name](#) command.

### 14.7.5.23 SHOW MASTER STATUS Syntax

```
SHOW MASTER STATUS
```

This statement provides status information about the binary log files of the master. It requires either the [SUPER](#) or [REPLICATION CLIENT](#) privilege.

Example:

```
mysql> SHOW MASTER STATUS\G
***** 1. row *****
      File: master-bin.000002
      Position: 1307
      Binlog_Do_DB: test
      Binlog_Ignore_DB: manual, mysql
      Executed_Gtid_Set: 3E11FA47-71CA-11E1-9E33-C80AA9429562:1-5
1 row in set (0.00 sec)
```

When global transaction IDs are in use, [Executed\\_Gtid\\_Set](#) shows the set of GTIDs for transactions that have been executed on the master. This is the same as the value for the [gtid\\_executed](#) system variable on this server, as well as the value for [Executed\\_Gtid\\_Set](#) in the output of [SHOW SLAVE STATUS](#) on this server.

### 14.7.5.24 SHOW OPEN TABLES Syntax

```
SHOW OPEN TABLES [{FROM | IN} db_name]
[LIKE 'pattern' | WHERE expr]
```

`SHOW OPEN TABLES` lists the non-TEMPORARY tables that are currently open in the table cache. See [Section 9.4.3.1, “How MySQL Opens and Closes Tables”](#). The `FROM` clause, if present, restricts the tables shown to those present in the *db\_name* database. The `LIKE` clause, if present, indicates which table names to match. The `WHERE` clause can be given to select rows using more general conditions, as discussed in [Section 23.34, “Extensions to SHOW Statements”](#).

`SHOW OPEN TABLES` output has the following columns:

- `Database`

The database containing the table.

- `Table`

The table name.

- `In_use`

The number of table locks or lock requests there are for the table. For example, if one client acquires a lock for a table using `LOCK TABLE t1 WRITE`, `In_use` will be 1. If another client issues `LOCK TABLE t1 WRITE` while the table remains locked, the client will block waiting for the lock, but the lock request causes `In_use` to be 2. If the count is zero, the table is open but not currently being used. `In_use` is also increased by the `HANDLER ... OPEN` statement and decreased by `HANDLER ... CLOSE`.

- `Name_locked`

Whether the table name is locked. Name locking is used for operations such as dropping or renaming tables.

If you have no privileges for a table, it does not show up in the output from `SHOW OPEN TABLES`.

## 14.7.5.25 SHOW PLUGINS Syntax

```
SHOW PLUGINS
```

`SHOW PLUGINS` displays information about server plugins. Plugin information is also available in the `INFORMATION_SCHEMA.PLUGINS` table. See [Section 23.16, “The INFORMATION\\_SCHEMA PLUGINS Table”](#).

Example of `SHOW PLUGINS` output:

```
mysql> SHOW PLUGINS\G
***** 1. row *****
  Name: binlog
  Status: ACTIVE
  Type: STORAGE ENGINE
  Library: NULL
  License: GPL
***** 2. row *****
  Name: CSV
  Status: ACTIVE
  Type: STORAGE ENGINE
  Library: NULL
  License: GPL
***** 3. row *****
  Name: MEMORY
  Status: ACTIVE
  Type: STORAGE ENGINE
```

```

Library: NULL
License: GPL
***** 4. row *****
  Name: MyISAM
  Status: ACTIVE
  Type: STORAGE ENGINE
Library: NULL
License: GPL
...

```

`SHOW PLUGINS` output has the following columns:

- **Name:** The name used to refer to the plugin in statements such as `INSTALL PLUGIN` and `UNINSTALL PLUGIN`.
- **Status:** The plugin status, one of `ACTIVE`, `INACTIVE`, `DISABLED`, or `DELETED`.
- **Type:** The type of plugin, such as `STORAGE ENGINE`, `INFORMATION_SCHEMA`, or `AUTHENTICATION`.
- **Library:** The name of the plugin shared library file. This is the name used to refer to the plugin file in statements such as `INSTALL PLUGIN` and `UNINSTALL PLUGIN`. This file is located in the directory named by the `plugin_dir` system variable. If the library name is `NULL`, the plugin is compiled in and cannot be uninstalled with `UNINSTALL PLUGIN`.
- **License:** How the plugin is licensed; for example, `GPL`.

For plugins installed with `INSTALL PLUGIN`, the **Name** and **Library** values are also registered in the `mysql.plugin` table.

For information about plugin data structures that form the basis of the information displayed by `SHOW PLUGINS`, see [Section 27.2, “The MySQL Plugin API”](#).

### 14.7.5.26 SHOW PRIVILEGES Syntax

```
SHOW PRIVILEGES
```

`SHOW PRIVILEGES` shows the list of system privileges that the MySQL server supports. The exact list of privileges depends on the version of your server.

```

mysql> SHOW PRIVILEGES\G
***** 1. row *****
Privilege: Alter
  Context: Tables
  Comment: To alter the table
***** 2. row *****
Privilege: Alter routine
  Context: Functions,Procedures
  Comment: To alter or drop stored functions/procedures
***** 3. row *****
Privilege: Create
  Context: Databases,Tables,Indexes
  Comment: To create new databases and tables
***** 4. row *****
Privilege: Create routine
  Context: Databases
  Comment: To use CREATE FUNCTION/PROCEDURE
***** 5. row *****
Privilege: Create temporary tables
  Context: Databases
  Comment: To use CREATE TEMPORARY TABLE
...

```

Privileges belonging to a specific user are displayed by the `SHOW GRANTS` statement. See [Section 14.7.5.21, “SHOW GRANTS Syntax”](#), for more information.

### 14.7.5.27 SHOW PROCEDURE CODE Syntax

```
SHOW PROCEDURE CODE proc_name
```

This statement is a MySQL extension that is available only for servers that have been built with debugging support. It displays a representation of the internal implementation of the named stored procedure. A similar statement, [SHOW FUNCTION CODE](#), displays information about stored functions (see [Section 14.7.5.19](#), “[SHOW FUNCTION CODE Syntax](#)”).

To use either statement, you must be the owner of the routine or have [SELECT](#) access to the `mysql.proc` table.

If the named routine is available, each statement produces a result set. Each row in the result set corresponds to one “instruction” in the routine. The first column is `Pos`, which is an ordinal number beginning with 0. The second column is `Instruction`, which contains an SQL statement (usually changed from the original source), or a directive which has meaning only to the stored-routine handler.

```
mysql> DELIMITER //
mysql> CREATE PROCEDURE p1 ()
-> BEGIN
-> DECLARE fanta INT DEFAULT 55;
-> DROP TABLE t2;
-> LOOP
-> INSERT INTO t3 VALUES (fanta);
-> END LOOP;
-> END//
Query OK, 0 rows affected (0.00 sec)

mysql> SHOW PROCEDURE CODE p1//
+-----+-----+
| Pos | Instruction |
+-----+-----+
| 0 | set fanta@0 55 |
| 1 | stmt 9 "DROP TABLE t2" |
| 2 | stmt 5 "INSERT INTO t3 VALUES (fanta)" |
| 3 | jump 2 |
+-----+-----+
4 rows in set (0.00 sec)
```

In this example, the nonexecutable `BEGIN` and `END` statements have disappeared, and for the `DECLARE variable_name` statement, only the executable part appears (the part where the default is assigned). For each statement that is taken from source, there is a code word `stmt` followed by a type (9 means `DROP`, 5 means `INSERT`, and so on). The final row contains an instruction `jump 2`, meaning `GOTO instruction #2`.

### 14.7.5.28 SHOW PROCEDURE STATUS Syntax

```
SHOW PROCEDURE STATUS
[LIKE 'pattern' | WHERE expr]
```

This statement is a MySQL extension. It returns characteristics of a stored procedure, such as the database, name, type, creator, creation and modification dates, and character set information. A similar statement, [SHOW FUNCTION STATUS](#), displays information about stored functions (see [Section 14.7.5.20](#), “[SHOW FUNCTION STATUS Syntax](#)”).

The `LIKE` clause, if present, indicates which procedure or function names to match. The `WHERE` clause can be given to select rows using more general conditions, as discussed in [Section 23.34](#), “[Extensions to SHOW Statements](#)”.

```
mysql> SHOW PROCEDURE STATUS LIKE 'sp1'\G
***** 1. row *****
```

```

        Db: test
        Name: spl
        Type: PROCEDURE
        Definer: testuser@localhost
        Modified: 2004-08-03 15:29:37
        Created: 2004-08-03 15:29:37
        Security_type: DEFINER
        Comment:
character_set_client: latin1
collation_connection: latin1_swedish_ci
Database Collation: latin1_swedish_ci

```

`character_set_client` is the session value of the `character_set_client` system variable when the routine was created. `collation_connection` is the session value of the `collation_connection` system variable when the routine was created. `Database Collation` is the collation of the database with which the routine is associated.

You can also get information about stored routines from the `ROUTINES` table in `INFORMATION_SCHEMA`. See [Section 23.20, “The INFORMATION\\_SCHEMA ROUTINES Table”](#).

### 14.7.5.29 SHOW PROCESSLIST Syntax

```
SHOW [FULL] PROCESSLIST
```

`SHOW PROCESSLIST` shows you which threads are running. You can also get this information from the `INFORMATION_SCHEMA.PROCESSLIST` table or the `mysqladmin processlist` command. If you have the `PROCESS` privilege, you can see all threads. Otherwise, you can see only your own threads (that is, threads associated with the MySQL account that you are using). If you do not use the `FULL` keyword, only the first 100 characters of each statement are shown in the `Info` field.

Process information is also available from the `performance_schema.threads` table. However, access to `threads` does not require a mutex and has minimal impact on server performance. `INFORMATION_SCHEMA.PROCESSLIST` and `SHOW PROCESSLIST` have negative performance consequences because they require a mutex. `threads` also shows information about background threads, which `INFORMATION_SCHEMA.PROCESSLIST` and `SHOW PROCESSLIST` do not. This means that `threads` can be used to monitor activity the other thread information sources cannot.

The `SHOW PROCESSLIST` statement is very useful if you get the “too many connections” error message and want to find out what is going on. MySQL reserves one extra connection to be used by accounts that have the `SUPER` privilege, to ensure that administrators should always be able to connect and check the system (assuming that you are not giving this privilege to all your users).

Threads can be killed with the `KILL` statement. See [Section 14.7.6.4, “KILL Syntax”](#).

Here is an example of `SHOW PROCESSLIST` output:

```

mysql> SHOW FULL PROCESSLIST\G
***** 1. row *****
Id: 1
User: system user
Host:
db: NULL
Command: Connect
Time: 1030455
State: Waiting for master to send event
Info: NULL
***** 2. row *****
Id: 2
User: system user
Host:
db: NULL
Command: Connect
Time: 1004
State: Has read all relay log; waiting for the slave

```

```

      I/O thread to update it
Info: NULL
***** 3. row *****
Id: 3112
User: replikator
Host: artemis:2204
db: NULL
Command: Binlog Dump
Time: 2144
State: Has sent all binlog to slave; waiting for binlog to be updated
Info: NULL
***** 4. row *****
Id: 3113
User: replikator
Host: iconnect2:45781
db: NULL
Command: Binlog Dump
Time: 2086
State: Has sent all binlog to slave; waiting for binlog to be updated
Info: NULL
***** 5. row *****
Id: 3123
User: stefan
Host: localhost
db: apollon
Command: Query
Time: 0
State: NULL
Info: SHOW FULL PROCESSLIST
5 rows in set (0.00 sec)

```

The columns produced by `SHOW PROCESSLIST` have the following meanings:

- **Id**

The connection identifier. This is the same type of value displayed in the **Id** column of the `INFORMATION_SCHEMA.PROCESSLIST` table, the `PROCESSLIST_ID` column of the Performance Schema `threads` table, and returned by the `CONNECTION_ID()` function.

- **User**

The MySQL user who issued the statement. If this is `system user`, it refers to a nonclient thread spawned by the server to handle tasks internally. This could be the I/O or SQL thread used on replication slaves or a delayed-row handler. `unauthenticated user` refers to a thread that has become associated with a client connection but for which authentication of the client user has not yet been done. `event_scheduler` refers to the thread that monitors scheduled events. For `system user`, there is no host specified in the **Host** column.

- **Host**

The host name of the client issuing the statement (except for `system user` where there is no host). `SHOW PROCESSLIST` reports the host name for TCP/IP connections in `host_name:client_port` format to make it easier to determine which client is doing what.

- **db**

The default database, if one is selected, otherwise `NULL`.

- **Command**

The type of command the thread is executing. For descriptions for thread commands, see [Section 9.14, “Examining Thread Information”](#). The value of this column corresponds to the `COM_xxx` commands of the client/server protocol and `Com_xxx` status variables. See [Section 6.1.7, “Server Status Variables”](#)

- **Time**

The time in seconds that the thread has been in its current state. For a slave SQL thread, the value is the number of seconds between the timestamp of the last replicated event and the real time of the slave machine. See [Section 18.2.2, “Replication Implementation Details”](#).

- **State**

An action, event, or state that indicates what the thread is doing. Descriptions for **State** values can be found at [Section 9.14, “Examining Thread Information”](#).

Most states correspond to very quick operations. If a thread stays in a given state for many seconds, there might be a problem that needs to be investigated.

For the `SHOW PROCESSLIST` statement, the value of **State** is `NULL`.

- **Info**

The statement the thread is executing, or `NULL` if it is not executing any statement. The statement might be the one sent to the server, or an innermost statement if the statement executes other statements. For example, if a `CALL` statement executes a stored procedure that is executing a `SELECT` statement, the **Info** value shows the `SELECT` statement.

### 14.7.5.30 SHOW PROFILE Syntax

```
SHOW PROFILE [type [, type] ... ]
  [FOR QUERY n]
  [LIMIT row_count [OFFSET offset]]

type:
  ALL
  | BLOCK IO
  | CONTEXT SWITCHES
  | CPU
  | IPC
  | MEMORY
  | PAGE FAULTS
  | SOURCE
  | SWAPS
```

The `SHOW PROFILE` and `SHOW PROFILES` statements display profiling information that indicates resource usage for statements executed during the course of the current session.

#### Note

These statements are deprecated and will be removed in a future MySQL release. Use the [Performance Schema](#) instead; see [Section 24.17.1, “Query Profiling Using Performance Schema”](#).

Profiling is controlled by the `profiling` session variable, which has a default value of 0 (`OFF`). Profiling is enabled by setting `profiling` to 1 or `ON`:

```
mysql> SET profiling = 1;
```

`SHOW PROFILES` displays a list of the most recent statements sent to the server. The size of the list is controlled by the `profiling_history_size` session variable, which has a default value of 15. The maximum value is 100. Setting the value to 0 has the practical effect of disabling profiling.

All statements are profiled except `SHOW PROFILE` and `SHOW PROFILES`, so you will find neither of those statements in the profile list. Malformed statements are profiled. For example, `SHOW PROFILING` is an illegal statement, and a syntax error occurs if you try to execute it, but it will show up in the profiling list.

`SHOW PROFILE` displays detailed information about a single statement. Without the `FOR QUERY n` clause, the output pertains to the most recently executed statement. If `FOR QUERY n` is included, `SHOW PROFILE` displays information for statement *n*. The values of *n* correspond to the `Query_ID` values displayed by `SHOW PROFILES`.

The `LIMIT row_count` clause may be given to limit the output to *row\_count* rows. If `LIMIT` is given, `OFFSET offset` may be added to begin the output *offset* rows into the full set of rows.

By default, `SHOW PROFILE` displays `Status` and `Duration` columns. The `Status` values are like the `State` values displayed by `SHOW PROCESSLIST`, although there might be some minor differences in interpretation for the two statements for some status values (see [Section 9.14, “Examining Thread Information”](#)).

Optional *type* values may be specified to display specific additional types of information:

- `ALL` displays all information
- `BLOCK IO` displays counts for block input and output operations
- `CONTEXT SWITCHES` displays counts for voluntary and involuntary context switches
- `CPU` displays user and system CPU usage times
- `IPC` displays counts for messages sent and received
- `MEMORY` is not currently implemented
- `PAGE FAULTS` displays counts for major and minor page faults
- `SOURCE` displays the names of functions from the source code, together with the name and line number of the file in which the function occurs
- `SWAPS` displays swap counts

Profiling is enabled per session. When a session ends, its profiling information is lost.

```
mysql> SELECT @@profiling;
+-----+
| @@profiling |
+-----+
|          0 |
+-----+
1 row in set (0.00 sec)

mysql> SET profiling = 1;
Query OK, 0 rows affected (0.00 sec)

mysql> DROP TABLE IF EXISTS t1;
Query OK, 0 rows affected, 1 warning (0.00 sec)

mysql> CREATE TABLE t1 (id INT);
Query OK, 0 rows affected (0.01 sec)

mysql> SHOW PROFILES;
+-----+-----+-----+
| Query_ID | Duration | Query |
+-----+-----+-----+
|          0 | 0.000088 | SET PROFILING = 1 |

| checking permissions | 0.000040 |
| creating table       | 0.000056 |
| After create        | 0.011363 |
| query end           | 0.000375 |
| freeing items       | 0.000089 |
| logging slow query  | 0.000019 |
| cleaning up         | 0.000005 |
+-----+-----+
7 rows in set (0.00 sec)

mysql> SHOW PROFILE FOR QUERY 1;
+-----+-----+
| Status          | Duration |
+-----+-----+
| query end       | 0.000107 |
| freeing items   | 0.000008 |
| logging slow query | 0.000015 |
| cleaning up     | 0.000006 |
+-----+-----+
4 rows in set (0.00 sec)

mysql> SHOW PROFILE CPU FOR QUERY 2;
+-----+-----+-----+-----+
| Status          | Duration | CPU_user | CPU_system |
+-----+-----+-----+-----+
| checking permissions | 0.000040 | 0.000038 | 0.000002 |
| creating table       | 0.000056 | 0.000028 | 0.000028 |
| After create        | 0.011363 | 0.000217 | 0.001571 |
| query end           | 0.000375 | 0.000013 | 0.000028 |
| freeing items       | 0.000089 | 0.000010 | 0.000014 |
| logging slow query  | 0.000019 | 0.000009 | 0.000010 |
| cleaning up         | 0.000005 | 0.000003 | 0.000002 |
+-----+-----+-----+-----+
7 rows in set (0.00 sec)

```

**Note**

Profiling is only partially functional on some architectures. For values that depend on the `getrusage()` system call, `NULL` is returned on systems such as Windows that do not support the call. In addition, profiling is per process and not per thread. This means that activity on threads within the server other than your own may affect the timing information that you see.

You can also get profiling information from the `PROFILING` table in `INFORMATION_SCHEMA`. See [Section 23.18, “The INFORMATION\\_SCHEMA PROFILING Table”](#). For example, the following queries produce the same result:

```

SHOW PROFILE FOR QUERY 2;

SELECT STATE, FORMAT(DURATION, 6) AS DURATION
FROM INFORMATION_SCHEMA.PROFILING
WHERE QUERY_ID = 2 ORDER BY SEQ;

```

### 14.7.5.31 SHOW PROFILES Syntax

```
SHOW PROFILES
```

The `SHOW PROFILES` statement, together with `SHOW PROFILE`, displays profiling information that indicates resource usage for statements executed during the course of the current session. For more information, see [Section 14.7.5.30, “SHOW PROFILE Syntax”](#).

**Note**

These statements are deprecated and will be removed in a future MySQL release. Use the Performance Schema instead; see [Chapter 24, MySQL Performance Schema](#).

### 14.7.5.32 SHOW RELAYLOG EVENTS Syntax

```
SHOW RELAYLOG EVENTS
[IN 'log_name'] [FROM pos] [LIMIT [offset,] row_count]
```

Shows the events in the relay log of a replication slave. If you do not specify 'log\_name', the first relay log is displayed. This statement has no effect on the master.

The `LIMIT` clause has the same syntax as for the `SELECT` statement. See [Section 14.2.9, “SELECT Syntax”](#).

#### Note

Issuing a `SHOW RELAYLOG EVENTS` with no `LIMIT` clause could start a very time- and resource-consuming process because the server returns to the client the complete contents of the relay log (including all statements modifying data that have been received by the slave).

#### Note

Some events relating to the setting of user and system variables are not included in the output from `SHOW RELAYLOG EVENTS`. To get complete coverage of events within a relay log, use `mysqlbinlog`.

### 14.7.5.33 SHOW SLAVE HOSTS Syntax

```
SHOW SLAVE HOSTS
```

Displays a list of replication slaves currently registered with the master.

`SHOW SLAVE HOSTS` should be executed on a server that acts as a replication master. The statement displays information about servers that are or have been connected as replication slaves, with each row of the result corresponding to one slave server, as shown here:

```
mysql> SHOW SLAVE HOSTS;
+-----+-----+-----+-----+-----+
| Server_id | Host      | Port | Master_id | Slave_UUID |
+-----+-----+-----+-----+-----+
| 192168010 | iconnect2 | 3306 | 192168011 | 14cb6624-7f93-11e0-b2c0-c80aa9429562 |
| 1921680101 | athena    | 3306 | 192168011 | 07af4990-f41f-11df-a566-7ac56fdaf645 |
+-----+-----+-----+-----+-----+
```

- **Server\_id**: The unique server ID of the slave server, as configured in the slave server's option file, or on the command line with `--server-id=value`.
- **Host**: The host name of the slave server as specified on the slave with the `--report-host` option. This can differ from the machine name as configured in the operating system.
- **User**: The slave server user name as, specified on the slave with the `--report-user` option. Statement output includes this column only if the master server is started with the `--show-slave-auth-info` option.
- **Password**: The slave server password as, specified on the slave with the `--report-password` option. Statement output includes this column only if the master server is started with the `--show-slave-auth-info` option.
- **Port**: The port on the master to which the slave server is listening, as specified on the slave with the `--report-port` option.

A zero in this column means that the slave port (`--report-port`) was not set.

- **Master\_id**: The unique server ID of the master server that the slave server is replicating from. This is the server ID of the server on which `SHOW SLAVE HOSTS` is executed, so this same value is listed for each row in the result.
- **Slave\_UUID**: The globally unique ID of this slave, as generated on the slave and found in the slave's `auto.cnf` file.

#### 14.7.5.34 SHOW SLAVE STATUS Syntax

```
SHOW SLAVE STATUS [NONBLOCKING # Removed in MySQL 5.7.6]
                  [FOR CHANNEL channel]
```

This statement provides status information on essential parameters of the slave threads. It requires either the `SUPER` or `REPLICATION CLIENT` privilege.

Between MySQL 5.7.1 and MySQL 5.7.5, an optional `NONBLOCKING` clause could be used. The `NONBLOCKING` clause caused `SHOW SLAVE STATUS`, when run concurrently with `STOP SLAVE`, to return without waiting for `STOP SLAVE` to finish shutting down the slave SQL thread or slave I/O thread (or both). This option was intended for use in monitoring and other applications where getting an immediate response from `SHOW SLAVE STATUS` was more important than ensuring that it returned the latest data. This option was removed in MySQL 5.7.6 due to locking changes in replication administrative statements. As of MySQL 5.7.9 the non-blocking behavior of `SHOW SLAVE STATUS` is fixed and the option became unnecessary.

If you issue this statement using the `mysql` client, you can use a `\G` statement terminator rather than a semicolon to obtain a more readable vertical layout:

```
mysql> SHOW SLAVE STATUS\G
***** 1. row *****
      Slave_IO_State: Waiting for master to send event
      Master_Host: localhost
      Master_User: root
      Master_Port: 13000
      Connect_Retry: 60
      Master_Log_File: master-bin.000002
      Read_Master_Log_Pos: 1307
      Relay_Log_File: slave-relay-bin.000003
      Relay_Log_Pos: 1508

```

As of MySQL 5.7.2, the Performance Schema provides tables that expose replication information. This is similar to the information available from the [SHOW SLAVE STATUS](#) statement, but represented in table form. For details, see [Section 24.10.11, “Performance Schema Replication Tables”](#).

The following list describes the fields returned by [SHOW SLAVE STATUS](#). For additional information about interpreting their meanings, see [Section 18.1.7.1, “Checking Replication Status”](#).

- [Slave\\_IO\\_State](#)

A copy of the [State](#) field of the [SHOW PROCESSLIST](#) output for the slave I/O thread. This tells you what the thread is doing: trying to connect to the master, waiting for events from the master, reconnecting to the master, and so on. For a listing of possible states, see [Section 9.14.5, “Replication Slave I/O Thread States”](#).

- [Master\\_Host](#)

The master host that the slave is connected to.

- [Master\\_User](#)

The user name of the account used to connect to the master.

- [Master\\_Port](#)

The port used to connect to the master.

- [Connect\\_Retry](#)

The number of seconds between connect retries (default 60). This can be set with the [CHANGE MASTER TO](#) statement.

- [Master\\_Log\\_File](#)

The name of the master binary log file from which the I/O thread is currently reading.

- [Read\\_Master\\_Log\\_Pos](#)

The position in the current master binary log file up to which the I/O thread has read.

- [Relay\\_Log\\_File](#)

The name of the relay log file from which the SQL thread is currently reading and executing.

- [Relay\\_Log\\_Pos](#)

The position in the current relay log file up to which the SQL thread has read and executed.

- `Relay_Master_Log_File`

The name of the master binary log file containing the most recent event executed by the SQL thread.

- `Slave_IO_Running`

Whether the I/O thread is started and has connected successfully to the master. Internally, the state of this thread is represented by one of the following three values:

- **MYSQL\_SLAVE\_NOT\_RUN.** The slave I/O thread is not running. For this state, `Slave_IO_Running` is `No`.
- **MYSQL\_SLAVE\_RUN\_NOT\_CONNECT.** The slave I/O thread is running, but is not connected to a replication master. For this state, `Slave_IO_Running` depends on the server version as shown in the following table.

| MySQL Version                                      | Slave_IO_Running |
|--|------------------|
| 4.1 (4.1.13 and earlier); 5.0 (5.0.11 and earlier) | Yes              |
| 4.1 (4.1.14 and later); 5.0 (5.0.12 and later)     | No               |
| 5.1 (5.1.45 and earlier)                           | No               |
| 5.1 (5.1.46 and later); 5.5; 5.6                   | Connecting       |

- **MYSQL\_SLAVE\_RUN\_CONNECT.** The slave I/O thread is running, and is connected to a replication master. For this state, `Slave_IO_Running` is `Yes`.

The value of the `Slave_running` system status variable corresponds with this value.

- `Slave_SQL_Running`

Whether the SQL thread is started.

- `Replicate_Do_DB`, `Replicate_Ignore_DB`

The lists of databases that were specified with the `--replicate-do-db` and `--replicate-ignore-db` options, if any.

- `Replicate_Do_Table`, `Replicate_Ignore_Table`, `Replicate_Wild_Do_Table`, `Replicate_Wild_Ignore_Table`

The lists of tables that were specified with the `--replicate-do-table`, `--replicate-ignore-table`, `--replicate-wild-do-table`, and `--replicate-wild-ignore-table` options, if any.

- `Last_Errno`, `Last_Error`

These columns are aliases for `Last_SQL_Errno` and `Last_SQL_Error`.

Issuing `RESET MASTER` or `RESET SLAVE` resets the values shown in these columns.

#### Note

When the slave SQL thread receives an error, it reports the error first, then stops the SQL thread. This means that there is a small window of time during which `SHOW SLAVE STATUS` shows a nonzero value for `Last_SQL_Errno` even though `Slave_SQL_Running` still displays `Yes`.

- `Skip_Counter`

The current value of the `sql_slave_skip_counter` system variable. See [Section 14.4.2.5, “SET GLOBAL sql\\_slave\\_skip\\_counter Syntax”](#).

- `Exec_Master_Log_Pos`

The position in the current master binary log file to which the SQL thread has read and executed, marking the start of the next transaction or event to be processed. You can use this value with the `CHANGE MASTER TO` statement's `MASTER_LOG_POS` option when starting a new slave from an existing slave, so that the new slave reads from this point. The coordinates given by (`Relay_Master_Log_File`, `Exec_Master_Log_Pos`) in the master's binary log correspond to the coordinates given by (`Relay_Log_File`, `Relay_Log_Pos`) in the relay log.

Inconsistencies in the sequence of transactions from the relay log which have been executed can cause this value to be a “low-water mark”. In other words, transactions appearing before the position are guaranteed to have committed, but transactions after the position may have committed or not. If these gaps need to be corrected, use `START SLAVE UNTIL SQL_AFTER_MTS_GAPS`. See [Section 18.4.1.34, “Replication and Transaction Inconsistencies”](#) for more information.

- `Relay_Log_Space`

The total combined size of all existing relay log files.

- `Until_Condition`, `Until_Log_File`, `Until_Log_Pos`

The values specified in the `UNTIL` clause of the `START SLAVE` statement.

`Until_Condition` has these values:

- `None` if no `UNTIL` clause was specified
- `Master` if the slave is reading until a given position in the master's binary log
- `Relay` if the slave is reading until a given position in its relay log
- `SQL_BEFORE_GTIDS` if the slave SQL thread is processing transactions until it has reached the first transaction whose GTID is listed in the `gtid_set`.
- `SQL_AFTER_GTIDS` if the slave threads are processing all transactions until the last transaction in the `gtid_set` has been processed by both threads.
- `SQL_AFTER_MTS_GAPS` if a multi-threaded slave's SQL threads are running until no more gaps are found in the relay log.

`Until_Log_File` and `Until_Log_Pos` indicate the log file name and position that define the coordinates at which the SQL thread stops executing.

For more information on `UNTIL` clauses, see [Section 14.4.2.6, “START SLAVE Syntax”](#).

- `Master_SSL_Allowed`, `Master_SSL_CA_File`, `Master_SSL_CA_Path`, `Master_SSL_Cert`, `Master_SSL_Cipher`, `Master_SSL_CRL_File`, `Master_SSL_CRL_Path`, `Master_SSL_Key`, `Master_SSL_Verify_Server_Cert`

These fields show the SSL parameters used by the slave to connect to the master, if any.

`Master_SSL_Allowed` has these values:

- `Yes` if an SSL connection to the master is permitted
- `No` if an SSL connection to the master is not permitted
- `Ignored` if an SSL connection is permitted but the slave server does not have SSL support enabled

The values of the other SSL-related fields correspond to the values of the `MASTER_SSL_CA`, `MASTER_SSL_CAPATH`, `MASTER_SSL_CERT`, `MASTER_SSL_CIPHER`, `MASTER_SSL_CRL`,

`MASTER_SSL_CRLPATH`, `MASTER_SSL_KEY`, and `MASTER_SSL_VERIFY_SERVER_CERT` options to the `CHANGE MASTER TO` statement. See [Section 14.4.2.1, “CHANGE MASTER TO Syntax”](#).

- `Seconds_Behind_Master`

This field is an indication of how “late” the slave is:

- When the slave is actively processing updates, this field shows the difference between the current timestamp on the slave and the original timestamp logged on the master for the event currently being processed on the slave.
- When no event is currently being processed on the slave, this value is 0.

In essence, this field measures the time difference in seconds between the slave SQL thread and the slave I/O thread. If the network connection between master and slave is fast, the slave I/O thread is very close to the master, so this field is a good approximation of how late the slave SQL thread is compared to the master. If the network is slow, this is *not* a good approximation; the slave SQL thread may quite often be caught up with the slow-reading slave I/O thread, so `Seconds_Behind_Master` often shows a value of 0, even if the I/O thread is late compared to the master. In other words, *this column is useful only for fast networks*.

This time difference computation works even if the master and slave do not have identical clock times, provided that the difference, computed when the slave I/O thread starts, remains constant from then on. Any changes—including NTP updates—can lead to clock skews that can make calculation of `Seconds_Behind_Master` less reliable.

In MySQL 5.7, this field is `NULL` (undefined or unknown) if the slave SQL thread is not running, or if the SQL thread has consumed all of the relay log and the slave I/O thread is not running. (In older versions of MySQL, this field was `NULL` if the slave SQL thread or the slave I/O thread was not running or was not connected to the master.) If the I/O thread is running but the relay log is exhausted, `Seconds_Behind_Master` is set to 0.

The value of `Seconds_Behind_Master` is based on the timestamps stored in events, which are preserved through replication. This means that if a master M1 is itself a slave of M0, any event from M1's binary log that originates from M0's binary log has M0's timestamp for that event. This enables MySQL to replicate `TIMESTAMP` successfully. However, the problem for `Seconds_Behind_Master` is that if M1 also receives direct updates from clients, the `Seconds_Behind_Master` value randomly fluctuates because sometimes the last event from M1 originates from M0 and sometimes is the result of a direct update on M1.

When using a multi-threaded slave, you should keep in mind that this value is based on `Exec_Master_Log_Pos`, and so may not reflect the position of the most recently committed transaction.

- `Last_IO_Errno`, `Last_IO_Error`

The error number and error message of the most recent error that caused the I/O thread to stop. An error number of 0 and message of the empty string mean “no error.” If the `Last_IO_Error` value is not empty, the error values also appear in the slave's error log.

I/O error information includes a timestamp showing when the most recent I/O thread error occurred. This timestamp uses the format `YYMMDD HH:MM:SS`, and appears in the `Last_SQL_Error_Timestamp` column.

Issuing `RESET MASTER` or `RESET SLAVE` resets the values shown in these columns.

- `Last_SQL_Errno`, `Last_SQL_Error`

The error number and error message of the most recent error that caused the SQL thread to stop. An error number of 0 and message of the empty string mean “no error.” If the `Last_SQL_Error` value is not empty, the error values also appear in the slave's error log.

If the slave is multi-threaded, the SQL thread is the coordinator for worker threads. In this case, as of MySQL 5.7.2, the `Last_SQL_Error` field shows exactly what the `Last_Error_Message` column in the Performance Schema `replication_applier_status_by_coordinator` table shows. The field value is modified to suggest that there may be more failures in the other worker threads which can be seen in the `replication_applier_status_by_worker` table that shows each worker thread's status. If that table is not available, the slave error log can be used. The log or the `replication_applier_status_by_worker` table should also be used to learn more about the failure shown by `SHOW SLAVE STATUS` or the coordinator table.

SQL error information includes a timestamp showing when the most recent SQL thread error occurred. This timestamp uses the format `YYMMDD HH:MM:SS`, and appears in the `Last_SQL_Error_Timestamp` column.

Issuing `RESET MASTER` or `RESET SLAVE` resets the values shown in these columns.

In MySQL 5.7, all error codes and messages displayed in the `Last_SQL_Errno` and `Last_SQL_Error` columns correspond to error values listed in [Section B.3, "Server Error Codes and Messages"](#). This was not always true in previous versions. (Bug #11760365, Bug #52768)

- `Replicate_Ignore_Server_Ids`

In MySQL 5.7, you set a slave to ignore events from 0 or more masters using the `IGNORE_SERVER_IDS` option of the `CHANGE MASTER TO` statement. By default this is blank, and is usually modified only when using a circular or other multi-master replication setup. The message shown for `Replicate_Ignore_Server_Ids` when not blank consists of a comma-delimited list of one or more numbers, indicating the server IDs to be ignored. For example:

```
Replicate_Ignore_Server_Ids: 2, 6, 9
```

#### Note

`Ignored_server_ids` also shows the server IDs to be ignored, but is a space-delimited list, which is preceded by the total number of server IDs to be ignored. For example, if a `CHANGE MASTER TO` statement containing the `IGNORE_SERVER_IDS = (2,6,9)` option has been issued to tell a slave to ignore masters having the server ID 2, 6, or 9, that information appears as shown here:

```
Ignored_server_ids: 3, 2, 6, 9
```

The first number (in this case 3) shows the number of server IDs being ignored.

`Replicate_Ignore_Server_Ids` filtering is performed by the I/O thread, rather than by the SQL thread, which means that events which are filtered out are not written to the relay log. This differs from the filtering actions taken by server options such `--replicate-do-table`, which apply to the SQL thread.

- `Master_Server_Id`

The `server_id` value from the master.

- `Master_UUID`

The `server_uuid` value from the master.

- `Master_Info_File`

The location of the `master.info` file.

- `SQL_Delay`

The number of seconds that the slave must lag the master.

- `SQL_Remaining_Delay`

When `Slave_SQL_Running_State` is `Waiting until MASTER_DELAY seconds after master executed event`, this field contains the number of delay seconds remaining. At other times, this field is `NULL`.

- `Slave_SQL_Running_State`

The state of the SQL thread (analogous to `Slave_IO_State`). The value is identical to the `State` value of the SQL thread as displayed by `SHOW PROCESSLIST`. [Section 9.14.6, “Replication Slave SQL Thread States”](#), provides a listing of possible states

- `Master_Retry_Count`

The number of times the slave can attempt to reconnect to the master in the event of a lost connection. This value can be set using the `MASTER_RETRY_COUNT` option of the `CHANGE MASTER TO` statement (preferred) or the older `--master-retry-count` server option (still supported for backward compatibility).

- `Master_Bind`

The network interface that the slave is bound to, if any. This is set using the `MASTER_BIND` option for the `CHANGE MASTER TO` statement.

- `Last_IO_Error_Timestamp`

A timestamp in `YYMMDD HH:MM:SS` format that shows when the most recent I/O error took place.

- `Last_SQL_Error_Timestamp`

A timestamp in `YYMMDD HH:MM:SS` format that shows when the last SQL error occurred.

- `Retrieved_Gtid_Set`

The set of global transaction IDs corresponding to all transactions received by this slave. Empty if GTIDs are not in use. See [GTID Sets](#) for more information.

This is the set of all GTIDs that exist or have existed in the relay logs. Each GTID is added as soon as the `Gtid_log_event` is received. This can cause partially transmitted transactions to have their GTIDs included in the set.

When all relay logs are lost due to executing `RESET SLAVE` or `CHANGE MASTER TO`, or due to the effects of the `--relay-log-recovery` option, the set is cleared. When `relay_log_purge = 1`, the newest relay log is always kept, and the set is not cleared.

Prior to MySQL 5.7.1, this value was printed using uppercase. In MySQL 5.7.1 and later, it is always printed using lowercase. (Bug #15869441)

- `Executed_Gtid_Set`

The set of global transaction IDs written in the binary log. This is the same as the value for the global `gtid_executed` system variable on this server, as well as the value for `Executed_Gtid_Set` in the output of `SHOW MASTER STATUS` on this server. Empty if GTIDs are not in use. See [GTID Sets](#) for more information.

Prior to MySQL 5.7.1, this value was printed using uppercase. In MySQL 5.7.1 and later, it is always printed using lowercase. (Bug #15869441)

- `Auto_Position`

1 if autopositioning is in use; otherwise 0.

This column was added in MySQL 5.7.1. (Bug #15992220)

- `Replicate_Rewrite_DB`

Beginning with MySQL 5.7.3, the `Replicate_Rewrite_DB` value displays any replication filtering rules that were specified. For example, if the following replication filter rule was set:

```
CHANGE REPLICATION FILTER REPLICATE_REWRITE_DB=((db1,db2), (db3,db4));
```

the `Replicate_Rewrite_DB` value displays:

```
Replicate_Rewrite_DB: (db1,db2),(db3,db4)
```

For more information, see [Section 14.4.2.2, “CHANGE REPLICATION FILTER Syntax”](#).

- `Channel_name`

The replication channel which is being displayed. There is always a default replication channel, and more replication channels can be added. See [Section 18.2.3, “Replication Channels”](#) for more information.

### 14.7.5.35 SHOW STATUS Syntax

```
SHOW [GLOBAL | SESSION] STATUS
    [LIKE 'pattern' | WHERE expr]
```

#### Note

As of MySQL 5.7.6, the value of the `show_compatibility_56` system variable affects the information available from and privileges required for the statement described here. For details, see the description of that variable in [Section 6.1.5, “Server System Variables”](#).

`SHOW STATUS` provides server status information (see [Section 6.1.7, “Server Status Variables”](#)). This statement does not require any privilege. It requires only the ability to connect to the server.

Status variable information is also available from these sources:

- Performance Schema tables. See [Section 24.10.14, “Performance Schema Status Variable Tables”](#).
- The `GLOBAL_STATUS` and `SESSION_STATUS` tables. See [Section 23.9, “The INFORMATION\\_SCHEMA GLOBAL\\_STATUS and SESSION\\_STATUS Tables”](#).
- The `mysqladmin extended-status` command. See [Section 5.5.2, “mysqladmin — Client for Administering a MySQL Server”](#).

For `SHOW STATUS`, a `LIKE` clause, if present, indicates which variable names to match. A `WHERE` clause can be given to select rows using more general conditions, as discussed in [Section 23.34, “Extensions to SHOW Statements”](#).

`SHOW STATUS` accepts an optional `GLOBAL` or `SESSION` variable scope modifier:

- With a `GLOBAL` modifier, the statement displays the global status values. A global status variable may represent status for some aspect of the server itself (for example, `Aborted_connects`), or the aggregated status over all connections to MySQL (for example, `Bytes_received` and `Bytes_sent`). If a variable has no global value, the session value is displayed.
- With a `SESSION` modifier, the statement displays the status variable values for the current connection. If a variable has no session value, the global value is displayed. `LOCAL` is a synonym for `SESSION`.

- If no modifier is present, the default is `SESSION`.

The scope for each status variable is listed at [Section 6.1.7, “Server Status Variables”](#).

Each invocation of the `SHOW STATUS` statement uses an internal temporary table and increments the global `Created_tmp_tables` value.

Partial output is shown here. The list of names and values may differ for your server. The meaning of each variable is given in [Section 6.1.7, “Server Status Variables”](#).

```
mysql> SHOW STATUS;
```

| Variable_name           | Value      |
|-------------------------|------------|
| Aborted_clients         | 0          |
| Aborted_connects        | 0          |
| Bytes_received          | 155372598  |
| Bytes_sent              | 1176560426 |
| Connections             | 30023      |
| Created_tmp_disk_tables | 0          |
| Created_tmp_tables      | 8340       |
| Created_tmp_files       | 60         |
| ...                     |            |
| Open_tables             | 1          |
| Open_files              | 2          |
| Open_streams            | 0          |
| Opened_tables           | 44600      |
| Questions               | 2026873    |
| ...                     |            |
| Table_locks_immediate   | 1920382    |
| Table_locks_waited      | 0          |
| Threads_cached          | 0          |
| Threads_created         | 30022      |
| Threads_connected       | 1          |
| Threads_running         | 1          |
| Uptime                  | 80380      |

With a `LIKE` clause, the statement displays only rows for those variables with names that match the pattern:

```
mysql> SHOW STATUS LIKE 'Key%';
```

| Variable_name      | Value    |
|--------------------|----------|
| Key_blocks_used    | 14955    |
| Key_read_requests  | 96854827 |
| Key_reads          | 162040   |
| Key_write_requests | 7589728  |
| Key_writes         | 3813196  |

### 14.7.5.36 SHOW TABLE STATUS Syntax

```
SHOW TABLE STATUS [{FROM | IN} db_name]
    [LIKE 'pattern' | WHERE expr]
```

`SHOW TABLE STATUS` works like `SHOW TABLES`, but provides a lot of information about each non-`TEMPORARY` table. You can also get this list using the `mysqlshow --status db_name` command. The `LIKE` clause, if present, indicates which table names to match. The `WHERE` clause can be given to select rows using more general conditions, as discussed in [Section 23.34, “Extensions to SHOW Statements”](#).

This statement also displays information about views.

`SHOW TABLE STATUS` output has the following columns:

- `Name`

The name of the table.

- `Engine`

The storage engine for the table. See [Chapter 16, Alternative Storage Engines](#).

- `Version`

The version number of the table's `.frm` file.

- `Row_format`

The row-storage format (`Fixed`, `Dynamic`, `Compressed`, `Redundant`, `Compact`). For `MyISAM` tables, (`Dynamic` corresponds to what `myisamchk -dvv` reports as `Packed`. The format of `InnoDB` tables is reported as `Redundant` or `Compact`. For the `Barracuda` file format of the `InnoDB Plugin`, the format may be `Compressed` or `Dynamic`.

- `Rows`

The number of rows. Some storage engines, such as `MyISAM`, store the exact count. For other storage engines, such as `InnoDB`, this value is an approximation, and may vary from the actual value by as much as 40 to 50%. In such cases, use `SELECT COUNT(*)` to obtain an accurate count.

The `Rows` value is `NULL` for tables in the `INFORMATION_SCHEMA` database.

- `Avg_row_length`

The average row length.

- `Data_length`

For `MyISAM`, `Data_length` is the length of the data file, in bytes.

For `InnoDB`, `Data_length` is the approximate amount of memory allocated for the clustered index, in bytes. Specifically, it is the clustered index size, in pages, multiplied by the `InnoDB` page size.

Refer to the notes at the end of this section for information regarding other storage engines.

- `Max_data_length`

For `MyISAM`, `Max_data_length` is maximum length of the data file. This is the total number of bytes of data that can be stored in the table, given the data pointer size used.

Unused for `InnoDB`.

Refer to the notes at the end of this section for information regarding other storage engines.

- `Index_length`

For `MyISAM`, `Index_length` is the length of the index file, in bytes.

For `InnoDB`, `Index_length` is the approximate amount of memory allocated for non-clustered indexes, in bytes. Specifically, it is the sum of non-clustered index sizes, in pages, multiplied by the `InnoDB` page size.

Refer to the notes at the end of this section for information regarding other storage engines.

- `Data_free`

The number of allocated but unused bytes.

This information is also shown for [InnoDB](#) tables (previously, it was in the [Comment](#) value). [InnoDB](#) tables report the free space of the tablespace to which the table belongs. For a table located in the shared tablespace, this is the free space of the shared tablespace. If you are using multiple tablespaces and the table has its own tablespace, the free space is for only that table. Free space means the number of bytes in completely free extents minus a safety margin. Even if free space displays as 0, it may be possible to insert rows as long as new extents need not be allocated.

For partitioned tables, this value is only an estimate and may not be absolutely correct. A more accurate method of obtaining this information in such cases is to query the [INFORMATION\\_SCHEMA.PARTITIONS](#) table, as shown in this example:

```
SELECT      SUM(DATA_FREE)
  FROM      INFORMATION_SCHEMA.PARTITIONS
 WHERE TABLE_SCHEMA = 'mydb'
 AND  TABLE_NAME   = 'mytable';
```

For more information, see [Section 23.15, “The INFORMATION\\_SCHEMA PARTITIONS Table”](#).

- [Auto\\_increment](#)

The next [AUTO\\_INCREMENT](#) value.

- [Create\\_time](#)

When the table was created.

- [Update\\_time](#)

When the data file was last updated. For some storage engines, this value is [NULL](#). For example, [InnoDB](#) stores multiple tables in its [system tablespace](#) and the data file timestamp does not apply. Even with [file-per-table](#) mode with each [InnoDB](#) table in a separate [.ibd](#) file, [change buffering](#) can delay the write to the data file, so the file modification time is different from the time of the last insert, update, or delete. For [MyISAM](#), the data file timestamp is used; however, on Windows the timestamp is not updated by updates so the value is inaccurate.

- [Check\\_time](#)

When the table was last checked. Not all storage engines update this time, in which case the value is always [NULL](#).

- [Collation](#)

The table's character set and collation.

- [Checksum](#)

The live checksum value (if any).

- [Create\\_options](#)

Extra options used with [CREATE TABLE](#). The original options supplied when [CREATE TABLE](#) is called are retained and the options reported here may differ from the active table settings and options.

- [Comment](#)

The comment used when creating the table (or information as to why MySQL could not access the table information).

**Notes:**

- For **MEMORY** tables, the `Data_length`, `Max_data_length`, and `Index_length` values approximate the actual amount of allocated memory. The allocation algorithm reserves memory in large amounts to reduce the number of allocation operations.
- For views, all the fields displayed by `SHOW TABLE STATUS` are `NULL` except that `Name` indicates the view name and `Comment` says `view`.

### 14.7.5.37 SHOW TABLES Syntax

```
SHOW [FULL] TABLES [{FROM | IN} db_name]
[LIKE 'pattern' | WHERE expr]
```

`SHOW TABLES` lists the non-**TEMPORARY** tables in a given database. You can also get this list using the `mysqlshow db_name` command. The `LIKE` clause, if present, indicates which table names to match. The `WHERE` clause can be given to select rows using more general conditions, as discussed in [Section 23.34, “Extensions to SHOW Statements”](#).

Matching performed by the `LIKE` clause is dependent on the setting of the `lower_case_table_names` system variable.

This statement also lists any views in the database. The `FULL` modifier is supported such that `SHOW FULL TABLES` displays a second output column. Values for the second column are `BASE TABLE` for a table and `VIEW` for a view.

If you have no privileges for a base table or view, it does not show up in the output from `SHOW TABLES` or `mysqlshow db_name`.

### 14.7.5.38 SHOW TRIGGERS Syntax

```
SHOW TRIGGERS [{FROM | IN} db_name]
[LIKE 'pattern' | WHERE expr]
```

`SHOW TRIGGERS` lists the triggers currently defined for tables in a database (the default database unless a `FROM` clause is given). This statement returns results only for databases and tables for which you have the **TRIGGER** privilege. The `LIKE` clause, if present, indicates which table names to match (not trigger names) and causes the statement to display triggers for those tables. The `WHERE` clause can be given to select rows using more general conditions, as discussed in [Section 23.34, “Extensions to SHOW Statements”](#).

For the trigger `ins_sum` as defined in [Section 22.3, “Using Triggers”](#), the output of this statement is as shown here:

```
mysql> SHOW TRIGGERS LIKE 'acc%\G
***** 1. row *****
      Trigger: ins_sum
      Event: INSERT
      Table: account
      Statement: SET @sum = @sum + NEW.amount
      Timing: BEFORE
      Created: 2013-07-09 10:39:34.96
      sql_mode: NO_ENGINE_SUBSTITUTION
      Definer: me@localhost
character_set_client: utf8
collation_connection: utf8_general_ci
Database Collation: latin1_swedish_ci
```

`SHOW TRIGGERS` output has the following columns:

- **Trigger**: The trigger name.
- **Event**: The type of operation that causes trigger activation. The value is `'INSERT'`, `'UPDATE'`, or `'DELETE'`.

- **Table**: The table for which the trigger is defined.
- **Statement**: The trigger body; that is, the statement executed when the trigger activates.
- **Timing**: Whether the trigger activates before or after the triggering event. The value is `'BEFORE'` or `'AFTER'`.
- **Created**: The date and time when the trigger was created. This is a `TIMESTAMP(2)` value (with a fractional part in hundredths of seconds) for triggers created in MySQL 5.7.2 or later, `NULL` for triggers created prior to 5.7.2.
- **sql\_mode**: The SQL mode in effect when the trigger executes.
- **Definer**: The account of the user who created the trigger, in `'user_name'@'host_name'` format.
- **character\_set\_client**: The session value of the `character_set_client` system variable when the trigger was created.
- **collation\_connection**: The session value of the `collation_connection` system variable when the trigger was created.
- **Database Collation**: The collation of the database with which the trigger is associated.

You can also obtain information about trigger objects from `INFORMATION_SCHEMA`, which contains a `TRIGGERS` table. See [Section 23.28, “The INFORMATION\\_SCHEMA TRIGGERS Table”](#).

### 14.7.5.39 SHOW VARIABLES Syntax

```
SHOW [GLOBAL | SESSION] VARIABLES
      [LIKE 'pattern' | WHERE expr]
```

#### Note

As of MySQL 5.7.6, the value of the `show_compatibility_56` system variable affects the information available from and privileges required for the statement described here. For details, see the description of that variable in [Section 6.1.5, “Server System Variables”](#).

`SHOW VARIABLES` shows the values of MySQL system variables (see [Section 6.1.5, “Server System Variables”](#)). This statement does not require any privilege. It requires only the ability to connect to the server.

System variable information is also available from these sources:

- Performance Schema tables. See [Section 24.10.13, “Performance Schema System Variable Tables”](#).
- The `GLOBAL_VARIABLES` and `SESSION_VARIABLES` tables. See [Section 23.10, “The INFORMATION\\_SCHEMA GLOBAL\\_VARIABLES and SESSION\\_VARIABLES Tables”](#).
- The `mysqladmin variables` command. See [Section 5.5.2, “mysqladmin — Client for Administering a MySQL Server”](#).

For `SHOW VARIABLES`, a `LIKE` clause, if present, indicates which variable names to match. A `WHERE` clause can be given to select rows using more general conditions, as discussed in [Section 23.34, “Extensions to SHOW Statements”](#).

`SHOW VARIABLES` accepts an optional `GLOBAL` or `SESSION` variable scope modifier:

- With a `GLOBAL` modifier, the statement displays global system variable values. These are the values used to initialize the corresponding session variables for new connections to MySQL. If a variable has no global value, no value is displayed.

- With a `SESSION` modifier, the statement displays the system variable values that are in effect for the current connection. If a variable has no session value, the global value is displayed. `LOCAL` is a synonym for `SESSION`.
- If no modifier is present, the default is `SESSION`.

The scope for each system variable is listed at [Section 6.1.5, “Server System Variables”](#).

`SHOW VARIABLES` is subject to a version-dependent display-width limit. For variables with very long values that are not completely displayed, use `SELECT` as a workaround. For example:

```
SELECT @@GLOBAL.innodb_data_file_path;
```

Most system variables can be set at server startup (read-only variables such as `version_comment` are exceptions). Many can be changed at runtime with the `SET` statement. See [Section 6.1.6, “Using System Variables”](#), and [Section 14.7.4.1, “SET Syntax for Variable Assignment”](#).

Partial output is shown here. The list of names and values may differ for your server. [Section 6.1.5, “Server System Variables”](#), describes the meaning of each variable, and [Section 6.1.1, “Configuring the Server”](#), provides information about tuning them.

```
mysql> SHOW VARIABLES;
```

| Variable_name                           | Value                     |
|---|---------------------------|
| auto_increment_increment                | 1                         |
| auto_increment_offset                   | 1                         |
| autocommit                              | ON                        |
| automatic_sp_privileges                 | ON                        |

| version_compile_os                      | Linux                     |

|               |       |  |
|---------------|-------|--|
| wait_timeout  | 28800 |  |
| warning_count | 0     |  |
| +-----+-----+ |       |  |

With a [LIKE](#) clause, the statement displays only rows for those variables with names that match the pattern. To obtain the row for a specific variable, use a [LIKE](#) clause as shown:

```
SHOW VARIABLES LIKE 'max_join_size';
SHOW SESSION VARIABLES LIKE 'max_join_size';
```

To get a list of variables whose name match a pattern, use the `%` wildcard character in a [LIKE](#) clause:

```
SHOW VARIABLES LIKE '%size%';
SHOW GLOBAL VARIABLES LIKE '%size%';
```

Wildcard characters can be used in any position within the pattern to be matched. Strictly speaking, because `_` is a wildcard that matches any single character, you should escape it as `\_` to match it literally. In practice, this is rarely necessary.

#### 14.7.5.40 SHOW WARNINGS Syntax

```
SHOW WARNINGS [LIMIT [offset,] row_count]
SHOW COUNT(*) WARNINGS
```

[SHOW WARNINGS](#) is a diagnostic statement that displays information about the conditions (errors, warnings, and notes) resulting from executing a statement in the current session. Warnings are generated for DML statements such as [INSERT](#), [UPDATE](#), and [LOAD DATA INFILE](#) as well as DDL statements such as [CREATE TABLE](#) and [ALTER TABLE](#).

The [LIMIT](#) clause has the same syntax as for the [SELECT](#) statement. See [Section 14.2.9, “SELECT Syntax”](#).

[SHOW WARNINGS](#) is also used following [EXPLAIN EXTENDED](#), to display the extra information generated by [EXPLAIN](#) when the [EXTENDED](#) keyword is used. See [Section 9.8.3, “EXPLAIN EXTENDED Output Format”](#).

As of MySQL 5.7.2, [SHOW WARNINGS](#) displays information about the conditions resulting from execution of the most recent nondiagnostic statement in the current session. If the most recent statement resulted in an error during parsing, [SHOW WARNINGS](#) shows the resulting conditions, regardless of statement type (diagnostic or nondiagnostic).

Before MySQL 5.7.2, [SHOW WARNINGS](#) displays information about the conditions resulting from the most recent statement in the current session that generated messages. It shows nothing if the most recent statement used a table and generated no messages. (That is, statements that use a table but generate no messages clear the message list.) Statements that do not use tables and do not generate messages have no effect on the message list.

The [SHOW COUNT\(\\*\) WARNINGS](#) diagnostic statement displays the total number of errors, warnings, and notes. You can also retrieve this number from the [warning\\_count](#) system variable:

```
SHOW COUNT(*) WARNINGS;
SELECT @@warning_count;
```

A difference in these statements is that the first is a diagnostic statement that does not clear the message list. The second, because it is a [SELECT](#) statement is considered nondiagnostic and, as of MySQL 5.7.2, does clear the message list.

A related diagnostic statement, [SHOW ERRORS](#), shows only error conditions (it excludes warnings and notes), and [SHOW COUNT\(\\*\) ERRORS](#) statement displays the total number of errors. See

Section 14.7.5.17, “[SHOW ERRORS Syntax](#)”. [GET DIAGNOSTICS](#) can be used to examine information for individual conditions. See [Section 14.6.7.3, “GET DIAGNOSTICS Syntax](#)”.

Here is a simple example that shows data-conversion warnings for [INSERT](#):

```
mysql> CREATE TABLE t1 (a TINYINT NOT NULL, b CHAR(4));
Query OK, 0 rows affected (0.05 sec)

mysql> INSERT INTO t1 VALUES(10,'mysql'), (NULL,'test'), (300,'xyz');
Query OK, 3 rows affected, 3 warnings (0.00 sec)
Records: 3 Duplicates: 0 Warnings: 3

mysql> SHOW WARNINGS\G
***** 1. row *****
Level: Warning
Code: 1265
Message: Data truncated for column 'b' at row 1
***** 2. row *****
Level: Warning
Code: 1048
Message: Column 'a' cannot be null
***** 3. row *****
Level: Warning
Code: 1264
Message: Out of range value for column 'a' at row 3
3 rows in set (0.00 sec)
```

The [max\\_error\\_count](#) system variable controls the maximum number of error, warning, and note messages for which the server stores information, and thus the number of messages that [SHOW WARNINGS](#) displays. To change the number of messages the server can store, change the value of [max\\_error\\_count](#). The default is 64.

[max\\_error\\_count](#) controls only how many messages are stored, not how many are counted. The value of [warning\\_count](#) is not limited by [max\\_error\\_count](#), even if the number of messages generated exceeds [max\\_error\\_count](#). The following example demonstrates this. The [ALTER TABLE](#) statement produces three warning messages (strict SQL mode is disabled for the example to prevent an error from occurring after a single conversion issue). Only one message is stored and displayed because [max\\_error\\_count](#) has been set to 1, but all three are counted (as shown by the value of [warning\\_count](#)):

```
mysql> SHOW VARIABLES LIKE 'max_error_count';
+-----+-----+
| Variable_name | Value |
+-----+-----+
| max_error_count | 64    |
+-----+-----+
1 row in set (0.00 sec)

mysql> SET max_error_count=1, sql_mode = '';
Query OK, 0 rows affected (0.00 sec)

mysql> ALTER TABLE t1 MODIFY b CHAR;
Query OK, 3 rows affected, 3 warnings (0.00 sec)
Records: 3 Duplicates: 0 Warnings: 3

mysql> SHOW WARNINGS;
+-----+-----+-----+
| Level | Code | Message |
+-----+-----+-----+
| Warning | 1263 | Data truncated for column 'b' at row 1 |
+-----+-----+-----+
1 row in set (0.00 sec)

mysql> SELECT @@warning_count;
+-----+
| @@warning_count |
+-----+
```

```
|          3 |
+-----+
1 row in set (0.01 sec)
```

To disable message storage, set `max_error_count` to 0. In this case, `warning_count` still indicates how many warnings occurred, but messages are not stored and cannot be displayed.

The `sql_notes` system variable controls whether note messages increment `warning_count` and whether the server stores them. By default, `sql_notes` is 1, but if set to 0, notes do not increment `warning_count` and the server does not store them:

```
mysql> SET sql_notes = 1;
mysql> DROP TABLE IF EXISTS test.no_such_table;
Query OK, 0 rows affected, 1 warning (0.00 sec)
mysql> SHOW WARNINGS;
+-----+-----+-----+
| Level | Code | Message |
+-----+-----+-----+
| Note  | 1051 | Unknown table 'test.no_such_table' |
+-----+-----+-----+
1 row in set (0.00 sec)

mysql> SET sql_notes = 0;
mysql> DROP TABLE IF EXISTS test.no_such_table;
Query OK, 0 rows affected (0.00 sec)
mysql> SHOW WARNINGS;
Empty set (0.00 sec)
```

The MySQL server sends to each client a count indicating the total number of errors, warnings, and notes resulting from the most recent statement executed by that client. From the C API, this value can be obtained by calling `mysql_warning_count()`. See [Section 26.8.7.78, “mysql\\_warning\\_count\(\)”](#).

In the `mysql` client, you can enable and disable automatic warnings display using the `warnings` and `nowarning` commands, respectively, or their shortcuts, `\W` and `\w` (see [Section 5.5.1.2, “mysql Commands”](#)). For example:

```
mysql> \W
Show warnings enabled.
mysql> SELECT 1/0;
+-----+
| 1/0 |
+-----+
| NULL |
+-----+
1 row in set, 1 warning (0.03 sec)

Warning (Code 1365): Division by 0
mysql> \w
Show warnings disabled.
```

## 14.7.6 Other Administrative Statements

### 14.7.6.1 BINLOG Syntax

```
BINLOG 'str'
```

`BINLOG` is an internal-use statement. It is generated by the `mysqlbinlog` program as the printable representation of certain events in binary log files. (See [Section 5.6.7, “mysqlbinlog — Utility for Processing Binary Log Files”](#).) The '*str*' value is a base 64-encoded string that the server decodes to determine the data change indicated by the corresponding event. This statement requires the `SUPER` privilege.

This statement can execute only format description events and row events.

## 14.7.6.2 CACHE INDEX Syntax

```
CACHE INDEX
  tbl_index_list [, tbl_index_list] ...
  [PARTITION (partition_list | ALL)]
  IN key_cache_name

tbl_index_list:
  tbl_name [[INDEX|KEY] (index_name[, index_name] ...)]

partition_list:
  partition_name[, partition_name][, ...]
```

The `CACHE INDEX` statement assigns table indexes to a specific key cache. It is used only for `MyISAM` tables. After the indexes have been assigned, they can be preloaded into the cache if desired with `LOAD INDEX INTO CACHE`.

The following statement assigns indexes from the tables `t1`, `t2`, and `t3` to the key cache named `hot_cache`:

```
mysql> CACHE INDEX t1, t2, t3 IN hot_cache;
```

| Table   | Op                 | Msg_type | Msg_text |
|---------|--------------------|----------|----------|
| test.t1 | assign_to_keycache | status   | OK       |
| test.t2 | assign_to_keycache | status   | OK       |
| test.t3 | assign_to_keycache | status   | OK       |

The syntax of `CACHE INDEX` enables you to specify that only particular indexes from a table should be assigned to the cache. The current implementation assigns all the table's indexes to the cache, so there is no reason to specify anything other than the table name.

The key cache referred to in a `CACHE INDEX` statement can be created by setting its size with a parameter setting statement or in the server parameter settings. For example:

```
mysql> SET GLOBAL keycache1.key_buffer_size=128*1024;
```

Key cache parameters can be accessed as members of a structured system variable. See [Section 6.1.6.1, “Structured System Variables”](#).

A key cache must exist before you can assign indexes to it:

```
mysql> CACHE INDEX t1 IN non_existent_cache;
ERROR 1284 (HY000): Unknown key cache 'non_existent_cache'
```

By default, table indexes are assigned to the main (default) key cache created at the server startup. When a key cache is destroyed, all indexes assigned to it become assigned to the default key cache again.

Index assignment affects the server globally: If one client assigns an index to a given cache, this cache is used for all queries involving the index, no matter which client issues the queries.

In MySQL 5.7, this statement is also supported for partitioned `MyISAM` tables. You can assign one or more indexes for one, several, or all partitions to a given key cache. For example, you can do the following:

```
CREATE TABLE pt (c1 INT, c2 VARCHAR(50), INDEX i(c1))
ENGINE=MyISAM
```

```

PARTITION BY HASH(c1)
PARTITIONS 4;

SET GLOBAL kc_fast.key_buffer_size = 128 * 1024;
SET GLOBAL kc_slow.key_buffer_size = 128 * 1024;

CACHE INDEX pt PARTITION (p0) IN kc_fast;
CACHE INDEX pt PARTITION (p1, p3) IN kc_slow;

```

The previous set of statements performs the following actions:

- Creates a partitioned table with 4 partitions; these partitions are automatically named `p0`, ..., `p3`; this table has an index named `i` on column `c1`.
- Creates 2 key caches named `kc_fast` and `kc_slow`
- Assigns the index for partition `p0` to the `kc_fast` key cache and the index for partitions `p1` and `p3` to the `kc_slow` key cache; the index for the remaining partition (`p2`) uses the server's default key cache.

If you wish instead to assign the indexes for all partitions in table `pt` to a single key cache named `kc_all`, you can use either one of the following 2 statements:

```

CACHE INDEX pt PARTITION (ALL) IN kc_all;

CACHE INDEX pt IN kc_all;

```

The two statements just shown are equivalent, and issuing either one of them has exactly the same effect. In other words, if you wish to assign indexes for all partitions of a partitioned table to the same key cache, then the `PARTITION (ALL)` clause is optional.

When assigning indexes for multiple partitions to a key cache, the partitions do not have to be contiguous, and you are not required to list their names in any particular order. Indexes for any partitions that are not explicitly assigned to a key cache automatically use the server's default key cache.

In MySQL 5.7, index preloading is also supported for partitioned `MyISAM` tables. For more information, see [Section 14.7.6.5, “LOAD INDEX INTO CACHE Syntax”](#).

In MySQL 5.7.1, `gtid_next` must be set to `AUTOMATIC` before issuing this statement. This restriction does not apply in MySQL 5.7.2 or later. (Bug #16062608, Bug #16715809, Bug #69045)

### 14.7.6.3 FLUSH Syntax

```

FLUSH [NO_WRITE_TO_BINLOG | LOCAL]
      flush_option [, flush_option] ...

```

The `FLUSH` statement has several variant forms that clear or reload various internal caches, flush tables, or acquire locks. To execute `FLUSH`, you must have the `RELOAD` privilege. Specific flush options might require additional privileges, as described later.

By default, the server writes `FLUSH` statements to the binary log so that they replicate to replication slaves. To suppress logging, specify the optional `NO_WRITE_TO_BINLOG` keyword or its alias `LOCAL`.

#### Note

`FLUSH LOGS`, `FLUSH TABLES WITH READ LOCK` (with or without a table list), and `FLUSH TABLES tbl_name ... FOR EXPORT` are not written to the binary log in any case because they would cause problems if replicated to a slave.

Sending a `SIGHUP` signal to the server causes several flush operations to occur that are similar to various forms of the `FLUSH` statement. See [Section 6.1.11, “Server Response to Signals”](#).

The `FLUSH` statement causes an implicit commit. See [Section 14.3.3, “Statements That Cause an Implicit Commit”](#).

The `RESET` statement is similar to `FLUSH`. See [Section 14.7.6.6, “RESET Syntax”](#), for information about using the `RESET` statement with replication.

`flush_option` can be any of the following items.

- `DES_KEY_FILE`

Reloads the DES keys from the file that was specified with the `--des-key-file` option at server startup time.

- `HOSTS`

Empties the host cache. You should flush the host cache if some of your hosts change IP address or if the error message `Host 'host_name' is blocked` occurs. (See [Section B.5.2.6, “Host 'host\\_name' is blocked”](#).) When more than `max_connect_errors` errors occur successively for a given host while connecting to the MySQL server, MySQL assumes that something is wrong and blocks the host from further connection requests. Flushing the host cache enables further connection attempts from the host. The default value of `max_connect_errors` is 100. To avoid this error message, start the server with `max_connect_errors` set to a large value.

- `[log_type] LOGS | RELAY LOGS [channel_option]`

With no `log_type` option, `FLUSH LOGS` closes and reopens all log files. If binary logging is enabled, the sequence number of the binary log file is incremented by one relative to the previous file.

`FLUSH LOGS` has no effect on tables used for the general query log or for the slow query log (see [Section 6.4.1, “Selecting General Query and Slow Query Log Output Destinations”](#)).

With a `log_type` option, only the specified log type is flushed. These `log_type` options are permitted:

- `BINARY` closes and reopens the binary log files. If binary logging is enabled, the sequence number of the binary log file is incremented by one relative to the previous file.
- `ENGINE` closes and reopens any flushable logs for installed storage engines. This causes `InnoDB` to flush its logs to disk.
- `ERROR` closes and reopens the error log file.
- `GENERAL` closes and reopens the general query log file.
- `RELAY` closes and reopens the relay log files. If binary logging is enabled, the sequence number of the binary log file is incremented by one relative to the previous file.

The `FOR CHANNEL channel` clause added in MySQL 5.7.6 enables you to choose which replication channel to apply a `FLUSH RELAY LOGS` statement to. If no clause is set and no extra replication channels exist, the statement applies to the default channel and behaves the same as versions of MySQL prior to 5.7.6. If multiple replication channels exist and no clause is set, *all* replication channels are flushed. Execute a `FLUSH RELAY LOGS FOR CHANNEL channel` statement to flush a specific replication channel's relay log. See [Section 18.2.3, “Replication Channels”](#) for more information.

**Note**

The `FOR CHANNEL channel` clause can only be used with the `RELAY LOGS log_type`.

- [SLOW](#) closes and reopens the slow query log file.

- [OPTIMIZER\\_COSTS](#)

Rereads the cost model tables so that the optimizer starts using the current cost estimates stored in them. The server writes a warning to the error log for any unrecognized entries. (For information about these tables, see [Section 9.9.5, “The Optimizer Cost Model”](#).) This operation affects only sessions that begin subsequent to the flush. Existing sessions continue to use the cost estimates that were current when they began.

This option was added in MySQL 5.7.5.

- [PRIVILEGES](#)

Reloads the privileges from the grant tables in the `mysql` database.

The server caches information in memory as a result of [GRANT](#), [CREATE USER](#), [CREATE SERVER](#), and [INSTALL PLUGIN](#) statements. This memory is not released by the corresponding [REVOKE](#), [DROP USER](#), [DROP SERVER](#), and [UNINSTALL PLUGIN](#) statements, so for a server that executes many instances of the statements that cause caching, there will be an increase in memory use. This cached memory can be freed with [FLUSH PRIVILEGES](#).

- [QUERY CACHE](#)

Defragment the query cache to better utilize its memory. [FLUSH QUERY CACHE](#) does not remove any queries from the cache, unlike [FLUSH TABLES](#) or [RESET QUERY CACHE](#).

- [STATUS](#)

**Note**

As of MySQL 5.7.6, the value of the [show\\_compatibility\\_56](#) system variable affects the operation of this option. For details, see the description of that variable in [Section 6.1.5, “Server System Variables”](#).

This option adds the current thread's session status variable values to the global values and resets the session values to zero. Some global variables may be reset to zero as well. It also resets the counters for key caches (default and named) to zero and sets [Max\\_used\\_connections](#) to the current number of open connections. This is something that may be of use when debugging a query. See [Section 1.7, “How to Report Bugs or Problems”](#).

- [TABLES](#)

[FLUSH TABLES](#) flushes tables, and, depending on the variant used, acquires locks. The permitted syntax is discussed later in this section.

- [USER\\_RESOURCES](#)

Resets all per-hour user resources to zero. This enables clients that have reached their hourly connection, query, or update limits to resume activity immediately. [FLUSH USER\\_RESOURCES](#) does not apply to the limit on maximum simultaneous connections. See [Section 7.3.4, “Setting Account Resource Limits”](#).

The [mysqladmin](#) utility provides a command-line interface to some flush operations, using commands such as [flush-hosts](#), [flush-logs](#), [flush-privileges](#), [flush-status](#), and [flush-tables](#). See [Section 5.5.2, “mysqladmin — Client for Administering a MySQL Server”](#).

**Note**

It is not possible to issue [FLUSH](#) statements within stored functions or triggers. However, you may use [FLUSH](#) in stored procedures, so long as these are

not called from stored functions or triggers. See [Section C.1, “Restrictions on Stored Programs”](#).

In MySQL 5.7.1, `gtid_next` must be set to `AUTOMATIC` before issuing this statement. This restriction does not apply in MySQL 5.7.2 or later. (Bug #16062608, Bug #16715809, Bug #69045)

## FLUSH TABLES Syntax

`FLUSH TABLES` has several forms, described following. If any variant of the `TABLES` option is used in a `FLUSH` statement, it must be the only option used. `FLUSH TABLE` is a synonym for `FLUSH TABLES`.

- `FLUSH TABLES`

Closes all open tables, forces all tables in use to be closed, and flushes the query cache. `FLUSH TABLES` also removes all query results from the query cache, like the `RESET QUERY CACHE` statement.

In MySQL 5.7, `FLUSH TABLES` is not permitted when there is an active `LOCK TABLES ... READ`. To flush and lock tables, use `FLUSH TABLES tbl_name ... WITH READ LOCK` instead.

- `FLUSH TABLES tbl_name [, tbl_name] ...`

With a list of one or more comma-separated table names, this statement is like `FLUSH TABLES` with no names except that the server flushes only the named tables. No error occurs if a named table does not exist.

- `FLUSH TABLES WITH READ LOCK`

Closes all open tables and locks all tables for all databases with a global read lock. This is a very convenient way to get backups if you have a file system such as Veritas or ZFS that can take snapshots in time. Use `UNLOCK TABLES` to release the lock.

`FLUSH TABLES WITH READ LOCK` acquires a global read lock and not table locks, so it is not subject to the same behavior as `LOCK TABLES` and `UNLOCK TABLES` with respect to table locking and implicit commits:

- `UNLOCK TABLES` implicitly commits any active transaction only if any tables currently have been locked with `LOCK TABLES`. The commit does not occur for `UNLOCK TABLES` following `FLUSH TABLES WITH READ LOCK` because the latter statement does not acquire table locks.
- Beginning a transaction causes table locks acquired with `LOCK TABLES` to be released, as though you had executed `UNLOCK TABLES`. Beginning a transaction does not release a global read lock acquired with `FLUSH TABLES WITH READ LOCK`.

`FLUSH TABLES WITH READ LOCK` does not prevent the server from inserting rows into the log tables (see [Section 6.4.1, “Selecting General Query and Slow Query Log Output Destinations”](#)).

- `FLUSH TABLES tbl_name [, tbl_name] ... WITH READ LOCK`

This statement flushes and acquires read locks for the named tables. The statement first acquires exclusive metadata locks for the tables, so it waits for transactions that have those tables open to complete. Then the statement flushes the tables from the table cache, reopens the tables, acquires table locks (like `LOCK TABLES ... READ`), and downgrades the metadata locks from exclusive to shared. After the statement acquires locks and downgrades the metadata locks, other sessions can read but not modify the tables.

Because this statement acquires table locks, you must have the `LOCK TABLES` privilege for each table, in addition to the `RELOAD` privilege that is required to use any `FLUSH` statement.

This statement applies only to existing base tables. If a name refers to a base table, that table is used. If it refers to a `TEMPORARY` table, it is ignored. If a name applies to a view, an `ER_WRONG_OBJECT` error occurs. Otherwise, an `ER_NO_SUCH_TABLE` error occurs.

Use `UNLOCK TABLES` to release the locks, `LOCK TABLES` to release the locks and acquire other locks, or `START TRANSACTION` to release the locks and begin a new transaction.

This variant of `FLUSH` enables tables to be flushed and locked in a single operation. It provides a workaround for the restriction in MySQL 5.7 that `FLUSH TABLES` is not permitted when there is an active `LOCK TABLES ... READ`.

This statement does not perform an implicit `UNLOCK TABLES`, so an error results if you use the statement while there is any active `LOCK TABLES` or use it a second time without first releasing the locks acquired.

If a flushed table was opened with `HANDLER`, the handler is implicitly flushed and loses its position.

- `FLUSH TABLES tbl_name [, tbl_name] ... FOR EXPORT`

This `FLUSH TABLES` variant applies to `InnoDB` tables. It ensures that changes to the named tables have been flushed to disk so that binary table copies can be made while the server is running.

The statement works like this:

1. It acquires shared metadata locks for the named tables. The statement blocks as long as other sessions have active transactions that have modified those tables or hold table locks for them. When the locks have been acquired, the statement blocks transactions that attempt to update the tables while permitting read-only operations to continue.
2. It checks whether all storage engines for the tables support `FOR EXPORT`. If any do not, an `ER_ILLEGAL_HA` error occurs and the statement fails.
3. The statement notifies the storage engine for each table to make the table ready for export. The storage engine must ensure that any pending changes are written to disk.
4. The statement puts the session in lock-tables mode so that the metadata locks acquired earlier are not released when the `FOR EXPORT` statement completes.

The `FLUSH TABLES ... FOR EXPORT` statement requires that you have the `SELECT` privilege for each table. Because this statement acquires table locks, you must also have the `LOCK TABLES` privilege for each table, in addition to the `RELOAD` privilege that is required to use any `FLUSH` statement.

This statement applies only to existing base tables. If a name refers to a base table, that table is used. If it refers to a `TEMPORARY` table, it is ignored. If a name applies to a view, an `ER_WRONG_OBJECT` error occurs. Otherwise, an `ER_NO_SUCH_TABLE` error occurs.

`InnoDB` supports `FOR EXPORT` for tables that have their own `.ibd` file (that is, tables that were created with the `innodb_file_per_table` setting enabled). `InnoDB` ensures when notified by the `FOR EXPORT` statement that any changes have been flushed to disk. This permits a binary copy of table contents to be made while the `FOR EXPORT` statement is in effect because the `.ibd` file is transaction consistent and can be copied while the server is running. `FOR EXPORT` does not apply to `InnoDB` system tablespace files, or to `InnoDB` tables that have any `FULLTEXT` indexes.

`FLUSH TABLES ... FOR EXPORT` does not work with partitioned `InnoDB` tables prior to MySQL 5.7.4, but is supported for such tables in MySQL 5.7.4 and later. (Bug #16943907)

When notified by `FOR EXPORT`, `InnoDB` writes to disk certain kinds of data that is normally held in memory or in separate disk buffers outside the tablespace files. For each table, `InnoDB` also produces a file named `table_name.cfg` in the same database directory as the table. The `.cfg` file contains metadata needed to reimport the tablespace files later, into the same or different server.

When the `FOR EXPORT` statement completes, `InnoDB` will have flushed all `dirty pages` to the table data files. Any `change buffer` entries are merged prior to flushing. At this point, the tables are locked

and quiescent: The tables are in a transactionally consistent state on disk and you can copy the `.ibd` tablespace files along with the corresponding `.cfg` files to get a consistent snapshot of those tables.

For the procedure to reimport the copied table data into a MySQL instance, see [Section 15.7.6, “Copying File-Per-Table Tablespaces to Another Server”](#).

After you are done with the tables, use `UNLOCK TABLES` to release the locks, `LOCK TABLES` to release the locks and acquire other locks, or `START TRANSACTION` to release the locks and begin a new transaction.

While any of these statements is in effect within the session, attempts to use `FLUSH TABLES ... FOR EXPORT` produce an error:

```
FLUSH TABLES ... WITH READ LOCK
FLUSH TABLES ... FOR EXPORT
LOCK TABLES ... READ
LOCK TABLES ... WRITE
```

While `FLUSH TABLES ... FOR EXPORT` is in effect within the session, attempts to use any of these statements produce an error:

```
FLUSH TABLES WITH READ LOCK
FLUSH TABLES ... WITH READ LOCK
FLUSH TABLES ... FOR EXPORT
```

#### 14.7.6.4 KILL Syntax

```
KILL [CONNECTION | QUERY] processlist_id
```

Each connection to `mysqld` runs in a separate thread. You can kill a thread with the `KILL processlist_id` statement.

Thread `processlist` identifiers can be determined from the `ID` column of the `INFORMATION_SCHEMA.PROCESSLIST` table, the `Id` column of `SHOW PROCESSLIST` output, and the `PROCESSLIST_ID` column of the Performance Schema `threads` table. The value for the current thread is returned by the `CONNECTION_ID()` function.

`KILL` permits an optional `CONNECTION` or `QUERY` modifier:

- `KILL CONNECTION` is the same as `KILL` with no modifier: It terminates the connection associated with the given *processlist\_id*, after terminating any statement the connection is executing.
- `KILL QUERY` terminates the statement the connection is currently executing, but leaves the connection itself intact.

If you have the `PROCESS` privilege, you can see all threads. If you have the `SUPER` privilege, you can kill all threads and statements. Otherwise, you can see and kill only your own threads and statements.

You can also use the `mysqladmin processlist` and `mysqladmin kill` commands to examine and kill threads.

#### Note

You cannot use `KILL` with the Embedded MySQL Server library because the embedded server merely runs inside the threads of the host application. It does not create any connection threads of its own.

When you use `KILL`, a thread-specific kill flag is set for the thread. In most cases, it might take some time for the thread to die because the kill flag is checked only at specific intervals:

- During `SELECT` operations, for `ORDER BY` and `GROUP BY` loops, the flag is checked after reading a block of rows. If the kill flag is set, the statement is aborted.
- `ALTER TABLE` operations that make a table copy check the kill flag periodically for each few copied rows read from the original table. If the kill flag was set, the statement is aborted and the temporary table is deleted.

The `KILL` statement returns without waiting for confirmation, but the kill flag check aborts the operation within a reasonably small amount of time. Aborting the operation to perform any necessary cleanup also takes some time.

- During `UPDATE` or `DELETE` operations, the kill flag is checked after each block read and after each updated or deleted row. If the kill flag is set, the statement is aborted. If you are not using transactions, the changes are not rolled back.
- `GET_LOCK()` aborts and returns `NULL`.
- If the thread is in the table lock handler (state: `Locked`), the table lock is quickly aborted.
- If the thread is waiting for free disk space in a write call, the write is aborted with a “disk full” error message.

### Warning

Killing a `REPAIR TABLE` or `OPTIMIZE TABLE` operation on a `MyISAM` table results in a table that is corrupted and unusable. Any reads or writes to such a table fail until you optimize or repair it again (without interruption).

## 14.7.6.5 LOAD INDEX INTO CACHE Syntax

```
LOAD INDEX INTO CACHE
  tbl_index_list [, tbl_index_list] ...

tbl_index_list:
  tbl_name
  [PARTITION (partition_list | ALL)]
  [[INDEX|KEY] (index_name[, index_name] ...)]
  [IGNORE LEAVES]

partition_list:
  partition_name[, partition_name][, ...]
```

The `LOAD INDEX INTO CACHE` statement preloads a table index into the key cache to which it has been assigned by an explicit `CACHE INDEX` statement, or into the default key cache otherwise.

`LOAD INDEX INTO CACHE` is used only for `MyISAM` tables. In MySQL 5.7, it is also supported for partitioned `MyISAM` tables; in addition, indexes on partitioned tables can be preloaded for one, several, or all partitions.

The `IGNORE LEAVES` modifier causes only blocks for the nonleaf nodes of the index to be preloaded.

`IGNORE LEAVES` is also supported for partitioned `MyISAM` tables.

The following statement preloads nodes (index blocks) of indexes for the tables `t1` and `t2`:

```
mysql> LOAD INDEX INTO CACHE t1, t2 IGNORE LEAVES;
+-----+-----+-----+-----+
| Table | Op          | Msg_type | Msg_text |
+-----+-----+-----+-----+
| test.t1 | preload_keys | status   | OK       |
| test.t2 | preload_keys | status   | OK       |
+-----+-----+-----+-----+
```

This statement preloads all index blocks from `t1`. It preloads only blocks for the nonleaf nodes from `t2`.

The syntax of `LOAD INDEX INTO CACHE` enables you to specify that only particular indexes from a table should be preloaded. The current implementation preloads all the table's indexes into the cache, so there is no reason to specify anything other than the table name.

In MySQL 5.7.1, `gtid_next` must be set to `AUTOMATIC` before issuing this statement. This restriction does not apply in MySQL 5.7.2 or later. (Bug #16062608, Bug #16715809, Bug #69045)

In MySQL 5.7, it is possible to preload indexes on specific partitions of partitioned `MyISAM` tables. For example, of the following 2 statements, the first preloads indexes for partition `p0` of a partitioned table `pt`, while the second preloads the indexes for partitions `p1` and `p3` of the same table:

```
LOAD INDEX INTO CACHE pt PARTITION (p0);
LOAD INDEX INTO CACHE pt PARTITION (p1, p3);
```

To preload the indexes for all partitions in table `pt`, you can use either one of the following 2 statements:

```
LOAD INDEX INTO CACHE pt PARTITION (ALL);
LOAD INDEX INTO CACHE pt;
```

The two statements just shown are equivalent, and issuing either one of them has exactly the same effect. In other words, if you wish to preload indexes for all partitions of a partitioned table, then the `PARTITION (ALL)` clause is optional.

When preloading indexes for multiple partitions, the partitions do not have to be contiguous, and you are not required to list their names in any particular order.

`LOAD INDEX INTO CACHE ... IGNORE LEAVES` fails unless all indexes in a table have the same block size. You can determine index block sizes for a table by using `myisamchk -dv` and checking the `Blocksize` column.

### 14.7.6.6 RESET Syntax

```
RESET reset_option [, reset_option] ...
```

The `RESET` statement is used to clear the state of various server operations. You must have the `RELOAD` privilege to execute `RESET`.

`RESET` acts as a stronger version of the `FLUSH` statement. See [Section 14.7.6.3, “FLUSH Syntax”](#).

The `RESET` statement causes an implicit commit. See [Section 14.3.3, “Statements That Cause an Implicit Commit”](#).

In MySQL 5.7.1, `gtid_next` must be set to `AUTOMATIC` before issuing this statement. This restriction does not apply in MySQL 5.7.2 or later. (Bug #16062608, Bug #16715809, Bug #69045)

*reset\_option* can be any of the following:

- `MASTER`

Deletes all binary logs listed in the index file, resets the binary log index file to be empty, and creates a new binary log file.

- `QUERY CACHE`

Removes all query results from the query cache.

- `SLAVE`

Makes the slave forget its replication position in the master binary logs. Also resets the relay log by deleting any existing relay log files and beginning a new one.

### 14.7.6.7 SHUTDOWN Syntax

SHUTDOWN

This statement stops the MySQL server. It requires the [SHUTDOWN](#) privilege.

[SHUTDOWN](#) was added in MySQL 5.7.9. It provides an SQL-level interface to the same functionality available using the `mysqladmin shutdown` command or the `mysql_shutdown()` C API function.

## 14.8 Utility Statements

### 14.8.1 DESCRIBE Syntax

The [DESCRIBE](#) and [EXPLAIN](#) statements are synonyms, used either to obtain information about table structure or query execution plans. For more information, see [Section 14.7.5.5, “SHOW COLUMNS Syntax”](#), and [Section 14.8.2, “EXPLAIN Syntax”](#).

### 14.8.2 EXPLAIN Syntax

```
{EXPLAIN | DESCRIBE | DESC}
    tbl_name [col_name | wild]

{EXPLAIN | DESCRIBE | DESC}
    [explain_type]
    {explainable_stmt | FOR CONNECTION connection_id}

explain_type: {
    EXTENDED
  | PARTITIONS
  | FORMAT = format_name
}

format_name: {
    TRADITIONAL
  | JSON
}

explainable_stmt: {
    SELECT statement
  | DELETE statement
  | INSERT statement
  | REPLACE statement
  | UPDATE statement
}
```

The [DESCRIBE](#) and [EXPLAIN](#) statements are synonyms. In practice, the [DESCRIBE](#) keyword is more often used to obtain information about table structure, whereas [EXPLAIN](#) is used to obtain a query execution plan (that is, an explanation of how MySQL would execute a query). The following discussion uses the [DESCRIBE](#) and [EXPLAIN](#) keywords in accordance with those uses, but the MySQL parser treats them as completely synonymous.

### Obtaining Table Structure Information

[DESCRIBE](#) provides information about the columns in a table:

```
mysql> DESCRIBE City;
+-----+-----+-----+-----+-----+-----+
| Field | Type | Null | Key | Default | Extra |
+-----+-----+-----+-----+-----+-----+
| Id    | int(11) | NO | PRI | NULL | auto_increment |
| Name  | char(35) | NO | | | |
| Country | char(3) | NO | UNI | | |
| District | char(20) | YES | MUL | | |
```

|            |         |        |        |        |        |
|------------|---------|--------|--------|--------|--------|
| Population | int(11) | NO     |        | 0      |        |
| -----+     | -----+  | -----+ | -----+ | -----+ | -----+ |

`DESCRIBE` is a shortcut for `SHOW COLUMNS`. These statements also display information for views. The description for `SHOW COLUMNS` provides more information about the output columns. See [Section 14.7.5.5, “SHOW COLUMNS Syntax”](#).

By default, `DESCRIBE` displays information about all columns in the table. *col\_name*, if given, is the name of a column in the table. In this case, the statement displays information only for the named column. *wild*, if given, is a pattern string. It can contain the SQL `%` and `_` wildcard characters. In this case, the statement displays output only for the columns with names matching the string. There is no need to enclose the string within quotation marks unless it contains spaces or other special characters.

The `DESCRIBE` statement is provided for compatibility with Oracle.

The `SHOW CREATE TABLE`, `SHOW TABLE STATUS`, and `SHOW INDEX` statements also provide information about tables. See [Section 14.7.5, “SHOW Syntax”](#).

## Obtaining Execution Plan Information

The `EXPLAIN` statement provides information about how MySQL executes statements:

- In MySQL 5.7, permitted explainable statements for `EXPLAIN` are `SELECT`, `DELETE`, `INSERT`, `REPLACE`, and `UPDATE`.
- When `EXPLAIN` is used with an explainable statement, MySQL displays information from the optimizer about the statement execution plan. That is, MySQL explains how it would process the statement, including information about how tables are joined and in which order. For information about using `EXPLAIN` to obtain execution plan information, see [Section 9.8.2, “EXPLAIN Output Format”](#).
- When `EXPLAIN` is used with `FOR CONNECTION connection_id` rather than an explainable statement, it displays the execution plan for the statement executing in the named connection. See [Section 9.8.4, “Obtaining Execution Plan Information for a Named Connection”](#).
- `EXPLAIN EXTENDED` can be used to obtain additional execution plan information. See [Section 9.8.3, “EXPLAIN EXTENDED Output Format”](#).

As of MySQL 5.7.3, the `EXPLAIN` statement is changed so that the effect of the `EXTENDED` keyword is always enabled. `EXTENDED` is still recognized for backward compatibility, but is superfluous and is deprecated; its use results in a warning. It will be removed from `EXPLAIN` syntax in a future MySQL release.

- `EXPLAIN PARTITIONS` is useful for examining queries involving partitioned tables. See [Section 21.3.5, “Obtaining Information About Partitions”](#).

As of MySQL 5.7.3, the `EXPLAIN` statement is changed so that the effect of the `PARTITIONS` keyword is always enabled. `PARTITIONS` is still recognized for backward compatibility, but is superfluous and is deprecated; its use results in a warning. It will be removed from `EXPLAIN` syntax in a future MySQL release.

- The `FORMAT` option can be used to select the output format. `TRADITIONAL` presents the output in tabular format. This is the default if no `FORMAT` option is present. `JSON` format displays the information in JSON format. With `FORMAT = JSON`, the output includes extended and partition information.

With the help of `EXPLAIN`, you can see where you should add indexes to tables so that the statement executes faster by using indexes to find rows. You can also use `EXPLAIN` to check whether the optimizer joins the tables in an optimal order. To give a hint to the optimizer to use a join order corresponding to the order in which the tables are named in a `SELECT` statement, begin the statement with `SELECT STRAIGHT_JOIN` rather than just `SELECT`. (See [Section 14.2.9, “SELECT Syntax”](#).)

The optimizer trace may sometimes provide information complementary to that of [EXPLAIN](#). However, the optimizer trace format and content are subject to change between versions. For details, see [MySQL Internals: Tracing the Optimizer](#).

If you have a problem with indexes not being used when you believe that they should be, run [ANALYZE TABLE](#) to update table statistics, such as cardinality of keys, that can affect the choices the optimizer makes. See [Section 14.7.2.1, “ANALYZE TABLE Syntax”](#).

## 14.8.3 HELP Syntax

```
HELP 'search_string'
```

The [HELP](#) statement returns online information from the MySQL Reference manual. Its proper operation requires that the help tables in the `mysql` database be initialized with help topic information (see [Section 6.1.10, “Server-Side Help”](#)).

The [HELP](#) statement searches the help tables for the given search string and displays the result of the search. The search string is not case sensitive.

The search string can contain the wildcard characters `%` and `_`. These have the same meaning as for pattern-matching operations performed with the [LIKE](#) operator. For example, [HELP](#) `'rep%'` returns a list of topics that begin with `rep`.

The [HELP](#) statement understands several types of search strings:

- At the most general level, use [contents](#) to retrieve a list of the top-level help categories:

```
HELP 'contents'
```

- For a list of topics in a given help category, such as [Data Types](#), use the category name:

```
HELP 'data types'
```

- For help on a specific help topic, such as the [ASCII\(\)](#) function or the [CREATE TABLE](#) statement, use the associated keyword or keywords:

```
HELP 'ascii'  
HELP 'create table'
```

In other words, the search string matches a category, many topics, or a single topic. You cannot necessarily tell in advance whether a given search string will return a list of items or the help information for a single help topic. However, you can tell what kind of response [HELP](#) returned by examining the number of rows and columns in the result set.

The following descriptions indicate the forms that the result set can take. Output for the example statements is shown using the familiar “tabular” or “vertical” format that you see when using the `mysql` client, but note that `mysql` itself reformats [HELP](#) result sets in a different way.

- Empty result set

No match could be found for the search string.

- Result set containing a single row with three columns

This means that the search string yielded a hit for the help topic. The result has three columns:

- [name](#): The topic name.
- [description](#): Descriptive help text for the topic.

- **example:** Usage example or examples. This column might be blank.

Example: `HELP 'replace'`

Yields:

```
name: REPLACE
description: Syntax:
REPLACE(str,from_str,to_str)

Returns the string str with all occurrences of the string from_str
replaced by the string to_str. REPLACE() performs a case-sensitive
match when searching for from_str.
example: mysql> SELECT REPLACE('www.mysql.com', 'w', 'Ww');
-> 'WwWwWw.mysql.com'
```

- Result set containing multiple rows with two columns

This means that the search string matched many help topics. The result set indicates the help topic names:

- **name:** The help topic name.
- **is\_it\_category:** `Y` if the name represents a help category, `N` if it does not. If it does not, the **name** value when specified as the argument to the `HELP` statement should yield a single-row result set containing a description for the named item.

Example: `HELP 'status'`

Yields:

| name                  | is_it_category |
|-----------------------|----------------|
| SHOW                  | N              |
| SHOW ENGINE           | N              |
| SHOW MASTER STATUS    | N              |
| SHOW PROCEDURE STATUS | N              |
| SHOW SLAVE STATUS     | N              |
| SHOW STATUS           | N              |
| SHOW TABLE STATUS     | N              |

- Result set containing multiple rows with three columns

This means the search string matches a category. The result set contains category entries:

- **source\_category\_name:** The help category name.
- **name:** The category or topic name
- **is\_it\_category:** `Y` if the name represents a help category, `N` if it does not. If it does not, the **name** value when specified as the argument to the `HELP` statement should yield a single-row result set containing a description for the named item.

Example: `HELP 'functions'`

Yields:

| source_category_name | name            | is_it_category |
|----------------------|-----------------|----------------|
| Functions            | CREATE FUNCTION | N              |

|           |                         |   |  |
|-----------|-------------------------|---|--|
| Functions | DROP FUNCTION           | N |  |
| Functions | Bit Functions           | Y |  |
| Functions | Comparison operators    | Y |  |
| Functions | Control flow functions  | Y |  |
| Functions | Date and Time Functions | Y |  |
| Functions | Encryption Functions    | Y |  |
| Functions | Information Functions   | Y |  |
| Functions | Logical operators       | Y |  |
| Functions | Miscellaneous Functions | Y |  |
| Functions | Numeric Functions       | Y |  |
| Functions | String Functions        | Y |  |

## 14.8.4 USE Syntax

USE *db\_name*

The `USE db_name` statement tells MySQL to use the *db\_name* database as the default (current) database for subsequent statements. The database remains the default until the end of the session or another `USE` statement is issued:

```
USE db1;
SELECT COUNT(*) FROM mytable;    # selects from db1.mytable
USE db2;
SELECT COUNT(*) FROM mytable;    # selects from db2.mytable
```

Making a particular database the default by means of the `USE` statement does not preclude you from accessing tables in other databases. The following example accesses the `author` table from the `db1` database and the `editor` table from the `db2` database:

```
USE db1;
SELECT author_name,editor_name FROM author,db2.editor
WHERE author.editor_id = db2.editor.editor_id;
```

---

## 15.1 Introduction to InnoDB

**InnoDB** is a general-purpose storage engine that balances high reliability and high performance. In MySQL 5.7, **InnoDB** is the default MySQL storage engine. Unless you have configured a different default storage engine, issuing a `CREATE TABLE` statement without an `ENGINE=` clause creates an **InnoDB** table.

### Key Advantages of InnoDB

Key advantages of **InnoDB** include:

- Its **DML** operations follow the **ACID** model, with **transactions** featuring **commit**, **rollback**, and **crash-recovery** capabilities to protect user data. See [Section 15.2, “InnoDB and the ACID Model”](#) for more information.
- Row-level **locking** and Oracle-style **consistent reads** increase multi-user concurrency and performance. See [Section 15.5, “InnoDB Locking and Transaction Model”](#) for more information.
- **InnoDB** tables arrange your data on disk to optimize queries based on **primary keys**. Each **InnoDB** table has a primary key index called the **clustered index** that organizes the data to minimize I/O for primary key lookups. See [Section 15.8.9, “Clustered and Secondary Indexes”](#) for more information.
- To maintain data **integrity**, **InnoDB** supports **FOREIGN KEY** constraints. With foreign keys, inserts, updates, and deletes are checked to ensure they do not result in inconsistencies across different tables. See [Section 15.8.7, “InnoDB and FOREIGN KEY Constraints”](#) for more information.

**Table 15.1 InnoDB Storage Engine Features**

|                                 |                  |                                     |                  |                                    |                  |
|---------------------------------|------------------|-------------------------------------|------------------|------------------------------------|------------------|
| <b>Storage limits</b>           | 64TB             | <b>Transactions</b>                 | Yes              | <b>Locking granularity</b>         | Row              |
| <b>MVCC</b>                     | Yes              | <b>Geospatial data type support</b> | Yes              | <b>Geospatial indexing support</b> | Yes <sup>a</sup> |
| <b>B-tree indexes</b>           | Yes              | <b>T-tree indexes</b>               | No               | <b>Hash indexes</b>                | No <sup>b</sup>  |
| <b>Full-text search indexes</b> | Yes <sup>c</sup> | <b>Clustered indexes</b>            | Yes              | <b>Data caches</b>                 | Yes              |
| <b>Index caches</b>             | Yes              | <b>Compressed data</b>              | Yes <sup>d</sup> | <b>Encrypted data<sup>e</sup></b>  | Yes              |

|  |     |  |     |  |     |
|--|-----|--|-----|--|-----|
| <b>Cluster database support</b>                    | No  | <b>Replication support<sup>f</sup></b> | Yes | <b>Foreign key support</b>                   | Yes |
| <b>Backup / point-in-time recovery<sup>g</sup></b> | Yes | <b>Query cache support</b>             | Yes | <b>Update statistics for data dictionary</b> | Yes |

<sup>a</sup>InnoDB support for geospatial indexing is available in MySQL 5.7.5 and higher.

<sup>b</sup>InnoDB utilizes hash indexes internally for its Adaptive Hash Index feature.

<sup>c</sup>InnoDB support for FULLTEXT indexes is available in MySQL 5.6.4 and higher.

<sup>d</sup>Compressed InnoDB tables require the InnoDB Barracuda file format.

<sup>e</sup>Implemented in the server (via encryption functions). Data-at-rest tablespace encryption is available in MySQL 5.7 and higher.

<sup>f</sup>Implemented in the server, rather than in the storage engine.

<sup>g</sup>Implemented in the server, rather than in the storage engine.

To compare the features of [InnoDB](#) with other storage engines provided with MySQL, see the *Storage Engine Features* table in [Chapter 16, Alternative Storage Engines](#).

## InnoDB Enhancements and New Features

For information about [InnoDB](#) enhancements and new features in MySQL 5.7, refer to:

- The [InnoDB](#) enhancements list in [Section 1.4, “What Is New in MySQL 5.7”](#).
- The [Release Notes](#).

## Additional InnoDB Information and Resources

- For [InnoDB](#)-related terms and definitions, see [MySQL Glossary](#).
- For a forum dedicated to the [InnoDB](#) storage engine, see [MySQL Forums::InnoDB](#).
- [InnoDB](#) is published under the same GNU GPL License Version 2 (of June 1991) as MySQL. For more information on MySQL licensing, see <http://www.mysql.com/company/legal/licensing/>.

### 15.1.1 Benefits of Using InnoDB Tables

If you use [MyISAM](#) tables but are not committed to them for technical reasons, you may find [InnoDB](#) tables beneficial for the following reasons:

- If your server crashes because of a hardware or software issue, regardless of what was happening in the database at the time, you don't need to do anything special after restarting the database. [InnoDB crash recovery](#) automatically finalizes any changes that were committed before the time of the crash, and undoes any changes that were in process but not committed. Just restart and continue where you left off.
- The [InnoDB](#) storage engine maintains its own [buffer pool](#) that caches table and index data in main memory as data is accessed. Frequently used data is processed directly from memory. This cache applies to many types of information and speeds up processing. On dedicated database servers, up to 80% of physical memory is often assigned to the [InnoDB](#) buffer pool.
- If you split up related data into different tables, you can set up [foreign keys](#) that enforce [referential integrity](#). Update or delete data, and the related data in other tables is updated or deleted automatically. Try to insert data into a secondary table without corresponding data in the primary table, and the bad data gets kicked out automatically.
- If data becomes corrupted on disk or in memory, a [checksum](#) mechanism alerts you to the bogus data before you use it.
- When you design your database with appropriate [primary key](#) columns for each table, operations involving those columns are automatically optimized. It is very fast to reference the primary key columns in [WHERE](#) clauses, [ORDER BY](#) clauses, [GROUP BY](#) clauses, and [join](#) operations.

- Inserts, updates, and deletes are optimized by an automatic mechanism called [change buffering](#). [InnoDB](#) not only allows concurrent read and write access to the same table, it caches changed data to streamline disk I/O.
- Performance benefits are not limited to giant tables with long-running queries. When the same rows are accessed over and over from a table, a feature called the [Adaptive Hash Index](#) takes over to make these lookups even faster, as if they came out of a hash table.
- You can compress tables and associated indexes.
- You can create and drop indexes with much less impact on performance and availability.
- Truncating a [file-per-table](#) tablespace is very fast, and can free up disk space for the operating system to reuse, rather than freeing up space within the [system tablespace](#) that only [InnoDB](#) could reuse.
- The storage layout for table data is more efficient for [BLOB](#) and long text fields, with the [DYNAMIC](#) row format.
- You can monitor the internal workings of the storage engine by querying [INFORMATION\\_SCHEMA](#) tables.
- You can monitor the performance details of the storage engine by querying [Performance Schema](#) tables.
- You can freely mix [InnoDB](#) tables with tables from other MySQL storage engines, even within the same statement. For example, you can use a [join](#) operation to combine data from [InnoDB](#) and [MEMORY](#) tables in a single query.
- [InnoDB](#) has been designed for CPU efficiency and maximum performance when processing large data volumes.
- [InnoDB](#) tables can handle large quantities of data, even on operating systems where file size is limited to 2GB.

For [InnoDB](#)-specific tuning techniques you can apply in your application code, see [Section 9.5](#), “[Optimizing for InnoDB Tables](#)”.

### 15.1.2 Best Practices for InnoDB Tables

This section describes best practices when using [InnoDB](#) tables.

- Specifying a [primary key](#) for every table using the most frequently queried column or columns, or an [auto-increment](#) value if there is no obvious primary key.
- Using [joins](#) wherever data is pulled from multiple tables based on identical ID values from those tables. For fast join performance, define [foreign keys](#) on the join columns, and declare those columns with the same data type in each table. Adding foreign keys ensures that referenced columns are indexed, which can improve performance. Foreign keys also propagate deletes or updates to all affected tables, and prevent insertion of data in a child table if the corresponding IDs are not present in the parent table.
- Turning off [autocommit](#). Committing hundreds of times a second puts a cap on performance (limited by the write speed of your storage device).
- Grouping sets of related [DML](#) operations into [transactions](#), by bracketing them with [START TRANSACTION](#) and [COMMIT](#) statements. While you don't want to commit too often, you also don't want to issue huge batches of [INSERT](#), [UPDATE](#), or [DELETE](#) statements that run for hours without committing.
- Not using [LOCK TABLES](#) statements. [InnoDB](#) can handle multiple sessions all reading and writing to the same table at once, without sacrificing reliability or high performance. To get exclusive write

access to a set of rows, use the `SELECT ... FOR UPDATE` syntax to lock just the rows you intend to update.

- Enabling the `innodb_file_per_table` option to put the data and indexes for individual tables into separate files, instead of in a single giant `system tablespace`. This setting is required to use some of the other features, such as table `compression` and fast `truncation`.

The `innodb_file_per_table` option is enabled by default as of MySQL 5.6.6.

- Evaluating whether your data and access patterns benefit from the `InnoDB` table `compression` feature (`ROW_FORMAT=COMPRESSED`) on the `CREATE TABLE` statement. You can compress `InnoDB` tables without sacrificing read/write capability.
- Running your server with the option `--sql_mode=NO_ENGINE_SUBSTITUTION` to prevent tables being created with a different storage engine if there is an issue with the engine specified in the `ENGINE=` clause of `CREATE TABLE`.

### 15.1.3 Checking InnoDB Availability

To determine whether your server supports `InnoDB`:

- Issue the command `SHOW ENGINES;` to see all the different MySQL storage engines. Look for `DEFAULT` in the `InnoDB` line. Alternatively, query the `INFORMATION_SCHEMA.ENGINES` table. (Now that `InnoDB` is the default MySQL storage engine, only very specialized environments might not support it.)
- If `InnoDB` is not present, you have a `mysqld` binary that was compiled without `InnoDB` support and you need to get a different one.
- If `InnoDB` is present but disabled, go back through your startup options and configuration file and get rid of any `skip-innodb` option.

### 15.1.4 Testing and Benchmarking with InnoDB

If `InnoDB` is not your default storage engine, you can determine if your database server or applications work correctly with `InnoDB` by restarting the server with `--default-storage-engine=InnoDB` defined on the command line or with `default-storage-engine=innodb` defined in the `[mysqld]` section of the `my.cnf` configuration file.

Since changing the default storage engine only affects new tables as they are created, run all your application installation and setup steps to confirm that everything installs properly. Then exercise all the application features to make sure all the data loading, editing, and querying features work. If a table relies on some `MyISAM`-specific feature, you'll receive an error; add the `ENGINE=MyISAM` clause to the `CREATE TABLE` statement to avoid the error.

If you did not make a deliberate decision about the storage engine, and you just want to preview how certain tables work when they're created under `InnoDB`, issue the command `ALTER TABLE table_name ENGINE=InnoDB;` for each table. Or, to run test queries and other statements without disturbing the original table, make a copy like so:

```
CREATE TABLE InnoDB_Table (...) ENGINE=InnoDB AS SELECT * FROM MyISAM_Table;
```

To get a true idea of the performance with a full application under a realistic workload, install the latest MySQL server and run benchmarks.

Test the full application lifecycle, from installation, through heavy usage, and server restart. Kill the server process while the database is busy to simulate a power failure, and verify that the data is recovered successfully when you restart the server.

Test any replication configurations, especially if you use different MySQL versions and options on the master and the slaves.

## 15.1.5 Turning Off InnoDB

Oracle recommends [InnoDB](#) as the preferred storage engine for typical database applications, from single-user wikis and blogs running on a local system, to high-end applications pushing the limits of performance. In MySQL 5.7, [InnoDB](#) is the default storage engine for new tables.

### Important

As of MySQL 5.7.5, [InnoDB](#) cannot be disabled. The `--skip-innodb` option is deprecated and has no effect, and its use results in a warning. It will be removed in a future MySQL release. This also applies to its synonyms (`--innodb=OFF`, `--disable-innodb`, and so forth). Before 5.7.5, if you do not want to use [InnoDB](#) tables:

- Start the server with the `--innodb=OFF` or `--skip-innodb` option to disable the [InnoDB](#) storage engine.
- Because the default storage engine is [InnoDB](#), the server will not start unless you also use `--default-storage-engine` and `--default-tmp-storage-engine` to set the default to some other engine for both permanent and [TEMPORARY](#) tables.
- To prevent the server from crashing when the [InnoDB-related information\\_schema tables](#) are queried, also disable the plugins associated with those tables. Specify in the `[mysqld]` section of the MySQL configuration file:

```
loose-innodb-trx=0
loose-innodb-locks=0
loose-innodb-lock-waits=0
loose-innodb-cmp=0
loose-innodb-cmp-per-index=0
loose-innodb-cmp-per-index-reset=0
loose-innodb-cmp-reset=0
loose-innodb-cmpmem=0
loose-innodb-cmpmem-reset=0
loose-innodb-buffer-page=0
loose-innodb-buffer-page-lru=0
loose-innodb-buffer-pool-stats=0
loose-innodb-metrics=0
loose-innodb-ft-default-stopword=0
loose-innodb-ft-inserted=0
loose-innodb-ft-deleted=0
loose-innodb-ft-being-deleted=0
loose-innodb-ft-config=0
loose-innodb-ft-index-cache=0
loose-innodb-ft-index-table=0
loose-innodb-sys-tables=0
loose-innodb-sys-tablestats=0
loose-innodb-sys-indexes=0
loose-innodb-sys-columns=0
loose-innodb-sys-fields=0
loose-innodb-sys-foreign=0
loose-innodb-sys-foreign-cols=0
```

## 15.2 InnoDB and the ACID Model

The [ACID](#) model is a set of database design principles that emphasize aspects of reliability that are important for business data and mission-critical applications. MySQL includes components such as the [InnoDB](#) storage engine that adhere closely to the ACID model, so that data is not corrupted and results are not distorted by exceptional conditions such as software crashes and hardware malfunctions. When you rely on ACID-compliant features, you do not need to reinvent the wheel of consistency checking and crash recovery mechanisms. In cases where you have additional software safeguards, ultra-reliable hardware, or an application that can tolerate a small amount of data loss or inconsistency, you can adjust MySQL settings to trade some of the ACID reliability for greater performance or throughput.

The following sections discuss how MySQL features, in particular the [InnoDB](#) storage engine, interact with the categories of the ACID model:

- **A**: atomicity.
- **C**: consistency.
- **I**: isolation.
- **D**: durability.

## Atomicity

The **atomicity** aspect of the ACID model mainly involves [InnoDB transactions](#). Related MySQL features include:

- Autocommit setting.
- [COMMIT](#) statement.
- [ROLLBACK](#) statement.
- Operational data from the [INFORMATION\\_SCHEMA](#) tables.

## Consistency

The **consistency** aspect of the ACID model mainly involves internal [InnoDB](#) processing to protect data from crashes. Related MySQL features include:

- [InnoDB doublewrite buffer](#).
- [InnoDB crash recovery](#).

## Isolation

The **isolation** aspect of the ACID model mainly involves [InnoDB transactions](#), in particular the [isolation level](#) that applies to each transaction. Related MySQL features include:

- [Autocommit](#) setting.
- [SET ISOLATION LEVEL](#) statement.
- The low-level details of [InnoDB locking](#). During performance tuning, you see these details through [INFORMATION\\_SCHEMA](#) tables.

## Durability

The **durability** aspect of the ACID model involves MySQL software features interacting with your particular hardware configuration. Because of the many possibilities depending on the capabilities of your CPU, network, and storage devices, this aspect is the most complicated to provide concrete guidelines for. (And those guidelines might take the form of buy “new hardware”.) Related MySQL features include:

- [InnoDB doublewrite buffer](#), turned on and off by the [innodb\\_doublewrite](#) configuration option.
- Configuration option [innodb\\_flush\\_log\\_at\\_trx\\_commit](#).
- Configuration option [sync\\_binlog](#).
- Configuration option [innodb\\_file\\_per\\_table](#).
- Write buffer in a storage device, such as a disk drive, SSD, or RAID array.
- Battery-backed cache in a storage device.

- The operating system used to run MySQL, in particular its support for the `fsync()` system call.
- Uninterruptible power supply (UPS) protecting the electrical power to all computer servers and storage devices that run MySQL servers and store MySQL data.
- Your backup strategy, such as frequency and types of backups, and backup retention periods.
- For distributed or hosted data applications, the particular characteristics of the data centers where the hardware for the MySQL servers is located, and network connections between the data centers.

## 15.3 InnoDB Multi-Versioning

InnoDB is a [multi-versioned storage engine](#): it keeps information about old versions of changed rows, to support transactional features such as concurrency and [rollback](#). This information is stored in the tablespace in a data structure called a [rollback segment](#) (after an analogous data structure in Oracle). InnoDB uses the information in the rollback segment to perform the undo operations needed in a transaction rollback. It also uses the information to build earlier versions of a row for a [consistent read](#).

Internally, InnoDB adds three fields to each row stored in the database. A 6-byte `DB_TRX_ID` field indicates the transaction identifier for the last transaction that inserted or updated the row. Also, a deletion is treated internally as an update where a special bit in the row is set to mark it as deleted. Each row also contains a 7-byte `DB_ROLL_PTR` field called the roll pointer. The roll pointer points to an undo log record written to the rollback segment. If the row was updated, the undo log record contains the information necessary to rebuild the content of the row before it was updated. A 6-byte `DB_ROW_ID` field contains a row ID that increases monotonically as new rows are inserted. If InnoDB generates a clustered index automatically, the index contains row ID values. Otherwise, the `DB_ROW_ID` column does not appear in any index.

Undo logs in the rollback segment are divided into insert and update undo logs. Insert undo logs are needed only in transaction rollback and can be discarded as soon as the transaction commits. Update undo logs are used also in consistent reads, but they can be discarded only after there is no transaction present for which InnoDB has assigned a snapshot that in a consistent read could need the information in the update undo log to build an earlier version of a database row.

Commit your transactions regularly, including those transactions that issue only consistent reads. Otherwise, InnoDB cannot discard data from the update undo logs, and the rollback segment may grow too big, filling up your tablespace.

The physical size of an undo log record in the rollback segment is typically smaller than the corresponding inserted or updated row. You can use this information to calculate the space needed for your rollback segment.

In the InnoDB multi-versioning scheme, a row is not physically removed from the database immediately when you delete it with an SQL statement. InnoDB only physically removes the corresponding row and its index records when it discards the update undo log record written for the deletion. This removal operation is called a [purge](#), and it is quite fast, usually taking the same order of time as the SQL statement that did the deletion.

If you insert and delete rows in smallish batches at about the same rate in the table, the purge thread can start to lag behind and the table can grow bigger and bigger because of all the “dead” rows, making everything disk-bound and very slow. In such a case, throttle new row operations, and allocate more resources to the purge thread by tuning the `innodb_max_purge_lag` system variable. See [Section 15.14, “InnoDB Startup Options and System Variables”](#) for more information.

## Multi-Versioning and Secondary Indexes

InnoDB multiversion concurrency control (MVCC) treats secondary indexes differently than clustered indexes. Records in a clustered index are updated in-place, and their hidden system columns point undo log entries from which earlier versions of records can be reconstructed. Unlike clustered index records, secondary index records do not contain hidden system columns nor are they updated in-place.

When a secondary index column is updated, old secondary index records are delete-marked, new records are inserted, and delete-marked records are eventually purged. When a secondary index record is delete-marked or the secondary index page is updated by a newer transaction, [InnoDB](#) looks up the database record in the clustered index. In the clustered index, the record's `DB_TRX_ID` is checked, and the correct version of the record is retrieved from the undo log if the record was modified after the reading transaction was initiated.

If a secondary index record is marked for deletion or the secondary index page is updated by a newer transaction, the [covering index](#) technique is not used. Instead of returning values from the index structure, [InnoDB](#) looks up the record in the clustered index.

However, if the [index condition pushdown \(ICP\)](#) optimization is enabled, and parts of the `WHERE` condition can be evaluated using only fields from the index, the MySQL server still pushes this part of the `WHERE` condition down to the storage engine where it is evaluated using the index. If no matching records are found, the clustered index lookup is avoided. If matching records are found, even among delete-marked records, [InnoDB](#) looks up the record in the clustered index.

## 15.4 InnoDB Architecture

This section provides an introduction to the major components of the [InnoDB](#) storage engine architecture.

### 15.4.1 Buffer Pool

The buffer pool is an area in main memory where [InnoDB](#) caches table and index data as data is accessed. The buffer pool allows frequently used data to be processed directly from memory, which speeds up processing. On dedicated database servers, up to 80% of physical memory is often assigned to the [InnoDB](#) buffer pool.

For efficiency of high-volume read operations, the buffer pool is divided into [pages](#) that can potentially hold multiple rows. For efficiency of cache management, the buffer pool is implemented as a linked list of pages; data that is rarely used is aged out of the cache, using a variation of the [LRU](#) algorithm.

For more information, see [Section 15.6.3.1, “The InnoDB Buffer Pool”](#), and [Section 15.6.3, “InnoDB Buffer Pool Configuration”](#).

### 15.4.2 Change Buffer

The change buffer is a special data structure that caches changes to [secondary index](#) pages when affected pages are not in the [buffer pool](#). The buffered changes, which may result from `INSERT`, `UPDATE`, or `DELETE` operations (DML), are merged later when the pages are loaded into the buffer pool by other read operations.

Unlike [clustered indexes](#), secondary indexes are usually non-unique, and inserts into secondary indexes happen in a relatively random order. Similarly, deletes and updates may affect secondary index pages that are not adjacently located in an index tree. Merging cached changes at a later time, when affected pages are read into the buffer pool by other operations, avoids substantial random access I/O that would be required to read-in secondary index pages from disk.

Periodically, the purge operation that runs when the system is mostly idle, or during a slow shutdown, writes the updated index pages to disk. The purge operation can write disk blocks for a series of index values more efficiently than if each value were written to disk immediately.

Change buffer merging may take several hours when there are numerous secondary indexes to update and many affected rows. During this time, disk I/O is increased, which can cause a significant slowdown for disk-bound queries. Change buffer merging may also continue to occur after a transaction is committed. In fact, change buffer merging may continue to occur after a server shutdown and restart (see [Section 15.21.2, “Forcing InnoDB Recovery”](#) for more information).

In memory, the change buffer occupies part of the [InnoDB](#) buffer pool. On disk, the change buffer is part of the system tablespace, so that index changes remain buffered across database restarts.

The type of data cached in the change buffer is governed by the `innodb_change_buffering` configuration option. For more information, see [Section 15.6.5, “Configuring InnoDB Change Buffering”](#). You can also configure the maximum change buffer size. For more information, see [Section 15.6.5.1, “Configuring the Change Buffer Maximum Size”](#).

## Monitoring the Change Buffer

The following options are available for change buffer monitoring:

- [InnoDB Standard Monitor](#) output includes status information for the change buffer. To view monitor data, issue the `SHOW ENGINE INNODB STATUS` command.

```
mysql> SHOW ENGINE INNODB STATUS\G
```

Change buffer status information is located under the `INSERT BUFFER AND ADAPTIVE HASH INDEX` heading and appears similar to the following:

```
-----
INSERT BUFFER AND ADAPTIVE HASH INDEX
-----
Ibuf: size 1, free list len 0, seg size 2, 0 merges
merged operations:
  insert 0, delete mark 0, delete 0
discarded operations:
  insert 0, delete mark 0, delete 0
Hash table size 4425293, used cells 32, node heap has 1 buffer(s)
13577.57 hash searches/s, 202.47 non-hash searches/s
```

For more information, see [Section 15.17.3, “InnoDB Standard Monitor and Lock Monitor Output”](#).

- The `INFORMATION_SCHEMA.INNODB_METRICS` table provides most of the data points found in [InnoDB Standard Monitor](#) output, plus other data points. To view change buffer metrics and a description of each, issue the following query:

```
mysql> SELECT NAME, COMMENT FROM INFORMATION_SCHEMA.INNODB_METRICS WHERE NAME LIKE '%ibuf%'\G
```

For `INNODB_METRICS` table usage information, see [Section 15.15.6, “InnoDB INFORMATION\\_SCHEMA Metrics Table”](#).

- The `INFORMATION_SCHEMA.INNODB_BUFFER_PAGE` table provides metadata about each page in the buffer pool, including change buffer index and change buffer bitmap pages. Change buffer pages are identified by `PAGE_TYPE`. `IBUF_INDEX` is the page type for change buffer index pages, and `IBUF_BITMAP` is the page type for change buffer bitmap pages.

### Warning

Querying the `INNODB_BUFFER_PAGE` table can introduce significant performance overhead. To avoid impacting performance, reproduce the issue you want to investigate on a test instance and run your queries on the test instance.

For example, you can query the `INNODB_BUFFER_PAGE` table to determine the approximate number of `IBUF_INDEX` and `IBUF_BITMAP` pages as a percentage of total buffer pool pages.

```
SELECT
  (SELECT COUNT(*) FROM INFORMATION_SCHEMA.INNODB_BUFFER_PAGE
   WHERE PAGE_TYPE LIKE 'IBUF%')
  ) AS change_buffer_pages,
  (
    SELECT COUNT(*)
    FROM INFORMATION_SCHEMA.INNODB_BUFFER_PAGE
  ) AS total_pages,
  (
    SELECT ((change_buffer_pages/total_pages)*100)
  ) AS change_buffer_page_percentage;
```

| change_buffer_pages | total_pages | change_buffer_page_percentage |
|---------------------|-------------|-------------------------------|
| 25                  | 8192        | 0.3052                        |

For information about other data provided by the `INNODB_BUFFER_PAGE` table, see [Section 23.31.1, “The INFORMATION\\_SCHEMA INNODB\\_BUFFER\\_PAGE Table”](#). For related usage information, see [Section 15.15.5, “InnoDB INFORMATION\\_SCHEMA Buffer Pool Tables”](#).

- [Performance Schema](#) provides change buffer mutex wait instrumentation for advanced performance monitoring. To view change buffer instrumentation, issue the following query:

```
mysql> SELECT * FROM performance_schema.setup_instruments
WHERE NAME LIKE '%wait/synch/mutex/innodb/ibuf%';
```

| NAME  | ENABLED | TIMED |
|---|---------|-------|
| wait/synch/mutex/innodb/ibuf_bitmap_mutex             | YES     | YES   |
| wait/synch/mutex/innodb/ibuf_mutex                    | YES     | YES   |
| wait/synch/mutex/innodb/ibuf_pessimistic_insert_mutex | YES     | YES   |

For information about monitoring [InnoDB](#) mutex waits, see [Section 15.16.2, “Monitoring InnoDB Mutex Waits Using Performance Schema”](#).

### 15.4.3 Adaptive Hash Index

The [adaptive hash index](#) (AHI) lets [InnoDB](#) perform more like an in-memory database on systems with appropriate combinations of workload and ample memory for the [buffer pool](#), without sacrificing any transactional features or reliability. This feature is enabled by the `innodb_adaptive_hash_index` option, or turned off by `--skip-innodb_adaptive_hash_index` at server startup.

Based on the observed pattern of searches, MySQL builds a hash index using a prefix of the index key. The prefix of the key can be any length, and it may be that only some of the values in the B-tree appear in the hash index. Hash indexes are built on demand for those pages of the index that are often accessed.

If a table fits almost entirely in main memory, a hash index can speed up queries by enabling direct lookup of any element, turning the index value into a sort of pointer. [InnoDB](#) has a mechanism that monitors index searches. If [InnoDB](#) notices that queries could benefit from building a hash index, it does so automatically.

With some [workloads](#), the speedup from hash index lookups greatly outweighs the extra work to monitor index lookups and maintain the hash index structure. Sometimes, the read/write lock that guards access to the adaptive hash index can become a source of contention under heavy workloads, such as multiple concurrent joins. Queries with `LIKE` operators and `%` wildcards also tend not to benefit from the AHI. For workloads where the adaptive hash index is not needed, turning it off reduces unnecessary performance overhead. Because it is difficult to predict in advance whether this feature is appropriate for a particular system, consider running benchmarks with it both enabled and disabled, using a realistic workload. The architectural changes in MySQL 5.6 and higher make more workloads suitable for disabling the adaptive hash index than in earlier releases, although it is still enabled by default.

As of MySQL 5.7.8, the adaptive hash index search system is partitioned. Each index is bound to a specific partition, and each partition is protected by a separate latch. Partitioning is controlled by the `innodb_adaptive_hash_index_parts` configuration option. Prior to MySQL 5.7.8, the adaptive hash index search system was protected by a single latch which could become a point of contention under heavy workloads. The `innodb_adaptive_hash_index_parts` option is set to 8 by default. The maximum setting is 512.

The hash index is always built based on an existing [B-tree](#) index on the table. [InnoDB](#) can build a hash index on a prefix of any length of the key defined for the B-tree, depending on the pattern of searches

that [InnoDB](#) observes for the B-tree index. A hash index can be partial, covering only those pages of the index that are often accessed.

You can monitor the use of the adaptive hash index and the contention for its use in the [SEMAPHORES](#) section of the output of the [SHOW ENGINE INNODB STATUS](#) command. If you see many threads waiting on an RW-latch created in [btr0sea.c](#), then it might be useful to disable adaptive hash indexing.

For more information about the performance characteristics of hash indexes, see [Section 9.3.8](#), “Comparison of B-Tree and Hash Indexes”.

## 15.4.4 Redo Log Buffer

The redo log buffer is the memory area that holds data to be written to the [redo log](#). Redo log buffer size is defined by the [innodb\\_log\\_buffer\\_size](#) configuration option. The redo log buffer is periodically flushed to the log file on disk. A large redo log buffer enables large transactions to run without the need to write redo log to disk before the transactions commit. Thus, if you have transactions that update, insert, or delete many rows, making the log buffer larger saves disk I/O.

The [innodb\\_flush\\_log\\_at\\_trx\\_commit](#) option controls how the contents of the redo log buffer are written to the log file. The [innodb\\_flush\\_log\\_at\\_timeout](#) option controls redo log flushing frequency.

## 15.4.5 System Tablespace

The [InnoDB](#) system tablespace contains the [InnoDB](#) data dictionary (metadata for [InnoDB](#)-related objects) and is the storage area for the doublewrite buffer, the change buffer, and undo logs. The system tablespace also contains table and index data for any user-created tables that are created in the system tablespace. The system tablespace is considered a shared tablespace since it is shared by multiple tables.

The system tablespace is represented by one or more data files. By default, one system data file, named [ibdata1](#), is created in the MySQL [data](#) directory. The size and number of system data files is controlled by the [innodb\\_data\\_file\\_path](#) startup option.

For related information, see [Section 15.6.1](#), “InnoDB Startup Configuration”, and [Section 15.7.1](#), “Resizing the InnoDB System Tablespace”.

## 15.4.6 InnoDB Data Dictionary

The [InnoDB](#) data dictionary is comprised of internal system tables that contain metadata used to keep track of objects such as tables, indexes, and table columns. The metadata is physically located in the [InnoDB](#) system tablespace. For historical reasons, data dictionary metadata overlaps to some degree with information stored in [InnoDB](#) table metadata files ([.frm](#) files).

## 15.4.7 Doublewrite Buffer

The doublewrite buffer is a storage area located in the system tablespace where [InnoDB](#) writes pages that are flushed from the [InnoDB](#) buffer pool, before the pages are written to their proper positions in the data file. Only after flushing and writing pages to the doublewrite buffer, does [InnoDB](#) write pages to their proper positions. If there is an operating system, storage subsystem, or [mysqld](#) process crash in the middle of a page write, [InnoDB](#) can later find a good copy of the page from the doublewrite buffer during crash recovery.

Although data is always written twice, the doublewrite buffer does not require twice as much I/O overhead or twice as many I/O operations. Data is written to the doublewrite buffer itself as a large sequential chunk, with a single [fsync\(\)](#) call to the operating system.

The doublewrite buffer is enabled by default in most cases. To disable the doublewrite buffer, set [innodb\\_doublewrite](#) to 0.

As of MySQL 5.7.4, if system tablespace files (“ibdata files”) are located on Fusion-io devices that support atomic writes, doublewrite buffering is automatically disabled and Fusion-io atomic writes are used for all data files. Because the doublewrite buffer setting is global, doublewrite buffering is also disabled for data files residing on non-Fusion-io hardware. This feature is only supported on Fusion-io hardware and is only enabled for Fusion-io NVMFS on Linux. To take full advantage of this feature, an `innodb_flush_method` setting of `O_DIRECT` is recommended.

## 15.4.8 Undo Logs

An undo log is a collection of undo log records associated with a single transaction. An undo log record contains information about how to undo the latest change by a transaction to a [clustered index](#) record. If another transaction needs to see the original data (as part of a consistent read operation), the unmodified data is retrieved from the undo log records. Undo logs exist within [undo log segments](#), which are contained within [rollback segments](#). By default, rollback segments are physically part of the [system tablespace](#). However, rollback segments can reside in separate [undo tablespaces](#). For more information, see [Section 15.7.7, “Storing InnoDB Undo Logs in Separate Tablespaces”](#). For information about multi-versioning, see [Section 15.3, “InnoDB Multi-Versioning”](#).

[InnoDB](#) supports 128 rollback segments, 32 of which are reserved as non-redo rollback segments for temporary table transactions. Each transaction that updates a temporary table (excluding read-only transactions) is assigned two rollback segments, one redo-enabled rollback segment and one non-redo rollback segment. Read-only transactions are only assigned non-redo rollback segments, as read-only transactions are only permitted to modify temporary tables.

This leaves 96 available rollback segments, each of which supports up to 1023 concurrent data-modifying transactions, for a total limit of approximately 96K concurrent data-modifying transactions. The 96K limit assumes that transactions do not modify temporary tables. If all data-modifying transactions also modify temporary tables, the total limit is approximately 32K concurrent data modifying transactions. For more information about rollback segments that are reserved for temporary table transactions, see [Section 15.4.12.1, “InnoDB Temporary Table Undo Logs”](#).

The `innodb_undo_logs` option defines the number of rollback segments used by [InnoDB](#).

## 15.4.9 File-Per-Table Tablespaces

A file-per-table tablespace is a single-table tablespace that is created in its own data file rather than in the system tablespace. Tables are created in file-per-table tablespaces when the `innodb_file_per_table` option is enabled. Otherwise, [InnoDB](#) tables are created in the system tablespace. Each file-per-table tablespace is represented by a single `.ibd` data file, which is created in the database directory by default.

File per-table tablespaces support [DYNAMIC](#) and [COMPRESSED](#) row formats which support features such as off-page storage for variable length data and table compression. For information about these features, and about other advantages of file-per-table tablespaces, see [Section 15.7.4, “InnoDB File-Per-Table Tablespaces”](#).

## 15.4.10 General Tablespaces

A shared [InnoDB](#) tablespace created using `CREATE TABLESPACE` syntax. General tablespaces can be created outside of the MySQL data directory, are capable of holding multiple tables, and support tables of all row formats. General tablespaces were introduced in MySQL 5.7.6.

Tables are added to a general tablespace using `CREATE TABLE tbl_name ... TABLESPACE [=] tablespace_name` or `ALTER TABLE tbl_name TABLESPACE [=] tablespace_name` syntax.

For more information, see [Section 15.7.9, “InnoDB General Tablespaces”](#).

## 15.4.11 Undo Tablespace

An undo tablespace comprises one or more files that contain [undo logs](#). Undo logs exist within [undo log segments](#), which are contained within [rollback segments](#). By default, rollback segments

are physically part of the [system tablespace](#). However, rollback segments can reside in separate undo tablespaces. An undo tablespace is created when the undo log is separated from the system tablespace using the [innodb\\_undo\\_tablespaces](#) and [innodb\\_undo\\_directory](#) configuration options.

For more information, see [Section 15.7.7, “Storing InnoDB Undo Logs in Separate Tablespaces”](#).

## 15.4.12 Temporary Tablespace

The temporary tablespace, introduced in MySQL 5.7.1, is a tablespace for non-compressed InnoDB temporary tables and related objects. The configuration option, [innodb\\_temp\\_data\\_file\\_path](#), defines a relative path for the temporary tablespace data file. If [innodb\\_temp\\_data\\_file\\_path](#) is not defined, a single auto-extending 12MB data file named [ibtmp1](#) is created in the data directory. The temporary tablespace is recreated on each server start and receives a dynamically generated space ID, which helps avoid conflicts with existing space IDs. The temporary tablespace cannot reside on a raw device. Startup is refused if the temporary tablespace cannot be created.

The temporary tablespace is removed on normal shutdown or on an aborted initialization. The temporary tablespace is not removed when a crash occurs. In this case, the database administrator may remove the temporary tablespace manually or restart the server with the same configuration, which removes and recreates the temporary tablespace.

### 15.4.12.1 InnoDB Temporary Table Undo Logs

Temporary table undo logs, introduced in MySQL 5.7.2, are used for temporary tables and related objects. This type of [undo log](#) is not a redo log, as temporary tables are not recovered during crash recovery and do not require redo logs. Temporary table undo logs are, however, used for rollback while the server is running. This special type of non-redo undo log benefits performance by avoiding redo logging I/O for temporary tables and related objects. Temporary table undo logs reside in the temporary tablespace. The default temporary tablespace file, [ibtmp1](#), is located in the data directory by default and is always recreated on server startup. A user defined location for the temporary tablespace file can be specified by setting [innodb\\_temp\\_data\\_file\\_path](#).

32 [rollback segments](#) are reserved for temporary table [undo logs](#) for transactions that modify temporary tables and related objects, which means that the maximum number of rollback segments available for data-modifying transactions that generate undo records is 96. With 96 available rollback segments, the limit on concurrent data-modifying transactions is 96K. For more information see [Section 15.3, “InnoDB Multi-Versioning”](#) and [Section 15.8.8, “Limits on InnoDB Tables”](#).

## 15.4.13 Redo Log

The redo log is a disk-based data structure used during crash recovery to correct data written by incomplete transactions. During normal operations, the redo log encodes requests to change InnoDB table data that result from SQL statements or low-level API calls. Modifications that did not finish updating the data files before an unexpected shutdown are replayed automatically during initialization, and before the connections are accepted. For information about the role of the redo log in crash recovery, see [Section 15.18.1, “The InnoDB Recovery Process”](#).

By default, the redo log is physically represented on disk as a set of files, named [ib\\_logfile0](#) and [ib\\_logfile1](#). MySQL writes to the redo log files in a circular fashion. Data in the redo log is encoded in terms of records affected; this data is collectively referred to as redo. The passage of data through the redo log is represented by an ever-increasing [LSN](#) value.

For related information, see:

- [Section 15.6.1, “InnoDB Startup Configuration”](#)
- [Section 9.5.4, “Optimizing InnoDB Redo Logging”](#)
- [Section 15.7.2, “Changing the Number or Size of InnoDB Redo Log Files”](#)

### 15.4.13.1 Group Commit for Redo Log Flushing

InnoDB, like any other ACID-compliant database engine, flushes the redo log of a transaction before it is committed. InnoDB uses group commit functionality to group multiple such flush requests together to avoid one flush for each commit. With group commit, InnoDB issues a single write to the log file to perform the commit action for multiple user transactions that commit at about the same time, significantly improving throughput.

For more information about performance of COMMIT and other transactional operations, see Section 9.5.2, “Optimizing InnoDB Transaction Management”.

## 15.5 InnoDB Locking and Transaction Model

To implement a large-scale, busy, or highly reliable database application, to port substantial code from a different database system, or to tune MySQL performance, it is important to understand InnoDB locking and the InnoDB transaction model.

This section discusses several topics related to InnoDB locking and the InnoDB transaction model with which you should be familiar.

- Section 15.5.1, “InnoDB Locking” describes lock types used by InnoDB.
- Section 15.5.2, “InnoDB Transaction Model” describes transaction isolation levels and the locking strategies used by each. It also discusses the use of autocommit, consistent non-locking reads, and locking reads.
- Section 15.5.3, “Locks Set by Different SQL Statements in InnoDB” discusses specific types of locks set in InnoDB for various statements.
- Section 15.5.4, “Phantom Rows” describes how InnoDB uses next-key locking to avoid phantom rows.
- Section 15.5.5, “Deadlocks in InnoDB” provides a deadlock example, discusses deadlock detection and rollback, and provides tips for minimizing and handling deadlocks in InnoDB.

### 15.5.1 InnoDB Locking

This section describes lock types used by InnoDB.

- Shared and Exclusive Locks
- Intention Locks
- Record Locks
- Gap Locks
- Next-Key Locks
- Insert Intention Locks
- AUTO-INC Locks
- Predicate Locks for Spatial Indexes

#### Shared and Exclusive Locks

InnoDB implements standard row-level locking where there are two types of locks, shared (S) locks and exclusive (X) locks.

- A shared (S) lock permits the transaction that holds the lock to read a row.
- An exclusive (X) lock permits the transaction that holds the lock to update or delete a row.

If transaction **T1** holds a shared (**S**) lock on row **r**, then requests from some distinct transaction **T2** for a lock on row **r** are handled as follows:

- A request by **T2** for an **S** lock can be granted immediately. As a result, both **T1** and **T2** hold an **S** lock on **r**.
- A request by **T2** for an **X** lock cannot be granted immediately.

If a transaction **T1** holds an exclusive (**X**) lock on row **r**, a request from some distinct transaction **T2** for a lock of either type on **r** cannot be granted immediately. Instead, transaction **T2** has to wait for transaction **T1** to release its lock on row **r**.

## Intention Locks

InnoDB supports *multiple granularity locking* which permits coexistence of row-level locks and locks on entire tables. To make locking at multiple granularity levels practical, additional types of locks called **intention locks** are used. Intention locks are table-level locks in InnoDB that indicate which type of lock (shared or exclusive) a transaction will require later for a row in that table. There are two types of intention locks used in InnoDB (assume that transaction **T** has requested a lock of the indicated type on table **t**):

- **Intention shared (IS)**: Transaction **T** intends to set **S** locks on individual rows in table **t**.
- **Intention exclusive (IX)**: Transaction **T** intends to set **X** locks on those rows.

For example, `SELECT ... LOCK IN SHARE MODE` sets an **IS** lock and `SELECT ... FOR UPDATE` sets an **IX** lock.

The intention locking protocol is as follows:

- Before a transaction can acquire an **S** lock on a row in table **t**, it must first acquire an **IS** or stronger lock on **t**.
- Before a transaction can acquire an **X** lock on a row, it must first acquire an **IX** lock on **t**.

These rules can be conveniently summarized by means of the following *lock type compatibility matrix*.

|           | <b>X</b> | <b>IX</b>  | <b>S</b>   | <b>IS</b>  |
|-----------|----------|------------|------------|------------|
| <b>X</b>  | Conflict | Conflict   | Conflict   | Conflict   |
| <b>IX</b> | Conflict | Compatible | Conflict   | Compatible |
| <b>S</b>  | Conflict | Conflict   | Compatible | Compatible |
| <b>IS</b> | Conflict | Compatible | Compatible | Compatible |

A lock is granted to a requesting transaction if it is compatible with existing locks, but not if it conflicts with existing locks. A transaction waits until the conflicting existing lock is released. If a lock request conflicts with an existing lock and cannot be granted because it would cause **deadlock**, an error occurs.

Thus, intention locks do not block anything except full table requests (for example, `LOCK TABLES ... WRITE`). The main purpose of **IX** and **IS** locks is to show that someone is locking a row, or going to lock a row in the table.

Transaction data for an intention lock appears similar to the following in `SHOW ENGINE INNODB STATUS` and InnoDB monitor output:

```
TABLE LOCK table `test`.`t` trx id 10080 lock mode IX
```

## Record Locks

A record lock is a lock on an index record. For example, `SELECT c1 FROM t WHERE c1 = 10 FOR UPDATE;` prevents any other transaction from inserting, updating, or deleting rows where the value of **t.c1** is 10.

Record locks always lock index records, even if a table is defined with no indexes. For such cases, InnoDB creates a hidden clustered index and uses this index for record locking. See [Section 15.8.9, “Clustered and Secondary Indexes”](#).

Transaction data for a record lock appears similar to the following in `SHOW ENGINE INNODB STATUS` and InnoDB monitor output:

```
RECORD LOCKS space id 58 page no 3 n bits 72 index `PRIMARY` of table `test`.`t`
trx id 10078 lock_mode X locks rec but not gap
Record lock, heap no 2 PHYSICAL RECORD: n_fields 3; compact format; info bits 0
 0: len 4; hex 8000000a; asc      ;;
 1: len 6; hex 00000000274f; asc    'O';
 2: len 7; hex b60000019d0110; asc      ;;
```

## Gap Locks

A gap lock is a lock on a gap between index records, or a lock on the gap before the first or after the last index record. For example, `SELECT c1 FROM t WHERE c1 BETWEEN 10 and 20 FOR UPDATE;` prevents other transactions from inserting a value of 15 into column `t.c1`, whether or not there was already any such value in the column, because the gaps between all existing values in the range are locked.

A gap might span a single index value, multiple index values, or even be empty.

Gap locks are part of the tradeoff between performance and concurrency, and are used in some transaction isolation levels and not others.

Gap locking is not needed for statements that lock rows using a unique index to search for a unique row. (This does not include the case that the search condition includes only some columns of a multiple-column unique index; in that case, gap locking does occur.) For example, if the `id` column has a unique index, the following statement uses only an index-record lock for the row having `id` value 100 and it does not matter whether other sessions insert rows in the preceding gap:

```
SELECT * FROM child WHERE id = 100;
```

If `id` is not indexed or has a nonunique index, the statement does lock the preceding gap.

It is also worth noting here that conflicting locks can be held on a gap by different transactions. For example, transaction A can hold a shared gap lock (gap S-lock) on a gap while transaction B holds an exclusive gap lock (gap X-lock) on the same gap. The reason conflicting gap locks are allowed is that if a record is purged from an index, the gap locks held on the record by different transactions must be merged.

Gap locks in InnoDB are “purely inhibitive”, which means they only stop other transactions from inserting to the gap. They do not prevent different transactions from taking gap locks on the same gap. Thus, a gap X-lock has the same effect as a gap S-lock.

Gap locking can be disabled explicitly. This occurs if you change the transaction isolation level to `READ COMMITTED` or enable the `innodb_locks_unsafe_for_binlog` system variable (which is now deprecated). Under these circumstances, gap locking is disabled for searches and index scans and is used only for foreign-key constraint checking and duplicate-key checking.

There are also other effects of using the `READ COMMITTED` isolation level or enabling `innodb_locks_unsafe_for_binlog`. Record locks for nonmatching rows are released after MySQL has evaluated the `WHERE` condition. For `UPDATE` statements, InnoDB does a “semi-consistent” read, such that it returns the latest committed version to MySQL so that MySQL can determine whether the row matches the `WHERE` condition of the `UPDATE`.

## Next-Key Locks

A next-key lock is a combination of a record lock on the index record and a gap lock on the gap before the index record.

[InnoDB](#) performs row-level locking in such a way that when it searches or scans a table index, it sets shared or exclusive locks on the index records it encounters. Thus, the row-level locks are actually index-record locks. A next-key lock on an index record also affects the “gap” before that index record. That is, a next-key lock is an index-record lock plus a gap lock on the gap preceding the index record. If one session has a shared or exclusive lock on record [R](#) in an index, another session cannot insert a new index record in the gap immediately before [R](#) in the index order.

Suppose that an index contains the values 10, 11, 13, and 20. The possible next-key locks for this index cover the following intervals, where a round bracket denotes exclusion of the interval endpoint and a square bracket denotes inclusion of the endpoint:

```
(negative infinity, 10]
(10, 11]
(11, 13]
(13, 20]
(20, positive infinity)
```

For the last interval, the next-key lock locks the gap above the largest value in the index and the “supremum” pseudo-record having a value higher than any value actually in the index. The supremum is not a real index record, so, in effect, this next-key lock locks only the gap following the largest index value.

By default, [InnoDB](#) operates in [REPEATABLE READ](#) transaction isolation level. In this case, [InnoDB](#) uses next-key locks for searches and index scans, which prevents phantom rows (see [Section 15.5.4, “Phantom Rows”](#)).

Transaction data for a next-key lock appears similar to the following in [SHOW ENGINE INNODB STATUS](#) and [InnoDB monitor](#) output:

```
RECORD LOCKS space id 58 page no 3 n bits 72 index `PRIMARY` of table `test`.`t`
trx id 10080 lock_mode X
Record lock, heap no 1 PHYSICAL RECORD: n_fields 1; compact format; info bits 0
 0: len 8; hex 73757072656d756d; asc supremum;;

Record lock, heap no 2 PHYSICAL RECORD: n_fields 3; compact format; info bits 0
 0: len 4; hex 8000000a; asc      ;;
 1: len 6; hex 00000000274f; asc      'O';
 2: len 7; hex b60000019d0110; asc      ;;
```

## Insert Intention Locks

An insert intention lock is a type of gap lock set by [INSERT](#) operations prior to row insertion. This lock signals the intent to insert in such a way that multiple transactions inserting into the same index gap need not wait for each other if they are not inserting at the same position within the gap. Suppose that there are index records with values of 4 and 7. Separate transactions that attempt to insert values of 5 and 6, respectively, each lock the gap between 4 and 7 with insert intention locks prior to obtaining the exclusive lock on the inserted row, but do not block each other because the rows are nonconflicting.

The following example demonstrates a transaction taking an insert intention lock prior to obtaining an exclusive lock on the inserted record. The example involves two clients, A and B.

Client A creates a table containing two index records (90 and 102) and then starts a transaction that places an exclusive lock on index records with an ID greater than 100. The exclusive lock includes a gap lock before record 102:

```
mysql> CREATE TABLE child (id int(11) NOT NULL, PRIMARY KEY(id)) ENGINE=InnoDB;
mysql> INSERT INTO child (id) values (90),(102);

mysql> START TRANSACTION;
mysql> SELECT * FROM child WHERE id > 100 FOR UPDATE;
+-----+
| id   |
+-----+
```

```
| 102 |
+-----+
```

Client B begins a transaction to insert a record into the gap. The transaction takes an insert intention lock while it waits to obtain an exclusive lock.

```
mysql> START TRANSACTION;
mysql> INSERT INTO child (id) VALUES (101);
```

Transaction data for an insert intention lock appears similar to the following in `SHOW ENGINE INNODB STATUS` and `InnoDB monitor` output:

```
RECORD LOCKS space id 31 page no 3 n bits 72 index `PRIMARY` of table `test`.`child`
trx id 8731 lock_mode X locks gap before rec insert intention waiting
Record lock, heap no 3 PHYSICAL RECORD: n_fields 3; compact format; info bits 0
0: len 4; hex 80000066; asc f;;
1: len 6; hex 000000002215; asc " ;;
2: len 7; hex 9000000172011c; asc r ;i...
```

## AUTO-INC Locks

An `AUTO-INC` lock is a special table-level lock taken by transactions inserting into tables with `AUTO_INCREMENT` columns. In the simplest case, if one transaction is inserting values into the table, any other transactions must wait to do their own inserts into that table, so that rows inserted by the first transaction receive consecutive primary key values.

The `innodb_autoinc_lock_mode` configuration option controls the algorithm used for auto-increment locking. It allows you to choose how to trade off between predictable sequences of auto-increment values and maximum concurrency for insert operations.

For more information, see [Section 15.8.6, “AUTO\\_INCREMENT Handling in InnoDB”](#).

## Predicate Locks for Spatial Indexes

As of MySQL 5.7.5, `InnoDB` supports `SPATIAL` indexing of columns containing spatial columns (see [Section 12.5.3.5, “Optimizing Spatial Analysis”](#)).

To handle locking for operations involving `SPATIAL` indexes, next-key locking does not work well to support `REPEATABLE READ` or `SERIALIZABLE` transaction isolation levels. There is no absolute ordering concept in multidimensional data, so it is not clear which is the “next” key.

To enable support of isolation levels for tables with `SPATIAL` indexes, `InnoDB` uses predicate locks. A `SPATIAL` index contains minimum bounding rectangle (MBR) values, so `InnoDB` enforces consistent read on the index by setting a predicate lock on the MBR value used for a query. Other transactions cannot insert or modify a row that would match the query condition.

## 15.5.2 InnoDB Transaction Model

In the `InnoDB` transaction model, the goal is to combine the best properties of a [multi-versioning](#) database with traditional two-phase locking. `InnoDB` performs locking at the row level and runs queries as nonlocking [consistent reads](#) by default, in the style of Oracle. The lock information in `InnoDB` is stored space-efficiently so that lock escalation is not needed. Typically, several users are permitted to lock every row in `InnoDB` tables, or any random subset of the rows, without causing `InnoDB` memory exhaustion.

### 15.5.2.1 Transaction Isolation Levels

Transaction isolation is one of the foundations of database processing. Isolation is the I in the acronym [ACID](#); the isolation level is the setting that fine-tunes the balance between performance and reliability, consistency, and reproducibility of results when multiple transactions are making changes and performing queries at the same time.

InnoDB offers all four transaction isolation levels described by the SQL:1992 standard: [READ UNCOMMITTED](#), [READ COMMITTED](#), [REPEATABLE READ](#), and [SERIALIZABLE](#). The default isolation level for InnoDB is [REPEATABLE READ](#).

A user can change the isolation level for a single session or for all subsequent connections with the [SET TRANSACTION](#) statement. To set the server's default isolation level for all connections, use the `--transaction-isolation` option on the command line or in an option file. For detailed information about isolation levels and level-setting syntax, see [Section 14.3.6, "SET TRANSACTION Syntax"](#).

InnoDB supports each of the transaction isolation levels described here using different [locking](#) strategies. You can enforce a high degree of consistency with the default [REPEATABLE READ](#) level, for operations on crucial data where [ACID](#) compliance is important. Or you can relax the consistency rules with [READ COMMITTED](#) or even [READ UNCOMMITTED](#), in situations such as bulk reporting where precise consistency and repeatable results are less important than minimizing the amount of overhead for locking. [SERIALIZABLE](#) enforces even stricter rules than [REPEATABLE READ](#), and is used mainly in specialized situations, such as with [XA](#) transactions and for troubleshooting issues with concurrency and [deadlocks](#).

The following list describes how MySQL supports the different transaction levels. The list goes from the most commonly used level to the least used.

- [REPEATABLE READ](#)

This is the default isolation level for InnoDB. [Consistent reads](#) within the same transaction read the [snapshot](#) established by the first read. This means that if you issue several plain (nonlocking) [SELECT](#) statements within the same transaction, these [SELECT](#) statements are consistent also with respect to each other. See [Section 15.5.2.3, "Consistent Nonlocking Reads"](#).

For [locking reads](#) ([SELECT](#) with [FOR UPDATE](#) or [LOCK IN SHARE MODE](#)), [UPDATE](#), and [DELETE](#) statements, locking depends on whether the statement uses a unique index with a unique search condition, or a range-type search condition.

- For a unique index with a unique search condition, InnoDB locks only the index record found, not the [gap](#) before it.
- For other search conditions, InnoDB locks the index range scanned, using [gap locks](#) or [next-key locks](#) to block insertions by other sessions into the gaps covered by the range. For information about gap locks and next-key locks, see [Section 15.5.1, "InnoDB Locking"](#).

- [READ COMMITTED](#)

Each consistent read, even within the same transaction, sets and reads its own fresh snapshot. For information about consistent reads, see [Section 15.5.2.3, "Consistent Nonlocking Reads"](#).

For locking reads ([SELECT](#) with [FOR UPDATE](#) or [LOCK IN SHARE MODE](#)), [UPDATE](#) statements, and [DELETE](#) statements, InnoDB locks only index records, not the gaps before them, and thus permits the free insertion of new records next to locked records. Gap locking is only used for foreign-key constraint checking and duplicate-key checking.

Because gap locking is disabled, phantom problems may occur, as other sessions can insert new rows into the gaps. For information about phantoms, see [Section 15.5.4, "Phantom Rows"](#).

If you use [READ COMMITTED](#), you *must* use row-based binary logging.

Using [READ COMMITTED](#) has additional effects:

- For [UPDATE](#) or [DELETE](#) statements, InnoDB holds locks only for rows that it updates or deletes. Record locks for nonmatching rows are released after MySQL has evaluated the [WHERE](#) condition. This greatly reduces the probability of deadlocks, but they can still happen.

- For **UPDATE** statements, if a row is already locked, **InnoDB** performs a “semi-consistent” read, returning the latest committed version to MySQL so that MySQL can determine whether the row matches the **WHERE** condition of the **UPDATE**. If the row matches (must be updated), MySQL reads the row again and this time **InnoDB** either locks it or waits for a lock on it.

Consider the following example, beginning with this table:

```
CREATE TABLE t (a INT NOT NULL, b INT) ENGINE = InnoDB;
INSERT INTO t VALUES (1,2),(2,3),(3,2),(4,3),(5,2);
COMMIT;
```

In this case, table has no indexes, so searches and index scans use the hidden clustered index for record locking (see [Section 15.8.9, “Clustered and Secondary Indexes”](#)).

Suppose that one client performs an **UPDATE** using these statements:

```
SET autocommit = 0;
UPDATE t SET b = 5 WHERE b = 3;
```

Suppose also that a second client performs an **UPDATE** by executing these statements following those of the first client:

```
SET autocommit = 0;
UPDATE t SET b = 4 WHERE b = 2;
```

As **InnoDB** executes each **UPDATE**, it first acquires an exclusive lock for each row, and then determines whether to modify it. If **InnoDB** does not modify the row, it releases the lock. Otherwise, **InnoDB** retains the lock until the end of the transaction. This affects transaction processing as follows.

When using the default **REPEATABLE READ** isolation level, the first **UPDATE** acquires x-locks and does not release any of them:

```
x-lock(1,2); retain x-lock
x-lock(2,3); update(2,3) to (2,5); retain x-lock
x-lock(3,2); retain x-lock
x-lock(4,3); update(4,3) to (4,5); retain x-lock
x-lock(5,2); retain x-lock
```

The second **UPDATE** blocks as soon as it tries to acquire any locks (because first update has retained locks on all rows), and does not proceed until the first **UPDATE** commits or rolls back:

```
x-lock(1,2); block and wait for first UPDATE to commit or roll back
```

If **READ COMMITTED** is used instead, the first **UPDATE** acquires x-locks and releases those for rows that it does not modify:

```
x-lock(1,2); unlock(1,2)
x-lock(2,3); update(2,3) to (2,5); retain x-lock
x-lock(3,2); unlock(3,2)
x-lock(4,3); update(4,3) to (4,5); retain x-lock
x-lock(5,2); unlock(5,2)
```

For the second **UPDATE**, **InnoDB** does a “semi-consistent” read, returning the latest committed version of each row to MySQL so that MySQL can determine whether the row matches the **WHERE** condition of the **UPDATE**:

```
x-lock(1,2); update(1,2) to (1,4); retain x-lock
```

```
x-lock(2,3); unlock(2,3)
x-lock(3,2); update(3,2) to (3,4); retain x-lock
x-lock(4,3); unlock(4,3)
x-lock(5,2); update(5,2) to (5,4); retain x-lock
```

The effects of using the `READ COMMITTED` isolation level are the same as enabling the deprecated `innodb_locks_unsafe_for_binlog` configuration option, with these exceptions:

- Enabling `innodb_locks_unsafe_for_binlog` is a global setting and affects all sessions, whereas the isolation level can be set globally for all sessions, or individually per session.
- `innodb_locks_unsafe_for_binlog` can be set only at server startup, whereas the isolation level can be set at startup or changed at runtime.

`READ COMMITTED` therefore offers finer and more flexible control than `innodb_locks_unsafe_for_binlog`.

- `READ UNCOMMITTED`

`SELECT` statements are performed in a nonlocking fashion, but a possible earlier version of a row might be used. Thus, using this isolation level, such reads are not consistent. This is also called a **dirty read**. Otherwise, this isolation level works like `READ COMMITTED`.

- `SERIALIZABLE`

This level is like `REPEATABLE READ`, but InnoDB implicitly converts all plain `SELECT` statements to `SELECT ... LOCK IN SHARE MODE` if `autocommit` is disabled. If `autocommit` is enabled, the `SELECT` is its own transaction. It therefore is known to be read only and can be serialized if performed as a consistent (nonlocking) read and need not block for other transactions. (To force a plain `SELECT` to block if other transactions have modified the selected rows, disable `autocommit`.)

### 15.5.2.2 autocommit, Commit, and Rollback

In InnoDB, all user activity occurs inside a transaction. If `autocommit` mode is enabled, each SQL statement forms a single transaction on its own. By default, MySQL starts the session for each new connection with `autocommit` enabled, so MySQL does a commit after each SQL statement if that statement did not return an error. If a statement returns an error, the commit or rollback behavior depends on the error. See [Section 15.21.4, “InnoDB Error Handling”](#).

A session that has `autocommit` enabled can perform a multiple-statement transaction by starting it with an explicit `START TRANSACTION` or `BEGIN` statement and ending it with a `COMMIT` or `ROLLBACK` statement. See [Section 14.3.1, “START TRANSACTION, COMMIT, and ROLLBACK Syntax”](#).

If `autocommit` mode is disabled within a session with `SET autocommit = 0`, the session always has a transaction open. A `COMMIT` or `ROLLBACK` statement ends the current transaction and a new one starts.

If a session that has `autocommit` disabled ends without explicitly committing the final transaction, MySQL rolls back that transaction.

Some statements implicitly end a transaction, as if you had done a `COMMIT` before executing the statement. For details, see [Section 14.3.3, “Statements That Cause an Implicit Commit”](#).

A `COMMIT` means that the changes made in the current transaction are made permanent and become visible to other sessions. A `ROLLBACK` statement, on the other hand, cancels all modifications made by the current transaction. Both `COMMIT` and `ROLLBACK` release all InnoDB locks that were set during the current transaction.

### Grouping DML Operations with Transactions

By default, connection to the MySQL server begins with `autocommit` mode enabled, which automatically commits every SQL statement as you execute it. This mode of operation might be

unfamiliar if you have experience with other database systems, where it is standard practice to issue a sequence of **DML** statements and commit them or roll them back all together.

To use multiple-statement **transactions**, switch autocommit off with the SQL statement **SET autocommit = 0** and end each transaction with **COMMIT** or **ROLLBACK** as appropriate. To leave autocommit on, begin each transaction with **START TRANSACTION** and end it with **COMMIT** or **ROLLBACK**. The following example shows two transactions. The first is committed; the second is rolled back.

```
shell> mysql test

mysql> CREATE TABLE customer (a INT, b CHAR (20), INDEX (a));
Query OK, 0 rows affected (0.00 sec)
mysql> -- Do a transaction with autocommit turned on.
mysql> START TRANSACTION;
Query OK, 0 rows affected (0.00 sec)
mysql> INSERT INTO customer VALUES (10, 'Heikki');
Query OK, 1 row affected (0.00 sec)
mysql> COMMIT;
Query OK, 0 rows affected (0.00 sec)
mysql> -- Do another transaction with autocommit turned off.
mysql> SET autocommit=0;
Query OK, 0 rows affected (0.00 sec)
mysql> INSERT INTO customer VALUES (15, 'John');
Query OK, 1 row affected (0.00 sec)
mysql> INSERT INTO customer VALUES (20, 'Paul');
Query OK, 1 row affected (0.00 sec)
mysql> DELETE FROM customer WHERE b = 'Heikki';
Query OK, 1 row affected (0.00 sec)
mysql> -- Now we undo those last 2 inserts and the delete.
mysql> ROLLBACK;
Query OK, 0 rows affected (0.00 sec)
mysql> SELECT * FROM customer;
+-----+-----+
| a     | b     |
+-----+-----+
| 10    | Heikki |
+-----+-----+
1 row in set (0.00 sec)
mysql>
```

## Transactions in Client-Side Languages

In APIs such as PHP, Perl DBI, JDBC, ODBC, or the standard C call interface of MySQL, you can send transaction control statements such as **COMMIT** to the MySQL server as strings just like any other SQL statements such as **SELECT** or **INSERT**. Some APIs also offer separate special transaction commit and rollback functions or methods.

### 15.5.2.3 Consistent Nonlocking Reads

A **consistent read** means that InnoDB uses multi-versioning to present to a query a snapshot of the database at a point in time. The query sees the changes made by transactions that committed before that point of time, and no changes made by later or uncommitted transactions. The exception to this rule is that the query sees the changes made by earlier statements within the same transaction. This exception causes the following anomaly: If you update some rows in a table, a **SELECT** sees the latest version of the updated rows, but it might also see older versions of any rows. If other sessions simultaneously update the same table, the anomaly means that you might see the table in a state that never existed in the database.

If the transaction **isolation level** is **REPEATABLE READ** (the default level), all consistent reads within the same transaction read the snapshot established by the first such read in that transaction. You can get a fresher snapshot for your queries by committing the current transaction and after that issuing new queries.

With `READ COMMITTED` isolation level, each consistent read within a transaction sets and reads its own fresh snapshot.

Consistent read is the default mode in which InnoDB processes `SELECT` statements in `READ COMMITTED` and `REPEATABLE READ` isolation levels. A consistent read does not set any locks on the tables it accesses, and therefore other sessions are free to modify those tables at the same time a consistent read is being performed on the table.

Suppose that you are running in the default `REPEATABLE READ` isolation level. When you issue a consistent read (that is, an ordinary `SELECT` statement), InnoDB gives your transaction a timepoint according to which your query sees the database. If another transaction deletes a row and commits after your timepoint was assigned, you do not see the row as having been deleted. Inserts and updates are treated similarly.

#### Note

The snapshot of the database state applies to `SELECT` statements within a transaction, not necessarily to `DML` statements. If you insert or modify some rows and then commit that transaction, a `DELETE` or `UPDATE` statement issued from another concurrent `REPEATABLE READ` transaction could affect those just-committed rows, even though the session could not query them. If a transaction does update or delete rows committed by a different transaction, those changes do become visible to the current transaction. For example, you might encounter a situation like the following:

```
SELECT COUNT(c1) FROM t1 WHERE c1 = 'xyz';
-- Returns 0: no rows match.
DELETE FROM t1 WHERE c1 = 'xyz';
-- Deletes several rows recently committed by other transaction.

SELECT COUNT(c2) FROM t1 WHERE c2 = 'abc';
-- Returns 0: no rows match.
UPDATE t1 SET c2 = 'cba' WHERE c2 = 'abc';
-- Affects 10 rows: another txn just committed 10 rows with 'abc' values.
SELECT COUNT(c2) FROM t1 WHERE c2 = 'cba';
-- Returns 10: this txn can now see the rows it just updated.
```

You can advance your timepoint by committing your transaction and then doing another `SELECT` or `START TRANSACTION WITH CONSISTENT SNAPSHOT`.

This is called *multi-versioned concurrency control*.

In the following example, session A sees the row inserted by B only when B has committed the insert and A has committed as well, so that the timepoint is advanced past the commit of B.

|      | Session A         | Session B                    |
|------|-------------------|------------------------------|
| time | SET autocommit=0; | SET autocommit=0;            |
|      | SELECT * FROM t;  |                              |
|      | empty set         |                              |
|      |                   | INSERT INTO t VALUES (1, 2); |
|      |                   |                              |
| v    | SELECT * FROM t;  |                              |
|      | empty set         | COMMIT;                      |
|      |                   |                              |
|      | SELECT * FROM t;  |                              |
|      | empty set         |                              |
|      | COMMIT;           |                              |
|      | SELECT * FROM t;  |                              |
|      | -----             |                              |
|      | 1   2             |                              |

If you want to see the “freshest” state of the database, use either the `READ COMMITTED` isolation level or a [locking read](#):

```
SELECT * FROM t LOCK IN SHARE MODE;
```

With `READ COMMITTED` isolation level, each consistent read within a transaction sets and reads its own fresh snapshot. With `LOCK IN SHARE MODE`, a locking read occurs instead: A `SELECT` blocks until the transaction containing the freshest rows ends (see [Section 15.5.2.4, “Locking Reads”](#)).

Consistent read does not work over certain DDL statements:

- Consistent read does not work over `DROP TABLE`, because MySQL cannot use a table that has been dropped and InnoDB destroys the table.
- Consistent read does not work over `ALTER TABLE`, because that statement makes a temporary copy of the original table and deletes the original table when the temporary copy is built. When you reissue a consistent read within a transaction, rows in the new table are not visible because those rows did not exist when the transaction's snapshot was taken. In this case, the transaction returns an error: `ER_TABLE_DEF_CHANGED`, “Table definition has changed, please retry transaction”.

The type of read varies for selects in clauses like `INSERT INTO ... SELECT`, `UPDATE ... (SELECT)`, and `CREATE TABLE ... SELECT` that do not specify `FOR UPDATE` or `LOCK IN SHARE MODE`:

- By default, InnoDB uses stronger locks and the `SELECT` part acts like `READ COMMITTED`, where each consistent read, even within the same transaction, sets and reads its own fresh snapshot.
- To use a consistent read in such cases, enable the `innodb_locks_unsafe_for_binlog` option and set the isolation level of the transaction to `READ UNCOMMITTED`, `READ COMMITTED`, or `REPEATABLE READ` (that is, anything other than `SERIALIZABLE`). In this case, no locks are set on rows read from the selected table.

### 15.5.2.4 Locking Reads

If you query data and then insert or update related data within the same transaction, the regular `SELECT` statement does not give enough protection. Other transactions can update or delete the same rows you just queried. InnoDB supports two types of [locking reads](#) that offer extra safety:

- `SELECT ... LOCK IN SHARE MODE`

Sets a shared mode lock on any rows that are read. Other sessions can read the rows, but cannot modify them until your transaction commits. If any of these rows were changed by another transaction that has not yet committed, your query waits until that transaction ends and then uses the latest values.

- `SELECT ... FOR UPDATE`

For index records the search encounters, locks the rows and any associated index entries, the same as if you issued an `UPDATE` statement for those rows. Other transactions are blocked from updating those rows, from doing `SELECT ... LOCK IN SHARE MODE`, or from reading the data in certain transaction isolation levels. Consistent reads ignore any locks set on the records that exist in the read view. (Old versions of a record cannot be locked; they are reconstructed by applying [undo logs](#) on an in-memory copy of the record.)

These clauses are primarily useful when dealing with tree-structured or graph-structured data, either in a single table or split across multiple tables. You traverse edges or tree branches from one place to another, while reserving the right to come back and change any of these “pointer” values.

All locks set by `LOCK IN SHARE MODE` and `FOR UPDATE` queries are released when the transaction is committed or rolled back.

**Note**

Locking of rows for update using `SELECT FOR UPDATE` only applies when autocommit is disabled (either by beginning transaction with `START TRANSACTION` or by setting `autocommit` to 0). If autocommit is enabled, the rows matching the specification are not locked.

**Usage Examples**

Suppose that you want to insert a new row into a table `child`, and make sure that the child row has a parent row in table `parent`. Your application code can ensure referential integrity throughout this sequence of operations.

First, use a consistent read to query the table `PARENT` and verify that the parent row exists. Can you safely insert the child row to table `CHILD`? No, because some other session could delete the parent row in the moment between your `SELECT` and your `INSERT`, without you being aware of it.

To avoid this potential issue, perform the `SELECT` using `LOCK IN SHARE MODE`:

```
SELECT * FROM parent WHERE NAME = 'Jones' LOCK IN SHARE MODE;
```

After the `LOCK IN SHARE MODE` query returns the parent `'Jones'`, you can safely add the child record to the `CHILD` table and commit the transaction. Any transaction that tries to acquire an exclusive lock in the applicable row in the `PARENT` table waits until you are finished, that is, until the data in all tables is in a consistent state.

For another example, consider an integer counter field in a table `CHILD_CODES`, used to assign a unique identifier to each child added to table `CHILD`. Do not use either consistent read or a shared mode read to read the present value of the counter, because two users of the database could see the same value for the counter, and a duplicate-key error occurs if two transactions attempt to add rows with the same identifier to the `CHILD` table.

Here, `LOCK IN SHARE MODE` is not a good solution because if two users read the counter at the same time, at least one of them ends up in deadlock when it attempts to update the counter.

To implement reading and incrementing the counter, first perform a locking read of the counter using `FOR UPDATE`, and then increment the counter. For example:

```
SELECT counter_field FROM child_codes FOR UPDATE;
UPDATE child_codes SET counter_field = counter_field + 1;
```

A `SELECT ... FOR UPDATE` reads the latest available data, setting exclusive locks on each row it reads. Thus, it sets the same locks a searched SQL `UPDATE` would set on the rows.

The preceding description is merely an example of how `SELECT ... FOR UPDATE` works. In MySQL, the specific task of generating a unique identifier actually can be accomplished using only a single access to the table:

```
UPDATE child_codes SET counter_field = LAST_INSERT_ID(counter_field + 1);
SELECT LAST_INSERT_ID();
```

The `SELECT` statement merely retrieves the identifier information (specific to the current connection). It does not access any table.

**15.5.3 Locks Set by Different SQL Statements in InnoDB**

A **locking read**, an `UPDATE`, or a `DELETE` generally set record locks on every index record that is scanned in the processing of the SQL statement. It does not matter whether there are `WHERE` conditions in the statement that would exclude the row. `InnoDB` does not remember the exact `WHERE` condition, but only knows which index ranges were scanned. The locks are normally **next-key locks** that also block inserts into the “gap” immediately before the record. However, **gap locking**

can be disabled explicitly, which causes next-key locking not to be used. For more information, see [Section 15.5.1, “InnoDB Locking”](#). The transaction isolation level also can affect which locks are set; see [Section 15.5.2.1, “Transaction Isolation Levels”](#).

If a secondary index is used in a search and index record locks to be set are exclusive, InnoDB also retrieves the corresponding clustered index records and sets locks on them.

Differences between shared and exclusive locks are described in [Section 15.5.1, “InnoDB Locking”](#).

If you have no indexes suitable for your statement and MySQL must scan the entire table to process the statement, every row of the table becomes locked, which in turn blocks all inserts by other users to the table. It is important to create good indexes so that your queries do not unnecessarily scan many rows.

For `SELECT ... FOR UPDATE` or `SELECT ... LOCK IN SHARE MODE`, locks are acquired for scanned rows, and expected to be released for rows that do not qualify for inclusion in the result set (for example, if they do not meet the criteria given in the `WHERE` clause). However, in some cases, rows might not be unlocked immediately because the relationship between a result row and its original source is lost during query execution. For example, in a `UNION`, scanned (and locked) rows from a table might be inserted into a temporary table before evaluation whether they qualify for the result set. In this circumstance, the relationship of the rows in the temporary table to the rows in the original table is lost and the latter rows are not unlocked until the end of query execution.

InnoDB sets specific types of locks as follows.

- `SELECT ... FROM` is a consistent read, reading a snapshot of the database and setting no locks unless the transaction isolation level is set to `SERIALIZABLE`. For `SERIALIZABLE` level, the search sets shared next-key locks on the index records it encounters. However, only an index record lock is required for statements that lock rows using a unique index to search for a unique row.
- `SELECT ... FROM ... LOCK IN SHARE MODE` sets shared next-key locks on all index records the search encounters. However, only an index record lock is required for statements that lock rows using a unique index to search for a unique row.
- `SELECT ... FROM ... FOR UPDATE` sets an exclusive next-key lock on every record the search encounters. However, only an index record lock is required for statements that lock rows using a unique index to search for a unique row.

For index records the search encounters, `SELECT ... FROM ... FOR UPDATE` blocks other sessions from doing `SELECT ... FROM ... LOCK IN SHARE MODE` or from reading in certain transaction isolation levels. Consistent reads will ignore any locks set on the records that exist in the read view.

- `UPDATE ... WHERE ...` sets an exclusive next-key lock on every record the search encounters. However, only an index record lock is required for statements that lock rows using a unique index to search for a unique row.
- When `UPDATE` modifies a clustered index record, implicit locks are taken on affected secondary index records. The `UPDATE` operation also takes shared locks on affected secondary index records when performing duplicate check scans prior to inserting new secondary index records, and when inserting new secondary index records.
- `DELETE FROM ... WHERE ...` sets an exclusive next-key lock on every record the search encounters. However, only an index record lock is required for statements that lock rows using a unique index to search for a unique row.
- `INSERT` sets an exclusive lock on the inserted row. This lock is an index-record lock, not a next-key lock (that is, there is no gap lock) and does not prevent other sessions from inserting into the gap before the inserted row.

Prior to inserting the row, a type of gap lock called an insert intention gap lock is set. This lock signals the intent to insert in such a way that multiple transactions inserting into the same index gap

need not wait for each other if they are not inserting at the same position within the gap. Suppose that there are index records with values of 4 and 7. Separate transactions that attempt to insert values of 5 and 6 each lock the gap between 4 and 7 with insert intention locks prior to obtaining the exclusive lock on the inserted row, but do not block each other because the rows are nonconflicting.

If a duplicate-key error occurs, a shared lock on the duplicate index record is set. This use of a shared lock can result in deadlock should there be multiple sessions trying to insert the same row if another session already has an exclusive lock. This can occur if another session deletes the row. Suppose that an [InnoDB](#) table `t1` has the following structure:

```
CREATE TABLE t1 (i INT, PRIMARY KEY (i)) ENGINE = InnoDB;
```

Now suppose that three sessions perform the following operations in order:

Session 1:

```
START TRANSACTION;
INSERT INTO t1 VALUES(1);
```

Session 2:

```
START TRANSACTION;
INSERT INTO t1 VALUES(1);
```

Session 3:

```
START TRANSACTION;
INSERT INTO t1 VALUES(1);
```

Session 1:

```
ROLLBACK;
```

The first operation by session 1 acquires an exclusive lock for the row. The operations by sessions 2 and 3 both result in a duplicate-key error and they both request a shared lock for the row. When session 1 rolls back, it releases its exclusive lock on the row and the queued shared lock requests for sessions 2 and 3 are granted. At this point, sessions 2 and 3 deadlock: Neither can acquire an exclusive lock for the row because of the shared lock held by the other.

A similar situation occurs if the table already contains a row with key value 1 and three sessions perform the following operations in order:

Session 1:

```
START TRANSACTION;
DELETE FROM t1 WHERE i = 1;
```

Session 2:

```
START TRANSACTION;
INSERT INTO t1 VALUES(1);
```

Session 3:

```
START TRANSACTION;
INSERT INTO t1 VALUES(1);
```

Session 1:

```
COMMIT;
```

The first operation by session 1 acquires an exclusive lock for the row. The operations by sessions 2 and 3 both result in a duplicate-key error and they both request a shared lock for the row. When session 1 commits, it releases its exclusive lock on the row and the queued shared lock requests for sessions 2 and 3 are granted. At this point, sessions 2 and 3 deadlock: Neither can acquire an exclusive lock for the row because of the shared lock held by the other.

- `INSERT ... ON DUPLICATE KEY UPDATE` differs from a simple `INSERT` in that an exclusive next-key lock rather than a shared lock is placed on the row to be updated when a duplicate-key error occurs.
- `REPLACE` is done like an `INSERT` if there is no collision on a unique key. Otherwise, an exclusive next-key lock is placed on the row to be replaced.
- `INSERT INTO T SELECT ... FROM S WHERE ...` sets an exclusive index record lock (without a gap lock) on each row inserted into `T`. If the transaction isolation level is `READ COMMITTED`, or `innodb_locks_unsafe_for_binlog` is enabled and the transaction isolation level is not `SERIALIZABLE`, InnoDB does the search on `S` as a consistent read (no locks). Otherwise, InnoDB sets shared next-key locks on rows from `S`. InnoDB has to set locks in the latter case: In roll-forward recovery from a backup, every SQL statement must be executed in exactly the same way it was done originally.

`CREATE TABLE ... SELECT ...` performs the `SELECT` with shared next-key locks or as a consistent read, as for `INSERT ... SELECT`.

When a `SELECT` is used in the constructs `REPLACE INTO t SELECT ... FROM s WHERE ...` or `UPDATE t ... WHERE col IN (SELECT ... FROM s ...)`, InnoDB sets shared next-key locks on rows from table `s`.

- While initializing a previously specified `AUTO_INCREMENT` column on a table, InnoDB sets an exclusive lock on the end of the index associated with the `AUTO_INCREMENT` column. In accessing the auto-increment counter, InnoDB uses a specific `AUTO-INC` table lock mode where the lock lasts only to the end of the current SQL statement, not to the end of the entire transaction. Other sessions cannot insert into the table while the `AUTO-INC` table lock is held; see [Section 15.5.2, “InnoDB Transaction Model”](#).

InnoDB fetches the value of a previously initialized `AUTO_INCREMENT` column without setting any locks.

- If a `FOREIGN KEY` constraint is defined on a table, any insert, update, or delete that requires the constraint condition to be checked sets shared record-level locks on the records that it looks at to check the constraint. InnoDB also sets these locks in the case where the constraint fails.
- `LOCK TABLES` sets table locks, but it is the higher MySQL layer above the InnoDB layer that sets these locks. InnoDB is aware of table locks if `innodb_table_locks = 1` (the default) and `autocommit = 0`, and the MySQL layer above InnoDB knows about row-level locks.

Otherwise, InnoDB's automatic deadlock detection cannot detect deadlocks where such table locks are involved. Also, because in this case the higher MySQL layer does not know about row-level locks, it is possible to get a table lock on a table where another session currently has row-level locks. However, this does not endanger transaction integrity, as discussed in [Section 15.5.5.2, “Deadlock Detection and Rollback”](#). See also [Section 15.8.8, “Limits on InnoDB Tables”](#).

## 15.5.4 Phantom Rows

The so-called *phantom* problem occurs within a transaction when the same query produces different sets of rows at different times. For example, if a `SELECT` is executed twice, but returns a row the second time that was not returned the first time, the row is a “phantom” row.

Suppose that there is an index on the `id` column of the `child` table and that you want to read and lock all rows from the table having an identifier value larger than 100, with the intention of updating some column in the selected rows later:

```
SELECT * FROM child WHERE id > 100 FOR UPDATE;
```

The query scans the index starting from the first record where `id` is bigger than 100. Let the table contain rows having `id` values of 90 and 102. If the locks set on the index records in the scanned range do not lock out inserts made in the gaps (in this case, the gap between 90 and 102), another session can insert a new row into the table with an `id` of 101. If you were to execute the same `SELECT` within the same transaction, you would see a new row with an `id` of 101 (a “phantom”) in the result set returned by the query. If we regard a set of rows as a data item, the new phantom child would violate the isolation principle of transactions that a transaction should be able to run so that the data it has read does not change during the transaction.

To prevent phantoms, InnoDB uses an algorithm called *next-key locking* that combines index-row locking with gap locking. InnoDB performs row-level locking in such a way that when it searches or scans a table index, it sets shared or exclusive locks on the index records it encounters. Thus, the row-level locks are actually index-record locks. In addition, a next-key lock on an index record also affects the “gap” before that index record. That is, a next-key lock is an index-record lock plus a gap lock on the gap preceding the index record. If one session has a shared or exclusive lock on record `R` in an index, another session cannot insert a new index record in the gap immediately before `R` in the index order.

When InnoDB scans an index, it can also lock the gap after the last record in the index. Just that happens in the preceding example: To prevent any insert into the table where `id` would be bigger than 100, the locks set by InnoDB include a lock on the gap following `id` value 102.

You can use next-key locking to implement a uniqueness check in your application: If you read your data in share mode and do not see a duplicate for a row you are going to insert, then you can safely insert your row and know that the next-key lock set on the successor of your row during the read prevents anyone meanwhile inserting a duplicate for your row. Thus, the next-key locking enables you to “lock” the nonexistence of something in your table.

Gap locking can be disabled as discussed in [Section 15.5.1, “InnoDB Locking”](#). This may cause phantom problems because other sessions can insert new rows into the gaps when gap locking is disabled.

## 15.5.5 Deadlocks in InnoDB

A deadlock is a situation where different transactions are unable to proceed because each holds a lock that the other needs. Because both transactions are waiting for a resource to become available, neither will ever release the locks it holds.

A deadlock can occur when transactions lock rows in multiple tables (through statements such as `UPDATE` or `SELECT ... FOR UPDATE`), but in the opposite order. A deadlock can also occur when such statements lock ranges of index records and gaps, with each transaction acquiring some locks but not others due to a timing issue. For a deadlock example, see [Section 15.5.5.1, “An InnoDB Deadlock Example”](#).

To reduce the possibility of deadlocks, use transactions rather than `LOCK TABLES` statements; keep transactions that insert or update data small enough that they do not stay open for long periods of time; when different transactions update multiple tables or large ranges of rows, use the same order of operations (such as `SELECT ... FOR UPDATE`) in each transaction; create indexes on the columns used in `SELECT ... FOR UPDATE` and `UPDATE ... WHERE` statements. The possibility

of deadlocks is not affected by the isolation level, because the isolation level changes the behavior of read operations, while deadlocks occur because of write operations. For more information about avoiding and recovering from deadlock conditions, see [Section 15.5.5.3, “How to Minimize and Handle Deadlocks”](#).

When deadlock detection is enabled (the default) and a deadlock does occur, InnoDB detects the condition and rolls back one of the transactions (the victim). If deadlock detection is disabled using the `innodb_deadlock_detect` configuration option, InnoDB relies on the `innodb_lock_wait_timeout` setting to roll back transactions in case of a deadlock. Thus, even if your application logic is correct, you must still handle the case where a transaction must be retried. To see the last deadlock in an InnoDB user transaction, use the `SHOW ENGINE INNODB STATUS` command. If frequent deadlocks highlight a problem with transaction structure or application error handling, run with the `innodb_print_all_deadlocks` setting enabled to print information about all deadlocks to the `mysqld` error log. For more information about how deadlocks are automatically detected and handled, see [Section 15.5.5.2, “Deadlock Detection and Rollback”](#).

### 15.5.5.1 An InnoDB Deadlock Example

The following example illustrates how an error can occur when a lock request would cause a deadlock. The example involves two clients, A and B.

First, client A creates a table containing one row, and then begins a transaction. Within the transaction, A obtains an `S` lock on the row by selecting it in share mode:

```
mysql> CREATE TABLE t (i INT) ENGINE = InnoDB;
Query OK, 0 rows affected (1.07 sec)

mysql> INSERT INTO t (i) VALUES(1);
Query OK, 1 row affected (0.09 sec)

mysql> START TRANSACTION;
Query OK, 0 rows affected (0.00 sec)

mysql> SELECT * FROM t WHERE i = 1 LOCK IN SHARE MODE;
+-----+
| i     |
+-----+
| 1     |
+-----+
```

Next, client B begins a transaction and attempts to delete the row from the table:

```
mysql> START TRANSACTION;
Query OK, 0 rows affected (0.00 sec)

mysql> DELETE FROM t WHERE i = 1;
```

The delete operation requires an `X` lock. The lock cannot be granted because it is incompatible with the `S` lock that client A holds, so the request goes on the queue of lock requests for the row and client B blocks.

Finally, client A also attempts to delete the row from the table:

```
mysql> DELETE FROM t WHERE i = 1;
ERROR 1213 (40001): Deadlock found when trying to get lock;
try restarting transaction
```

Deadlock occurs here because client A needs an `X` lock to delete the row. However, that lock request cannot be granted because client B already has a request for an `X` lock and is waiting for client A to release its `S` lock. Nor can the `S` lock held by A be upgraded to an `X` lock because of the prior request by B for an `X` lock. As a result, InnoDB generates an error for one of the clients and releases its locks. The client returns this error:

```
ERROR 1213 (40001): Deadlock found when trying to get lock;  
try restarting transaction
```

At that point, the lock request for the other client can be granted and it deletes the row from the table.

### 15.5.5.2 Deadlock Detection and Rollback

When [deadlock detection](#) is enabled (the default), [InnoDB](#) automatically detects transaction [deadlocks](#) and rolls back a transaction or transactions to break the deadlock. [InnoDB](#) tries to pick small transactions to roll back, where the size of a transaction is determined by the number of rows inserted, updated, or deleted.

[InnoDB](#) is aware of table locks if `innodb_table_locks = 1` (the default) and `autocommit = 0`, and the MySQL layer above it knows about row-level locks. Otherwise, [InnoDB](#) cannot detect deadlocks where a table lock set by a MySQL `LOCK TABLES` statement or a lock set by a storage engine other than [InnoDB](#) is involved. Resolve these situations by setting the value of the `innodb_lock_wait_timeout` system variable.

When [InnoDB](#) performs a complete rollback of a transaction, all locks set by the transaction are released. However, if just a single SQL statement is rolled back as a result of an error, some of the locks set by the statement may be preserved. This happens because [InnoDB](#) stores row locks in a format such that it cannot know afterward which lock was set by which statement.

If a `SELECT` calls a stored function in a transaction, and a statement within the function fails, that statement rolls back. Furthermore, if `ROLLBACK` is executed after that, the entire transaction rolls back.

If the `LATEST DETECTED DEADLOCK` section of [InnoDB](#) Monitor output includes a message stating, “TOO DEEP OR LONG SEARCH IN THE LOCK TABLE WAITS-FOR GRAPH, WE WILL ROLL BACK FOLLOWING TRANSACTION,” this indicates that the number of transactions on the wait-for list has reached a limit of 200. A wait-for list that exceeds 200 transactions is treated as a deadlock and the transaction attempting to check the wait-for list is rolled back. The same error may also occur if the locking thread must look at more than 1,000,000 locks owned by transactions on the wait-for list.

For techniques to organize database operations to avoid deadlocks, see [Section 15.5.5, “Deadlocks in InnoDB”](#).

### Disabling Deadlock Detection

On high concurrency systems, deadlock detection can cause a slowdown when numerous threads wait for the same lock. At times, it may be more efficient to disable deadlock detection and rely on the `innodb_lock_wait_timeout` setting for transaction rollback when a deadlock occurs. Deadlock detection can be disabled using the `innodb_deadlock_detect` configuration option.

### 15.5.5.3 How to Minimize and Handle Deadlocks

This section builds on the conceptual information about deadlocks in [Section 15.5.5.2, “Deadlock Detection and Rollback”](#). It explains how to organize database operations to minimize deadlocks and the subsequent error handling required in applications.

[Deadlocks](#) are a classic problem in transactional databases, but they are not dangerous unless they are so frequent that you cannot run certain transactions at all. Normally, you must write your applications so that they are always prepared to re-issue a transaction if it gets rolled back because of a deadlock.

[InnoDB](#) uses automatic row-level locking. You can get deadlocks even in the case of transactions that just insert or delete a single row. That is because these operations are not really “atomic”; they automatically set locks on the (possibly several) index records of the row inserted or deleted.

You can cope with deadlocks and reduce the likelihood of their occurrence with the following techniques:

- At any time, issue the `SHOW ENGINE INNODB STATUS` command to determine the cause of the most recent deadlock. That can help you to tune your application to avoid deadlocks.
- If frequent deadlock warnings cause concern, collect more extensive debugging information by enabling the `innodb_print_all_deadlocks` configuration option. Information about each deadlock, not just the latest one, is recorded in the MySQL [error log](#). Disable this option when you are finished debugging.
- Always be prepared to re-issue a transaction if it fails due to deadlock. Deadlocks are not dangerous. Just try again.
- Keep transactions small and short in duration to make them less prone to collision.
- Commit transactions immediately after making a set of related changes to make them less prone to collision. In particular, do not leave an interactive `mysql` session open for a long time with an uncommitted transaction.
- If you use [locking reads](#) (`SELECT ... FOR UPDATE` or `SELECT ... LOCK IN SHARE MODE`), try using a lower isolation level such as `READ COMMITTED`.
- When modifying multiple tables within a transaction, or different sets of rows in the same table, do those operations in a consistent order each time. Then transactions form well-defined queues and do not deadlock. For example, organize database operations into functions within your application, or call stored routines, rather than coding multiple similar sequences of `INSERT`, `UPDATE`, and `DELETE` statements in different places.
- Add well-chosen indexes to your tables. Then your queries need to scan fewer index records and consequently set fewer locks. Use `EXPLAIN SELECT` to determine which indexes the MySQL server regards as the most appropriate for your queries.
- Use less locking. If you can afford to permit a `SELECT` to return data from an old snapshot, do not add the clause `FOR UPDATE` or `LOCK IN SHARE MODE` to it. Using the `READ COMMITTED` isolation level is good here, because each consistent read within the same transaction reads from its own fresh snapshot.
- If nothing else helps, serialize your transactions with table-level locks. The correct way to use `LOCK TABLES` with transactional tables, such as InnoDB tables, is to begin a transaction with `SET autocommit = 0` (not `START TRANSACTION`) followed by `LOCK TABLES`, and to not call `UNLOCK TABLES` until you commit the transaction explicitly. For example, if you need to write to table `t1` and read from table `t2`, you can do this:

```
SET autocommit=0;
LOCK TABLES t1 WRITE, t2 READ, ...;
... do something with tables t1 and t2 here ...
COMMIT;
UNLOCK TABLES;
```

Table-level locks prevent concurrent updates to the table, avoiding deadlocks at the expense of less responsiveness for a busy system.

- Another way to serialize transactions is to create an auxiliary “semaphore” table that contains just a single row. Have each transaction update that row before accessing other tables. In that way, all transactions happen in a serial fashion. Note that the InnoDB instant deadlock detection algorithm also works in this case, because the serializing lock is a row-level lock. With MySQL table-level locks, the timeout method must be used to resolve deadlocks.

## 15.6 InnoDB Configuration

This section provides configuration information and procedures for InnoDB initialization, startup, and various components and features of the InnoDB storage engine. For information about optimizing database operations for InnoDB tables, see [Section 9.5, “Optimizing for InnoDB Tables”](#).

## 15.6.1 InnoDB Startup Configuration

The first decisions to make about [InnoDB](#) configuration involve the configuration of data files, log files, page size, and memory buffers. It is recommended that you define data file, log file, and page size configuration before creating the [InnoDB](#) instance. Modifying data file or log file configuration after the [InnoDB](#) instance is created may involve a non-trivial procedure, and page size can only be defined when the [InnoDB](#) instance is first initialized.

In addition to these topics, this section provides information about specifying [InnoDB](#) options in a configuration file, viewing [InnoDB](#) initialization information, and important storage considerations.

- [Specifying Options in a MySQL Configuration File](#)
- [Viewing InnoDB Initialization Information](#)
- [Important Storage Considerations](#)
- [System Tablespace Data File Configuration](#)
- [InnoDB Log File Configuration](#)
- [InnoDB Page Size Configuration](#)
- [InnoDB Undo Tablespace Configuration](#)
- [InnoDB Temporary Tablespace Configuration](#)
- [InnoDB Memory Configuration](#)

### Specifying Options in a MySQL Configuration File

Because MySQL uses data file, log file, and page size configuration settings to initialize the [InnoDB](#) instance, it is recommended that you define these settings in a configuration file that MySQL reads at startup, prior to initializing [InnoDB](#) for the first time. [InnoDB](#) is initialized when the MySQL server is started, and the first initialization of [InnoDB](#) normally occurs the first time you start the MySQL server.

You can place [InnoDB](#) options in the `[mysqld]` group of any option file that your server reads when it starts. The locations of MySQL option files are described in [Section 5.2.6, “Using Option Files”](#).

To make sure that `mysqld` reads options only from a specific file, use the `--defaults-file` option as the first option on the command line when starting the server:

```
mysqld --defaults-file=path_to_configuration_file
```

### Viewing InnoDB Initialization Information

To view [InnoDB](#) initialization information during startup, start `mysqld` from a command prompt. When `mysqld` is started from a command prompt, initialization information is printed to the console.

For example, on Windows, if `mysqld` is located in `C:\Program Files\MySQL\MySQL Server 5.7\bin`, start the MySQL server like this:

```
C:\> "C:\Program Files\MySQL\MySQL Server 5.7\bin\mysqld" --console
```

On Unix-like systems, `mysqld` is located in the `bin` directory of your MySQL installation:

```
sell> bin/mysqld --user=mysql &
```

If you do not send server output to the console, check the error log after startup to see the initialization information [InnoDB](#) printed during the startup process.

For information about starting MySQL using other methods, see [Section 2.10.5, “Starting and Stopping MySQL Automatically”](#).

## Important Storage Considerations

Review the following storage-related considerations before proceeding with your startup configuration.

- In some cases, database performance improves if the data is not all placed on the same physical disk. Putting log files on a different disk from data is very often beneficial for performance. For example, you can place system tablespace data files and log files on different disks. You can also use raw disk partitions (raw devices) for InnoDB data files, which may speed up I/O. See [Section 15.7.3, “Using Raw Disk Partitions for the System Tablespace”](#).
- InnoDB is a transaction-safe (ACID compliant) storage engine for MySQL that has commit, rollback, and crash-recovery capabilities to protect user data. **However, it cannot do so** if the underlying operating system or hardware does not work as advertised. Many operating systems or disk subsystems may delay or reorder write operations to improve performance. On some operating systems, the very `fsync()` system call that should wait until all unwritten data for a file has been flushed might actually return before the data has been flushed to stable storage. Because of this, an operating system crash or a power outage may destroy recently committed data, or in the worst case, even corrupt the database because of write operations having been reordered. If data integrity is important to you, perform some “pull-the-plug” tests before using anything in production. On OS X 10.3 and higher, InnoDB uses a special `fcntl()` file flush method. Under Linux, it is advisable to **disable the write-back cache**.

On ATA/SATA disk drives, a command such `hdparm -W0 /dev/hda` may work to disable the write-back cache. **Beware that some drives or disk controllers may be unable to disable the write-back cache.**

- With regard to InnoDB recovery capabilities that protect user data, InnoDB uses a file flush technique involving a structure called the [doublewrite buffer](#), which is enabled by default (`innodb_doublewrite=ON`). The doublewrite buffer adds safety to recovery following a crash or power outage, and improves performance on most varieties of Unix by reducing the need for `fsync()` operations. It is recommended that the `innodb_doublewrite` option remains enabled if you are concerned with data integrity or possible failures. For additional information about the doublewrite buffer, see [Section 15.12.1, “InnoDB Disk I/O”](#).
- If reliability is a consideration for your data, do not configure InnoDB to use data files or log files on NFS volumes. Potential problems vary according to OS and version of NFS, and include such issues as lack of protection from conflicting writes, and limitations on maximum file sizes.

## System Tablespace Data File Configuration

System tablespace data files are configured using the `innodb_data_file_path` and `innodb_data_home_dir` configuration options.

The `innodb_data_file_path` configuration option is used to configure the InnoDB system tablespace data files. The value of `innodb_data_file_path` should be a list of one or more data file specifications. If you name more than one data file, separate them by semicolon (:) characters:

```
innodb_data_file_path=datafile_spec1[:datafile_spec2]...
```

For example, the following setting explicitly creates a minimally sized system tablespace:

```
[mysqld]
innodb_data_file_path=ibdata1:12M:autoextend
```

This setting configures a single 12MB data file named `ibdata1` that is auto-extending. No location for the file is given, so by default, InnoDB creates it in the MySQL data directory.

Sizes are specified using **K**, **M**, or **G** suffix letters to indicate units of KB, MB, or GB.

A tablespace containing a fixed-size 50MB data file named `ibdata1` and a 50MB auto-extending file named `ibdata2` in the data directory can be configured like this:

```
[mysqld]
innodb_data_file_path=ibdata1:50M;ibdata2:50M:autoextend
```

The full syntax for a data file specification includes the file name, its size, and several optional attributes:

```
file_name:file_size[:autoextend[:max:max_file_size]]
```

The `autoextend` and `max` attributes can be used only for the last data file in the `innodb_data_file_path` line.

If you specify the `autoextend` option for the last data file, InnoDB extends the data file if it runs out of free space in the tablespace. The increment is 64MB at a time by default. To modify the increment, change the `innodb_autoextend_increment` system variable.

If the disk becomes full, you might want to add another data file on another disk. For tablespace reconfiguration instructions, see [Section 15.7.1, “Resizing the InnoDB System Tablespace”](#).

InnoDB is not aware of the file system maximum file size, so be cautious on file systems where the maximum file size is a small value such as 2GB. To specify a maximum size for an auto-extending data file, use the `max` attribute following the `autoextend` attribute. Use the `max` attribute only in cases where constraining disk usage is of critical importance, because exceeding the maximum size causes a fatal error, possibly including a crash. The following configuration permits `ibdata1` to grow up to a limit of 500MB:

```
[mysqld]
innodb_data_file_path=ibdata1:12M:autoextend:max:500M
```

InnoDB creates tablespace files in the MySQL data directory by default (`datadir`). To specify a location explicitly, use the `innodb_data_home_dir` option. For example, to create two files named `ibdata1` and `ibdata2` in a directory named `/myibdata`, configure InnoDB like this:

```
[mysqld]
innodb_data_home_dir = /myibdata
innodb_data_file_path=ibdata1:50M;ibdata2:50M:autoextend
```

#### Note

InnoDB does not create directories, so make sure that the `/myibdata` directory exists before you start the server. Use the Unix or DOS `mkdir` command to create any necessary directories.

Make sure that the MySQL server has the proper access rights to create files in the data directory. More generally, the server must have access rights in any directory where it needs to create data files.

InnoDB forms the directory path for each data file by textually concatenating the value of `innodb_data_home_dir` to the data file name, adding a path name separator (slash or backslash) between values if necessary. If the `innodb_data_home_dir` option is not specified in `my.cnf` at all, the default value is the “dot” directory `./`, which means the MySQL data directory. (The MySQL server changes its current working directory to its data directory when it begins executing.)

If you specify `innodb_data_home_dir` as an empty string, you can specify absolute paths for the data files listed in the `innodb_data_file_path` value. The following example is equivalent to the preceding one:

```
[mysqld]
innodb_data_home_dir =
innodb_data_file_path=/ibdata/ibdata1:50M;/ibdata/ibdata2:50M:autoextend
```

## InnoDB Log File Configuration

By default, InnoDB creates two 48MB log files in the MySQL data directory (`datadir`) named `ib_logfile0` and `ib_logfile1`.

The following options can be used to modify the default configuration:

- `innodb_log_group_home_dir` defines directory path to the InnoDB log files (the redo logs). If this option is not configured, InnoDB log files are created in the MySQL data directory (`datadir`).

You might use this option to place InnoDB log files in a different physical storage location than InnoDB data files to avoid potential I/O resource conflicts. For example:

```
[mysqld]
innodb_log_group_home_dir = /dr3/iblogs
```

### Note

InnoDB does not create directories, so make sure that the log directory exists before you start the server. Use the Unix or DOS `mkdir` command to create any necessary directories.

Make sure that the MySQL server has the proper access rights to create files in the log directory. More generally, the server must have access rights in any directory where it needs to create log files.

- `innodb_log_files_in_group` defines the number of log files in the log group. The default and recommended value is 2.
- `innodb_log_file_size` defines the size in bytes of each log file in the log group. The combined size of log files (`innodb_log_file_size * innodb_log_files_in_group`) cannot exceed a maximum value that is slightly less than 512GB. A pair of 255 GB log files, for example, approaches the limit but does not exceed it. The default log file size is 48MB. Generally, the combined size of the log files should be large enough that the server can smooth out peaks and troughs in workload activity, which often means that there is enough redo log space to handle more than an hour of write activity. The larger the value, the less checkpoint flush activity is needed in the buffer pool, saving disk I/O. For additional information, see [Section 9.5.4, “Optimizing InnoDB Redo Logging”](#).

## InnoDB Undo Tablespace Configuration

By default, InnoDB undo logs are part of the system tablespace. However, you can choose to store InnoDB undo logs in one or more separate undo tablespaces, typically on a different storage device.

The `innodb_undo_directory` configuration option defines the path where InnoDB creates separate tablespaces for the undo logs. This option is typically used in conjunction with the `innodb_undo_logs` and `innodb_undo_tablespaces` options, which determine the disk layout of the undo logs outside the system tablespace.

For more information, see [Section 15.7.7, “Storing InnoDB Undo Logs in Separate Tablespaces”](#).

## InnoDB Temporary Tablespace Configuration

By default, InnoDB creates a single auto-extending temporary tablespace data file named `ibtmp1` in the MySQL data directory (`datadir`) that is slightly larger than 12MB. The default configuration can be modified at startup using the `innodb_temp_data_file_path` configuration option.

The `innodb_temp_data_file_path` option specifies the path, file name, and file size for InnoDB temporary tablespace data files. The full directory path for a file is formed by concatenating `innodb_data_home_dir` to the path specified by `innodb_temp_data_file_path`. File size is specified in KB, MB, or GB (1024MB) by appending K, M, or G to the size value. The sum of the sizes of the files must be slightly larger than 12MB.

## InnoDB Page Size Configuration

The `innodb_page_size` option specifies the page size for all [InnoDB](#) tablespaces in a MySQL instance. This value is set when the instance is created and remains constant afterward. Valid values are 64k, 32k, 16k (the default), 8k, and 4k. Alternatively, you can specify page size in bytes (65536, 32768, 16384, 8192, 4096).

The default page size of 16k is appropriate for a wide range of workloads, particularly for queries involving table scans and DML operations involving bulk updates. Smaller page sizes might be more efficient for OLTP workloads involving many small writes, where contention can be an issue when a single page contains many rows. Smaller pages might also be efficient with SSD storage devices, which typically use small block sizes. Keeping the [InnoDB](#) page size close to the storage device block size minimizes the amount of unchanged data that is rewritten to disk.

## InnoDB Memory Configuration

MySQL allocates memory to various caches and buffers to improve performance of database operations. When allocating memory for [InnoDB](#), always consider memory required by the operating system, memory allocated to other applications, and memory allocated for other MySQL buffers and caches. For example, if you use [MyISAM](#) tables, consider the amount of memory allocated for the key buffer (`key_buffer_size`). For an overview of MySQL buffers and caches, see [Section 9.12.4.1, “How MySQL Uses Memory”](#).

Buffers specific to [InnoDB](#) are configured using the following parameters:

- `innodb_buffer_pool_size` defines size of the buffer pool, which is the memory area that holds cached data for [InnoDB](#) tables, indexes, and other auxiliary buffers. The size of the buffer pool is important for system performance, and it is typically recommended that `innodb_buffer_pool_size` is configured to 50 to 75 percent of system memory. The default buffer pool size is 128MB. For additional guidance, see [Section 9.12.4.1, “How MySQL Uses Memory”](#). For information about how to configure [InnoDB](#) buffer pool size, see [Section 15.6.3.2, “Configuring InnoDB Buffer Pool Size”](#). Buffer pool size can be configured at startup or dynamically.

On systems with a large amount of memory, you can improve concurrency by dividing the buffer pool into multiple buffer pool instances. The number of buffer pool instances is controlled by the `innodb_buffer_pool_instances` option. By default, [InnoDB](#) creates one buffer pool instance. The number of buffer pool instances can be configured at startup. For more information, see [Section 15.6.3.3, “Configuring Multiple Buffer Pool Instances”](#).

- `innodb_log_buffer_size` defines the size in bytes of the buffer that [InnoDB](#) uses to write to the log files on disk. The default size is 16MB. A large log buffer enables large transactions to run without a need to write the log to disk before the transactions commit. If you have transactions that update, insert, or delete many rows, you might consider increasing the size of the log buffer to save disk I/O. `innodb_log_buffer_size` can be configured at startup. For related information, see [Section 9.5.4, “Optimizing InnoDB Redo Logging”](#).

### Warning

On 32-bit GNU/Linux x86, be careful not to set memory usage too high. `glibc` may permit the process heap to grow over thread stacks, which crashes your server. It is a risk if the memory allocated to the `mysqld` process for global and per-thread buffers and caches is close to or exceeds 2GB.

A formula similar to the following that calculates global and per-thread memory allocation for MySQL can be used to estimate MySQL memory usage. You may need to modify the formula to account for buffers and caches in your MySQL version and configuration. For an overview of MySQL buffers and caches, see [Section 9.12.4.1, “How MySQL Uses Memory”](#).

```
innodb_buffer_pool_size
+ key_buffer_size
+ max_connections*(sort_buffer_size+read_buffer_size+binlog_cache_size)
+ max_connections*2MB
```

Each thread uses a stack (often 2MB, but only 256KB in MySQL binaries provided by Oracle Corporation.) and in the worst case also uses `sort_buffer_size + read_buffer_size` additional memory.

On Linux, if the kernel is enabled for large page support, InnoDB can use large pages to allocate memory for its buffer pool. See [Section 9.12.4.2, “Enabling Large Page Support”](#).

## 15.6.2 Configuring InnoDB for Read-Only Operation

You can now query InnoDB tables where the MySQL data directory is on read-only media, by enabling the `--innodb-read-only` configuration option at server startup.

### How to Enable

To prepare an instance for read-only operation, make sure all the necessary information is [flushed](#) to the data files before storing it on the read-only medium. Run the server with change buffering disabled (`innodb_change_buffering=0`) and do a [slow shutdown](#).

To enable read-only mode for an entire MySQL instance, specify the following configuration options at server startup:

- `--innodb-read-only=1`
- If the instance is on read-only media such as a DVD or CD, or the `/var` directory is not writeable by all: `--pid-file=path_on_writeable_media` and `--event-scheduler=disabled`

### Usage Scenarios

This mode of operation is appropriate in situations such as:

- Distributing a MySQL application, or a set of MySQL data, on a read-only storage medium such as a DVD or CD.
- Multiple MySQL instances querying the same data directory simultaneously, typically in a data warehousing configuration. You might use this technique to avoid [bottlenecks](#) that can occur with a heavily loaded MySQL instance, or you might use different configuration options for the various instances to tune each one for particular kinds of queries.
- Querying data that has been put into a read-only state for security or data integrity reasons, such as archived backup data.

#### Note

This feature is mainly intended for flexibility in distribution and deployment, rather than raw performance based on the read-only aspect. See [Section 9.5.3, “Optimizing InnoDB Read-Only Transactions”](#) for ways to tune the performance of read-only queries, which do not require making the entire server read-only.

### How It Works

When the server is run in read-only mode through the `--innodb-read-only` option, certain InnoDB features and components are reduced or turned off entirely:

- No [change buffering](#) is done, in particular no merges from the change buffer. To make sure the change buffer is empty when you prepare the instance for read-only operation, disable change buffering (`innodb_change_buffering=0`) and do a [slow shutdown](#) first.

- There is no [crash recovery](#) phase at startup. The instance must have performed a [slow shutdown](#) before being put into the read-only state.
- Because the [redo log](#) is not used in read-only operation, you can set `innodb_log_file_size` to the smallest size possible (1 MB) before making the instance read-only.
- All background threads other than I/O read threads are turned off. As a consequence, a read-only instance cannot encounter any [deadlocks](#).
- Information about deadlocks, monitor output, and so on is not written to temporary files. As a consequence, `SHOW ENGINE INNODB STATUS` does not produce any output.
- If the MySQL server is started with `--innodb-read-only` but the data directory is still on writeable media, the root user can still perform [DCL](#) operations such as `GRANT` and `REVOKE`.
- Changes to configuration option settings that would normally change the behavior of write operations, have no effect when the server is in read-only mode.
- The [MVCC](#) processing to enforce [isolation levels](#) is turned off. All queries read the latest version of a record, because update and deletes are not possible.
- The [undo log](#) is not used. Disable any settings for the `innodb_undo_tablespaces` and `innodb_undo_directory` configuration options.

## 15.6.3 InnoDB Buffer Pool Configuration

This section provides configuration and tuning information for the [InnoDB](#) buffer pool.

### 15.6.3.1 The InnoDB Buffer Pool

[InnoDB](#) maintains a storage area called the [buffer pool](#) for caching data and indexes in memory. Knowing how the [InnoDB](#) buffer pool works, and taking advantage of it to keep frequently accessed data in memory, is an important aspect of MySQL tuning. For information about how the [InnoDB](#) buffer pool works, see [InnoDB Buffer Pool LRU Algorithm](#).

You can configure the various aspects of the [InnoDB](#) buffer pool to improve performance.

- Ideally, you set the size of the buffer pool to as large a value as practical, leaving enough memory for other processes on the server to run without excessive paging. The larger the buffer pool, the more [InnoDB](#) acts like an in-memory database, reading data from disk once and then accessing the data from memory during subsequent reads. See [Section 15.6.3.2, “Configuring InnoDB Buffer Pool Size”](#).
- With 64-bit systems with large memory sizes, you can split the buffer pool into multiple parts, to minimize contention for the memory structures among concurrent operations. For details, see [Section 15.6.3.3, “Configuring Multiple Buffer Pool Instances”](#).
- You can keep frequently accessed data in memory despite sudden spikes of activity for operations such as backups or reporting. For details, see [Section 15.6.3.4, “Making the Buffer Pool Scan Resistant”](#).
- You can control when and how [InnoDB](#) performs read-ahead requests to prefetch pages into the buffer pool asynchronously, in anticipation that the pages will be needed soon. For details, see [Section 15.6.3.5, “Configuring InnoDB Buffer Pool Prefetching \(Read-Ahead\)”](#).
- You can control when background flushing of dirty pages occurs and whether or not [InnoDB](#) dynamically adjusts the rate of flushing based on workload. For details, see [Section 15.6.3.6, “Configuring InnoDB Buffer Pool Flushing”](#).
- You can fine-tune aspects of [InnoDB](#) buffer pool flushing behavior to improve performance. For details, see [Section 15.6.3.7, “Fine-tuning InnoDB Buffer Pool Flushing”](#).

- You can configure how [InnoDB](#) preserves the current buffer pool state to avoid a lengthy warmup period after a server restart. You can also save the current buffer pool state while the server is running. For details, see [Section 15.6.3.8, “Saving and Restoring the Buffer Pool State”](#).

## InnoDB Buffer Pool LRU Algorithm

[InnoDB](#) manages the buffer pool as a list, using a variation of the least recently used (LRU) algorithm. When room is needed to add a new page to the pool, [InnoDB](#) evicts the least recently used page and adds the new page to the middle of the list. This “midpoint insertion strategy” treats the list as two sublists:

- At the head, a sublist of “new” (or “young”) pages that were accessed recently.
- At the tail, a sublist of “old” pages that were accessed less recently.

This algorithm keeps pages that are heavily used by queries in the new sublist. The old sublist contains less-used pages; these pages are candidates for [eviction](#).

The LRU algorithm operates as follows by default:

- 3/8 of the buffer pool is devoted to the old sublist.
- The midpoint of the list is the boundary where the tail of the new sublist meets the head of the old sublist.
- When [InnoDB](#) reads a page into the buffer pool, it initially inserts it at the midpoint (the head of the old sublist). A page can be read in because it is required for a user-specified operation such as an SQL query, or as part of a [read-ahead](#) operation performed automatically by [InnoDB](#).
- Accessing a page in the old sublist makes it “young”, moving it to the head of the buffer pool (the head of the new sublist). If the page was read in because it was required, the first access occurs immediately and the page is made young. If the page was read in due to read-ahead, the first access does not occur immediately (and might not occur at all before the page is evicted).
- As the database operates, pages in the buffer pool that are not accessed “age” by moving toward the tail of the list. Pages in both the new and old sublists age as other pages are made new. Pages in the old sublist also age as pages are inserted at the midpoint. Eventually, a page that remains unused for long enough reaches the tail of the old sublist and is evicted.

By default, pages read by queries immediately move into the new sublist, meaning they will stay in the buffer pool for a long time. A table scan (such as performed for a [mysqldump](#) operation, or a [SELECT](#) statement with no [WHERE](#) clause) can bring a large amount of data into the buffer pool and evict an equivalent amount of older data, even if the new data is never used again. Similarly, pages that are loaded by the read-ahead background thread and then accessed only once move to the head of the new list. These situations can push frequently used pages to the old sublist, where they become subject to eviction. For information about optimizing this behavior, see [Section 15.6.3.4, “Making the Buffer Pool Scan Resistant”](#), and [Section 15.6.3.5, “Configuring InnoDB Buffer Pool Prefetching \(Read-Ahead\)”](#).

[InnoDB](#) Standard Monitor output contains several fields in the [BUFFER POOL AND MEMORY](#) section that pertain to operation of the buffer pool LRU algorithm. For details, see [Section 15.6.3.9, “Monitoring the Buffer Pool Using the InnoDB Standard Monitor”](#).

## InnoDB Buffer Pool Configuration Options

Several configuration options affect different aspects of the [InnoDB](#) buffer pool.

- [`innodb\_buffer\_pool\_size`](#)

Specifies the size of the buffer pool. If the buffer pool is small and you have sufficient memory, making the buffer pool larger can improve performance by reducing the amount of disk I/O needed as queries access [InnoDB](#) tables. As of MySQL 5.7.5, the [`innodb\_buffer\_pool\_size`](#) option

is dynamic, which allows you to configure buffer pool size without restarting the server. See [Section 15.6.3.2, “Configuring InnoDB Buffer Pool Size”](#) for more information.

- `innodb_buffer_pool_chunk_size`

Defines the chunk size for InnoDB buffer pool resizing operations. See [Section 15.6.3.2, “Configuring InnoDB Buffer Pool Size”](#) for more information.

- `innodb_buffer_pool_instances`

Divides the buffer pool into a user-specified number of separate regions, each with its own LRU list and related data structures, to reduce contention during concurrent memory read and write operations. This option only takes effect when you set `innodb_buffer_pool_size` to a value of 1GB or more. The total size you specify is divided among all the buffer pools. For best efficiency, specify a combination of `innodb_buffer_pool_instances` and `innodb_buffer_pool_size` so that each buffer pool instance is at least 1 gigabyte. See [Section 15.6.3.3, “Configuring Multiple Buffer Pool Instances”](#) for more information.

- `innodb_old_blocks_pct`

Specifies the approximate percentage of the buffer pool that InnoDB uses for the old block sublist. The range of values is 5 to 95. The default value is 37 (that is, 3/8 of the pool). See [Section 15.6.3.4, “Making the Buffer Pool Scan Resistant”](#) for more information.

- `innodb_old_blocks_time`

Specifies how long in milliseconds (ms) a page inserted into the old [sublist](#) must stay there after its first access before it can be moved to the new sublist. If the value is 0, a page inserted into the old sublist moves immediately to the new sublist the first time it is accessed, no matter how soon after insertion the access occurs. If the value is greater than 0, pages remain in the old sublist until an access occurs at least that many milliseconds after the first access. For example, a value of 1000 causes pages to stay in the old sublist for 1 second after the first access before they become eligible to move to the new sublist.

Setting `innodb_old_blocks_time` greater than 0 prevents one-time table scans from flooding the new sublist with pages used only for the scan. Rows in a page read in for a scan are accessed many times in rapid succession, but the page is unused after that. If `innodb_old_blocks_time` is set to a value greater than time to process the page, the page remains in the “old” sublist and ages to the tail of the list to be evicted quickly. This way, pages used only for a one-time scan do not act to the detriment of heavily used pages in the new sublist.

`innodb_old_blocks_time` can be set at runtime, so you can change it temporarily while performing operations such as table scans and dumps:

```
SET GLOBAL innodb_old_blocks_time = 1000;  
... perform queries that scan tables ...  
SET GLOBAL innodb_old_blocks_time = 0;
```

This strategy does not apply if your intent is to “warm up” the buffer pool by filling it with a table's content. For example, benchmark tests often perform a table or index scan at server startup, because that data would normally be in the buffer pool after a period of normal use. In this case, leave `innodb_old_blocks_time` set to 0, at least until the warmup phase is complete.

See [Section 15.6.3.4, “Making the Buffer Pool Scan Resistant”](#) for more information.

- `innodb_read_ahead_threshold`

Controls the sensitivity of linear [read-ahead](#) that InnoDB uses to prefetch pages into the buffer pool.

See [Section 15.6.3.5, “Configuring InnoDB Buffer Pool Prefetching \(Read-Ahead\)”](#) for more information.

- `innodb_random_read_ahead`

Enables random [read-ahead](#) technique for prefetching pages into the buffer pool. Random read-ahead is a technique that predicts when pages might be needed soon based on pages already in the buffer pool, regardless of the order in which those pages were read. `innodb_random_read_ahead` is disabled by default.

See [Section 15.6.3.5, “Configuring InnoDB Buffer Pool Prefetching \(Read-Ahead\)”](#) for more information.

- `innodb_adaptive_flushing`

Specifies whether to dynamically adjust the rate of flushing [dirty pages](#) in the buffer pool based on workload. Adjusting the flush rate dynamically is intended to avoid bursts of I/O activity. This setting is enabled by default.

See [Section 15.6.3.6, “Configuring InnoDB Buffer Pool Flushing”](#) for more information.

- `innodb_adaptive_flushing_lwm`

Low water mark representing percentage of [redo log](#) capacity at which [adaptive flushing](#) is enabled.

See [Section 15.6.3.7, “Fine-tuning InnoDB Buffer Pool Flushing”](#) for more information.

- `innodb_flush_neighbors`

Specifies whether [flushing](#) a page from the buffer pool also flushes other [dirty pages](#) in the same [extent](#).

See [Section 15.6.3.7, “Fine-tuning InnoDB Buffer Pool Flushing”](#) for more information.

- `innodb_flushing_avg_loops`

Number of iterations for which InnoDB keeps the previously calculated snapshot of the flushing state, controlling how quickly [adaptive flushing](#) responds to changing [workloads](#).

See [Section 15.6.3.7, “Fine-tuning InnoDB Buffer Pool Flushing”](#) for more information.

- `innodb_lru_scan_depth`

A parameter that influences the algorithms and heuristics for the [flush](#) operation for the buffer pool. Primarily of interest to performance experts tuning I/O-intensive workloads. It specifies, per buffer pool instance, how far down the buffer pool LRU list the `page_cleaner` thread scans looking for [dirty pages](#) to flush.

See [Section 15.6.3.7, “Fine-tuning InnoDB Buffer Pool Flushing”](#) for more information.

- `innodb_max_dirty_pages_pct`

InnoDB tries to [flush](#) data from the buffer pool so that the percentage of [dirty pages](#) does not exceed this value. Specify an integer in the range from 0 to 99. The default value is 75.

See [Section 15.6.3.6, “Configuring InnoDB Buffer Pool Flushing”](#) for more information.

- `innodb_max_dirty_pages_pct_lwm`

Low water mark representing percentage of [dirty pages](#) where preflushing is enabled to control the dirty page ratio. The default of 0 disables the pre-flushing behavior entirely.

See [Section 15.6.3.7, “Fine-tuning InnoDB Buffer Pool Flushing”](#) for more information.

- `innodb_buffer_pool_filename`

---

Specifies the name of the file that holds the list of tablespace IDs and page IDs produced by `innodb_buffer_pool_dump_at_shutdown` or `innodb_buffer_pool_dump_now`.

See [Section 15.6.3.8, “Saving and Restoring the Buffer Pool State”](#) for more information.

- `innodb_buffer_pool_dump_at_shutdown`

Specifies whether to record the pages cached in the buffer pool when the MySQL server is shut down, to shorten the `warmup` process at the next restart.

See [Section 15.6.3.8, “Saving and Restoring the Buffer Pool State”](#) for more information.

- `innodb_buffer_pool_load_at_startup`

Specifies that, on MySQL server startup, the buffer pool is automatically `warmed up` by loading the same pages it held at an earlier time. Typically used in combination with `innodb_buffer_pool_dump_at_shutdown`.

See [Section 15.6.3.8, “Saving and Restoring the Buffer Pool State”](#) for more information.

- `innodb_buffer_pool_dump_now`

Immediately records the pages cached in the buffer pool.

See [Section 15.6.3.8, “Saving and Restoring the Buffer Pool State”](#) for more information.

- `innodb_buffer_pool_load_now`

Immediately `warms up` the buffer pool by loading a set of data pages, without waiting for a server restart. Can be useful to bring cache memory back to a known state during benchmarking, or to ready the MySQL server to resume its normal workload after running queries for reports or maintenance. Typically used with `innodb_buffer_pool_dump_now`.

See [Section 15.6.3.8, “Saving and Restoring the Buffer Pool State”](#) for more information.

- `innodb_buffer_pool_dump_pct`

Specifies the percentage of the most recently used pages for each buffer pool to read out and dump. The range is 1 to 100.

See [Section 15.6.3.8, “Saving and Restoring the Buffer Pool State”](#) for more information.

- `innodb_buffer_pool_load_abort`

Interrupts the process of restoring buffer pool contents triggered by `innodb_buffer_pool_load_at_startup` or `innodb_buffer_pool_load_now`.

See [Section 15.6.3.8, “Saving and Restoring the Buffer Pool State”](#) for more information.

### 15.6.3.2 Configuring InnoDB Buffer Pool Size

You can configure `InnoDB` buffer pool size offline (at startup) or online, while the server is running. Behavior described in this section applies to both methods. For additional information about configuring buffer pool size online, see [Configuring InnoDB Buffer Pool Size Online](#).

When increasing or decreasing `innodb_buffer_pool_size`, the operation is performed in chunks. Chunk size is defined by the `innodb_buffer_pool_chunk_size` configuration option, which has a default of `128M`. For more information, see [Configuring InnoDB Buffer Pool Chunk Size](#).

Buffer pool size must always be equal to or a multiple of `innodb_buffer_pool_chunk_size` \* `innodb_buffer_pool_instances`. If you configure `innodb_buffer_pool_size` to a value that is not equal to or a multiple of `innodb_buffer_pool_chunk_size` \*

`innodb_buffer_pool_instances`, buffer pool size is automatically adjusted to a value that is equal to or a multiple of `innodb_buffer_pool_chunk_size * innodb_buffer_pool_instances` that is not less than the specified buffer pool size.

In the following example, `innodb_buffer_pool_size` is set to 8G, and `innodb_buffer_pool_instances` is set to 16. `innodb_buffer_pool_chunk_size` is 128M, which is the default value.

8G is a valid `innodb_buffer_pool_size` value because 8G is a multiple of `innodb_buffer_pool_instances=16 * innodb_buffer_pool_chunk_size=128M`, which is 2G.

```
shell> mysqld --innodb_buffer_pool_size=8G --innodb_buffer_pool_instances=16
```

```
mysql> SELECT @@innodb_buffer_pool_size/1024/1024/1024;
```

```
+-----+
| @@innodb_buffer_pool_size/1024/1024/1024 |
+-----+
|                                     8.000000000000 |
+-----+
```

In this example, `innodb_buffer_pool_size` is set to 9G, and `innodb_buffer_pool_instances` is set to 16. `innodb_buffer_pool_chunk_size` is 128M, which is the default value. In this case, 9G is not a multiple of `innodb_buffer_pool_instances=16 * innodb_buffer_pool_chunk_size=128M`, so `innodb_buffer_pool_size` is adjusted to 10G, which is the next multiple of `innodb_buffer_pool_chunk_size * innodb_buffer_pool_instances` that is not less than the specified buffer pool size.

```
shell> mysqld --innodb_buffer_pool_size=9G --innodb_buffer_pool_instances=16
```

```
mysql> SELECT @@innodb_buffer_pool_size/1024/1024/1024;
```

```
+-----+
| @@innodb_buffer_pool_size/1024/1024/1024 |
+-----+
|                                     10.000000000000 |
+-----+
```

## Configuring InnoDB Buffer Pool Chunk Size

`innodb_buffer_pool_chunk_size` can be increased or decreased in 1MB (1048576 byte) units but can only be modified at startup, in a command line string or in a MySQL configuration file.

Command line:

```
shell> mysqld --innodb_buffer_pool_chunk_size=134217728
```

Configuration file:

```
[mysqld]
innodb_buffer_pool_chunk_size=134217728
```

The following conditions apply when altering `innodb_buffer_pool_chunk_size`:

- If the new `innodb_buffer_pool_chunk_size` value \* `innodb_buffer_pool_instances` is larger than the current buffer pool size when the buffer pool is initialized, `innodb_buffer_pool_chunk_size` is truncated to `innodb_buffer_pool_size / innodb_buffer_pool_instances`.

For example, if the buffer pool is initialized with a size of 2GB (2147483648 bytes), 4 buffer pool instances, and a chunk size of 1GB (1073741824 bytes), chunk size is truncated to a value equal to `innodb_buffer_pool_size / innodb_buffer_pool_instances`, as shown below:

```
shell> mysqld --innodb_buffer_pool_size=2147483648 --innodb_buffer_pool_instances=4
--innodb_buffer_pool_chunk_size=1073741824;
```

```
mysql> SELECT @@innodb_buffer_pool_size;
```

```
+-----+
```

```

| @@innodb_buffer_pool_size |
+-----+
| 2147483648 |
+-----+

mysql> SELECT @@innodb_buffer_pool_instances;
+-----+
| @@innodb_buffer_pool_instances |
+-----+
| 4 |
+-----+

# Chunk size was set to 1GB (1073741824 bytes) on startup but was
# truncated to innodb_buffer_pool_size / innodb_buffer_pool_instances

mysql> SELECT @@innodb_buffer_pool_chunk_size;
+-----+
| @@innodb_buffer_pool_chunk_size |
+-----+
| 536870912 |
+-----+

```

- Buffer pool size must always be equal to or a multiple of `innodb_buffer_pool_chunk_size * innodb_buffer_pool_instances`. If you alter `innodb_buffer_pool_chunk_size`, `innodb_buffer_pool_size` is automatically adjusted to a value that is equal to or a multiple of `innodb_buffer_pool_chunk_size * innodb_buffer_pool_instances` that is not less than current buffer pool size. The adjustment occurs when the buffer pool is initialized. This behavior is demonstrated in the following example:

```

# The buffer pool has a default size of 128MB (134217728 bytes)

mysql> SELECT @@innodb_buffer_pool_size;
+-----+
| @@innodb_buffer_pool_size |
+-----+
| 134217728 |
+-----+

# The chunk size is also 128MB (134217728 bytes)

mysql> SELECT @@innodb_buffer_pool_chunk_size;
+-----+
| @@innodb_buffer_pool_chunk_size |
+-----+
| 134217728 |
+-----+

# There is a single buffer pool instance

mysql> SELECT @@innodb_buffer_pool_instances;
+-----+
| @@innodb_buffer_pool_instances |
+-----+
| 1 |
+-----+

# Chunk size is decreased by 1MB (1048576 bytes) at startup
# (134217728 - 1048576 = 133169152):

shell> mysqld --innodb_buffer_pool_chunk_size=133169152

mysql> SELECT @@innodb_buffer_pool_chunk_size;
+-----+
| @@innodb_buffer_pool_chunk_size |
+-----+
| 133169152 |
+-----+

# Buffer pool size increases from 134217728 to 266338304
# Buffer pool size is automatically adjusted to a value that is equal to
# or a multiple of innodb_buffer_pool_chunk_size * innodb_buffer_pool_instances

```

```
# that is not less than current buffer pool size
```

```
mysql> SELECT @@innodb_buffer_pool_size;
+-----+
| @@innodb_buffer_pool_size |
+-----+
|                266338304 |
+-----+
```

This example demonstrates the same behavior but with multiple buffer pool instances:

```
# The buffer pool has a default size of 2GB (2147483648 bytes)
```

```
mysql> SELECT @@innodb_buffer_pool_size;
+-----+
| @@innodb_buffer_pool_size |
+-----+
|                2147483648 |
+-----+
```

```
# The chunk size is .5 GB (536870912 bytes)
```

```
mysql> SELECT @@innodb_buffer_pool_chunk_size;
+-----+
| @@innodb_buffer_pool_chunk_size |
+-----+
|                536870912 |
+-----+
```

```
# There are 4 buffer pool instances
```

```
mysql> SELECT @@innodb_buffer_pool_instances;
+-----+
| @@innodb_buffer_pool_instances |
+-----+
|                        4 |
+-----+
```

```
# Chunk size is decreased by 1MB (1048576 bytes) at startup
# (536870912 - 1048576 = 535822336):
```

```
shell> mysqld --innodb_buffer_pool_chunk_size=535822336
```

```
mysql> SELECT @@innodb_buffer_pool_chunk_size;
+-----+
| @@innodb_buffer_pool_chunk_size |
+-----+
|                535822336 |
+-----+
```

```
# Buffer pool size increases from 2147483648 to 4286578688
# Buffer pool size is automatically adjusted to a value that is equal to
# or a multiple of innodb_buffer_pool_chunk_size * innodb_buffer_pool_instances
# that is not less than current buffer pool size of 2147483648
```

```
mysql> SELECT @@innodb_buffer_pool_size;
+-----+
| @@innodb_buffer_pool_size |
+-----+
|                4286578688 |
+-----+
```

Care should be taken when changing `innodb_buffer_pool_chunk_size`, as changing this value can increase the size of the buffer pool, as shown in the examples above. Before you change `innodb_buffer_pool_chunk_size`, calculate the effect it will have on `innodb_buffer_pool_size` to ensure that the resulting buffer pool size is acceptable.

**Note**

To avoid potential performance issues, the number of chunks (`innodb_buffer_pool_size / innodb_buffer_pool_chunk_size`) should not exceed 1000.

**Configuring InnoDB Buffer Pool Size Online**

As of MySQL 5.7.5, the `innodb_buffer_pool_size` configuration option can be set dynamically using a `SET` statement, allowing you to resize the buffer pool without restarting the server. For example:

```
mysql> SET GLOBAL innodb_buffer_pool_size=402653184;
```

Active transactions and operations performed through InnoDB APIs should be completed before resizing the buffer pool. When initiating a resizing operation, the operation does not start until all active transactions are completed. Once the resizing operation is in progress, new transactions and operations that require access to the buffer pool must wait until the resizing operation finishes. The exception to the rule is that concurrent access to the buffer pool is permitted while the buffer pool is defragmented and pages are withdrawn when buffer pool size is decreased. A drawback of allowing concurrent access is that it could result in a temporary shortage of available pages while pages are being withdrawn.

**Note**

Nested transactions could fail if initiated after the buffer pool resizing operation begins.

**Monitoring Online Buffer Pool Resizing Progress**

The `Innodb_buffer_pool_resize_status` reports buffer pool resizing progress. For example:

```
mysql> SHOW STATUS WHERE Variable_name='InnoDB_buffer_pool_resize_status';
+-----+-----+
| Variable_name | Value |
+-----+-----+
| Innodb_buffer_pool_resize_status | Resizing also other hash tables. |
+-----+-----+
```

Buffer pool resizing progress is also logged in the server error log file. This example shows notes that are logged when increasing the size of the buffer pool:

```
[Note] InnoDB: Resizing buffer pool from 134217728 to 4294967296. (unit=134217728)
[Note] InnoDB: disabled adaptive hash index.
[Note] InnoDB: buffer pool 0 : 31 chunks (253952 blocks) was added.
[Note] InnoDB: buffer pool 0 : hash tables were resized.
[Note] InnoDB: Resized hash tables at lock_sys, adaptive hash index, dictionary.
[Note] InnoDB: completed to resize buffer pool from 134217728 to 4294967296.
[Note] InnoDB: re-enabled adaptive hash index.
```

This example shows notes that are logged when decreasing the size of the buffer pool:

```
[Note] InnoDB: Resizing buffer pool from 4294967296 to 134217728. (unit=134217728)
[Note] InnoDB: disabled adaptive hash index.
[Note] InnoDB: buffer pool 0 : start to withdraw the last 253952 blocks.
[Note] InnoDB: buffer pool 0 : withdrew 253952 blocks from free list. tried to relocate 0 pages.
(253952/253952)
[Note] InnoDB: buffer pool 0 : withdrawn target 253952 blocks.
[Note] InnoDB: buffer pool 0 : 31 chunks (253952 blocks) was freed.
[Note] InnoDB: buffer pool 0 : hash tables were resized.
[Note] InnoDB: Resized hash tables at lock_sys, adaptive hash index, dictionary.
[Note] InnoDB: completed to resize buffer pool from 4294967296 to 134217728.
[Note] InnoDB: re-enabled adaptive hash index.
```

## Online Buffer Pool Resizing Internals

The resizing operation is performed by a background thread. When increasing the size of the buffer pool, the resizing operation:

- Adds pages in `chunks` (chunk size is defined by `innodb_buffer_pool_chunk_size`)
- Coverts hash tables, lists, and pointers to use new addresses in memory
- Adds new pages to the free list

While these operations are in progress, other threads are blocked from accessing the buffer pool.

When decreasing the size of the buffer pool, the resizing operation:

- Defragments the buffer pool and withdraws (frees) pages
- Removes pages in `chunks` (chunk size is defined by `innodb_buffer_pool_chunk_size`)
- Converts hash tables, lists, and pointers to use new addresses in memory

Of these operations, only defragmenting the buffer pool and withdrawing pages allow other threads to access to the buffer pool concurrently.

### 15.6.3.3 Configuring Multiple Buffer Pool Instances

For systems with buffer pools in the multi-gigabyte range, dividing the buffer pool into separate instances can improve concurrency, by reducing contention as different threads read and write to cached pages. This feature is typically intended for systems with a `buffer pool` size in the multi-gigabyte range. Multiple buffer pool instances are configured using the `innodb_buffer_pool_instances` configuration option, and you might also adjust the `innodb_buffer_pool_size` value.

When the `InnoDB` buffer pool is large, many data requests can be satisfied by retrieving from memory. You might encounter bottlenecks from multiple threads trying to access the buffer pool at once. You can enable multiple buffer pools to minimize this contention. Each page that is stored in or read from the buffer pool is assigned to one of the buffer pools randomly, using a hashing function. Each buffer pool manages its own free lists, flush lists, LRUs, and all other data structures connected to a buffer pool, and is protected by its own buffer pool mutex.

To enable multiple buffer pool instances, set the `innodb_buffer_pool_instances` configuration option to a value greater than 1 (the default) up to 64 (the maximum). This option takes effect only when you set `innodb_buffer_pool_size` to a size of 1GB or more. The total size you specify is divided among all the buffer pools. For best efficiency, specify a combination of `innodb_buffer_pool_instances` and `innodb_buffer_pool_size` so that each buffer pool instance is at least 1GB.

For information about modifying `InnoDB` buffer pool size, see [Section 15.6.3.2, “Configuring InnoDB Buffer Pool Size”](#).

### 15.6.3.4 Making the Buffer Pool Scan Resistant

Rather than using a strict `LRU` algorithm, `InnoDB` uses a technique to minimize the amount of data that is brought into the `buffer pool` and never accessed again. The goal is to make sure that frequently accessed (“hot”) pages remain in the buffer pool, even as `read-ahead` and `full table scans` bring in new blocks that might or might not be accessed afterward.

Newly read blocks are inserted into the middle of the `LRU` list. All newly read pages are inserted at a location that by default is `3/8` from the tail of the `LRU` list. The pages are moved to the front of the list (the most-recently used end) when they are accessed in the buffer pool for the first time. Thus, pages that are never accessed never make it to the front portion of the `LRU` list, and “age out” sooner than

with a strict LRU approach. This arrangement divides the LRU list into two segments, where the pages downstream of the insertion point are considered “old” and are desirable victims for LRU eviction.

For an explanation of the inner workings of the [InnoDB](#) buffer pool and specifics about the LRU algorithm, see [Section 15.6.3.1, “The InnoDB Buffer Pool”](#).

You can control the insertion point in the LRU list and choose whether [InnoDB](#) applies the same optimization to blocks brought into the buffer pool by table or index scans. The configuration parameter `innodb_old_blocks_pct` controls the percentage of “old” blocks in the LRU list. The default value of `innodb_old_blocks_pct` is 37, corresponding to the original fixed ratio of 3/8. The value range is 5 (new pages in the buffer pool age out very quickly) to 95 (only 5% of the buffer pool is reserved for hot pages, making the algorithm close to the familiar LRU strategy).

The optimization that keeps the buffer pool from being churned by read-ahead can avoid similar problems due to table or index scans. In these scans, a data page is typically accessed a few times in quick succession and is never touched again. The configuration parameter `innodb_old_blocks_time` specifies the time window (in milliseconds) after the first access to a page during which it can be accessed without being moved to the front (most-recently used end) of the LRU list. The default value of `innodb_old_blocks_time` is 1000. Increasing this value makes more and more blocks likely to age out faster from the buffer pool.

Both `innodb_old_blocks_pct` and `innodb_old_blocks_time` are dynamic, global and can be specified in the MySQL option file (`my.cnf` or `my.ini`) or changed at runtime with the `SET GLOBAL` command. Changing the setting requires the `SUPER` privilege.

To help you gauge the effect of setting these parameters, the `SHOW ENGINE INNODB STATUS` command reports buffer pool statistics. For details, see [Section 15.6.3.9, “Monitoring the Buffer Pool Using the InnoDB Standard Monitor”](#).

Because the effects of these parameters can vary widely based on your hardware configuration, your data, and the details of your workload, always benchmark to verify the effectiveness before changing these settings in any performance-critical or production environment.

In mixed workloads where most of the activity is OLTP type with periodic batch reporting queries which result in large scans, setting the value of `innodb_old_blocks_time` during the batch runs can help keep the working set of the normal workload in the buffer pool.

When scanning large tables that cannot fit entirely in the buffer pool, setting `innodb_old_blocks_pct` to a small value keeps the data that is only read once from consuming a significant portion of the buffer pool. For example, setting `innodb_old_blocks_pct=5` restricts this data that is only read once to 5% of the buffer pool.

When scanning small tables that do fit into memory, there is less overhead for moving pages around within the buffer pool, so you can leave `innodb_old_blocks_pct` at its default value, or even higher, such as `innodb_old_blocks_pct=50`.

The effect of the `innodb_old_blocks_time` parameter is harder to predict than the `innodb_old_blocks_pct` parameter, is relatively small, and varies more with the workload. To arrive at an optimal value, conduct your own benchmarks if the performance improvement from adjusting `innodb_old_blocks_pct` is not sufficient.

### 15.6.3.5 Configuring InnoDB Buffer Pool Prefetching (Read-Ahead)

A [read-ahead](#) request is an I/O request to prefetch multiple pages in the [buffer pool](#) asynchronously, in anticipation that these pages will be needed soon. The requests bring in all the pages in one [extent](#). [InnoDB](#) uses two read-ahead algorithms to improve I/O performance:

**Linear** read-ahead is a technique that predicts what pages might be needed soon based on pages in the buffer pool being accessed sequentially. You control when [InnoDB](#) performs a read-ahead

operation by adjusting the number of sequential page accesses required to trigger an asynchronous read request, using the configuration parameter `innodb_read_ahead_threshold`. Before this parameter was added, InnoDB would only calculate whether to issue an asynchronous prefetch request for the entire next extent when it read in the last page of the current extent.

The configuration parameter `innodb_read_ahead_threshold` controls how sensitive InnoDB is in detecting patterns of sequential page access. If the number of pages read sequentially from an extent is greater than or equal to `innodb_read_ahead_threshold`, InnoDB initiates an asynchronous read-ahead operation of the entire following extent. `innodb_read_ahead_threshold` can be set to any value from 0-64. The default value is 56. The higher the value, the more strict the access pattern check. For example, if you set the value to 48, InnoDB triggers a linear read-ahead request only when 48 pages in the current extent have been accessed sequentially. If the value is 8, InnoDB triggers an asynchronous read-ahead even if as few as 8 pages in the extent are accessed sequentially. You can set the value of this parameter in the MySQL [configuration file](#), or change it dynamically with the `SET GLOBAL` command, which requires the `SUPER` privilege.

**Random** read-ahead is a technique that predicts when pages might be needed soon based on pages already in the buffer pool, regardless of the order in which those pages were read. If 13 consecutive pages from the same extent are found in the buffer pool, InnoDB asynchronously issues a request to prefetch the remaining pages of the extent. To enable this feature, set the configuration variable `innodb_random_read_ahead` to `ON`.

The `SHOW ENGINE INNODB STATUS` command displays statistics to help you evaluate the effectiveness of the read-ahead algorithm. Statistics include counter information for the following global status variables:

- `Innodb_buffer_pool_read_ahead`
- `Innodb_buffer_pool_read_ahead_evicted`
- `Innodb_buffer_pool_read_ahead_rnd`

This information can be useful when fine-tuning the `innodb_random_read_ahead` setting.

For more information about I/O performance, see [Section 9.5.8, “Optimizing InnoDB Disk I/O”](#) and [Section 9.12.2, “Optimizing Disk I/O”](#).

### 15.6.3.6 Configuring InnoDB Buffer Pool Flushing

InnoDB performs certain tasks in the background, including [flushing](#) of [dirty pages](#) (those pages that have been changed but are not yet written to the database files) from the [buffer pool](#).

InnoDB starts flushing buffer pool pages when the percentage of dirty pages in the buffer pool reaches the low water mark setting defined by `innodb_max_dirty_pages_pct_lwm`. This option is intended to control the ratio of dirty pages in the buffer pool and ideally prevent the percentage of dirty pages from reaching `innodb_max_dirty_pages_pct`. If the percentage of dirty pages in the buffer pool exceeds `innodb_max_dirty_pages_pct`, InnoDB begins to aggressively flush buffer pool pages.

InnoDB uses an algorithm to estimate the required rate of flushing, based on the speed of redo log generation and the current rate of flushing. The intent is to smooth overall performance by ensuring that buffer flush activity keeps up with the need to keep the buffer pool “clean”. Automatically adjusting the rate of flushing can help to avoid sudden dips in throughput, when excessive buffer pool flushing limits the I/O capacity available for ordinary read and write activity.

InnoDB uses its log files in a circular fashion. Before reusing a portion of a log file, InnoDB flushes to disk all dirty buffer pool pages whose redo entries are contained in that portion of the log file, a process known as a [sharp checkpoint](#). If a workload is write-intensive, it generates a lot of redo information, all written to the log file. If all available space in the log files is used up, a sharp checkpoint occurs, causing a temporary reduction in throughput. This situation can happen even if `innodb_max_dirty_pages_pct` is not reached.

InnoDB uses a heuristic-based algorithm to avoid such a scenario, by measuring the number of dirty pages in the buffer pool and the rate at which redo is being generated. Based on these numbers, InnoDB decides how many dirty pages to flush from the buffer pool each second. This self-adapting algorithm is able to deal with sudden changes in workload.

Internal benchmarking has shown that this algorithm not only maintains throughput over time, but can also improve overall throughput significantly.

Because adaptive flushing can significantly affect the I/O pattern of a workload, the `innodb_adaptive_flushing` configuration parameter lets you turn off this feature. The default value for `innodb_adaptive_flushing` is `ON`, enabling the adaptive flushing algorithm. You can set the value of this parameter in the MySQL option file (`my.cnf` or `my.ini`) or change it dynamically with the `SET GLOBAL` command, which requires the `SUPER` privilege.

For information about fine-tuning InnoDB buffer pool flushing behavior, see [Section 15.6.3.7, “Fine-tuning InnoDB Buffer Pool Flushing”](#).

For more information about InnoDB I/O performance, see [Section 9.5.8, “Optimizing InnoDB Disk I/O”](#).

### 15.6.3.7 Fine-tuning InnoDB Buffer Pool Flushing

The configuration options `innodb_flush_neighbors` and `innodb_lru_scan_depth` let you fine-tune certain aspects of the [flushing](#) process for the InnoDB buffer pool. These options primarily help write-intensive [workloads](#). With heavy [DML](#) activity, flushing can fall behind if it is not aggressive enough, resulting in excessive memory use in the buffer pool; or, disk writes due to flushing can saturate your I/O capacity if that mechanism is too aggressive. The ideal settings depend on your workload, data access patterns, and storage configuration (for example, whether data is stored on [HDD](#) or [SSD](#) devices).

For systems with constant heavy [workloads](#), or workloads that fluctuate widely, several configuration options let you fine-tune the [flushing](#) behavior for InnoDB tables:

- `innodb_adaptive_flushing_lwm`
- `innodb_max_dirty_pages_pct_lwm`
- `innodb_io_capacity_max`
- `innodb_flushing_avg_loops`

These options feed into the formula used by the `innodb_adaptive_flushing` option.

The `innodb_adaptive_flushing`, `innodb_io_capacity` and `innodb_max_dirty_pages_pct` options are limited or extended by the following options:

- `innodb_adaptive_flushing_lwm`
- `innodb_io_capacity_max`
- `innodb_max_dirty_pages_pct_lwm`

The InnoDB [adaptive flushing](#) mechanism is not appropriate in all cases. It gives the most benefit when the [redo log](#) is in danger of filling up. The `innodb_adaptive_flushing_lwm` option specifies a “low water mark” percentage of redo log capacity; when that threshold is crossed, InnoDB turns on adaptive flushing even if not specified by the `innodb_adaptive_flushing` option.

If flushing activity falls far behind, InnoDB can flush more aggressively than specified by `innodb_io_capacity`. `innodb_io_capacity_max` represents an upper limit on the I/O capacity used in such emergency situations, so that the spike in I/O does not consume all the capacity of the server.

InnoDB tries to flush data from the buffer pool so that the percentage of dirty pages does not exceed the value of `innodb_max_dirty_pages_pct`. The default value for `innodb_max_dirty_pages_pct` is 75.

**Note**

The `innodb_max_dirty_pages_pct` setting establishes a target for flushing activity. It does not affect the rate of flushing. For information about managing the rate of flushing, see [Section 15.6.3.6, “Configuring InnoDB Buffer Pool Flushing”](#).

The `innodb_max_dirty_pages_pct_lwm` option specifies a “low water mark” value that represents the percentage of dirty pages where pre-flushing is enabled to control the dirty page ratio and ideally prevent the percentage of dirty pages from reaching `innodb_max_dirty_pages_pct`. A value of `innodb_max_dirty_pages_pct_lwm=0` disables the “pre-flushing” behavior.

Most of the options referenced above are most applicable to servers that run write-heavy workloads for long periods of time and have little reduced load time to catch up with changes waiting to be written to disk.

`innodb_flushing_avg_loops` defines the number of iterations for which InnoDB keeps the previously calculated snapshot of the flushing state, which controls how quickly adaptive flushing responds to foreground load changes. Setting a high value for `innodb_flushing_avg_loops` means that InnoDB keeps the previously calculated snapshot longer, so adaptive flushing responds more slowly. A high value also reduces positive feedback between foreground and background work, but when setting a high value it is important to ensure that InnoDB redo log utilization does not reach 75% (the hardcoded limit at which async flushing starts) and that the `innodb_max_dirty_pages_pct` setting keeps the number of dirty pages to a level that is appropriate for the workload.

Systems with consistent workloads, a large `innodb_log_file_size`, and small spikes that do not reach 75% redo log space utilization should use a high `innodb_flushing_avg_loops` value to keep flushing as smooth as possible. For systems with extreme load spikes or log files that do not provide a lot of space, consider a smaller `innodb_flushing_avg_loops` value. A smaller value allows flushing to closely track the load and helps avoid reaching 75% redo log space utilization.

### 15.6.3.8 Saving and Restoring the Buffer Pool State

To reduce the [warmup](#) period after restarting the server, InnoDB saves a percentage of the most recently used pages for each buffer pool at server shutdown and restores these pages at server startup. The percentage of recently used pages that is stored is defined by the `innodb_buffer_pool_dump_at_shutdown` configuration option.

After restarting a busy server, there is typically a warmup period with steadily increasing throughput, as disk pages that were in the buffer pool are brought back into memory (as the same data is queried, updated, and so on). The ability to restore the buffer pool at startup shortens the warmup period by reloading disk pages that were in the buffer pool before the restart rather than waiting for DML operations to access corresponding rows. Also, I/O requests can be performed in large batches, making the overall I/O faster. Page loading happens in the background, and does not delay database startup.

In addition to saving the buffer pool state at shutdown and restoring it at startup, you can save and restore the buffer pool state at any time, while the server is running. For example, you can save the state of the buffer pool after reaching a stable throughput under a steady workload. You could also restore the previous buffer pool state after running reports or maintenance jobs that bring data pages into the buffer pool that are only required for those operations, or after running some other non-typical workload.

Even though a buffer pool can be many gigabytes in size, the buffer pool data that InnoDB saves to disk is tiny by comparison. Only tablespace IDs and page IDs necessary to locate the appropriate

pages are saved to disk. This information is derived from the [INNODB\\_BUFFER\\_PAGE\\_LRU INFORMATION\\_SCHEMA](#) table. By default, tablespace ID and page ID data is saved in a file named [ib\\_buffer\\_pool](#), which is saved to the [InnoDB](#) data directory. The file name and location can be modified using the [innodb\\_buffer\\_pool\\_filename](#) configuration parameter.

Because data is cached in and aged out of the buffer pool as it is with regular database operations, there is no problem if the disk pages are recently updated, or if a DML operation involves data that has not yet been loaded. The loading mechanism skips requested pages that no longer exist.

The underlying mechanism involves a background thread that is dispatched to perform the dump and load operations.

Disk pages from compressed tables are loaded into the buffer pool in their compressed form. Pages are uncompressed as usual when page contents are accessed during DML operations. Because uncompressing pages is a CPU-intensive process, it is more efficient for concurrency to perform the operation in a connection thread rather than in the single thread that performs the buffer pool restore operation.

## Configuring the Dump Percentage for Buffer Pool Pages

Before dumping pages from the buffer pool, you can configure the percentage of most-recently-used buffer pool pages that you want to dump by setting the [innodb\\_buffer\\_pool\\_dump\\_pct](#) option. If you plan to dump buffer pool pages while the server is running, you can configure the option dynamically:

```
SET GLOBAL innodb_buffer_pool_dump_pct=40;
```

If you plan to dump buffer pool pages at server shutdown, set [innodb\\_buffer\\_pool\\_dump\\_pct](#) in your configuration file.

```
[mysqld]
innodb_buffer_pool_dump_pct=40
```

The [innodb\\_buffer\\_pool\\_dump\\_pct](#) default value was changed from 100 (dump all pages) to 25 (dump 25% of most-recently-used pages) in MySQL 5.7.7 when [innodb\\_buffer\\_pool\\_dump\\_at\\_shutdown](#) and [innodb\\_buffer\\_pool\\_load\\_at\\_startup](#) were enabled by default.

## Saving the Buffer Pool State at Shutdown and Restoring it at Startup

To save the state of the buffer pool at server shutdown, issue the following statement prior to shutting down the server:

```
SET GLOBAL innodb_buffer_pool_dump_at_shutdown=ON;
```

[innodb\\_buffer\\_pool\\_dump\\_at\\_shutdown](#) is enabled by default in MySQL 5.7.7.

To restore the buffer pool state at server startup, specify the `--` [innodb\\_buffer\\_pool\\_load\\_at\\_startup](#) option when starting the server:

```
mysqld --innodb_buffer_pool_load_at_startup=ON;
```

[innodb\\_buffer\\_pool\\_load\\_at\\_startup](#) is enabled by default in MySQL 5.7.7.

## Saving and Restoring the Buffer Pool State Online

To save the state of the buffer pool while MySQL server is running, issue the following statement:

```
SET GLOBAL innodb_buffer_pool_dump_now=ON;
```

To restore the buffer pool state while MySQL is running, issue the following statement:

```
SET GLOBAL innodb_buffer_pool_load_now=ON;
```

## Displaying Buffer Pool Dump Progress

To display progress when saving the buffer pool state to disk, issue the following statement:

```
SHOW STATUS LIKE 'Innodb_buffer_pool_dump_status';
```

If the operation has not yet started, “not started” is returned. If the operation is complete, the completion time is printed (e.g. Finished at 110505 12:18:02). If the operation is in progress, status information is provided (e.g. Dumping buffer pool 5/7, page 237/2873).

## Displaying Buffer Pool Load Progress

To display progress when loading the buffer pool, issue the following statement:

```
SHOW STATUS LIKE 'Innodb_buffer_pool_load_status';
```

If the operation has not yet started, “not started” is returned. If the operation is complete, the completion time is printed (e.g. Finished at 110505 12:23:24). If the operation is in progress, status information is provided (e.g. Loaded 123/22301 pages).

## Aborting a Buffer Pool Load Operation

To abort a buffer pool load operation, issue the following statement:

```
SET GLOBAL innodb_buffer_pool_load_abort=ON;
```

## Monitoring Buffer Pool Load Progress Using Performance Schema

As of MySQL 5.7.6, you can monitor buffer pool load progress using [Performance Schema](#).

The following example demonstrates how to enable the `stage/innodb/buffer pool load` stage event instrument and related consumer tables to monitor buffer pool load progress.

For information about buffer pool dump and load procedures used in this example, see [Section 15.6.3.8, “Saving and Restoring the Buffer Pool State”](#). For information about Performance Schema stage event instruments and related consumers, see [Section 24.10.5, “Performance Schema Stage Event Tables”](#).

1. Enable the `stage/innodb/buffer pool load` instrument:

```
mysql> UPDATE performance_schema.setup_instruments SET ENABLED = 'YES'
      WHERE NAME LIKE 'stage/innodb/buffer%';
```

2. Enable the stage event consumer tables, which include `events_stages_current`, `events_stages_history`, and `events_stages_history_long`.

```
mysql> UPDATE performance_schema.setup_consumers SET ENABLED = 'YES'
      WHERE NAME LIKE '%stages%';
```

3. Dump the current buffer pool state by enabling `innodb_buffer_pool_dump_now`.

```
mysql> SET GLOBAL innodb_buffer_pool_dump_now=ON;
```

4. Check the buffer pool dump status to ensure that the operation has completed.

```
mysql> SHOW STATUS LIKE 'Innodb_buffer_pool_dump_status'\G
***** 1. row *****
Variable_name: Innodb_buffer_pool_dump_status
Value: Buffer pool(s) dump completed at 150202 16:38:58
```

5. Load the buffer pool by enabling `innodb_buffer_pool_load_now`:

```
mysql> SET GLOBAL innodb_buffer_pool_load_now=ON;
```

6. Check the current status of the buffer pool load operation by querying the Performance Schema `events_stages_current` table. The `WORK_COMPLETED` column shows the number of buffer pool pages loaded. The `WORK_ESTIMATED` column provides an estimate of the remaining work, in pages.

```
mysql> SELECT EVENT_NAME, WORK_COMPLETED, WORK_ESTIMATED
FROM performance_schema.events_stages_current;
```

| EVENT_NAME                    | WORK_COMPLETED | WORK_ESTIMATED |
|-------------------------------|----------------|----------------|
| stage/innodb/buffer pool load | 5353           | 7167           |

The `events_stages_current` table returns an empty set if the buffer pool load operation has completed. In this case, you can check the `events_stages_history` table to view data for the completed event. For example:

```
mysql> SELECT EVENT_NAME, WORK_COMPLETED, WORK_ESTIMATED
FROM performance_schema.events_stages_history;
```

| EVENT_NAME                    | WORK_COMPLETED | WORK_ESTIMATED |
|-------------------------------|----------------|----------------|
| stage/innodb/buffer pool load | 7167           | 7167           |

#### Note

You can also monitor buffer pool load progress using Performance Schema when loading the buffer pool at startup using `innodb_buffer_pool_load_at_startup`. In this case, the `stage/innodb/buffer pool load` instrument and related consumers must be enabled at startup. For more information, see [Section 24.2.2, “Performance Schema Startup Configuration”](#).

### 15.6.3.9 Monitoring the Buffer Pool Using the InnoDB Standard Monitor

InnoDB Standard Monitor output, which can be accessed using `SHOW ENGINE INNODB STATUS`, provides metrics that pertain to operation of the InnoDB buffer pool. Buffer pool metrics are located in the `BUFFER POOL AND MEMORY` section of InnoDB Standard Monitor output and appear similar to the following:

```
-----
BUFFER POOL AND MEMORY
-----
Total large memory allocated 2198863872
Dictionary memory allocated 776332
Buffer pool size      131072
Free buffers          124908
Database pages        5720
Old database pages    2071
Modified db pages     910
Pending reads         0
Pending writes: LRU 0, flush list 0, single page 0
Pages made young 4, not young 0
0.10 youngs/s, 0.00 non-youngs/s
Pages read 197, created 5523, written 5060
0.00 reads/s, 190.89 creates/s, 244.94 writes/s
Buffer pool hit rate 1000 / 1000, young-making rate 0 / 1000 not
0 / 1000
Pages read ahead 0.00/s, evicted without access 0.00/s, Random read
ahead 0.00/s
```

```
LRU len: 5720, unzip_LRU len: 0
I/O sum[0]:cur[0], unzip sum[0]:cur[0]
```

The following table describes [InnoDB](#) buffer pool metrics reported by the [InnoDB](#) Standard Monitor.

#### Note

Per second averages provided in [InnoDB](#) Standard Monitor output are based on the elapsed time since [InnoDB](#) Standard Monitor output was last printed.

**Table 15.2 InnoDB Buffer Pool Metrics**

| Name                        | Description  |
|-----------------------------|--|
| Total memory allocated      | The total memory allocated for the buffer pool in bytes.   |
| Dictionary memory allocated | The total memory allocated for the <a href="#">InnoDB</a> data dictionary in bytes.  |
| Buffer pool size            | The total size in pages allocated to the buffer pool.  |
| Free buffers                | The total size in pages of the buffer pool free list.  |
| Database pages              | The total size in pages of the buffer pool LRU list.   |
| Old database pages          | The total size in pages of the buffer pool old LRU sublist.  |
| Modified db pages           | The current number of pages modified in the buffer pool.   |
| Pending reads               | The number of buffer pool pages waiting to be read in to the buffer pool.  |
| Pending writes LRU          | The number of old dirty pages within the buffer pool to be written from the bottom of the LRU list.  |
| Pending writes flush list   | The number of buffer pool pages to be flushed during checkpointing.  |
| Pending writes single page  | The number of pending independent page writes within the buffer pool.  |
| Pages made young            | The total number of pages made young in the buffer pool LRU list (moved to the head of sublist of “new” pages).  |
| Pages made not young        | The total number of pages not made young in the buffer pool LRU list (pages that have remained in the “old” sublist without being made young).                                       |
| young/s                     | The per second average of accesses to old pages in the buffer pool LRU list that have resulted in making pages young. See the notes that follow this table for more information.     |
| non-young/s                 | The per second average of accesses to old pages in the buffer pool LRU list that have resulted in not making pages young. See the notes that follow this table for more information. |
| Pages read                  | The total number of pages read from the buffer pool.   |
| Pages created               | The total number of pages created within the buffer pool.  |
| Pages written               | The total number of pages written from the buffer pool.  |
| reads/s                     | The per second average number of buffer pool page reads per second.  |
| creates/s                   | The per second average number of buffer pool pages created per second.   |
| writes/s                    | The per second average number of buffer pool page writes per second.   |
| Buffer pool hit rate        | The buffer pool page hit rate for pages read from the buffer pool memory vs from disk storage.   |

| Name                         | Description   |
|------------------------------|---|
| young-making rate            | The average hit rate at which page accesses have resulted in making pages young. See the notes that follow this table for more information.     |
| not (young-making rate)      | The average hit rate at which page accesses have not resulted in making pages young. See the notes that follow this table for more information. |
| Pages read ahead             | The per second average of read ahead operations.  |
| Pages evicted without access | The per second average of the pages evicted without being accessed from the buffer pool.  |
| Random read ahead            | The per second average of random read ahead operations.   |
| LRU len                      | The total size in pages of the buffer pool LRU list.  |
| unzip_LRU len                | The total size in pages of the buffer pool unzip_LRU list.  |
| I/O sum                      | The total number of buffer pool LRU list pages accessed, for the last 50 seconds.   |
| I/O cur                      | The total number of buffer pool LRU list pages accessed.  |
| I/O unzip sum                | The total number of buffer pool unzip_LRU list pages accessed.  |
| I/O unzip cur                | The total number of buffer pool unzip_LRU list pages accessed.  |

**Notes:**

- The [young/s](#) metric only relates to old pages. It is based on the number of accesses to pages and not the number of pages. There can be multiple accesses to a given page, all of which are counted. If you see very low [young/s](#) values when there are no large scans occurring, you might need to reduce the delay time or increase the percentage of the buffer pool used for the old sublist. Increasing the percentage makes the old sublist larger, so pages in that sublist take longer to move to the tail and to be evicted. This increases the likelihood that the pages will be accessed again and be made young.
- The [non-young/s](#) metric only relates to old pages. It is based on the number of accesses to pages and not the number of pages. There can be multiple accesses to a given page, all of which are counted. If you do not see a lot of [non-young/s](#) when you are doing large table scans (and lots of [young/s](#)), increase the delay value.
- The [young-making](#) rate accounts for accesses to all buffer pool pages, not just accesses to pages in the old sublist. The [young-making](#) rate and [not](#) rate do not normally add up to the overall buffer pool hit rate. Page hits in the old sublist cause pages to move to the new sublist, but page hits in the new sublist cause pages to move to the head of the list only if they are a certain distance from the head.
- [not \(young-making rate\)](#) is the average hit rate at which page accesses have not resulted in making pages young due to the delay defined by [innodb\\_old\\_blocks\\_time](#) not being met, or due to page hits in the new sublist that did not result in pages being moved to the head. This rate accounts for accesses to all buffer pool pages, not just accesses to pages in the old sublist.

InnoDB buffer pool [server status variables](#) and the [INNODB\\_BUFFER\\_POOL\\_STATS](#) table provide many of the same buffer pool metrics found in InnoDB Standard Monitor output. For more information about the [INNODB\\_BUFFER\\_POOL\\_STATS](#) table, see [Example 15.19, “Querying the INNODB\\_BUFFER\\_POOL\\_STATS Table”](#).

## 15.6.4 Configuring the Memory Allocator for InnoDB

When InnoDB was developed, the memory allocators supplied with operating systems and run-time libraries were often lacking in performance and scalability. At that time, there were no memory allocator libraries tuned for multi-core CPUs. Therefore, InnoDB implemented its own memory allocator in the

`mem` subsystem. This allocator is guarded by a single mutex, which may become a [bottleneck](#). InnoDB also implements a wrapper interface around the system allocator (`malloc` and `free`) that is likewise guarded by a single mutex.

Today, as multi-core systems have become more widely available, and as operating systems have matured, significant improvements have been made in the memory allocators provided with operating systems. These new memory allocators perform better and are more scalable than they were in the past. Most workloads, especially those where memory is frequently allocated and released (such as multi-table joins), benefit from using a more highly tuned memory allocator as opposed to the internal, InnoDB-specific memory allocator.

You can control whether InnoDB uses its own memory allocator or an allocator of the operating system, by setting the value of the system configuration parameter `innodb_use_sys_malloc` in the MySQL option file (`my.cnf` or `my.ini`). If set to `ON` or `1` (the default), InnoDB uses the `malloc` and `free` functions of the underlying system rather than manage memory pools itself. This parameter is not dynamic, and takes effect only when the system is started. To continue to use the InnoDB memory allocator, set `innodb_use_sys_malloc` to `0`.

When the InnoDB memory allocator is disabled, InnoDB ignores the value of the parameter `innodb_additional_mem_pool_size`. The InnoDB memory allocator uses an additional memory pool for satisfying allocation requests without having to fall back to the system memory allocator. When the InnoDB memory allocator is disabled, all such allocation requests are fulfilled by the system memory allocator.

On Unix-like systems that use dynamic linking, replacing the memory allocator may be as easy as making the environment variable `LD_PRELOAD` or `LD_LIBRARY_PATH` point to the dynamic library that implements the allocator. On other systems, some relinking may be necessary. Please refer to the documentation of the memory allocator library of your choice.

Since InnoDB cannot track all memory use when the system memory allocator is used (`innodb_use_sys_malloc` is `ON`), the section “BUFFER POOL AND MEMORY” in the output of the `SHOW ENGINE INNODB STATUS` command only includes the buffer pool statistics in the “Total memory allocated”. Any memory allocated using the `mem` subsystem or using `ut_malloc` is excluded.

#### Note

`innodb_use_sys_malloc` and `innodb_additional_mem_pool_size` were deprecated in MySQL 5.6.3 and are removed in MySQL 5.7.4.

For more information about the performance implications of InnoDB memory usage, see [Section 9.10, “Buffering and Caching”](#).

## 15.6.5 Configuring InnoDB Change Buffering

When `INSERT`, `UPDATE`, and `DELETE` operations are performed on a table, the values of indexed columns (particularly the values of secondary keys) are often in an unsorted order, requiring substantial I/O to bring secondary indexes up to date. InnoDB has a [change buffer](#) that caches changes to secondary index entries when the relevant [page](#) is not in the [buffer pool](#), thus avoiding expensive I/O operations by not immediately reading in the page from disk. The buffered changes are merged when the page is loaded to the buffer pool, and the updated page is later flushed to disk. The InnoDB main thread merges buffered changes when the server is nearly idle, and during a [slow shutdown](#).

Because it can result in fewer disk reads and writes, the change buffer feature is most valuable for workloads that are I/O-bound, for example applications with a high volume of DML operations such as bulk inserts.

However, the change buffer occupies a part of the buffer pool, reducing the memory available to cache data pages. If the working set almost fits in the buffer pool, or if your tables have relatively few secondary indexes, it may be useful to disable change buffering. If the working set fits entirely within

the buffer, change buffering does not impose extra overhead, because it only applies to pages that are not in the buffer pool.

You can control the extent to which InnoDB performs change buffering using the `innodb_change_buffering` configuration parameter. You can enable or disable buffering for inserts, delete operations (when index records are initially marked for deletion) and purge operations (when index records are physically deleted). An update operation is a combination of an insert and a delete. The default `innodb_change_buffering` value is `all`.

Permitted `innodb_change_buffering` values include:

- `all`

The default value: buffer inserts, delete-marking operations, and purges.

- `none`

Do not buffer any operations.

- `inserts`

Buffer insert operations.

- `deletes`

Buffer delete-marking operations.

- `changes`

Buffer both inserts and delete-marking operations.

- `purges`

Buffer the physical deletion operations that happen in the background.

You can set the `innodb_change_buffering` parameter in the MySQL option file (`my.cnf` or `my.ini`) or change it dynamically with the `SET GLOBAL` command, which requires the `SUPER` privilege. Changing the setting affects the buffering of new operations; the merging of existing buffered entries is not affected.

For related information, see [Section 15.4.2, “Change Buffer”](#). For information about configuring change buffer size, see [Section 15.6.5.1, “Configuring the Change Buffer Maximum Size”](#).

### 15.6.5.1 Configuring the Change Buffer Maximum Size

As of MySQL 5.6.2, the `innodb_change_buffer_max_size` configuration option allows you to configure the maximum size of the change buffer as a percentage of the total size of the buffer pool. By default, `innodb_change_buffer_max_size` is set to 25. The maximum setting is 50.

You might consider increasing `innodb_change_buffer_max_size` on a MySQL server with heavy insert, update, and delete activity, where change buffer merging does not keep pace with new change buffer entries, causing the change buffer to reach its maximum size limit.

You might consider decreasing `innodb_change_buffer_max_size` on a MySQL server with static data used for reporting, or if the change buffer consumes too much of the memory space that is shared with the buffer pool, causing pages to age out of the buffer pool sooner than desired.

Test different settings with a representative workload to determine an optimal configuration. The `innodb_change_buffer_max_size` setting is dynamic, which allows you modify the setting without restarting the server.

## 15.6.6 Configuring Thread Concurrency for InnoDB

InnoDB uses operating system [threads](#) to process requests from user transactions. (Transactions may issue many requests to InnoDB before they commit or roll back.) On modern operating systems and servers with multi-core processors, where context switching is efficient, most workloads run well without any limit on the number of concurrent threads. Scalability improvements in MySQL 5.5 and up reduce the need to limit the number of concurrently executing threads inside InnoDB.

In situations where it is helpful to minimize context switching between threads, InnoDB can use a number of techniques to limit the number of concurrently executing operating system threads (and thus the number of requests that are processed at any one time). When InnoDB receives a new request from a user session, if the number of threads concurrently executing is at a pre-defined limit, the new request sleeps for a short time before it tries again. A request that cannot be rescheduled after the sleep is put in a first-in/first-out queue and eventually is processed. Threads waiting for locks are not counted in the number of concurrently executing threads.

You can limit the number of concurrent threads by setting the configuration parameter [innodb\\_thread\\_concurrency](#). Once the number of executing threads reaches this limit, additional threads sleep for a number of microseconds, set by the configuration parameter [innodb\\_thread\\_sleep\\_delay](#), before being placed into the queue.

Previously, it required experimentation to find the optimal value for [innodb\\_thread\\_sleep\\_delay](#), and the optimal value could change depending on the workload. In MySQL 5.6.3 and higher, you can set the configuration option [innodb\\_adaptive\\_max\\_sleep\\_delay](#) to the highest value you would allow for [innodb\\_thread\\_sleep\\_delay](#), and InnoDB automatically adjusts [innodb\\_thread\\_sleep\\_delay](#) up or down depending on the current thread-scheduling activity. This dynamic adjustment helps the thread scheduling mechanism to work smoothly during times when the system is lightly loaded and when it is operating near full capacity.

The default value for [innodb\\_thread\\_concurrency](#) and the implied default limit on the number of concurrent threads has been changed in various releases of MySQL and InnoDB. The default value of [innodb\\_thread\\_concurrency](#) is 0, so that by default there is no limit on the number of concurrently executing threads.

InnoDB causes threads to sleep only when the number of concurrent threads is limited. When there is no limit on the number of threads, all contend equally to be scheduled. That is, if [innodb\\_thread\\_concurrency](#) is 0, the value of [innodb\\_thread\\_sleep\\_delay](#) is ignored.

When there is a limit on the number of threads (when [innodb\\_thread\\_concurrency](#) is > 0), InnoDB reduces context switching overhead by permitting multiple requests made during the execution of a *single SQL statement* to enter InnoDB without observing the limit set by [innodb\\_thread\\_concurrency](#). Since an SQL statement (such as a join) may comprise multiple row operations within InnoDB, InnoDB assigns a specified number of “tickets” that allow a thread to be scheduled repeatedly with minimal overhead.

When a new SQL statement starts, a thread has no tickets, and it must observe [innodb\\_thread\\_concurrency](#). Once the thread is entitled to enter InnoDB, it is assigned a number of tickets that it can use for subsequently entering InnoDB to perform row operations. If the tickets run out, the thread is evicted, and [innodb\\_thread\\_concurrency](#) is observed again which may place the thread back into the first-in/first-out queue of waiting threads. When the thread is once again entitled to enter InnoDB, tickets are assigned again. The number of tickets assigned is specified by the global option [innodb\\_concurrency\\_tickets](#), which is 5000 by default. A thread that is waiting for a lock is given one ticket once the lock becomes available.

The correct values of these variables depend on your environment and workload. Try a range of different values to determine what value works for your applications. Before limiting the number of concurrently executing threads, review configuration options that may improve the performance of InnoDB on multi-core and multi-processor computers, such as [innodb\\_adaptive\\_hash\\_index](#).

For general performance information about MySQL thread handling, see [Section 9.12.5.1, “How MySQL Uses Threads for Client Connections”](#).

## 15.6.7 Configuring the Number of Background InnoDB I/O Threads

InnoDB uses background [threads](#) to service various types of I/O requests. You can configure the number of background threads that service read and write I/O on data pages, using the configuration parameters [innodb\\_read\\_io\\_threads](#) and [innodb\\_write\\_io\\_threads](#). These parameters signify the number of background threads used for read and write requests respectively. They are effective on all supported platforms. You can set the value of these parameters in the MySQL option file ([my.cnf](#) or [my.ini](#)); you cannot change them dynamically. The default value for these parameters is 4 and the permissible values range from 1-64.

The purpose of this change is to make InnoDB more scalable on high end systems. Each background thread can handle up to 256 pending I/O requests. A major source of background I/O is the [read-ahead](#) requests. InnoDB tries to balance the load of incoming requests in such way that most of the background threads share work equally. InnoDB also attempts to allocate read requests from the same extent to the same thread to increase the chances of coalescing the requests together. If you have a high end I/O subsystem and you see more than  $64 \times \text{innodb\_read\_io\_threads}$  pending read requests in `SHOW ENGINE INNODB STATUS`, you might gain by increasing the value of [innodb\\_read\\_io\\_threads](#).

For more information about InnoDB I/O performance, see [Section 9.5.8, “Optimizing InnoDB Disk I/O”](#).

## 15.6.8 Configuring the InnoDB Master Thread I/O Rate

The [master thread](#) in InnoDB is a thread that performs various tasks in the background. Most of these tasks are I/O related, such as flushing dirty pages from the buffer pool or writing changes from the insert buffer to the appropriate secondary indexes. The master thread attempts to perform these tasks in a way that does not adversely affect the normal working of the server. It tries to estimate the free I/O bandwidth available and tune its activities to take advantage of this free capacity. Historically, InnoDB has used a hard coded value of 100 IOPs (input/output operations per second) as the total I/O capacity of the server.

The parameter [innodb\\_io\\_capacity](#) indicates the overall I/O capacity available to InnoDB. This parameter should be set to approximately the number of I/O operations that the system can perform per second. The value depends on your system configuration. When [innodb\\_io\\_capacity](#) is set, the master threads estimates the I/O bandwidth available for background tasks based on the set value. Setting the value to 100 reverts to the old behavior.

You can set the value of [innodb\\_io\\_capacity](#) to any number 100 or greater. The default value is 200, reflecting that the performance of typical modern I/O devices is higher than in the early days of MySQL. Typically, values around the previous default of 100 are appropriate for consumer-level storage devices, such as hard drives up to 7200 RPMs. Faster hard drives, RAID configurations, and SSDs benefit from higher values.

The [innodb\\_io\\_capacity](#) setting is a total limit for all buffer pool instances. When dirty pages are flushed, the [innodb\\_io\\_capacity](#) limit is divided equally among buffer pool instances. For more information, see the [innodb\\_io\\_capacity](#) system variable description.

You can set the value of this parameter in the MySQL option file ([my.cnf](#) or [my.ini](#)) or change it dynamically with the `SET GLOBAL` command, which requires the [SUPER](#) privilege.

The [innodb\\_flush\\_sync](#) configuration option, introduced in MySQL 5.7.8, causes the [innodb\\_io\\_capacity](#) setting to be ignored during bursts of I/O activity that occur at checkpoints. [innodb\\_flush\\_sync](#) is enabled by default.

Formerly, the InnoDB master thread also performed any needed [purge](#) operations. In MySQL 5.6.5 and higher, those I/O operations are moved to other background threads, whose number is controlled by the [innodb\\_purge\\_threads](#) configuration option.

For more information about InnoDB I/O performance, see [Section 9.5.8, “Optimizing InnoDB Disk I/O”](#).

## 15.6.9 Configuring Spin Lock Polling

Many InnoDB [mutexes](#) and [rw-locks](#) are reserved for a short time. On a multi-core system, it can be more efficient for a thread to continuously check if it can acquire a mutex or rw-lock for a while before sleeping. If the mutex or rw-lock becomes available during this polling period, the thread can continue immediately, in the same time slice. However, too-frequent polling by multiple threads of a shared object can cause “cache ping pong”, different processors invalidating portions of each others' cache. InnoDB minimizes this issue by waiting a random time between subsequent polls. The delay is implemented as a busy loop.

You can control the maximum delay between testing a mutex or rw-lock using the parameter [innodb\\_spin\\_wait\\_delay](#). The duration of the delay loop depends on the C compiler and the target processor. (In the 100MHz Pentium era, the unit of delay was one microsecond.) On a system where all processor cores share a fast cache memory, you might reduce the maximum delay or disable the busy loop altogether by setting [innodb\\_spin\\_wait\\_delay=0](#). On a system with multiple processor chips, the effect of cache invalidation can be more significant and you might increase the maximum delay.

The default value of [innodb\\_spin\\_wait\\_delay](#) is 6. The spin wait delay is a dynamic, global parameter that you can specify in the MySQL option file ([my.cnf](#) or [my.ini](#)) or change at runtime with the command [SET GLOBAL innodb\\_spin\\_wait\\_delay=delay](#), where [delay](#) is the desired maximum delay. Changing the setting requires the [SUPER](#) privilege.

For performance considerations for InnoDB locking operations, see [Section 9.11, “Optimizing Locking Operations”](#).

## 15.6.10 Configuring InnoDB Purge Scheduling

The [purge](#) operations (a type of garbage collection) that InnoDB performs automatically is now done in one or more separate threads, rather than as part of the [master thread](#). This change improves scalability, because the main database operations run independently from maintenance work happening in the background.

To control this feature, increase the value of the configuration option [innodb\\_purge\\_threads](#). If DML action is concentrated on a single table or a few tables, keep the setting low so that the threads do not contend with each other for access to the busy tables. If DML operations are spread across many tables, increase the setting. Its maximum is 32.

There is another related configuration option, [innodb\\_purge\\_batch\\_size](#) with a default value of 300 and maximum value of 5000. This option is mainly intended for experimentation and tuning of purge operations, and should not be interesting to typical users.

For more information about InnoDB I/O performance, see [Section 9.5.8, “Optimizing InnoDB Disk I/O”](#).

## 15.6.11 Configuring Optimizer Statistics for InnoDB

This section describes how to configure persistent and non-persistent optimizer statistics for [InnoDB](#) tables.

Persistent optimizer statistics are persisted across server restarts, allowing for greater [plan stability](#) and more consistent query performance. Persistent optimizer statistics also provide control and flexibility with these additional benefits:

- You can use the [innodb\\_stats\\_auto\\_recalc](#) configuration option to control whether statistics are updated automatically after substantial changes to a table.
- You can use the [STATS\\_PERSISTENT](#), [STATS\\_AUTO\\_RECALC](#), and [STATS\\_SAMPLE\\_PAGES](#) clauses with [CREATE TABLE](#) and [ALTER TABLE](#) statements to configure optimizer statistics for individual tables.

- You can query optimizer statistics data in the `mysql.innodb_table_stats` and `mysql.innodb_index_stats` tables.
- You can view the `last_update` column of the `mysql.innodb_table_stats` and `mysql.innodb_index_stats` tables to see when statistics were last updated.
- You can manually modify the `mysql.innodb_table_stats` and `mysql.innodb_index_stats` tables to force a specific query optimization plan or to test alternative plans without modifying the database.

The persistent optimizer statistics feature is enabled by default (`innodb_stats_persistent=ON`).

Non-persistent optimizer statistics are cleared on each server restart and after some other operations, and recomputed on the next table access. As a result, different estimates could be produced when recomputing statistics, leading to different choices in execution plans and variations in query performance.

This section also provides information about estimating `ANALYZE TABLE` complexity, which may be useful when attempting to achieve a balance between accurate statistics and `ANALYZE TABLE` execution time.

#### 15.6.11.1 Configuring Persistent Optimizer Statistics Parameters

The persistent optimizer statistics feature improves [plan stability](#) by storing statistics to disk and making them persistent across server restarts so that the [optimizer](#) is more likely to make consistent choices each time for a given query.

Optimizer statistics are persisted to disk when `innodb_stats_persistent=ON` or when individual tables are created or altered with `STATS_PERSISTENT=1`. `innodb_stats_persistent` is enabled by default.

Formerly, optimizer statistics were cleared on each server restart and after some other operations, and recomputed on the next table access. Consequently, different estimates could be produced when recalculating statistics, leading to different choices in query execution plans and thus variations in query performance.

Persistent statistics are stored in the `mysql.innodb_table_stats` and `mysql.innodb_index_stats` tables, as described in [InnoDB Persistent Statistics Tables](#).

To revert to using non-persistent optimizer statistics, you can modify tables using an `ALTER TABLE tbl_name STATS_PERSISTENT=0` statement. For related information, see [Section 15.6.11.2, “Configuring Non-Persistent Optimizer Statistics Parameters”](#)

### Configuring Automatic Statistics Calculation for Persistent Optimizer Statistics

The `innodb_stats_auto_recalc` configuration option, which is enabled by default, determines whether statistics are calculated automatically whenever a table undergoes substantial changes (to more than 10% of the rows). You can also configure automatic statistics recalculation for individual tables using a `STATS_AUTO_RECALC` clause in a `CREATE TABLE` or `ALTER TABLE` statement. `innodb_stats_auto_recalc` is enabled by default.

Because of the asynchronous nature of automatic statistics recalculation (which occurs in the background), statistics may not be recalculated instantly after running a DML operation that affects more than 10% of a table, even when `innodb_stats_auto_recalc` is enabled. In some cases, statistics recalculation may be delayed by a few seconds. If up-to-date statistics are required immediately after changing significant portions of a table, run `ANALYZE TABLE` to initiate a synchronous (foreground) recalculation of statistics.

If `innodb_stats_auto_recalc` is disabled, ensure the accuracy of optimizer statistics by issuing the `ANALYZE TABLE` statement for each applicable table after making substantial changes to indexed columns. You might run this statement in your setup scripts after representative data has been loaded

into the table, and run it periodically after DML operations significantly change the contents of indexed columns, or on a schedule at times of low activity. When a new index is added to an existing table, index statistics are calculated and added to the `innodb_index_stats` table regardless of the value of `innodb_stats_auto_recalc`.

### Caution

To ensure statistics are gathered when a new index is created, either enable the `innodb_stats_auto_recalc` option, or run `ANALYZE TABLE` after creating each new index when the persistent statistics mode is enabled.

## Configuring Optimizer Statistics Parameters for Individual Tables

`innodb_stats_persistent`, `innodb_stats_auto_recalc`, and `innodb_stats_persistent_sample_pages` are global configuration options. To override these system-wide settings and configure optimizer statistics parameters for individual tables, you can define `STATS_PERSISTENT`, `STATS_AUTO_RECALC`, and `STATS_SAMPLE_PAGES` clauses in `CREATE TABLE` or `ALTER TABLE` statements.

- `STATS_PERSISTENT` specifies whether to enable [persistent statistics](#) for an InnoDB table. The value `DEFAULT` causes the persistent statistics setting for the table to be determined by the `innodb_stats_persistent` configuration option. The value `1` enables persistent statistics for the table, while the value `0` turns off this feature. After enabling persistent statistics through a `CREATE TABLE` or `ALTER TABLE` statement, issue an `ANALYZE TABLE` statement to calculate the statistics, after loading representative data into the table.
- `STATS_AUTO_RECALC` specifies whether to automatically recalculate [persistent statistics](#) for an InnoDB table. The value `DEFAULT` causes the persistent statistics setting for the table to be determined by the `innodb_stats_auto_recalc` configuration option. The value `1` causes statistics to be recalculated when 10% of the data in the table has changed. The value `0` prevents automatic recalculation for this table; with this setting, issue an `ANALYZE TABLE` statement to recalculate the statistics after making substantial changes to the table.
- `STATS_SAMPLE_PAGES` specifies the number of index pages to sample when estimating cardinality and other statistics for an indexed column, such as those calculated by `ANALYZE TABLE`.

All three clauses are specified in the following `CREATE TABLE` example:

```
CREATE TABLE `t1` (
  `id` int(8) NOT NULL auto_increment,
  `data` varchar(255),
  `date` datetime,
  PRIMARY KEY (`id`),
  INDEX `DATE_IX` (`date`)
) ENGINE=InnoDB,
  STATS_PERSISTENT=1,
  STATS_AUTO_RECALC=1,
  STATS_SAMPLE_PAGES=25;
```

## Configuring the Number of Sampled Pages for InnoDB Optimizer Statistics

The MySQL query optimizer uses estimated [statistics](#) about key distributions to choose the indexes for an execution plan, based on the relative [selectivity](#) of the index. Operations such as `ANALYZE TABLE` cause InnoDB to sample random pages from each index on a table to estimate the [cardinality](#) of the index. (This technique is known as [random dives](#).)

To give you control over the quality of the statistics estimate (and thus better information for the query optimizer), you can change the number of sampled pages using the parameter `innodb_stats_persistent_sample_pages`, which can be set at runtime.

`innodb_stats_persistent_sample_pages` has a default value of 20. As a general guideline, consider modifying this parameter when encountering the following issues:

1. *Statistics are not accurate enough and the optimizer chooses suboptimal plans*, as shown by `EXPLAIN` output. The accuracy of statistics can be checked by comparing the actual cardinality of an index (as returned by running `SELECT DISTINCT` on the index columns) with the estimates provided in the `mysql.innodb_index_stats` persistent statistics table.

If it is determined that statistics are not accurate enough, the value of `innodb_stats_persistent_sample_pages` should be increased until the statistics estimates are sufficiently accurate. Increasing `innodb_stats_persistent_sample_pages` too much, however, could cause `ANALYZE TABLE` to run slowly.

2. *`ANALYZE TABLE` is too slow*. In this case `innodb_stats_persistent_sample_pages` should be decreased until `ANALYZE TABLE` execution time is acceptable. Decreasing the value too much, however, could lead to the first problem of inaccurate statistics and suboptimal query execution plans.

If a balance cannot be achieved between accurate statistics and `ANALYZE TABLE` execution time, consider decreasing the number of indexed columns in the table or limiting the number of partitions to reduce `ANALYZE TABLE` complexity. The number of columns in the table's primary key is also important to consider, as primary key columns are appended to each non-unique index.

For related information, see [Section 15.6.11.3, “Estimating ANALYZE TABLE Complexity for InnoDB Tables”](#).

## Including Delete-marked Records in Persistent Statistics Calculations

By default, InnoDB reads uncommitted data when calculating statistics. In the case of an uncommitted transaction that deletes rows from a table, InnoDB excludes records that are delete-marked when calculating row estimates and index statistics, which can lead to non-optimal execution plans for other transactions that are operating on the table concurrently using a transaction isolation level other than `READ UNCOMMITTED`. To avoid this scenario, `innodb_stats_include_delete_marked` can be enabled to ensure that InnoDB includes delete-marked records when calculating persistent optimizer statistics.

When `innodb_stats_include_delete_marked` is enabled, `ANALYZE TABLE` considers delete-marked records when recalculating statistics.

`innodb_stats_include_delete_marked` is a global setting that affects all InnoDB tables, and it is only applicable to persistent optimizer statistics.

`innodb_stats_include_delete_marked` was introduced in MySQL 5.7.16.

## InnoDB Persistent Statistics Tables

The persistent statistics feature relies on the internally managed tables in the `mysql` database, named `innodb_table_stats` and `innodb_index_stats`. These tables are set up automatically in all install, upgrade, and build-from-source procedures.

**Table 15.3 Columns of `innodb_table_stats`**

| Column name                          | Description   |
|--------------------------------------|---|
| <code>database_name</code>           | Database name   |
| <code>table_name</code>              | Table name, partition name, or subpartition name                  |
| <code>last_update</code>             | A timestamp indicating the last time that InnoDB updated this row |
| <code>n_rows</code>                  | The number of rows in the table                                   |
| <code>clustered_index_size</code>    | The size of the primary index, in pages                           |
| <code>sum_of_other_index_size</code> | The total size of other (non-primary) indexes, in pages           |

**Table 15.4 Columns of innodb\_index\_stats**

| Column name                   | Description   |
|-------------------------------|---|
| <code>database_name</code>    | Database name   |
| <code>table_name</code>       | Table name, partition name, or subpartition name  |
| <code>index_name</code>       | Index name  |
| <code>last_update</code>      | A timestamp indicating the last time that InnoDB updated this row                           |
| <code>stat_name</code>        | The name of the statistic, whose value is reported in the <code>stat_value</code> column    |
| <code>stat_value</code>       | The value of the statistic that is named in <code>stat_name</code> column                   |
| <code>sample_size</code>      | The number of pages sampled for the estimate provided in the <code>stat_value</code> column |
| <code>stat_description</code> | Description of the statistic that is named in the <code>stat_name</code> column             |

Both the `innodb_table_stats` and `innodb_index_stats` tables include a `last_update` column showing when InnoDB last updated index statistics, as shown in the following example:

```
mysql> select * from innodb_table_stats \G
***** 1. row *****
      database_name: sakila
        table_name: actor
      last_update: 2014-05-28 16:16:44
          n_rows: 200
  clustered_index_size: 1
sum_of_other_index_sizes: 1
...
```

```
mysql> select * from innodb_index_stats \G
***** 1. row *****
      database_name: sakila
        table_name: actor
        index_name: PRIMARY
      last_update: 2014-05-28 16:16:44
          stat_name: n_diff_pfx01
          stat_value: 200
        sample_size: 1
...
```

The `innodb_table_stats` and `innodb_index_stats` tables are ordinary tables and can be updated manually. The ability to update statistics manually makes it possible to force a specific query optimization plan or test alternative plans without modifying the database. If you manually update statistics, issue the `FLUSH TABLE tbl_name` command to make MySQL reload the updated statistics.

## InnoDB Persistent Statistics Tables Example

The `innodb_table_stats` table contains one row per table. The data collected is demonstrated in the following example.

Table `t1` contains a primary index (columns `a`, `b`) secondary index (columns `c`, `d`), and unique index (columns `e`, `f`):

```
CREATE TABLE t1 (
  a INT, b INT, c INT, d INT, e INT, f INT,
  PRIMARY KEY (a, b), KEY i1 (c, d), UNIQUE KEY i2uniq (e, f)
) ENGINE=INNODB;
```

After inserting five rows of sample data, the table appears as follows:

```
mysql> SELECT * FROM t1;
+---+---+---+---+---+---+
| a | b | c | d | e | f |
+---+---+---+---+---+---+
| 1 | 2 | 3 | 4 | 5 | 6 |
| 2 | 3 | 4 | 5 | 6 | 7 |
| 3 | 4 | 5 | 6 | 7 | 8 |
| 4 | 5 | 6 | 7 | 8 | 9 |
| 5 | 6 | 7 | 8 | 9 | 10 |
```

|   |   |    |    |     |     |
|---|---|----|----|-----|-----|
| 1 | 1 | 10 | 11 | 100 | 101 |
| 1 | 2 | 10 | 11 | 200 | 102 |
| 1 | 3 | 10 | 11 | 100 | 103 |
| 1 | 4 | 10 | 12 | 200 | 104 |
| 1 | 5 | 10 | 12 | 100 | 105 |

To immediately update statistics, run `ANALYZE TABLE` (if `innodb_stats_auto_recalc` is enabled, statistics are updated automatically within a few seconds assuming that the 10% threshold for changed table rows is reached):

```
mysql> ANALYZE TABLE t1;
```

| Table   | Op      | Msg_type | Msg_text |
|---------|---------|----------|----------|
| test.t1 | analyze | status   | OK       |

Table statistics for table `t1` show the last time InnoDB updated the table statistics (2014-03-14 14:36:34), the number of rows in the table (5), the clustered index size (1 page), and the combined size of the other indexes (2 pages).

```
mysql> SELECT * FROM mysql.innodb_table_stats WHERE table_name like 't1'\G
***** 1. row *****
      database_name: test
      table_name: t1
      last_update: 2014-03-14 14:36:34
      n_rows: 5
      clustered_index_size: 1
      sum_of_other_index_sizes: 2
```

The `innodb_index_stats` table contains multiple rows for each index. Each row in the `innodb_index_stats` table provides data related to a particular index statistic which is named in the `stat_name` column and described in the `stat_description` column. For example:

```
mysql> SELECT index_name, stat_name, stat_value, stat_description
-> FROM mysql.innodb_index_stats WHERE table_name like 't1';
```

| index_name | stat_name    | stat_value | stat_description                  |
|------------|--------------|------------|-----------------------------------|
| PRIMARY    | n_diff_pfx01 | 1          | a                                 |
| PRIMARY    | n_diff_pfx02 | 5          | a,b                               |
| PRIMARY    | n_leaf_pages | 1          | Number of leaf pages in the index |
| PRIMARY    | size         | 1          | Number of pages in the index      |
| i1         | n_diff_pfx01 | 1          | c                                 |
| i1         | n_diff_pfx02 | 2          | c,d                               |
| i1         | n_diff_pfx03 | 2          | c,d,a                             |
| i1         | n_diff_pfx04 | 5          | c,d,a,b                           |
| i1         | n_leaf_pages | 1          | Number of leaf pages in the index |
| i1         | size         | 1          | Number of pages in the index      |
| i2uniq     | n_diff_pfx01 | 2          | e                                 |
| i2uniq     | n_diff_pfx02 | 5          | e,f                               |
| i2uniq     | n_leaf_pages | 1          | Number of leaf pages in the index |
| i2uniq     | size         | 1          | Number of pages in the index      |

The `stat_name` column shows the following types of statistics:

- `size`: Where `stat_name=size`, the `stat_value` column displays the total number of pages in the index.
- `n_leaf_pages`: Where `stat_name=n_leaf_pages`, the `stat_value` column displays the number of leaf pages in the index.
- `n_diff_pfxNN`: Where `stat_name=n_diff_pfx01`, the `stat_value` column displays the number of distinct values in the first column of the index. Where `stat_name=n_diff_pfx02`, the `stat_value` column displays the number of distinct values in the first two columns of the index, and

so on. Additionally, where `stat_name=n_diff_pfxNN`, the `stat_description` column shows a comma separated list of the index columns that are counted.

To further illustrate the `n_diff_pfxNN` statistic, which provides cardinality data, consider the `t1` table example. As shown below, the `t1` table is created with a primary index (columns `a`, `b`), a secondary index (columns `c`, `d`), and a unique index (columns `e`, `f`):

```
CREATE TABLE t1 (
  a INT, b INT, c INT, d INT, e INT, f INT,
  PRIMARY KEY (a, b), KEY i1 (c, d), UNIQUE KEY i2uniq (e, f)
) ENGINE=INNODB;
```

After inserting five rows of sample data, the table appears as follows:

```
mysql> SELECT * FROM t1;
+----+-----+-----+-----+-----+-----+
| a | b | c | d | e | f |
+----+-----+-----+-----+-----+-----+
| 1 | 1 | 10 | 11 | 100 | 101 |
| 1 | 2 | 10 | 11 | 200 | 102 |
| 1 | 3 | 10 | 11 | 100 | 103 |
| 1 | 4 | 10 | 12 | 200 | 104 |
| 1 | 5 | 10 | 12 | 100 | 105 |
+----+-----+-----+-----+-----+-----+
```

When you query the `index_name`, `stat_name`, `stat_value`, and `stat_description` where `stat_name LIKE 'n_diff%'`, the following result set is returned:

```
mysql> SELECT index_name, stat_name, stat_value, stat_description
-> FROM mysql.innodb_index_stats
-> WHERE table_name like 't1' AND stat_name LIKE 'n_diff%';
+----+-----+-----+-----+
| index_name | stat_name | stat_value | stat_description |
+----+-----+-----+-----+
| PRIMARY | n_diff_pfx01 | 1 | a |
| PRIMARY | n_diff_pfx02 | 5 | a,b |
| i1 | n_diff_pfx01 | 1 | c |
| i1 | n_diff_pfx02 | 2 | c,d |
| i1 | n_diff_pfx03 | 2 | c,d,a |
| i1 | n_diff_pfx04 | 5 | c,d,a,b |
| i2uniq | n_diff_pfx01 | 2 | e |
| i2uniq | n_diff_pfx02 | 5 | e,f |
+----+-----+-----+-----+
```

For the `PRIMARY` index, there are two `n_diff%` rows. The number of rows is equal to the number of columns in the index.

#### Note

For non-unique indexes, InnoDB appends the columns of the primary key.

- Where `index_name=PRIMARY` and `stat_name=n_diff_pfx01`, the `stat_value` is 1, which indicates that there is a single distinct value in the first column of the index (column `a`). The number of distinct values in column `a` is confirmed by viewing the data in column `a` in table `t1`, in which there is a single distinct value (1). The counted column (`a`) is shown in the `stat_description` column of the result set.
- Where `index_name=PRIMARY` and `stat_name=n_diff_pfx02`, the `stat_value` is 5, which indicates that there are five distinct values in the two columns of the index (`a`, `b`). The number of distinct values in columns `a` and `b` is confirmed by viewing the data in columns `a` and `b` in table `t1`, in which there are five distinct values: (1, 1), (1, 2), (1, 3), (1, 4) and (1, 5). The counted columns (`a`, `b`) are shown in the `stat_description` column of the result set.

For the secondary index (`i1`), there are four `n_diff%` rows. Only two columns are defined for the secondary index (`c`, `d`) but there are four `n_diff%` rows for the secondary index because InnoDB

suffixes all non-unique indexes with the primary key. As a result, there are four `n_diff%` rows instead of two to account for the both the secondary index columns (`c,d`) and the primary key columns (`a,b`).

- Where `index_name=i1` and `stat_name=n_diff_pfx01`, the `stat_value` is 1, which indicates that there is a single distinct value in the first column of the index (column `c`). The number of distinct values in column `c` is confirmed by viewing the data in column `c` in table `t1`, in which there is a single distinct value: (10). The counted column (`c`) is shown in the `stat_description` column of the result set.
- Where `index_name=i1` and `stat_name=n_diff_pfx02`, the `stat_value` is 2, which indicates that there are two distinct values in the first two columns of the index (`c,d`). The number of distinct values in columns `c` and `d` is confirmed by viewing the data in columns `c` and `d` in table `t1`, in which there are two distinct values: (10,11) and (10,12). The counted columns (`c,d`) are shown in the `stat_description` column of the result set.
- Where `index_name=i1` and `stat_name=n_diff_pfx03`, the `stat_value` is 2, which indicates that there are two distinct values in the first three columns of the index (`c,d,a`). The number of distinct values in columns `c`, `d`, and `a` is confirmed by viewing the data in column `c`, `d`, and `a` in table `t1`, in which there are two distinct values: (10,11,1) and (10,12,1). The counted columns (`c,d,a`) are shown in the `stat_description` column of the result set.
- Where `index_name=i1` and `stat_name=n_diff_pfx04`, the `stat_value` is 5, which indicates that there are five distinct values in the four columns of the index (`c,d,a,b`). The number of distinct values in columns `c`, `d`, `a` and `b` is confirmed by viewing the data in columns `c`, `d`, `a`, and `b` in table `t1`, in which there are five distinct values: (10,11,1,1), (10,11,1,2), (10,11,1,3), (10,12,1,4) and (10,12,1,5). The counted columns (`c,d,a,b`) are shown in the `stat_description` column of the result set.

For the unique index (`i2uniq`), there are two `n_diff%` rows.

- Where `index_name=i2uniq` and `stat_name=n_diff_pfx01`, the `stat_value` is 2, which indicates that there are two distinct values in the first column of the index (column `e`). The number of distinct values in column `e` is confirmed by viewing the data in column `e` in table `t1`, in which there are two distinct values: (100) and (200). The counted column (`e`) is shown in the `stat_description` column of the result set.
- Where `index_name=i2uniq` and `stat_name=n_diff_pfx02`, the `stat_value` is 5, which indicates that there are five distinct values in the two columns of the index (`e,f`). The number of distinct values in columns `e` and `f` is confirmed by viewing the data in columns `e` and `f` in table `t1`, in which there are five distinct values: (100,101), (200,102), (100,103), (200,104) and (100,105). The counted columns (`e,f`) are shown in the `stat_description` column of the result set.

## Retrieving Index Size Using the `innodb_index_stats` Table

The size of indexes for tables, partitions, or subpartitions can be retrieved using the `innodb_index_stats` table. In the following example, index sizes are retrieved for table `t1`. For a definition of table `t1` and corresponding index statistics, see [InnoDB Persistent Statistics Tables Example](#).

```
mysql> SELECT SUM(stat_value) pages, index_name,
-> SUM(stat_value)*@@innodb_page_size size
-> FROM mysql.innodb_index_stats WHERE table_name='t1'
-> AND stat_name = 'size' GROUP BY index_name;
```

| pages | index_name | size  |
|-------|------------|-------|
| 1     | PRIMARY    | 16384 |
| 1     | i1         | 16384 |
| 1     | i2uniq     | 16384 |

For partitions or subpartitions, the same query with a modified `WHERE` clause can be used to retrieve index sizes. For example, the following query retrieves index sizes for partitions of table `t1`:

```
mysql> SELECT SUM(stat_value) pages, index_name,
-> SUM(stat_value)*@@innodb_page_size size
-> FROM mysql.innodb_index_stats WHERE table_name like 't1#P%'
-> AND stat_name = 'size' GROUP BY index_name;
```

### 15.6.11.2 Configuring Non-Persistent Optimizer Statistics Parameters

This section describes how to configure non-persistent optimizer statistics. Optimizer statistics are not persisted to disk when `innodb_stats_persistent=OFF` or when individual tables are created or altered with `STATS_PERSISTENT=0`. Instead, statistics are stored in memory, and are lost when the server is shut down. Statistics are also updated periodically by certain operations and under certain conditions.

As of MySQL 5.6.6, optimizer statistics are persisted to disk by default, enabled by the `innodb_stats_persistent` configuration option. For information about persistent optimizer statistics, see [Section 15.6.11.1, “Configuring Persistent Optimizer Statistics Parameters”](#).

### Optimizer Statistics Updates

Optimizer statistics are updated when:

- Running `ANALYZE TABLE`.
- Running `SHOW TABLE STATUS`, `SHOW INDEX`, or querying the `INFORMATION_SCHEMA.TABLES` or `INFORMATION_SCHEMA.STATISTICS` tables with the `innodb_stats_on_metadata` option enabled.

The default setting for `innodb_stats_on_metadata` was changed to `OFF` when persistent optimizer statistics were enabled by default in MySQL 5.6.6. Enabling `innodb_stats_on_metadata` may reduce access speed for schemas that have a large number of tables or indexes, and reduce stability of execution plans for queries that involve InnoDB tables. `innodb_stats_on_metadata` is configured globally using a `SET` statement.

```
SET GLOBAL innodb_stats_on_metadata=ON
```

- Starting a `mysql` client with the `--auto-rehash` option enabled, which is the default. The `auto-rehash` option causes all InnoDB tables to be opened, and the open table operations cause statistics to be recalculated.

To improve the start up time of the `mysql` client and to updating statistics, you can turn off `auto-rehash` using the `--disable-auto-rehash` option. The `auto-rehash` feature enables automatic name completion of database, table, and column names for interactive users.

- A table is first opened.
- InnoDB detects that 1 / 16 of table has been modified since the last time statistics were updated.

### Configuring the Number of Sampled Pages

The MySQL query optimizer uses estimated [statistics](#) about key distributions to choose the indexes for an execution plan, based on the relative [selectivity](#) of the index. When InnoDB updates optimizer statistics, it samples random pages from each index on a table to estimate the [cardinality](#) of the index. (This technique is known as [random dives](#).)

To give you control over the quality of the statistics estimate (and thus better information for the query optimizer), you can change the number of sampled pages using the parameter `innodb_stats_transient_sample_pages`. The default number of sampled pages is 8, which could be insufficient to produce an accurate estimate, leading to poor index choices by the query optimizer. This technique is especially important for large tables and tables used in [joins](#). Unnecessary [full table scans](#) for such tables can be a substantial performance issue. See [Section 9.2.1.21, “How to Avoid Full Table Scans”](#) for tips on tuning such queries. `innodb_stats_transient_sample_pages` is a global parameter that can be set at runtime.

The value of `innodb_stats_transient_sample_pages` affects the index sampling for all InnoDB tables and indexes when `innodb_stats_persistent=0`. Be aware of the following potentially significant impacts when you change the index sample size:

- Small values like 1 or 2 can result in inaccurate estimates of cardinality.
- Increasing the `innodb_stats_transient_sample_pages` value might require more disk reads. Values much larger than 8 (say, 100), can cause a significant slowdown in the time it takes to open a table or execute `SHOW TABLE STATUS`.
- The optimizer might choose very different query plans based on different estimates of index selectivity.

Whatever value of `innodb_stats_transient_sample_pages` works best for a system, set the option and leave it at that value. Choose a value that results in reasonably accurate estimates for all tables in your database without requiring excessive I/O. Because the statistics are automatically recalculated at various times other than on execution of `ANALYZE TABLE`, it does not make sense to increase the index sample size, run `ANALYZE TABLE`, then decrease sample size again.

Smaller tables generally require fewer index samples than larger tables. If your database has many large tables, consider using a higher value for `innodb_stats_transient_sample_pages` than if you have mostly smaller tables.

### 15.6.11.3 Estimating ANALYZE TABLE Complexity for InnoDB Tables

`ANALYZE TABLE` complexity for InnoDB tables is dependent on:

- The number of pages sampled, as defined by `innodb_stats_persistent_sample_pages`.
- The number of indexed columns in a table
- The number of partitions. If a table has no partitions, the number of partitions is considered to be 1.

Using these parameters, an approximate formula for estimating `ANALYZE TABLE` complexity would be:

The value of `innodb_stats_persistent_sample_pages` \* number of indexed columns in a table \* the number of partitions

Typically, the greater the resulting value, the greater the execution time for `ANALYZE TABLE`.

#### Note

`innodb_stats_persistent_sample_pages` defines the number of pages sampled at a global level. To set the number of pages sampled for an individual table, use the `STATS_SAMPLE_PAGES` option with `CREATE TABLE` or `ALTER TABLE`. For more information, see [Section 15.6.11.1, “Configuring Persistent Optimizer Statistics Parameters”](#).

If `innodb_stats_persistent=OFF`, the number of pages sampled is defined by `innodb_stats_transient_sample_pages`. See [Section 15.6.11.2, “Configuring Non-Persistent Optimizer Statistics Parameters”](#) for additional information.

For a more in-depth approach to estimating `ANALYZE TABLE` complexity, consider the following example.

In **Big O notation**, `ANALYZE TABLE` complexity is described as:

```
O(n_sample
  * (n_cols_in_uniq_i
    + n_cols_in_non_uniq_i
    + n_cols_in_pk * (1 + n_non_uniq_i))
  * n_part)
```

where:

- `n_sample` is the number of pages sampled (defined by `innodb_stats_persistent_sample_pages`)
- `n_cols_in_uniq_i` is total number of all columns in all unique indexes (not counting the primary key columns)
- `n_cols_in_non_uniq_i` is the total number of all columns in all non-unique indexes
- `n_cols_in_pk` is the number of columns in the primary key (if a primary key is not defined, [InnoDB](#) creates a single column primary key internally)
- `n_non_uniq_i` is the number of non-unique indexes in the table
- `n_part` is the number of partitions. If no partitions are defined, the table is considered to be a single partition.

Now, consider the following table (table `t`), which has a primary key (2 columns), a unique index (2 columns), and two non-unique indexes (two columns each):

```
CREATE TABLE t (
  a INT,
  b INT,
  c INT,
  d INT,
  e INT,
  f INT,
  g INT,
  h INT,
  PRIMARY KEY (a, b),
  UNIQUE KEY iluniq (c, d),
  KEY i2nonuniq (e, f),
  KEY i3nonuniq (g, h)
);
```

For the column and index data required by the algorithm described above, query the `mysql.innodb_index_stats` persistent index statistics table for table `t`. The `n_diff_pfx%` statistics show the columns that are counted for each index. For example, columns `a` and `b` are counted for the primary key index. For the non-unique indexes, the primary key columns (`a,b`) are counted in addition to the user defined columns.

#### Note

For additional information about the [InnoDB](#) persistent statistics tables, see [Section 15.6.11.1, “Configuring Persistent Optimizer Statistics Parameters”](#)

```
SELECT index_name, stat_name, stat_description
FROM mysql.innodb_index_stats
WHERE
  database_name='test' AND
  table_name='t' AND
  stat_name like 'n_diff_pfx%';
```

| index_name | stat_name    | stat_description |
|------------|--------------|------------------|
| PRIMARY    | n_diff_pfx01 | a                |
| PRIMARY    | n_diff_pfx02 | a,b              |
| iluniq     | n_diff_pfx01 | c                |
| iluniq     | n_diff_pfx02 | c,d              |
| i2nonuniq  | n_diff_pfx01 | e                |
| i2nonuniq  | n_diff_pfx02 | e,f              |
| i2nonuniq  | n_diff_pfx03 | e,f,a            |
| i2nonuniq  | n_diff_pfx04 | e,f,a,b          |
| i3nonuniq  | n_diff_pfx01 | g                |
| i3nonuniq  | n_diff_pfx02 | g,h              |

|                     |              |         |  |
|---------------------|--------------|---------|--|
| i3nonuniq           | n_diff_pfx03 | g,h,a   |  |
| i3nonuniq           | n_diff_pfx04 | g,h,a,b |  |
| +-----+-----+-----+ |              |         |  |

Based on the index statistics data shown above and the table definition, the following values can be determined:

- `n_cols_in_uniq_i`, the total number of all columns in all unique indexes not counting the primary key columns, is 2 (`c` and `d`)
- `n_cols_in_non_uniq_i`, the total number of all columns in all non-unique indexes, is 4 (`e`, `f`, `g` and `h`)
- `n_cols_in_pk`, the number of columns in the primary key, is 2 (`a` and `b`)
- `n_non_uniq_i`, the number of non-unique indexes in the table, is 2 (`i2nonuniq` and `i3nonuniq`)
- `n_part`, the number of partitions, is 1.

You can now calculate `innodb_stats_persistent_sample_pages * (2 + 4 + 2 * (1 + 2)) * 1` to determine the number of leaf pages that are scanned. With `innodb_stats_persistent_sample_pages` set to the default value of 20, and with a default page size of 16 KiB (`innodb_page_size=16384`), you can then estimate that `20 * 12 * 16384 bytes` are read for table `t`, or about 4 MiB.

#### Note

All 4 MiB may not be read from disk, as some leaf pages may already be cached in the buffer pool.

## 15.6.12 Configuring the Merge Threshold for Index Pages

Starting in MySQL 5.7.6, you can configure the `MERGE_THRESHOLD` value for index pages. If the “page-full” percentage for an index page falls below the `MERGE_THRESHOLD` value when a row is deleted or when a row is shortened by an `UPDATE` operation, InnoDB attempts to merge the index page with a neighboring index page. The default `MERGE_THRESHOLD` value is 50, which is the previously hardcoded value. The minimum `MERGE_THRESHOLD` value is 1 and the maximum value is 50.

When the “page-full” percentage for an index page falls below 50%, which is the default `MERGE_THRESHOLD` setting, InnoDB attempts to merge the index page with a neighboring page. If both pages are close to 50% full, a page split can occur soon after the pages are merged. If this merge-split behavior occurs frequently, it can have an adverse affect on performance. To avoid frequent merge-splits, you can lower the `MERGE_THRESHOLD` value so that InnoDB attempts page merges at a lower “page-full” percentage. Merging pages at a lower page-full percentage leaves more room in index pages and helps reduce merge-split behavior.

The `MERGE_THRESHOLD` for index pages can be defined for a table or for individual indexes. A `MERGE_THRESHOLD` value defined for an individual index takes priority over a `MERGE_THRESHOLD` value defined for the table. If undefined, the `MERGE_THRESHOLD` value defaults to 50.

### Setting `MERGE_THRESHOLD` for a Table

You can set the `MERGE_THRESHOLD` value for a table using the `table_option COMMENT` clause of the `CREATE TABLE` statement. For example:

```
CREATE TABLE t1 (
  id INT,
  KEY id_index (id)
) COMMENT='MERGE_THRESHOLD=45';
```

You can also set the `MERGE_THRESHOLD` value for an existing table using the `table_option COMMENT` clause with `ALTER TABLE`:

```
CREATE TABLE t1 (
  id INT,
  KEY id_index (id)
);

ALTER TABLE t1 COMMENT='MERGE_THRESHOLD=40';
```

## Setting MERGE\_THRESHOLD for Individual Indexes

To set the `MERGE_THRESHOLD` value for an individual index, you can use the *index\_option COMMENT* clause with `CREATE TABLE`, `ALTER TABLE`, or `CREATE INDEX`, as shown in the following examples:

- Setting `MERGE_THRESHOLD` for an individual index using `CREATE TABLE`:

```
CREATE TABLE t1 (
  id INT,
  KEY id_index (id) COMMENT 'MERGE_THRESHOLD=40'
);
```

- Setting `MERGE_THRESHOLD` for an individual index using `ALTER TABLE`:

```
CREATE TABLE t1 (
  id INT,
  KEY id_index (id)
);

ALTER TABLE t1 DROP KEY id_index;
ALTER TABLE t1 ADD KEY id_index (id) COMMENT 'MERGE_THRESHOLD=40';
```

- Setting `MERGE_THRESHOLD` for an individual index using `CREATE INDEX`:

```
CREATE TABLE t1 (id INT);
CREATE INDEX id_index ON t1 (id) COMMENT 'MERGE_THRESHOLD=40';
```

### Note

You cannot modify the `MERGE_THRESHOLD` value at the index level for `GEN_CLUST_INDEX`, which is the clustered index created by `InnoDB` when an `InnoDB` table is created without a primary key or unique key index. You can only modify the `MERGE_THRESHOLD` value for `GEN_CLUST_INDEX` by setting `MERGE_THRESHOLD` for the table.

## Querying the MERGE\_THRESHOLD Value for an Index

The current `MERGE_THRESHOLD` value for an index can be obtained by querying the `INNODB_SYS_INDEXES` table. For example:

```
mysql> SELECT * FROM INFORMATION_SCHEMA.INNODB_SYS_INDEXES WHERE NAME='id_index' \G
***** 1. row *****
INDEX_ID: 91
NAME: id_index
TABLE_ID: 68
TYPE: 0
N_FIELDS: 1
PAGE_NO: 4
SPACE: 57
MERGE_THRESHOLD: 40
```

You can use `SHOW CREATE TABLE` to view the `MERGE_THRESHOLD` value for a table, if explicitly defined using the *table\_option COMMENT* clause:

```
mysql> SHOW CREATE TABLE t2 \G
***** 1. row *****
Table: t2
Create Table: CREATE TABLE `t2` (
  `id` int(11) DEFAULT NULL,
  KEY `id_index` (`id`) COMMENT 'MERGE_THRESHOLD=40'
```

```
) ENGINE=InnoDB DEFAULT CHARSET=latin1
```

### Note

A `MERGE_THRESHOLD` value defined at the index level takes priority over a `MERGE_THRESHOLD` value defined for the table. If undefined, `MERGE_THRESHOLD` defaults to 50% (`MERGE_THRESHOLD=50`, which is the previously hardcoded value).

Likewise, you can use `SHOW INDEX` to view the `MERGE_THRESHOLD` value for an index, if explicitly defined using the `index_option COMMENT` clause:

```
mysql> SHOW INDEX FROM t2 \G
***** 1. row *****
      Table: t2
    Non_unique: 1
      Key_name: id_index
  Seq_in_index: 1
   Column_name: id
    Collation: A
  Cardinality: 0
     Sub_part: NULL
       Packed: NULL
         Null: YES
   Index_type: BTREE
     Comment:
Index_comment: MERGE_THRESHOLD=40
```

## Measuring the Effect of MERGE\_THRESHOLD Settings

The `INNODB_METRICS` table provides two counters that can be used to measure the effect of a `MERGE_THRESHOLD` setting on index page merges.

```
mysql> SELECT NAME, COMMENT FROM INFORMATION_SCHEMA.INNODB_METRICS
WHERE NAME like '%index_page_merge%';
+-----+-----+
| NAME                                | COMMENT                                |
+-----+-----+
| index_page_merge_attempts           | Number of index page merge attempts  |
| index_page_merge_successful          | Number of successful index page merges |
+-----+-----+
```

When lowering the `MERGE_THRESHOLD` value, the objectives are:

- A smaller number of page merge attempts and successful page merges
- A similar number of page merge attempts and successful page merges

A `MERGE_THRESHOLD` setting that is too small could result in large data files due to an excessive amount of empty page space.

For information about using `INNODB_METRICS` counters, see [Section 15.15.6, “InnoDB INFORMATION\\_SCHEMA Metrics Table”](#).

## 15.7 InnoDB Tablespaces

### 15.7.1 Resizing the InnoDB System Tablespace

This section describes how to increase or decrease the size of the `InnoDB` system tablespace.

#### Increasing the Size of the InnoDB System Tablespace

The easiest way to increase the size of the `InnoDB` system tablespace is to configure it from the beginning to be auto-extending. Specify the `autoextend` attribute for the last data file in the tablespace definition. Then `InnoDB` increases the size of that file automatically in 64MB

increments when it runs out of space. The increment size can be changed by setting the value of the `innodb_autoextend_increment` system variable, which is measured in megabytes.

You can expand the system tablespace by a defined amount by adding another data file:

1. Shut down the MySQL server.
2. If the previous last data file is defined with the keyword `autoextend`, change its definition to use a fixed size, based on how large it has actually grown. Check the size of the data file, round it down to the closest multiple of 1024 × 1024 bytes (= 1MB), and specify this rounded size explicitly in `innodb_data_file_path`.
3. Add a new data file to the end of `innodb_data_file_path`, optionally making that file auto-extending. Only the last data file in the `innodb_data_file_path` can be specified as auto-extending.
4. Start the MySQL server again.

For example, this tablespace has just one auto-extending data file `ibdata1`:

```
innodb_data_home_dir =
innodb_data_file_path = /ibdata/ibdata1:10M:autoextend
```

Suppose that this data file, over time, has grown to 988MB. Here is the configuration line after modifying the original data file to use a fixed size and adding a new auto-extending data file:

```
innodb_data_home_dir =
innodb_data_file_path = /ibdata/ibdata1:988M;/disk2/ibdata2:50M:autoextend
```

When you add a new data file to the system tablespace configuration, make sure that the filename does not refer to an existing file. **InnoDB** creates and initializes the file when you restart the server.

## Decreasing the Size of the InnoDB System Tablespace

You cannot remove a data file from the system tablespace. To decrease the system tablespace size, use this procedure:

1. Use `mysqldump` to dump all your **InnoDB** tables, including **InnoDB** tables located in the MySQL database. As of 5.6, there are five **InnoDB** tables included in the MySQL database:

```
mysql> select table_name from information_schema.tables where table_schema='mysql' and engine='InnoDB';
+-----+
| table_name |
+-----+
| innodb_index_stats |
| innodb_table_stats |
| slave_master_info |
| slave_relay_log_info |
| slave_worker_info |
+-----+
5 rows in set (0.00 sec)
```

2. Stop the server.
3. Remove all the existing tablespace files (`*.ibd`), including the `ibdata` and `ib_log` files. Do not forget to remove `*.ibd` files for tables located in the MySQL database.
4. Remove any `.frm` files for **InnoDB** tables.
5. Configure a new tablespace.
6. Restart the server.

7. Import the dump files.

#### Note

If your databases only use the [InnoDB](#) engine, it may be simpler to dump **all** databases, stop the server, remove all databases and [InnoDB](#) log files, restart the server, and import the dump files.

## 15.7.2 Changing the Number or Size of InnoDB Redo Log Files

To change the number or the size of your [InnoDB redo log](#) files, perform the following steps:

1. Stop the MySQL server and make sure that it shuts down without errors.
2. Edit `my.cnf` to change the log file configuration. To change the log file size, configure `innodb_log_file_size`. To increase the number of log files, configure `innodb_log_files_in_group`.
3. Start the MySQL server again.

If [InnoDB](#) detects that the `innodb_log_file_size` differs from the redo log file size, it will write a log checkpoint, close and remove the old log files, create new log files at the requested size, and open the new log files.

## 15.7.3 Using Raw Disk Partitions for the System Tablespace

You can use raw disk partitions as data files in the [InnoDB system tablespace](#). This technique enables nonbuffered I/O on Windows and on some Linux and Unix systems without file system overhead. Perform tests with and without raw partitions to verify whether this change actually improves performance on your system.

When you use a raw disk partition, ensure that the user ID that runs the MySQL server has read and write privileges for that partition. For example, if you run the server as the `mysql` user, the partition must be readable and writeable by `mysql`. If you run the server with the `--memlock` option, the server must be run as `root`, so the partition must be readable and writeable by `root`.

The procedures described below involve option file modification. For additional information, see [Section 5.2.6, “Using Option Files”](#).

### Allocating a Raw Disk Partition on Linux and Unix Systems

1. When you create a new data file, specify the keyword `newraw` immediately after the data file size for the `innodb_data_file_path` option. The partition must be at least as large as the size that you specify. Note that 1MB in [InnoDB](#) is 1024 × 1024 bytes, whereas 1MB in disk specifications usually means 1,000,000 bytes.

```
[mysqld]
innodb_data_home_dir=
innodb_data_file_path=/dev/hdd1:3Gnewraw:/dev/hdd2:2Gnewraw
```

2. Restart the server. [InnoDB](#) notices the `newraw` keyword and initializes the new partition. However, do not create or change any [InnoDB](#) tables yet. Otherwise, when you next restart the server, [InnoDB](#) reinitializes the partition and your changes are lost. (As a safety measure [InnoDB](#) prevents users from modifying data when any partition with `newraw` is specified.)
3. After [InnoDB](#) has initialized the new partition, stop the server, change `newraw` in the data file specification to `raw`:

```
[mysqld]
innodb_data_home_dir=
```

```
innodb_data_file_path=/dev/hdd1:3Graw:/dev/hdd2:2Graw
```

4. Restart the server. [InnoDB](#) now permits changes to be made.

## Allocating a Raw Disk Partition on Windows

On Windows systems, the same steps and accompanying guidelines described for Linux and Unix systems apply except that the `innodb_data_file_path` setting differs slightly on Windows.

1. When you create a new data file, specify the keyword `newraw` immediately after the data file size for the `innodb_data_file_path` option:

```
[mysql]
innodb_data_home_dir=
innodb_data_file_path=//./D::10Gnewraw
```

The `//./` corresponds to the Windows syntax of `\\.\` for accessing physical drives. In the example above, `D:` is the drive letter of the partition.

2. Restart the server. [InnoDB](#) notices the `newraw` keyword and initializes the new partition.
3. After [InnoDB](#) has initialized the new partition, stop the server, change `newraw` in the data file specification to `raw`:

```
[mysql]
innodb_data_home_dir=
innodb_data_file_path=//./D::10Graw
```

4. Restart the server. [InnoDB](#) now permits changes to be made.

## 15.7.4 InnoDB File-Per-Table Tablespaces

Historically, all [InnoDB](#) tables and indexes were stored in the [system tablespace](#). This monolithic approach was targeted at machines dedicated entirely to database processing, with carefully planned data growth, where any disk storage allocated to MySQL would never be needed for other purposes. [InnoDB's file-per-table tablespace](#) feature provides a more flexible alternative, where each [InnoDB](#) table and its indexes are stored in a separate `.ibd` data file. Each such `.ibd` data file represents an individual [tablespace](#). This feature is controlled by the `innodb_file_per_table` configuration option, which is enabled by default in MySQL 5.6.6 and higher.

### Advantages of File-Per-Table Tablespaces

- You can reclaim disk space when truncating or dropping a table stored in a file-per-table tablespace. Truncating or dropping tables stored in the shared [system tablespace](#) creates free space internally in the system tablespace data files ([ibdata files](#)) which can only be used for new [InnoDB](#) data.

Similarly, a table-copying `ALTER TABLE` operation on table that resides in a shared tablespace can increase the amount of space used by the tablespace. Such operations may require as much additional space as the data in the table plus indexes. The additional space required for the table-copying `ALTER TABLE` operation is not released back to the operating system as it is for file-per-table tablespaces.

- The `TRUNCATE TABLE` operation is faster when run on tables stored in file-per-table tablespaces.
- You can store specific tables on separate storage devices, for I/O optimization, space management, or backup purposes. In previous releases, you had to move entire database directories to other drives and create symbolic links in the MySQL data directory, as described in [Section 9.12.3, "Using Symbolic Links"](#). In MySQL 5.6.6 and higher, you can specify the location of each table using the syntax `CREATE TABLE ... DATA DIRECTORY = absolute_path_to_directory`, as explained in [Section 15.7.5, "Creating a File-Per-Table Tablespace Outside the Data Directory"](#).

- You can run `OPTIMIZE TABLE` to compact or recreate a file-per-table tablespace. When you run an `OPTIMIZE TABLE`, InnoDB creates a new `.ibd` file with a temporary name, using only the space required to store actual data. When the optimization is complete, InnoDB removes the old `.ibd` file and replaces it with the new one. If the previous `.ibd` file grew significantly but the actual data only accounted for a portion of its size, running `OPTIMIZE TABLE` can reclaim the unused space.
- You can move individual InnoDB tables rather than entire databases.
- You can copy individual InnoDB tables from one MySQL instance to another (known as the [transportable tablespace](#) feature).
- Tables created in file-per-table tablespaces use the [Barracuda](#) file format. The Barracuda file format enables features such as [compressed](#) and [dynamic](#) row formats.
- You can enable more efficient storage for tables with large `BLOB` or `TEXT` columns using the [dynamic row format](#).
- File-per-table tablespaces may improve chances for a successful recovery and save time when a corruption occurs, when a server cannot be restarted, or when backup and binary logs are unavailable.
- File-per-table tablespaces are convenient for per-table status reporting when copying or backing up tables.
- You can monitor table size at a file system level, without accessing MySQL.
- Common Linux file systems do not permit concurrent writes to a single file when `innodb_flush_method` is set to `O_DIRECT`. As a result, there are possible performance improvements when using file-per-table tablespaces in conjunction with `innodb_flush_method`.
- The system tablespace stores the data dictionary and undo logs, and is limited in size by InnoDB tablespace size limits. See [Section 15.8.8, “Limits on InnoDB Tables”](#). With file-per-table tablespaces, each table has its own tablespace, which provides room for growth.

## Potential Disadvantages of File-Per-Table Tablespaces

- With file-per-table tablespaces, each table may have unused space, which can only be utilized by rows of the same table. This could lead to wasted space if not properly managed.
- `fsync` operations must run on each open table rather than on a single file. Because there is a separate `fsync` operation for each file, write operations on multiple tables cannot be combined into a single I/O operation. This may require InnoDB to perform a higher total number of `fsync` operations.
- `mysqld` must keep one open file handle per table, which may impact performance if you have numerous tables in file-per-table tablespaces.
- More file descriptors are used.
- `innodb_file_per_table` is enabled by default in MySQL 5.6.6 and higher. You may consider disabling it if backward compatibility with MySQL 5.5 or 5.1 is a concern. Disabling `innodb_file_per_table` prevents `ALTER TABLE` from moving an InnoDB table from the system tablespace to an individual `.ibd` file in cases where `ALTER TABLE` recreates the table (`ALGORITHM=COPY`).

For example, when restructuring the clustered index for an InnoDB table, the table is re-created using the current setting for `innodb_file_per_table`. This behavior does not apply when adding or dropping InnoDB secondary indexes. When a secondary index is created without rebuilding the table, the index is stored in the same file as the table data, regardless of the current `innodb_file_per_table` setting. This behavior also does not apply to tables added to the system tablespace using `CREATE TABLE ... TABLESPACE` or `ALTER TABLE ... TABLESPACE` syntax. These tables are not affected by the `innodb_file_per_table` setting.

- If many tables are growing there is potential for more fragmentation which can impede `DROP TABLE` and table scan performance. However, when fragmentation is managed, having files in their own tablespace can improve performance.
- The buffer pool is scanned when dropping a file-per-table tablespace, which can take several seconds for buffer pools that are tens of gigabytes in size. The scan is performed with a broad internal lock, which may delay other operations. Tables in the system tablespace are not affected.
- The `innodb_autoextend_increment` variable, which defines increment size (in MB) for extending the size of an auto-extending shared tablespace file when it becomes full, does not apply to file-per-table tablespace files, which are auto-extending regardless of the `innodb_autoextend_increment` setting. The initial extensions are by small amounts, after which extensions occur in increments of 4MB.

#### 15.7.4.1 Enabling and Disabling File-Per-Table Tablespaces

The `innodb_file_per_table` option is enabled by default as of MySQL 5.6.6.

To set the `innodb_file_per_table` option at startup, start the server with the `--innodb_file_per_table` command-line option, or add this line to the `[mysqld]` section of `my.cnf`:

```
[mysqld]
innodb_file_per_table=1
```

You can also set `innodb_file_per_table` dynamically, while the server is running:

```
SET GLOBAL innodb_file_per_table=1;
```

With `innodb_file_per_table` enabled, you can store InnoDB tables in a `tbl_name.ibd` file. Unlike the MyISAM storage engine, with its separate `tbl_name.MYD` and `tbl_name.MYI` files for indexes and data, InnoDB stores the data and the indexes together in a single `.ibd` file. The `tbl_name.frm` file is still created as usual.

If you disable `innodb_file_per_table` in your startup options and restart the server, or disable it with the `SET GLOBAL` command, InnoDB creates new tables inside the system tablespace unless you have explicitly placed the table in file-per-table tablespace or general tablespace using the `CREATE TABLE ... TABLESPACE` option, introduced in MySQL 5.7.6.

You can always read and write any InnoDB tables, regardless of the file-per-table setting.

To move a table from the system tablespace to its own tablespace, change the `innodb_file_per_table` setting and rebuild the table:

```
SET GLOBAL innodb_file_per_table=1;
ALTER TABLE table_name ENGINE=InnoDB;
```

Tables added to the system tablespace using `CREATE TABLE ... TABLESPACE` or `ALTER TABLE ... TABLESPACE` syntax are not affected by the `innodb_file_per_table` setting. To move these tables from the system tablespace to a file-per-table tablespace, they must be moved explicitly using `ALTER TABLE ... TABLESPACE` syntax.

#### Note

InnoDB always needs the system tablespace because it puts its internal [data dictionary](#) and [undo logs](#) there. The `.ibd` files are not sufficient for InnoDB to operate.

When a table is moved out of the system tablespace into its own `.ibd` file, the data files that make up the system tablespace remain the same size. The space formerly occupied by the table can be reused for new InnoDB data, but is not reclaimed for use by the operating system. When moving large InnoDB

tables out of the system tablespace, where disk space is limited, you may prefer to enable `innodb_file_per_table` and recreate the entire instance using the `mysqldump` command. As mentioned above, tables added to the system tablespace using `CREATE TABLE ... TABLESPACE` or `ALTER TABLE ... TABLESPACE` syntax are not affected by the `innodb_file_per_table` setting. These tables must be moved individually.

### 15.7.5 Creating a File-Per-Table Tablespace Outside the Data Directory

To create a new `InnoDB file-per-table` tablespace in a specific location outside the MySQL data directory, use the `DATA DIRECTORY = absolute_path_to_directory` clause of the `CREATE TABLE` statement.

Plan the location in advance, because you cannot use the `DATA DIRECTORY` clause with the `ALTER TABLE` statement. The directory you specify could be on another storage device with particular performance or capacity characteristics, such as a fast `SSD` or a high-capacity `HDD`.

Within the destination directory, MySQL creates a subdirectory corresponding to the database name, and within that a `.ibd` file for the new table. In the database directory beneath the MySQL `DATADIR` directory, MySQL creates a `table_name.isl` file containing the path name for the table. The `.isl` file is treated by MySQL like a symbolic link. (`Using actual symbolic links` has never been supported for `InnoDB` tables.)

The following example demonstrates creating a file-per-table tablespace outside the MySQL data directory. It shows the `.ibd` created in the specified directory, and the `.isl` created in the database directory beneath the MySQL data directory.

```
mysql> USE test;
Database changed

mysql> SHOW VARIABLES LIKE 'innodb_file_per_table';
+-----+-----+
| Variable_name | Value |
+-----+-----+
| innodb_file_per_table | ON    |
+-----+-----+
1 row in set (0.00 sec)

mysql> CREATE TABLE t1 (c1 INT PRIMARY KEY) DATA DIRECTORY = '/alternative/directory';
Query OK, 0 rows affected (0.03 sec)

# MySQL creates a .ibd file for the new table in a subdirectory that corresponding
# to the database name

db_user@ubuntu:~/alternative/directory/test$ ls
t1.ibd

# MySQL creates a .isl file containing the path name for the table in a directory
# beneath the MySQL data directory

db_user@ubuntu:~/mysql/data/test$ ls
db.opt  t1.frm  t1.isl
```

As of MySQL 5.7.6, you can also use `CREATE TABLE ... TABLESPACE` in combination with the `DATA DIRECTORY` clause to create a file-per-table tablespace outside the MySQL data directory. To do so, you must specify `innodb_file_per_table` as the tablespace name.

```
CREATE TABLE t2 (c1 INT PRIMARY KEY) TABLESPACE = innodb_file_per_table
DATA DIRECTORY = '/alternative/directory';
```

You do not have to enable `innodb_file_per_table` when using this method.

#### Usage Notes:

- MySQL initially holds the `.ibd` file open, preventing you from dismounting the device, but might eventually close the table if the server is busy. Be careful not to accidentally dismount an external

device while MySQL is running, or to start MySQL while the device is disconnected. Attempting to access a table when the associated `.ibd` file is missing causes a serious error that requires a server restart.

A server restart might fail if the `.ibd` file is still not at the expected path. In this case, manually remove the `table_name.isl` file in the database directory, and after restarting perform a `DROP TABLE` to delete the `.frm` file and remove the information about the table from the `data dictionary`.

- Do not put MySQL tables on an NFS-mounted volume. NFS uses a message-passing protocol to write to files, which could cause data inconsistency if network messages are lost or received out of order.
- If you use an LVM snapshot, file copy, or other file-based mechanism to back up the `.ibd` file, always use the `FLUSH TABLES ... FOR EXPORT` statement first to make sure all changes that were buffered in memory are `flushed` to disk before the backup occurs.
- The `DATA DIRECTORY` clause is a supported alternative to [using symbolic links](#), which has always been problematic and was never supported for individual `InnoDB` tables.

## 15.7.6 Copying File-Per-Table Tablespaces to Another Server

This section describes how to copy [file-per-table](#) tablespaces from one database server to another, otherwise known as the [Transportable Tablespaces](#) feature. Prior to MySQL 5.7.4, only non-partitioned `InnoDB` tables are supported. As of MySQL 5.7.4, partitioned `InnoDB` tables and individual `InnoDB` table partitions and subpartitions are also supported.

For information about other `InnoDB` table copying methods, see [Section 15.8.4, “Moving or Copying InnoDB Tables to Another Machine”](#).

There are many reasons why you might copy an `InnoDB file-per-table` tablespace to a different database server:

- To run reports without putting extra load on a production server.
- To set up identical data for a table on a new [slave server](#).
- To restore a backed-up version of a table or partition after a problem or mistake.
- As a faster way of moving data around than importing the results of a `mysqldump` command. The data is available immediately, rather than having to be re-inserted and the indexes rebuilt.
- To move a [file-per-table](#) tablespace to a server with storage medium that better suits system requirements. For example, you may want to have busy tables on an [SSD](#) device, or large tables on a high-capacity [HDD](#) device.

### Limitations and Usage Notes

- The tablespace copy procedure is only possible when `innodb_file_per_table` is set to `ON`, which is the default setting as of MySQL 5.6.6. Tables residing in the shared system tablespace cannot be quiesced.
- When a table is quiesced, only read-only transactions are allowed on the affected table.
- When importing a tablespace, the page size must match the page size of the importing instance.
- Prior to MySQL 5.7.4, `DISCARD TABLESPACE` is not supported for partitioned tables meaning that transportable tablespaces is also unsupported. If you run `ALTER TABLE ... DISCARD TABLESPACE` on a partitioned table, the following error is returned: `ERROR 1031 (HY000): Table storage engine for 'part' doesn't have this option`. As of MySQL 5.7.4, `ALTER TABLE ... DISCARD TABLESPACE` is supported for partitioned `InnoDB` tables, and `ALTER TABLE ... DISCARD PARTITION ... TABLESPACE` is supported for `InnoDB` table partitions.

- `DISCARD TABLESPACE` is not supported for tablespaces with a parent-child (primary key-foreign key) relationship when `foreign_key_checks` is set to 1. Before discarding a tablespace for parent-child tables, set `foreign_key_checks=0`. Partitioned `InnoDB` tables do not support foreign keys.
- `ALTER TABLE ... IMPORT TABLESPACE` does not enforce foreign key constraints on imported data. If there are foreign key constraints between tables, all tables should be exported at the same (logical) point in time. Partitioned `InnoDB` tables do not support foreign keys.
- `ALTER TABLE ... IMPORT TABLESPACE` and `ALTER TABLE ... IMPORT PARTITION ... TABLESPACE` do not require a `.cfg` metadata file to import a tablespace. However, metadata checks are not performed when importing without a `.cfg` file, and a warning similar to the following will be issued:

```
Message: InnoDB: IO Read error: (2, No such file or directory) Error opening '.\test\t.cfg', will attempt to import without schema verification
1 row in set (0.00 sec)
```

The ability to import without a `.cfg` file may be more convenient when no schema mismatches are expected. Additionally, the ability to import without a `.cfg` file could be useful in crash recovery scenarios in which metadata cannot be collected from an `.ibd` file.

- Due to a `.cfg` metadata file limitation, schema mismatches are not reported for partition type or partition definition differences when importing tablespace files for partitioned tables. Column differences are reported.
- When running `ALTER TABLE ... DISCARD PARTITION ... TABLESPACE` and `ALTER TABLE ... IMPORT PARTITION ... TABLESPACE` on subpartitioned tables, both partition and subpartition table names are allowed. When a partition name is specified, subpartitions of that partition are included in the operation.
- In MySQL 5.6 or later, importing a tablespace file from another server works if both servers have GA (General Availability) status and their versions are within the same series. Otherwise, the file must have been created on the server into which it is imported.
- In replication scenarios, `innodb_file_per_table` must be set to `ON` on both the master and slave.
- On Windows, `InnoDB` stores database, tablespace, and table names internally in lowercase. To avoid import problems on case-sensitive operating systems such as Linux and UNIX, create all databases, tablespaces, and tables using lowercase names. A convenient way to accomplish this is to add the following line to the `[mysqld]` section of your `my.cnf` or `my.ini` file before creating databases, tablespaces, or tables:

```
[mysqld]
lower_case_table_names=1
```

- `ALTER TABLE ... DISCARD TABLESPACE` and `ALTER TABLE ... IMPORT TABLESPACE` are not supported with tables that belong to an `InnoDB` general tablespace. For more information, see `CREATE TABLESPACE`.
- As of MySQL 5.7.9, the default row format for `InnoDB` tables is configurable using the `innodb_default_row_format` configuration option. Attempting to import a table that does not explicitly define a row format (`ROW_FORMAT`), or that uses `ROW_FORMAT=DEFAULT`, could result in a schema mismatch error if the `innodb_default_row_format` setting on the source server differs from the setting on the destination server. For related information, see [Section 15.11.2, “Specifying the Row Format for a Table”](#).
- When exporting a tablespace that is encrypted using the `InnoDB` tablespace encryption feature, `InnoDB` generates a `.cfp` file in addition to a `.cfg` metadata file. The `.cfp` file must be copied to the destination server together with the `.cfg` file and tablespace file before performing the `ALTER`

`TABLE ... IMPORT TABLESPACE` operation on the destination server. The `.cfg` file contains a transfer key and an encrypted tablespace key. On import, `InnoDB` uses the transfer key to decrypt the tablespace key. For related information, see [Section 15.7.10, “InnoDB Tablespace Encryption”](#).

### 15.7.6.1 Transportable Tablespace Examples

#### Note

If you are transporting tables that are encrypted using the `InnoDB` tablespace encryption, see [Limitations and Usage Notes](#) before you begin for additional procedural information.

#### Example 1: Copying an InnoDB Table From One Server To Another

This procedure demonstrates how to copy a regular `InnoDB` table from a running MySQL server instance to another running instance. The same procedure with minor adjustments can be used to perform a full table restore on the same instance.

1. On the source server, create a table if one does not exist:

```
mysql> use test;
mysql> CREATE TABLE t(c1 INT) engine=InnoDB;
```

2. On the destination server, create a table if one does not exist:

```
mysql> use test;
mysql> CREATE TABLE t(c1 INT) engine=InnoDB;
```

3. On the destination server, discard the existing tablespace. (Before a tablespace can be imported, `InnoDB` must discard the tablespace that is attached to the receiving table.)

```
mysql> ALTER TABLE t DISCARD TABLESPACE;
```

4. On the source server, run `FLUSH TABLES ... FOR EXPORT` to quiesce the table and create the `.cfg` metadata file:

```
mysql> use test;
mysql> FLUSH TABLES t FOR EXPORT;
```

The metadata (`.cfg`) is created in the `InnoDB` data directory.

#### Note

`FLUSH TABLES ... FOR EXPORT` is available as of MySQL 5.6.6. The statement ensures that changes to the named table have been flushed to disk so that a binary table copy can be made while the server is running. When `FLUSH TABLES ... FOR EXPORT` is run, `InnoDB` produces a `.cfg` file in the same database directory as the table. The `.cfg` file contains metadata used for schema verification when importing the tablespace file.

5. Copy the `.ibd` file and `.cfg` metadata file from the source server to the destination server. For example:

```
shell> scp /path/to/datadir/test/t.{ibd,cfg} destination-server:/path/to/datadir/test
```

#### Note

The `.ibd` file and `.cfg` file must be copied before releasing the shared locks, as described in the next step.

- On the source server, use `UNLOCK TABLES` to release the locks acquired by `FLUSH TABLES ... FOR EXPORT`:

```
mysql> use test;
mysql> UNLOCK TABLES;
```

- On the destination server, import the tablespace:

```
mysql> use test;
mysql> ALTER TABLE t IMPORT TABLESPACE;
```

#### Note

The `ALTER TABLE ... IMPORT TABLESPACE` feature does not enforce foreign key constraints on imported data. If there are foreign key constraints between tables, all tables should be exported at the same (logical) point in time. In this case you would stop updating the tables, commit all transactions, acquire shared locks on the tables, and then perform the export operation.

### Example 2: Copying an InnoDB Partitioned Table From One Server To Another

This procedure demonstrates how to copy a partitioned `InnoDB` table from a running MySQL server instance to another running instance. The same procedure with minor adjustments can be used to perform a full restore of a partitioned `InnoDB` table on the same instance.

- On the source server, create a partitioned table if one does not exist. In the following example, a table with three partitions (p0, p1, p2) is created:

```
mysql> use test;
mysql> CREATE TABLE t1 (i int) ENGINE = InnoDB PARTITION BY KEY (i) PARTITIONS 3;
```

In the `/datadir/test` directory, you will see a separate tablespace (`.ibd`) file for each of the three partitions.

```
mysql> \! ls /path/to/datadir/test/
db.opt  t1.frm  t1#P#p0.ibd  t1#P#p1.ibd  t1#P#p2.ibd
```

- On the destination server, create the same partitioned table:

```
mysql> use test;
mysql> CREATE TABLE t1 (i int) ENGINE = InnoDB PARTITION BY KEY (i) PARTITIONS 3;
```

In the `/datadir/test` directory, you will see a separate tablespace (`.ibd`) file for each of the three partitions.

```
mysql> \! ls /path/to/datadir/test/
db.opt  t1.frm  t1#P#p0.ibd  t1#P#p1.ibd  t1#P#p2.ibd
```

- On the destination server, discard the tablespace for the partitioned table. (Before the tablespace can be imported on the destination server, the tablespace that is attached to the receiving table must be discarded.)

```
mysql> ALTER TABLE t1 DISCARD TABLESPACE;
```

The three `.ibd` files that make up the tablespace for the partitioned table are discarded from the `/datadir/test` directory, leaving the following files:

```
mysql> \! ls /path/to/datadir/test/  
db.opt  t1.frm
```

4. On the source server, run `FLUSH TABLES ... FOR EXPORT` to quiesce the partitioned table and create the `.cfg` metadata files:

```
mysql> use test;  
mysql> FLUSH TABLES t1 FOR EXPORT;
```

Metadata (`.cfg`) files, one for each tablespace (`.ibd`) file, are created in the `/datadir/test` directory on the source server:

```
mysql> \! ls /path/to/datadir/test/  
db.opt  t1#P#p0.ibd  t1#P#p1.ibd  t1#P#p2.ibd  
t1.frm  t1#P#p0.cfg  t1#P#p1.cfg  t1#P#p2.cfg
```

### Note

`FLUSH TABLES ... FOR EXPORT` statement ensures that changes to the named table have been flushed to disk so that binary table copy can be made while the server is running. When `FLUSH TABLES ... FOR EXPORT` is run, InnoDB produces a `.cfg` metadata file for the table's tablespace files in the same database directory as the table. The `.cfg` files contain metadata used for schema verification when importing tablespace files. `FLUSH TABLES ... FOR EXPORT` can only be run on the table, not on individual table partitions.

5. Copy the `.ibd` and `.cfg` files from the source server database directory to the destination server database directory. For example:

```
shell> scp /path/to/datadir/test/t1*.{ibd,cfg} destination-server:/path/to/datadir/test
```

### Note

The `.ibd` and `.cfg` files must be copied before releasing the shared locks, as described in the next step.

6. On the source server, use `UNLOCK TABLES` to release the locks acquired by `FLUSH TABLES ... FOR EXPORT`:

```
mysql> use test;  
mysql> UNLOCK TABLES;
```

7. On the destination server, import the tablespace for the partitioned table:

```
mysql> use test;  
mysql> ALTER TABLE t1 IMPORT TABLESPACE;
```

## Example 3: Copying InnoDB Table Partitions From One Server To Another

This procedure demonstrates how to copy InnoDB table partitions from a running MySQL server instance to another running instance. The same procedure with minor adjustments can be used to perform a restore of InnoDB table partitions on the same instance. In the following example, a partitioned table with four partitions (p0, p1, p2, p3) is created on the source server. Two of the partitions (p2 and p3) are copied to the destination server.

1. On the source server, create a partitioned table if one does not exist. In the following example, a table with four partitions (p0, p1, p2, p3) is created:

```
mysql> use test;
mysql> CREATE TABLE t1 (i int) ENGINE = InnoDB PARTITION BY KEY (i) PARTITIONS 4;
```

In the `/datadir/test` directory, you will see a separate tablespace (`.ibd`) file for each of the four partitions.

```
mysql> \! ls /path/to/datadir/test/
db.opt  t1.frm  t1#P#p0.ibd  t1#P#p1.ibd  t1#P#p2.ibd  t1#P#p3.ibd
```

2. On the destination server, create the same partitioned table:

```
mysql> use test;
mysql> CREATE TABLE t1 (i int) ENGINE = InnoDB PARTITION BY KEY (i) PARTITIONS 4;
```

In the `/datadir/test` directory, you will see a separate tablespace (`.ibd`) file for each of the four partitions.

```
mysql> \! ls /path/to/datadir/test/
db.opt  t1.frm  t1#P#p0.ibd  t1#P#p1.ibd  t1#P#p2.ibd  t1#P#p3.ibd
```

3. On the destination server, discard the tablespace partitions that you plan to import from the source server. (Before tablespace partitions can be imported on the destination server, the corresponding partitions that are attached to the receiving table must be discarded.)

```
mysql> ALTER TABLE t1 DISCARD PARTITION p2, p3 TABLESPACE;
```

The `.ibd` files for the two discarded partitions are removed from the `/datadir/test` directory on the destination server, leaving the following files:

```
mysql> \! ls /path/to/datadir/test/
db.opt  t1.frm  t1#P#p0.ibd  t1#P#p1.ibd
```

## Note

When `ALTER TABLE ... DISCARD PARTITION ... TABLESPACE` is run on subpartitioned tables, both partition and subpartition table names are allowed. When a partition name is specified, subpartitions of that partition are included in the operation.

4. On the source server, run `FLUSH TABLES ... FOR EXPORT` to quiesce the partitioned table and create the `.cfg` metadata files.

```
mysql> use test;
mysql> FLUSH TABLES t1 FOR EXPORT;
```

The metadata files (`.cfg` files) are created in the `/datadir/test` directory on the source server. There is a `.cfg` file for each tablespace (`.ibd`) file.

```
mysql> \! ls /path/to/datadir/test/
db.opt  t1#P#p0.ibd  t1#P#p1.ibd  t1#P#p2.ibd  t1#P#p3.ibd
t1.frm  t1#P#p0.cfg  t1#P#p1.cfg  t1#P#p2.cfg  t1#P#p3.cfg
```

## Note

`FLUSH TABLES ... FOR EXPORT` statement ensures that changes to the named table have been flushed to disk so that binary table copy can be made while the server is running. When `FLUSH TABLES ... FOR EXPORT` is run, InnoDB produces a `.cfg` metadata file for the table's

tablespace files in the same database directory as the table. The `.cfg` files contain metadata used for schema verification when importing tablespace files. `FLUSH TABLES ... FOR EXPORT` can only be run on the table, not on individual table partitions.

- Copy the `.ibd` and `.cfg` files from the source server database directory to the destination server database directory. In this example, only the `.ibd` and `.cfg` files for partition 2 (p2) and partition 3 (p3) are copied to the `data` directory on the destination server. Partition 0 (p0) and partition 1 (p1) remain on the source server.

```
shell> scp t1#P#p2.ibd t1#P#p2.cfg t1#P#p3.ibd t1#P#p3.cfg destination-server:/path/to/datadir/test
```

#### Note

The `.ibd` files and `.cfg` files must be copied before releasing the shared locks, as described in the next step.

- On the source server, use `UNLOCK TABLES` to release the locks acquired by `FLUSH TABLES ... FOR EXPORT`:

```
mysql> use test;
mysql> UNLOCK TABLES;
```

- On the destination server, import the tablespace partitions (p2 and p3):

```
mysql> use test;
mysql> ALTER TABLE t1 IMPORT PARTITION p2, p3 TABLESPACE;
```

#### Note

When `ALTER TABLE ... IMPORT PARTITION ... TABLESPACE` is run on subpartitioned tables, both partition and subpartition table names are allowed. When a partition name is specified, subpartitions of that partition are included in the operation.

## 15.7.6.2 Transportable Tablespace Internals

The following information describes internals and error log messaging for the transportable tablespaces copy procedure for a regular `InnoDB` table.

When `ALTER TABLE ... DISCARD TABLESPACE` is run on the destination instance:

- The table is locked in X mode.
- The tablespace is detached from the table.

When `FLUSH TABLES ... FOR EXPORT` is run on the source instance:

- The table being flushed for export is locked in shared mode.
- The purge coordinator thread is stopped.
- Dirty pages are synchronized to disk.
- Table metadata is written to the binary `.cfg` file.

Expected error log messages for this operation:

```
2013-09-24T13:10:19.903526Z 2 [Note] InnoDB: Sync to disk of '"test"."t"' started.
2013-09-24T13:10:19.903586Z 2 [Note] InnoDB: Stopping purge
```

```
2013-09-24T13:10:19.903725Z 2 [Note] InnoDB: Writing table metadata to './test/t.cfg'
2013-09-24T13:10:19.904014Z 2 [Note] InnoDB: Table '"test"."t"' flushed to disk
```

When `UNLOCK TABLES` is run on the source instance:

- The binary `.cfg` file is deleted.
- The shared lock on the table or tables being imported is released and the purge coordinator thread is restarted.

Expected error log messages for this operation:

```
2013-09-24T13:10:21.181104Z 2 [Note] InnoDB: Deleting the meta-data file './test/t.cfg'
2013-09-24T13:10:21.181180Z 2 [Note] InnoDB: Resuming purge
```

When `ALTER TABLE ... IMPORT TABLESPACE` is run on the destination instance, the import algorithm performs the following operations for each tablespace being imported:

- Each tablespace page is checked for corruption.
- The space ID and log sequence numbers (LSNs) on each page are updated
- Flags are validated and LSN updated for the header page.
- Btree pages are updated.
- The page state is set to dirty so that it will be written to disk.

Expected error log messages for this operation:

```
2013-07-18 15:15:01 34960 [Note] InnoDB: Importing tablespace for table 'test/t' that was exported from
2013-07-18 15:15:01 34960 [Note] InnoDB: Phase I - Update all pages
2013-07-18 15:15:01 34960 [Note] InnoDB: Sync to disk
2013-07-18 15:15:01 34960 [Note] InnoDB: Sync to disk - done!
2013-07-18 15:15:01 34960 [Note] InnoDB: Phase III - Flush changes to disk
2013-07-18 15:15:01 34960 [Note] InnoDB: Phase IV - Flush complete
```

#### Note

You may also receive a warning that a tablespace is discarded (if you discarded the tablespace for the destination table) and a message stating that statistics could not be calculated due to a missing `.ibd` file:

```
2013-07-18 15:14:38 34960 [Warning] InnoDB: Table "test"."t" tablespace is set as discarded
2013-07-18 15:14:38 7f34d9a37700 InnoDB: cannot calculate statistics for table "test"
http://dev.mysql.com/doc/refman/5.7/en/innodb-troubleshooting.html
```

## 15.7.7 Storing InnoDB Undo Logs in Separate Tablespaces

You can store [InnoDB undo logs](#) in one or more separate [undo tablespaces](#) outside of the [system tablespace](#). This layout is different from the default configuration in which undo logs reside in the [system tablespace](#). The I/O patterns for undo logs make undo tablespaces good candidates to move to [SSD](#) storage, while keeping the system tablespace on hard disk storage. Users cannot drop the separate tablespaces created to hold [InnoDB](#) undo logs, or the individual [segments](#) inside those tablespaces. However, as of MySQL 5.7.5, undo logs stored in undo tablespaces can be truncated. For more information, see [Section 15.7.8, “Truncating Undo Logs That Reside in Undo Tablespaces”](#).

Because undo tablespace files handle I/O operations formerly done inside the system tablespace, the definition of system tablespace is extended to include undo tablespace files.

The undo tablespace feature involves the following configuration options:

- `innodb_undo_tablespaces`
- `innodb_undo_directory`
- `innodb_rollback_segments` becomes `innodb_undo_logs`. The old name is still available for compatibility.

The `innodb_undo_tablespaces` and `innodb_undo_directory` configuration options are non-dynamic startup options that can only be enabled when initializing a MySQL instance, which means that undo tablespaces can only be created when initializing a MySQL instance.

## Configuring Separate Undo Tablespaces

The following procedure assumes the configuration is performed on a test instance prior to production deployment.

1. Chose a directory location where you want InnoDB to create separate undo tablespaces for the undo logs. Specify the directory path as the argument to the `innodb_undo_directory` option in your MySQL configuration file or startup script. If no path is specified, undo tablespaces are created in the MySQL data directory, as defined by `datadir`.
2. Decide on a starting value for the `innodb_undo_logs` option, which defines the number of rollback segments used by InnoDB. (Undo logs exist within `undo log segments`, which are contained within `rollback segments`.) You can start with a relatively low value and increase it over time to examine the effect on performance.

One rollback segment is always assigned to the system tablespace, and as of MySQL 5.7.2, 32 rollback segments are reserved for use by temporary tables and are hosted in the temporary tablespace (`ibtmp1`). Therefore, to allocate rollback segments to undo tablespaces, `innodb_undo_logs` must be set to a value greater than 33. For example, if you have two undo tablespaces (`innodb_undo_tablespaces=2`), `innodb_undo_logs` must be set to 35 to assign one rollback segment to each of the two undo tablespaces.

### Note

When you configure separate undo tablespaces, the rollback segment in the system tablespace is rendered inactive.

3. Decide on a non-zero value for the `innodb_undo_tablespaces` option. The rollback segments specified by the `innodb_undo_logs` value are divided between this number of separate tablespaces. The `innodb_undo_tablespaces` value is fixed for the life of the MySQL instance, so if you are uncertain about the optimal value, estimate on the high side.
4. Create a new MySQL instance, using the values you chose in the configuration file or in your MySQL startup script. Use a realistic workload with data volume similar to your production servers. Alternatively, use the transportable tablespaces feature to copy existing database tables to your newly configured MySQL instance. See [Section 15.7.6, “Copying File-Per-Table Tablespaces to Another Server”](#) for more information.
5. Benchmark the performance of I/O intensive workloads.
6. Periodically increase the value of `innodb_undo_logs` and rerun performance tests. Find the value where you stop experiencing gains in I/O performance.
7. Deploy a new production instance using the ideal settings for these options. Set it up as a [slave server](#) in a [replication](#) configuration, or transfer data from an earlier production instance.

## Performance and Scalability Considerations

Keeping the undo logs in separate files allows the MySQL team to implement I/O and memory optimizations related to this transactional data. For example, because the undo data is written to disk

and then rarely used (only in case of crash recovery), it does not need to be kept in the file system memory cache, in turn allowing a higher percentage of system memory to be devoted to the [InnoDB buffer pool](#).

The typical SSD best practice of keeping the [InnoDB](#) system tablespace on a hard drive and moving the per-table tablespaces to SSD, is assisted by moving the undo information into separate tablespace files.

## Internals

The physical undo tablespace files are named `undoN.ibd`, where *N* is the space ID, including leading zeros.

MySQL instances containing separate undo tablespaces cannot be downgraded to earlier releases such as MySQL 5.5 or 5.1.

### 15.7.8 Truncating Undo Logs That Reside in Undo Tablespaces

As of MySQL 5.7.5, you can truncate [undo logs](#) that reside in [undo tablespaces](#), provided that the following conditions are true:

- Your MySQL instance is configured with a minimum of two undo tablespaces (`innodb_undo_tablespaces=2`). When an undo tablespace is truncated, it is temporarily taken offline. For the server to function, there must be at least one other active undo tablespace. The number of undo tablespaces is defined by the `innodb_undo_tablespaces` option, which can only be set when the MySQL instance is initialized. The default value is 0. To check the value of `innodb_undo_tablespaces`, submit the following query:

```
mysql> SELECT @@innodb_undo_tablespaces;
+-----+
| @@innodb_undo_tablespaces |
+-----+
| 2 |
+-----+
1 row in set (0.00 sec)
```

- `innodb_undo_logs`, which defines the number of [rollback segments](#) used by [InnoDB](#), must be set to 35 or greater. A setting of 35 or greater ensures that a redo-enabled undo log is assigned to each of the two undo tablespaces. With an `innodb_undo_logs` setting of 35:
  - The first rollback segment always resides in the [system tablespace](#) (when undo tablespaces are present, this rollback segment is inactive)
  - Rollback segments 2 to 33 reside in the shared temporary tablespace (`ibtmp1`)
  - The 34th rollback segment resides in the first undo tablespace (if present)
  - The 35th rollback segment resides in the second undo tablespace (if present)

There is a many-to-one relationship between rollback segments and undo tablespaces. If the number of allocated rollback segments is greater than 35, the “additional” rollback segments are assigned to undo tablespaces in a round-robin fashion. For example, if you have 2 undo tablespaces (undo tablespace 1 and undo-tablespace 2) and `innodb_undo_logs=37`, undo-tablespace 1 and undo-tablespace 2 would each be assigned a second rollback segment.

By default, `innodb_undo_logs` is set to 128, which is also the maximum value. To check the value of `innodb_undo_logs`, submit the following query:

```
mysql> SELECT @@innodb_undo_logs;
+-----+
| @@innodb_undo_logs |
+-----+
```

```
| 128 |
+-----+
1 row in set (0.00 sec)
```

`innodb_undo_logs` is a dynamic global variable and can be configured using a `SET GLOBAL` statement:

```
mysql> SET GLOBAL innodb_undo_logs=128;
```

## Enabling Truncation of Undo Tablespaces

To truncate undo logs that reside in undo tablespaces, you must first enable `innodb_undo_log_truncate`.

```
mysql> SET GLOBAL innodb_undo_log_truncate=ON;
```

When you enable `innodb_undo_log_truncate`, undo tablespace files that exceed the size limit defined by `innodb_max_undo_log_size` are marked for truncation. `innodb_max_undo_log_size` is a dynamic global variable with a default value of 1024 MiB (1073741824 bytes).

```
mysql> SELECT @@innodb_max_undo_log_size;
+-----+
| @@innodb_max_undo_log_size |
+-----+
| 1073741824 |
+-----+
1 row in set (0.00 sec)
```

You can configure `innodb_max_undo_log_size` using a `SET GLOBAL` statement:

```
mysql> SET GLOBAL innodb_max_undo_log_size=2147483648;
Query OK, 0 rows affected (0.00 sec)
```

When `innodb_undo_log_truncate` is enabled:

1. Undo tablespaces that exceed the `innodb_max_undo_log_size` setting are marked for truncation. Selection of an undo tablespace for truncation is performed in a round-robin fashion to avoid truncating the same undo tablespace each time.
2. Rollback segments residing in the selected undo tablespace are made inactive so that they are not allocated to new transactions. Existing transactions that are currently using rollback segments are allowed to complete.
3. The `purge` system frees rollback segments that are no longer needed.
4. After all rollback segments in the undo tablespace are freed, the truncate operation runs and the undo tablespace is truncated to its initial size. The initial size of an undo tablespace file is 10MB.

### Note

If you check the size of an undo tablespace after a truncation operation, the file size may be larger than 10MB due to immediate use following the completion of the truncation operation. The `innodb_undo_directory` option defines the location of undo tablespace files. The default value of "." represents directory where `InnoDB` creates its other log files by default.

```
mysql> select @@innodb_undo_directory;
+-----+
| @@innodb_undo_directory |
+-----+
| . |
+-----+
1 row in set (0.00 sec)
```

5. The rollback segments are reactivated so that they can be allocated to new transactions.

## Expediting Truncation of Undo Tablespace Files

An undo tablespace cannot be truncated until its rollback segments are freed. Normally, the purge system frees rollback segments once every 128 times that purge is invoked. To expedite the truncation of undo tablespaces, you can use the `innodb_purge_rseg_truncate_frequency` option to temporarily increase the frequency with which the purge system frees rollback segments. By default, `innodb_purge_rseg_truncate_frequency` is 128, which is also the maximum value.

```
mysql> select @@innodb_purge_rseg_truncate_frequency;
+-----+
| @@innodb_purge_rseg_truncate_frequency |
+-----+
|                                     128 |
+-----+
1 row in set (0.00 sec)
```

To increase the frequency with which the purge thread frees rollback segments, decrease the value of `innodb_purge_rseg_truncate_frequency`. For example:

```
mysql> SET GLOBAL innodb_purge_rseg_truncate_frequency=32;
Query OK, 0 rows affected (0.00 sec)
```

## Performance Impact of Truncating Undo Tablespace Files Online

While an undo tablespace truncation operation is in progress, rollback segments in one undo tablespace are temporarily deactivated. For example, if you have 2 undo tablespaces (`innodb_undo_tablespaces=2`) and 128 allocated undo logs (`innodb_undo_logs=128`), 95 of the undo logs reside in the two undo tablespaces (48 rollback segments in one undo tablespace and 47 in the other). If the first undo tablespace is taken offline, 48 undo logs are made inactive, reducing the undo log resource by slightly more than half. While the truncation operation is in progress, the remaining undo logs assume responsibility for the entire system load, which may result in a slight performance degradation. The degree of performance degradation depends on a number of factors including:

- Number of undo tablespaces
- Number of undo logs
- Undo tablespace size
- Speed of the I/O subsystem
- Existing long running transactions
- System load

### 15.7.9 InnoDB General Tablespaces

A *general tablespace* is a new type of [InnoDB](#) tablespace, introduced in MySQL 5.7.6. The general tablespace feature provides the following capabilities:

- Similar to the system tablespace, general tablespaces are shared tablespaces that can store data for multiple tables.
- General tablespaces have a potential memory advantage over [file-per-table tablespaces](#). The server keeps tablespace metadata in memory for the lifetime of a tablespace. Multiple tables in fewer general tablespaces consume less memory for tablespace metadata than the same number of tables in separate file-per-table tablespaces.
- General tablespace data files may be placed in a directory relative to or independent of the MySQL data directory, which provides you with many of the data file and storage management capabilities of [file-per-table tablespaces](#). As with file-per-table tablespaces, the ability to place data files outside

of the MySQL data directory allows you to manage performance of critical tables separately, setup RAID or DRBD for specific tables, or bind tables to particular disks, for example.

- General tablespaces support both Antelope and Barracuda file formats, and therefore support all table row formats and associated features. With support for both file formats, general tablespaces have no dependence on `innodb_file_format` or `innodb_file_per_table` settings, nor do these variables have any effect on general tablespaces.
- The `TABLESPACE` option can be used with `CREATE TABLE` to create tables in a general tablespaces, file-per-table tablespace, or in the system tablespace.
- The `TABLESPACE` option can be used with `ALTER TABLE` to move tables between general tablespaces, file-per-table tablespaces, and the system tablespace. Previously, it was not possible to move a table from a file-per-table tablespace to the system tablespace. With the general tablespace feature, you can now do so.

## Creating a General Tablespace

General tablespaces are created using `CREATE TABLESPACE` syntax.

```
CREATE TABLESPACE tablespace_name
  ADD DATAFILE 'file_name'
  [FILE_BLOCK_SIZE = value]
  [ENGINE [=] engine_name]
```

A general tablespace may be created in the MySQL data directory or in a directory outside of the MySQL data directory. To avoid conflicts with implicitly created file-per-table tablespaces, creating a general tablespace in a subdirectory under the MySQL data directory is not supported. Also, when creating a general tablespace outside of the MySQL data directory, the directory must exist prior to creating the tablespace.

As of MySQL 5.7.8, an `isl` file is created in the MySQL data directory when a general tablespace is created outside of the MySQL data directory.

Examples:

Creating a general tablespace in the MySQL data directory:

```
mysql> CREATE TABLESPACE `ts1` ADD DATAFILE 'ts1.ibd' Engine=InnoDB;
```

Creating a general tablespace in a directory outside of the MySQL data directory:

```
mysql> CREATE TABLESPACE `ts1` ADD DATAFILE '/my/tablespace/directory/ts1.ibd' Engine=InnoDB;
```

You can specify a path that is relative to the MySQL data directory as long as the tablespace directory is not under the MySQL data directory. In this example, the `my_tablespace` directory is at the same level as the MySQL data directory:

```
mysql> CREATE TABLESPACE `ts1` ADD DATAFILE '../my_tablespace/ts1.ibd' Engine=InnoDB;
```

### Note

The `ENGINE = InnoDB` clause must be defined as part of the `CREATE TABLESPACE` statement or `InnoDB` must be defined as the default storage engine (`default_storage_engine=InnoDB`).

## Adding Tables to a General Tablespace

After creating an `InnoDB` general tablespace, you can use `CREATE TABLE tbl_name ... TABLESPACE [=] tablespace_name` or `ALTER TABLE tbl_name TABLESPACE [=] tablespace_name` to add tables to the tablespace, as shown in the following examples:

`CREATE TABLE:`

```
mysql> CREATE TABLE t1 (c1 INT PRIMARY KEY) TABLESPACE ts1 ROW_FORMAT=COMPACT;
```

**ALTER TABLE:**

```
mysql> ALTER TABLE t2 TABLESPACE ts1;
```

For detailed syntax information, see [CREATE TABLE](#) and [ALTER TABLE](#).

## General Tablespace Row Format Support

General tablespaces support all table row formats ([REDUNDANT](#), [COMPACT](#), [DYNAMIC](#), [COMPRESSED](#)) with the caveat that compressed and uncompressed tables cannot coexist in the same general tablespace due to different physical page sizes.

For a general tablespace to contain compressed tables ([ROW\\_FORMAT=COMPRESSED](#)), [FILE\\_BLOCK\\_SIZE](#) must be specified, and the [FILE\\_BLOCK\\_SIZE](#) value must be a valid compressed page size in relation to the [innodb\\_page\\_size](#) value. Also, the physical page size of the compressed table ([KEY\\_BLOCK\\_SIZE](#)) must be equal to [FILE\\_BLOCK\\_SIZE/1024](#). For example, if [innodb\\_page\\_size](#)=16K and [FILE\\_BLOCK\\_SIZE](#)=8K, the [KEY\\_BLOCK\\_SIZE](#) of the table must be 8.

The following table shows permitted [FILE\\_BLOCK\\_SIZE](#) and [KEY\\_BLOCK\\_SIZE](#) values for each [innodb\\_page\\_size](#) value. [FILE\\_BLOCK\\_SIZE](#) values may also be specified in bytes. To determine a valid [KEY\\_BLOCK\\_SIZE](#) value for a given [FILE\\_BLOCK\\_SIZE](#), divide the [FILE\\_BLOCK\\_SIZE](#) value by 1024. Table compression is not support for 32K and 64K InnoDB page sizes. For more information about [KEY\\_BLOCK\\_SIZE](#), see [CREATE TABLE](#), and [Section 15.9.1.2, “Creating Compressed Tables”](#).

**Table 15.5 FILE\_BLOCK\_SIZE and KEY\_BLOCK\_SIZE Values for CREATE TABLESPACE**

| InnoDB Page Size<br>(innodb_page_size) | Permitted FILE_BLOCK_SIZE<br>Values | Permitted KEY_BLOCK_SIZE<br>Values   |
|--|-------------------------------------|--|
| 64K                                    | 64K (65536)                         | Compression is not supported   |
| 32K                                    | 32K (32768)                         | Compression is not supported   |
| 16K                                    | 16K (16384)                         | N/A: If <a href="#">innodb_page_size</a> is equal to <a href="#">FILE_BLOCK_SIZE</a> , the tablespace cannot contain a compressed table. |
|  | 8K (8192)                           | 8  |
|  | 4K (4096)                           | 4  |
|  | 2K (2048)                           | 2  |
|  | 1K (1024)                           | 1  |
| 8K                                     | 8K (8192)                           | N/A: If <a href="#">innodb_page_size</a> is equal to <a href="#">FILE_BLOCK_SIZE</a> , the tablespace cannot contain a compressed table. |
|  | 4K (4096)                           | 4  |
|  | 2K (2048)                           | 2  |
|  | 1K (1024)                           | 1  |
| 4K                                     | 4K (4096)                           | N/A: If <a href="#">innodb_page_size</a> is equal to <a href="#">FILE_BLOCK_SIZE</a> , the tablespace cannot contain a compressed table. |
|  | 2K (2048)                           | 2  |
|  | 1K (1024)                           | 1  |

This example demonstrates creating a general tablespace and adding a compressed table. The example assumes a default `innodb_page_size` of 16K. The `FILE_BLOCK_SIZE` of 8192 requires that the compressed table have a `KEY_BLOCK_SIZE` of 8.

```
mysql> CREATE TABLESPACE `ts2` ADD DATAFILE 'ts2.ibd' FILE_BLOCK_SIZE = 8192 Engine=InnoDB;
Query OK, 0 rows affected (0.01 sec)

mysql> CREATE TABLE t4 (c1 INT PRIMARY KEY) TABLESPACE ts2 ROW_FORMAT=COMPRESSED
KEY_BLOCK_SIZE=8;
Query OK, 0 rows affected (0.00 sec)
```

If you do not specify `FILE_BLOCK_SIZE` when creating a general tablespace, `FILE_BLOCK_SIZE` defaults to `innodb_page_size`. When `FILE_BLOCK_SIZE` is equal to `innodb_page_size`, the tablespace may only contain tables with an uncompressed row format (`COMPACT`, `REDUNDANT`, and `DYNAMIC` row formats).

## Moving Non-Partitioned Tables Between Tablespaces Using ALTER TABLE

You can use `ALTER TABLE` with the `TABLESPACE` option to move a non-partitioned InnoDB table to an existing general tablespace, to a new file-per-table tablespace, or to the system tablespace.

### Note

Running an `ALTER TABLE tbl_name TABLESPACE [=] tablespace_name` operation on a *partitioned* table only modifies the table's default tablespace. It does not move the table's partitions.

To move a non-partitioned table from a file-per-table tablespace or from the system tablespace to a general tablespace, specify the name of the general tablespace. The general tablespace must exist. See `CREATE TABLESPACE` for more information.

```
ALTER TABLE tbl_name TABLESPACE [=] tablespace_name
```

To move a non-partitioned table from a general tablespace or file-per-table tablespace to the system tablespace, specify `innodb_system` as the tablespace name.

```
ALTER TABLE tbl_name ... TABLESPACE [=] innodb_system
```

To move a non-partitioned table from the system tablespace or a general tablespace to a file-per-table tablespace, specify `innodb_file_per_table` as the tablespace name.

```
ALTER TABLE tbl_name ... TABLESPACE [=] innodb_file_per_table
```

`ALTER TABLE ... TABLESPACE` operations always cause a full table rebuild, even if the `TABLESPACE` attribute has not changed from its previous value.

`ALTER TABLE ... TABLESPACE` syntax does not support moving a table from a temporary tablespace to a persistent tablespace.

The `DATA DIRECTORY` clause is permitted with `CREATE TABLE ... TABLESPACE=innodb_file_per_table` but is otherwise not supported for use in combination with the `TABLESPACE` option.

## General Tablespace Table Partition Support

The `TABLESPACE` option may be used to assign individual table partitions or subpartitions to a [general tablespace](#), a separate file-per-table tablespace, or the system tablespace. General tablespace support for table partitions and subpartitions was added in MySQL 5.7.8. All partitions must belong to the same storage engine. Usage is demonstrated in the following examples.

```
mysql> CREATE TABLESPACE `ts1` ADD DATAFILE 'ts1.ibd' Engine=InnoDB;
mysql> CREATE TABLESPACE `ts2` ADD DATAFILE 'ts2.ibd' Engine=InnoDB;
```

```
mysql> CREATE TABLE t1 (a INT, b INT) ENGINE = InnoDB
-> PARTITION BY RANGE(a) SUBPARTITION BY KEY(b) (
-> PARTITION p1 VALUES LESS THAN (100) TABLESPACE=`ts1`,
-> PARTITION p2 VALUES LESS THAN (1000) TABLESPACE=`ts2`,
-> PARTITION p3 VALUES LESS THAN (10000) TABLESPACE `innodb_file_per_table`,
-> PARTITION p4 VALUES LESS THAN (100000) TABLESPACE `innodb_system`);

mysql> CREATE TABLE t2 (a INT, b INT) ENGINE = InnoDB
-> PARTITION BY RANGE(a) SUBPARTITION BY KEY(b) (
-> PARTITION p1 VALUES LESS THAN (100) TABLESPACE=`ts1`
-> (SUBPARTITION sp1,
-> SUBPARTITION sp2),
-> PARTITION p2 VALUES LESS THAN (1000)
-> (SUBPARTITION sp3,
-> SUBPARTITION sp4 TABLESPACE=`ts2`),
-> PARTITION p3 VALUES LESS THAN (10000)
-> (SUBPARTITION sp5 TABLESPACE `innodb_system`,
-> SUBPARTITION sp6 TABLESPACE `innodb_file_per_table`));
```

The `TABLESPACE` option is also supported with `ALTER TABLE`.

```
mysql> ALTER TABLE t1 ADD PARTITION (PARTITION p5 VALUES LESS THAN (1000000) TABLESPACE = `ts1`);
```

#### Note

If the `TABLESPACE = tablespace_name` option is not defined, the `ALTER TABLE ... ADD PARTITION` operation adds the partition to the table's default tablespace, which can be specified at the table level during `CREATE TABLE` or `ALTER TABLE`.

To verify that partitions were placed in the specified tablespaces, you can query `INFORMATION_SCHEMA.INNODB_SYS_TABLES`:

```
mysql> SELECT NAME, SPACE, SPACE_TYPE FROM INFORMATION_SCHEMA.INNODB_SYS_TABLES
-> WHERE NAME LIKE '%t1%';
```

| NAME                  | SPACE | SPACE_TYPE |
|-----------------------|-------|------------|
| test/t1#P#p1#SP#p1sp0 | 57    | General    |
| test/t1#P#p2#SP#p2sp0 | 58    | General    |
| test/t1#P#p3#SP#p3sp0 | 59    | Single     |
| test/t1#P#p4#SP#p4sp0 | 0     | System     |
| test/t1#P#p5#SP#p5sp0 | 57    | General    |

```
mysql> SELECT NAME, SPACE, SPACE_TYPE FROM INFORMATION_SCHEMA.INNODB_SYS_TABLES
-> WHERE NAME LIKE '%t2%';
```

| NAME                | SPACE | SPACE_TYPE |
|---------------------|-------|------------|
| test/t2#P#p1#SP#sp1 | 57    | General    |
| test/t2#P#p1#SP#sp2 | 57    | General    |
| test/t2#P#p2#SP#sp3 | 60    | Single     |
| test/t2#P#p2#SP#sp4 | 58    | General    |
| test/t2#P#p3#SP#sp5 | 0     | System     |
| test/t2#P#p3#SP#sp6 | 61    | Single     |

## Moving Table Partitions Between Tablespaces Using ALTER TABLE

To move table partitions to a different tablespace, you must move each partition using an `ALTER TABLE tbl_name REORGANIZE PARTITION` statement.

The following example demonstrates how to move table partitions to a different tablespace. `INFORMATION_SCHEMA.INNODB_SYS_TABLES` and `INFORMATION_SCHEMA.INNODB_SYS_TABLESPACES` are queried to verify that partitions are placed in the expected tablespace.

**Note**

If the `TABLESPACE = tablespace_name` option is not defined in the `REORGANIZE PARTITION` statement, InnoDB moves the partition to the table's default tablespace. In this example, tablespace `ts1`, which is defined at the table level, is the default tablespace for table `t1`. Partition `P3` is moved from the system tablespace to tablespace `ts1` since no `TABLESPACE` option is specified in the `ALTER TABLE t1 REORGANIZE PARTITION` statement for partition `P3`.

To change a partitioned table's default tablespace, you can run `ALTER TABLE tbl_name TABLESPACE [=] tablespace_name` on the *partitioned* table.

```
mysql> CREATE TABLESPACE ts1 ADD DATAFILE 'ts1.ibd';
mysql> CREATE TABLESPACE ts2 ADD DATAFILE 'ts2.ibd';

mysql> CREATE TABLE t1 ( a INT NOT NULL, PRIMARY KEY (a))
-> ENGINE=InnoDB TABLESPACE ts1
-> PARTITION BY RANGE (a) PARTITIONS 3 (
-> PARTITION P1 VALUES LESS THAN (2),
-> PARTITION P2 VALUES LESS THAN (4) TABLESPACE `innodb_file_per_table`,
-> PARTITION P3 VALUES LESS THAN (6) TABLESPACE `innodb_system`);

mysql> SELECT A.NAME as partition_name, A.SPACE_TYPE as space_type, B.NAME as space_name
-> FROM INFORMATION_SCHEMA.INNODB_SYS_TABLES A
-> LEFT JOIN INFORMATION_SCHEMA.INNODB_SYS_TABLESPACES B
-> ON A.SPACE = B.SPACE WHERE A.NAME LIKE '%t1%' ORDER BY A.NAME;
+-----+-----+-----+
| partition_name | space_type | space_name |
+-----+-----+-----+
| test/t1#P#P1   | General    | ts1         |
| test/t1#P#P2   | Single     | test/t1#P#P2 |
| test/t1#P#P3   | System     | NULL        |
+-----+-----+-----+

mysql> ALTER TABLE t1 REORGANIZE PARTITION P1
-> INTO (PARTITION P1 VALUES LESS THAN (2) TABLESPACE = `ts2`);

mysql> ALTER TABLE t1 REORGANIZE PARTITION P2
-> INTO (PARTITION P2 VALUES LESS THAN (4) TABLESPACE = `ts2`);

mysql> ALTER TABLE t1 REORGANIZE PARTITION P3
-> INTO (PARTITION P3 VALUES LESS THAN (6));

mysql> SELECT A.NAME AS partition_name, A.SPACE_TYPE AS space_type, B.NAME AS space_name
-> FROM INFORMATION_SCHEMA.INNODB_SYS_TABLES A
-> LEFT JOIN INFORMATION_SCHEMA.INNODB_SYS_TABLESPACES B
-> ON A.SPACE = B.SPACE WHERE A.NAME LIKE '%t1%' ORDER BY A.NAME;
+-----+-----+-----+
| partition_name | space_type | space_name |
+-----+-----+-----+
| test/t1#P#P1   | General    | ts2         |
| test/t1#P#P2   | General    | ts2         |
| test/t1#P#P3   | General    | ts1         |
+-----+-----+-----+
```

## Dropping a General Tablespace

The `DROP TABLESPACE` statement is used to drop an InnoDB general tablespace.

All tables must be dropped from the tablespace prior to a `DROP TABLESPACE` operation. If the tablespace is not empty, `DROP TABLESPACE` returns an error.

If a `DROP TABLESPACE` operation on an *empty* general tablespace returns an error, the tablespace may contain an orphan temporary or intermediate table that was left by an `ALTER TABLE` operation that was interrupted by a server exit. For more information, see [Section 15.21.3, “Troubleshooting InnoDB Data Dictionary Operations”](#).

A general InnoDB tablespace is not deleted automatically when the last table in the tablespace is dropped. The tablespace must be dropped explicitly using `DROP TABLESPACE tablespace_name`.

A general tablespace does not belong to any particular database. A `DROP DATABASE` operation can drop tables that belong to a general tablespace but it cannot drop the tablespace, even if the `DROP DATABASE` operation drops all tables that belong to the tablespace. A general tablespace must be dropped explicitly using `DROP TABLESPACE tablespace_name`.

Similar to the system tablespace, truncating or dropping tables stored in a general tablespace creates free space internally in the general tablespace `.ibd data file` which can only be used for new InnoDB data. Space is not released back to the operating system as it is when a file-per-table tablespace is deleted during a `DROP TABLE` operation.

This example demonstrates how to drop an InnoDB general tablespace. The general tablespace `ts1` is created with a single table. The table must be dropped before dropping the tablespace.

```
mysql> CREATE TABLESPACE `ts1` ADD DATAFILE 'ts1.ibd' Engine=InnoDB;
Query OK, 0 rows affected (0.01 sec)

mysql> CREATE TABLE t1 (c1 INT PRIMARY KEY) TABLESPACE ts10 Engine=InnoDB;
Query OK, 0 rows affected (0.02 sec)

mysql> DROP TABLE t1;
Query OK, 0 rows affected (0.01 sec)

mysql> DROP TABLESPACE ts1;
Query OK, 0 rows affected (0.01 sec)
```

#### Note

`tablespace_name` is a case-sensitive identifier in MySQL.

## General Tablespace Limitations

- A generated or existing tablespace cannot be changed to a general tablespace.
- Creation of temporary general tablespaces is not supported.
- General tablespaces do not support temporary tables.
- Partitioned InnoDB tables, and using the `TABLESPACE=tablespace_name` to assign individual table partitions or subpartitions to a general tablespace, are only supported in MySQL 5.7.8 or higher.
- Tables stored in a general tablespace may only be opened in MySQL 5.7.6 or later.
- Similar to the system tablespace, truncating or dropping tables stored in a general tablespace creates free space internally in the general tablespace `.ibd data file` which can only be used for new InnoDB data. Space is not released back to the operating system as it is for file-per-table tablespaces.

Additionally, a table-copying `ALTER TABLE` operation on table that resides in a shared tablespace (a general tablespace or the system tablespace) can increase the amount of space used by the tablespace. Such operations require as much additional space as the data in the table plus indexes. The additional space required for the table-copying `ALTER TABLE` operation is not released back to the operating system as it is for file-per-table tablespaces.

- `ALTER TABLE ... DISCARD TABLESPACE` and `ALTER TABLE ... IMPORT TABLESPACE` are not supported for tables that belong to a general tablespace.
- General tablespaces created on Windows using a relative data file path cannot be opened on Unix-like systems. This limitation is removed in MySQL 5.7.8 (Bug #20555168).

- In MySQL 5.7.6 and MySQL 5.7.7, tables stored in general tablespaces may not open (due to a missing general tablespace file) after moving the MySQL data directory to a new location. This limitation is addressed in MySQL 5.7.8 with the introduction of `isl` files for general tablespaces created outside of the MySQL data directory (Bug #20563954).

For more information see [Section 14.1.19, “CREATE TABLESPACE Syntax”](#).

## 15.7.10 InnoDB Tablespace Encryption

**InnoDB** supports data encryption for **InnoDB** tables stored in **file-per-table** tablespaces. This feature provides at-rest encryption for physical tablespace data files.

**InnoDB** tablespace encryption uses a two tier encryption key architecture, consisting of a master encryption key and tablespace keys. When an **InnoDB** table is encrypted, a tablespace key is encrypted and stored in the tablespace header. When an application or authenticated user wants to access encrypted tablespace data, **InnoDB** uses a master encryption key to decrypt the tablespace key. The decrypted version of a tablespace key never changes, but the master encryption key may be changed as required. This action is referred to as *master key rotation*.

The **InnoDB** tablespace encryption feature relies on a keyring plugin for master encryption key management.

All MySQL editions provide a `keyring_file` plugin, which stores master encryption key data in a `keyring` file in the location specified by the `keyring_file_data` configuration option.

### Warning

The **InnoDB** tablespace encryption feature in non-enterprise editions of MySQL uses the `keyring_file` plugin for encryption key management, which is not intended as a regulatory compliance solution. Security standards such as PCI, FIPS, and others require use of key management systems to secure, manage, and protect encryption keys in key vaults or hardware security modules (HSMs).

MySQL Enterprise Edition offers the `keyring_okv` plugin, which includes a KMIP client (KMIP v1.2) that works with Oracle Key Vault (OKV) to provide encryption key management. When **InnoDB** tablespace encryption uses OKV for encryption key management, the feature is referred to as “MySQL Enterprise Transparent Data Encryption (TDE)”.

A secure and robust encryption key management solution such as OKV is critical for security and for compliance with various security standards. Among other benefits, using a key vault ensures that keys are stored securely, never lost, and only known to authorized key administrators. A key vault also maintains an encryption key history.

**InnoDB** tablespace encryption supports the Advanced Encryption Standard (AES) block-based encryption algorithm. It uses Electronic Codebook (ECB) block encryption mode for tablespace key encryption and Cipher Block Chaining (CBC) block encryption mode for data encryption.

For frequently asked questions about the **InnoDB** tablespace encryption feature, see [Section A.16, “MySQL 5.7 FAQ: InnoDB Tablespace Encryption”](#).

## InnoDB Tablespace Encryption Prerequisites

- A keyring plugin (the `keyring_file` plugin or `keyring_okv` plugin) must be installed and configured. Keyring plugin installation is performed at startup using the `--early-plugin-load` option. Early loading ensures that the plugin is available prior to initialization of the **InnoDB** storage engine. For keyring plugin installation and configuration instructions, see [Section 7.5.4, “The MySQL Keyring”](#).

Only one keyring plugin should be enabled at a time. Enabling multiple keyring plugins is not supported.

### Important

Once encrypted tables are created in a MySQL instance, the keyring plugin that was loaded when creating the encrypted tables must continue to be loaded using the `--early-plugin-load` option, prior to InnoDB initialization. Failing to do so results in errors on startup and during InnoDB recovery.

To verify that a keyring plugin is active, use the `SHOW PLUGINS` statement or query the `INFORMATION_SCHEMA.PLUGINS` table. For example:

```
mysql> SELECT PLUGIN_NAME, PLUGIN_STATUS FROM INFORMATION_SCHEMA.PLUGINS
      -> WHERE PLUGIN_NAME LIKE 'keyring%';
+-----+-----+
| PLUGIN_NAME | PLUGIN_STATUS |
+-----+-----+
| keyring_file | ACTIVE        |
+-----+-----+
```

- The `innodb_file_per_table` option must be enabled (the default). InnoDB tablespace encryption only supports `file-per-table` tablespaces. Alternatively, you can specify the `TABLESPACE='innodb_file_per_table'` option when creating an encrypted table or altering an existing table to enable encryption.
- Before using the InnoDB tablespace encryption feature with production data, ensure that you have taken steps to prevent loss of the master encryption key. *If the master encryption key is lost, data stored in encrypted tablespace files is unrecoverable.* If you are using the `keyring_file` plugin, it is recommended that you create a backup of the `keyring` file immediately after creating the first encrypted table and before and after master key rotation. The `keyring` file location is defined by the `keyring_file_data` configuration option. If you are using the `keyring_okv` plugin, ensure that you have performed the necessary `keyring_okv` plugin and Oracle Key Vault (OKV) configuration. For keyring plugin configuration, see [Section 7.5.4, “The MySQL Keyring”](#). For OKV configuration, refer to the OKV documentation available at the [Oracle Key Vault](#) site.

## Enabling and Disabling InnoDB Tablespace Encryption

To enable encryption for a new InnoDB table, specify the `ENCRYPTION` option in a `CREATE TABLE` statement.

```
mysql> CREATE TABLE t1 (c1 INT) ENCRYPTION='Y';
```

To enable encryption for an existing InnoDB table, specify the `ENCRYPTION` option in an `ALTER TABLE` statement.

```
mysql> ALTER TABLE t1 ENCRYPTION='Y';
```

To disable encryption for an InnoDB table, set `ENCRYPTION='N'` using `ALTER TABLE`.

```
mysql> ALTER TABLE t1 ENCRYPTION='N';
```

### Note

Plan appropriately when altering an existing table with the `ENCRYPTION` option. `ALTER TABLE ... ENCRYPTION` operations rebuild the table using `ALGORITHM=COPY`. `ALGORITHM=INPLACE` is not supported.

## InnoDB Tablespace Encryption and Master Key Rotation

The master encryption key should be rotated periodically and whenever you suspect that the key may have been compromised.

Master key rotation is an atomic, instance-level operation. Each time the master encryption key is rotated, all tablespace keys in the MySQL instance are re-encrypted and saved back to their respective tablespace headers. As an atomic operation, re-encryption must succeed for all tablespace keys once a rotation operation is initiated. If master key rotation is interrupted by a server failure, [InnoDB](#) rolls the operation forward on server restart. For more information, see [InnoDB Tablespace Encryption and Recovery](#).

Rotating the master encryption key only changes the master encryption key and re-encrypts tablespace keys. It does not decrypt or re-encrypt associated tablespace data.

Rotating the master encryption key requires the [SUPER](#) privilege.

To rotate the master encryption key, run:

```
mysql> ALTER INSTANCE ROTATE INNODB MASTER KEY;
```

`ALTER INSTANCE ROTATE INNODB MASTER KEY` supports concurrent DML. However, it cannot be run concurrently with `CREATE TABLE ... ENCRYPTED` or `ALTER TABLE ... ENCRYPTED` operations, and locks are taken to prevent conflicts that could arise from concurrent execution of these statements. If one of the conflicting statements is running, it must complete before another can proceed.

## InnoDB Tablespace Encryption and Recovery

If a server failure occurs during master key rotation, [InnoDB](#) continues the operation on server restart.

The keyring plugin that was installed when tables were encrypted must be loaded prior to storage engine initialization so that the information necessary to decrypt tablespace data pages can be retrieved from tablespace headers before [InnoDB](#) initialization and recovery activities access tablespace data. (See [InnoDB Tablespace Encryption Prerequisites](#).)

When [InnoDB](#) initialization and recovery begin, the master key rotation operation resumes. Due to the server failure, some tablespaces keys may already be encrypted using the new master encryption key. [InnoDB](#) reads the encryption data from each tablespace header, and if the data indicates that the tablespace key is encrypted using the old master encryption key, [InnoDB](#) retrieves the old key from the keyring and uses it to decrypt the tablespace key. [InnoDB](#) then re-encrypts the tablespace key using the new master encryption key and saves the re-encrypted tablespace key back to the tablespace header.

## Exporting Encrypted Tables

When an encrypted table is exported, [InnoDB](#) generates a *transfer key* that is used to encrypt the tablespace key. The encrypted tablespace key and transfer key are stored in a `tablespace_name.cfp` file. This file together with the encrypted tablespace file is required to perform an import operation. On import, [InnoDB](#) uses the transfer key to decrypt the tablespace key in the `tablespace_name.cfp` file. For related information, see [Section 15.7.6, “Copying File-Per-Table Tablespaces to Another Server”](#).

## InnoDB Tablespace Encryption and Replication

- The `ALTER INSTANCE ROTATE INNODB MASTER KEY` statement is only supported in replication environments where the master and slaves run a version of MySQL that supports the tablespace encryption feature.
- Successful `ALTER INSTANCE ROTATE INNODB MASTER KEY` statements are written to the binary log for replication on slaves.
- If an `ALTER INSTANCE ROTATE INNODB MASTER KEY` statement fails, it is not logged to the binary log and is not replicated on slaves.

- Replication of an `ALTER INSTANCE ROTATE INNODB MASTER KEY` operation fails if the keyring plugin is installed on the master but not on the slave.
- If the `keyring_file` plugin is installed on both the master and a slave but the slave does not have a `keyring` file, the replicated `ALTER INSTANCE ROTATE INNODB MASTER KEY` statement creates the `keyring` file on the slave, assuming the `keyring` file data is not cached in memory. `ALTER INSTANCE ROTATE INNODB MASTER KEY` will use `keyring` file data that is cached in memory, if available.

## Identifying Tables that Use InnoDB Tablespace Encryption

When the `ENCRYPTION` option is specified in a `CREATE TABLE` or `ALTER TABLE` statement, it is recorded in the `CREATE_OPTIONS` field of `INFORMATION_SCHEMA.TABLES`. This field may be queried to identify encrypted tables in a MySQL instance.

```
mysql> SELECT TABLE_SCHEMA, TABLE_NAME, CREATE_OPTIONS FROM INFORMATION_SCHEMA.TABLES
-> WHERE CREATE_OPTIONS LIKE '%ENCRYPTION="Y"%';
```

| TABLE_SCHEMA | TABLE_NAME | CREATE_OPTIONS |
|--------------|------------|----------------|
| test         | t1         | ENCRYPTION="Y" |

## InnoDB Tablespace Encryption Usage Notes

- If the server exits or is stopped during normal operation, it is recommended to restart the server using the same encryption settings that were configured previously.
- The first master encryption key is generated when the first new or existing table is encrypted.
- Master key rotation re-encrypts tablespaces keys but does not change the tablespace key itself. To change a tablespace key, you must disable and re-enable table encryption using `ALTER TABLE tbl_name ENCRYPTION`, which is an `ALGORITHM=COPY` operation that rebuilds the table.
- If a table is created with both the `COMPRESSION` and `ENCRYPTION` options, compression is performed before tablespace data is encrypted.
- `keyring_file` plugin usage notes:
  - If a `keyring` file is empty or missing, the first execution of `ALTER INSTANCE ROTATE INNODB MASTER KEY` creates a master encryption key.
  - Uninstalling the `keyring_file` plugin does not remove an existing `keyring` file.
  - It is recommended that you not place the `keyring` file under the same directory as tablespace data files. The location of the `keyring` file is specified by the `keyring_file_data` option.
  - Modifying the `keyring_file_data` option at runtime or restarting the server with a new `keyring_file_data` setting can cause previously encrypted tables to become inaccessible, resulting in the loss of data.

## InnoDB Tablespace Encryption Limitations

- Advanced Encryption Standard (AES) is the only supported encryption algorithm. InnoDB tablespace encryption uses Electronic Codebook (ECB) block encryption mode for tablespace key encryption and Cipher Block Chaining (CBC) block encryption mode for data encryption.
- Altering the `ENCRYPTION` attribute of a table is an `ALGORITHM=COPY` operation. `ALGORITHM=INPLACE` is not supported.
- InnoDB tablespace encryption only supports InnoDB tables that are stored in a `file-per-table` tablespaces. Encryption is not supported for tables stored in other InnoDB tablespace types

including [general tablespaces](#), the [system tablespace](#), undo log tablespaces, and the temporary tablespace.

- You cannot move or copy an encrypted table from a [file-per-table](#) tablespace to an unsupported [InnoDB](#) tablespace type.
- Tablespace encryption only applies to data in the tablespace. Data is not encrypted in the redo log, undo log, or binary log.
- Direct migration from the [keyring\\_file](#) plugin to the [keyring\\_okv](#) plugin, or vice-versa, is currently unsupported. Changing keyring plugins requires decrypting tables, uninstalling the current keyring plugin, installing and configuring the other keyring plugin, and re-encrypting tables.

## 15.8 InnoDB Tables and Indexes

### 15.8.1 Creating InnoDB Tables

To create an [InnoDB](#) table, use the `CREATE TABLE` statement. You do not need to specify the `ENGINE=InnoDB` clause if [InnoDB](#) is defined as the default storage engine, which is the default as of MySQL 5.5. You might still use `ENGINE=InnoDB` clause if you plan to use `mysqldump` or replication to replay the `CREATE TABLE` statement on a server where the default storage engine is not [InnoDB](#).

```
-- Default storage engine = InnoDB.
CREATE TABLE t1 (a INT, b CHAR (20), PRIMARY KEY (a));
-- Backward-compatible with older MySQL.
CREATE TABLE t2 (a INT, b CHAR (20), PRIMARY KEY (a)) ENGINE=InnoDB;
```

An [InnoDB](#) table and its indexes can be created in the [system tablespace](#), in a [file-per-table](#) tablespace, or in a [general tablespace](#) (introduced in MySQL 5.7.6). When `innodb_file_per_table` is enabled, which is the default setting as of MySQL 5.6.6, an [InnoDB](#) table is implicitly created in an individual file-per-table tablespace. Conversely, when `innodb_file_per_table` is disabled, an [InnoDB](#) table is implicitly created in the system tablespace. With the introduction of general tablespaces in MySQL 5.7.6, you can use `CREATE TABLE ... TABLESPACE` syntax to explicitly create an [InnoDB](#) table in any of the three tablespace types.

When you create an [InnoDB](#) table, MySQL creates a `.frm` file in a database directory under the MySQL data directory. For a table created in a file-per-table tablespace, an `.ibd` file is also created. A table created in the system tablespace is created in the existing system tablespace `ibdata files`. A table created in a general tablespace is created in an existing general tablespace `.ibd` file.

Internally, [InnoDB](#) adds an entry for each table to the [InnoDB](#) data dictionary. The entry includes the database name. For example, if table `t1` is created in the `test` database, the data dictionary entry is `'test/t1'`. This means you can create a table of the same name (`t1`) in a different database, and the table names do not collide inside [InnoDB](#).

### Viewing the Properties of InnoDB Tables

To view the properties of [InnoDB](#) tables, issue a `SHOW TABLE STATUS` statement:

```
mysql > SHOW TABLE STATUS FROM test LIKE 't%' \G;
***** 1. row *****
      Name: t1
      Engine: InnoDB
      Version: 10
      Row_format: Compact
        Rows: 0
    Avg_row_length: 0
      Data_length: 16384
    Max_data_length: 0
      Index_length: 0
        Data_free: 0
    Auto_increment: NULL
```

```
Create_time: 2015-03-16 15:13:31
Update_time: NULL
Check_time: NULL
Collation: latin1_swedish_ci
Checksum: NULL
Create_options:
Comment:
1 row in set (0.00 sec)
```

In the status output, you see the [Row format](#) property of table `t1` is `Compact`. The [Dynamic](#) or [Compressed](#) row format is required take advantage of [InnoDB](#) features such as table compression and off-page storage for long column values. To use these row formats, you can enable [innodb\\_file\\_per\\_table](#) (the default as of MySQL 5.6.6) and set [innodb\\_file\\_format](#) to [Barracuda](#), which implicitly creates [InnoDB](#) tables in file-per-table tablespaces:

```
SET GLOBAL innodb_file_per_table=1;
SET GLOBAL innodb_file_format=barracuda;
CREATE TABLE t3 (a INT, b CHAR (20), PRIMARY KEY (a)) ROW_FORMAT=DYNAMIC;
CREATE TABLE t4 (a INT, b CHAR (20), PRIMARY KEY (a)) ROW_FORMAT=COMPRESSED;
```

Or, you can use [CREATE TABLE ... TABLESPACE](#) syntax to create an [InnoDB](#) table in a general tablespace. General tablespaces support all row formats. For more information, see [Section 15.7.9, “InnoDB General Tablespaces”](#).

```
CREATE TABLE t1 (c1 INT PRIMARY KEY) TABLESPACE ts1 ROW_FORMAT=DYNAMIC;
```

[CREATE TABLE ... TABLESPACE](#) syntax can also be used to create [InnoDB](#) tables with a [Dynamic](#) row format in the system tablespace, along side tables with a [Compact](#) or [Redundant](#) row format.

```
CREATE TABLE t1 (c1 INT PRIMARY KEY) TABLESPACE = innodb_system ROW_FORMAT=DYNAMIC;
```

[InnoDB](#) table properties may also be queried using the [InnoDB](#) Information Schema system tables:

```
SELECT * FROM INFORMATION_SCHEMA.INNODB_SYS_TABLES WHERE NAME='test/t1' \G
***** 1. row *****
TABLE_ID: 45
NAME: test/t1
FLAG: 1
N_COLS: 5
SPACE: 35
FILE_FORMAT: Antelope
ROW_FORMAT: Compact
ZIP_PAGE_SIZE: 0
SPACE_TYPE: Single
1 row in set (0.00 sec)
```

## Defining a Primary Key for InnoDB Tables

Always set up a [primary key](#) for each [InnoDB](#) table, specifying the column or columns that:

- Are referenced by the most important queries.
- Are never left blank.
- Never have duplicate values.
- Rarely if ever change value once inserted.

For example, in a table containing information about people, you would not create a primary key on [\(firstname, lastname\)](#) because more than one person can have the same name, some people have blank last names, and sometimes people change their names. With so many constraints, often there is not an obvious set of columns to use as a primary key, so you create a new column with a numeric ID to serve as all or part of the primary key. You can declare an [auto-increment](#) column so that ascending values are filled in automatically as rows are inserted:

```
-- The value of ID can act like a pointer between related items in different tables.
```

```
CREATE TABLE t5 (id INT AUTO_INCREMENT, b CHAR (20), PRIMARY KEY (id));
-- The primary key can consist of more than one column. Any autoinc column must come first.
CREATE TABLE t6 (id INT AUTO_INCREMENT, a INT, b CHAR (20), PRIMARY KEY (id,a));
```

Although the table works correctly without defining a primary key, the primary key is involved with many aspects of performance and is a crucial design aspect for any large or frequently used table. It is recommended that you always specify a primary key in the `CREATE TABLE` statement. If you create the table, load data, and then run `ALTER TABLE` to add a primary key later, that operation is much slower than defining the primary key when creating the table.

## 15.8.2 Role of the .frm File for InnoDB Tables

MySQL stores its data dictionary information for tables in [.frm files](#) in database directories. Unlike other MySQL storage engines, [InnoDB](#) also encodes information about the table in its own internal data dictionary inside the tablespace. When MySQL drops a table or a database, it deletes one or more [.frm](#) files as well as the corresponding entries inside the [InnoDB](#) data dictionary. You cannot move [InnoDB](#) tables between databases simply by moving the [.frm](#) files.

## 15.8.3 Physical Row Structure of InnoDB Tables

The physical row structure of an [InnoDB](#) table depends on the row format specified when the table is created. If a row format is not specified, the default row format is used. In MySQL 5.7.6 and earlier, [InnoDB](#) uses the [Antelope](#) file format and its `COMPACT` row format by default. In MySQL 5.7.7, the `innodb_file_format` default was changed to `Barracuda`, and in MySQL 5.7.9, the default row format is defined by the `innodb_default_row_format` configuration option, which has a default value of `DYNAMIC`.

The `REDUNDANT` format is available to retain compatibility with older versions of MySQL.

To check the row format of an [InnoDB](#) table, you can use `SHOW TABLE STATUS`. For example:

```
mysql> SHOW TABLE STATUS IN test1\G
***** 1. row *****
      Name: t1
      Engine: InnoDB
      Version: 10
      Row_format: Dynamic
      Rows: 0
      Avg_row_length: 0
      Data_length: 16384
      Max_data_length: 0
      Index_length: 16384
      Data_free: 0
      Auto_increment: 1
      Create_time: 2016-09-14 16:29:38
      Update_time: NULL
      Check_time: NULL
      Collation: latin1_swedish_ci
      Checksum: NULL
      Create_options:
      Comment:
```

You can also check the row format of an [InnoDB](#) table by querying `INFORMATION_SCHEMA.INNODB_SYS_TABLES`.

```
mysql> SELECT NAME, ROW_FORMAT FROM INFORMATION_SCHEMA.INNODB_SYS_TABLES WHERE NAME='test1/t1';
+-----+-----+
| NAME      | ROW_FORMAT |
+-----+-----+
| test1/t1  | Dynamic   |
+-----+-----+
```

## Redundant Row Format Characteristics

Rows in [InnoDB](#) tables that use `REDUNDANT` row format have the following characteristics:

- Each index record contains a 6-byte header. The header is used to link together consecutive records, and also in row-level locking.
- Records in the clustered index contain fields for all user-defined columns. In addition, there is a 6-byte transaction ID field and a 7-byte roll pointer field.
- If no primary key was defined for a table, each clustered index record also contains a 6-byte row ID field.
- Each secondary index record also contains all the primary key fields defined for the clustered index key that are not in the secondary index.
- A record contains a pointer to each field of the record. If the total length of the fields in a record is less than 128 bytes, the pointer is one byte; otherwise, two bytes. The array of these pointers is called the record directory. The area where these pointers point is called the data part of the record.
- Internally, [InnoDB](#) stores fixed-length character columns such as [CHAR\(10\)](#) in a fixed-length format. [InnoDB](#) does not truncate trailing spaces from [VARCHAR](#) columns.
- [InnoDB](#) encodes fixed-length fields greater than or equal to 768 bytes in length as variable-length fields, which can be stored off-page. For example, a [CHAR\(255\)](#) column can exceed 768 bytes if the maximum byte length of the character set is greater than 3, as it is with [utf8mb4](#).
- An SQL [NULL](#) value reserves one or two bytes in the record directory. Besides that, an SQL [NULL](#) value reserves zero bytes in the data part of the record if stored in a variable length column. In a fixed-length column, it reserves the fixed length of the column in the data part of the record. Reserving the fixed space for [NULL](#) values enables an update of the column from [NULL](#) to a non-[NULL](#) value to be done in place without causing fragmentation of the index page.

## COMPACT Row Format Characteristics

The [COMPACT](#) row format decreases row storage space by about 20% compared to the [REDUNDANT](#) format at the cost of increasing CPU use for some operations. If your workload is a typical one that is limited by cache hit rates and disk speed, [COMPACT](#) format is likely to be faster. If the workload is a rare case that is limited by CPU speed, compact format might be slower.

Rows in [InnoDB](#) tables that use [COMPACT](#) row format have the following characteristics:

- Each index record contains a 5-byte header that may be preceded by a variable-length header. The header is used to link together consecutive records, and also in row-level locking.
- The variable-length part of the record header contains a bit vector for indicating [NULL](#) columns. If the number of columns in the index that can be [NULL](#) is  $N$ , the bit vector occupies  $\text{CEILING}(N/8)$  bytes. (For example, if there are anywhere from 9 to 15 columns that can be [NULL](#), the bit vector uses two bytes.) Columns that are [NULL](#) do not occupy space other than the bit in this vector. The variable-length part of the header also contains the lengths of variable-length columns. Each length takes one or two bytes, depending on the maximum length of the column. If all columns in the index are [NOT NULL](#) and have a fixed length, the record header has no variable-length part.
- For each non-[NULL](#) variable-length field, the record header contains the length of the column in one or two bytes. Two bytes are only needed if part of the column is stored externally in overflow pages or the maximum length exceeds 255 bytes and the actual length exceeds 127 bytes. For an externally stored column, the 2-byte length indicates the length of the internally stored part plus the 20-byte pointer to the externally stored part. The internal part is 768 bytes, so the length is 768+20. The 20-byte pointer stores the true length of the column.
- The record header is followed by the data contents of the non-[NULL](#) columns.
- Records in the clustered index contain fields for all user-defined columns. In addition, there is a 6-byte transaction ID field and a 7-byte roll pointer field.

- If no primary key was defined for a table, each clustered index record also contains a 6-byte row ID field.
- Each secondary index record also contains all the primary key fields defined for the clustered index key that are not in the secondary index. If any of these primary key fields are variable length, the record header for each secondary index has a variable-length part to record their lengths, even if the secondary index is defined on fixed-length columns.
- Internally, for nonvariable-length character sets, InnoDB stores fixed-length character columns such as `CHAR(10)` in a fixed-length format.

InnoDB does not truncate trailing spaces from `VARCHAR` columns.

- Internally, for variable-length character sets such as `utf8mb3` and `utf8mb4`, InnoDB attempts to store `CHAR(N)` in `N` bytes by trimming trailing spaces. If the byte length of a `CHAR(N)` column value exceeds `N` bytes, InnoDB trims trailing spaces to a minimum of the column value byte length. The maximum length of a `CHAR(N)` column is the maximum character byte length  $\times N$ .

InnoDB reserves a minimum of `N` bytes for `CHAR(N)`. Reserving the minimum space `N` in many cases enables column updates to be done in place without causing fragmentation of the index page. By comparison, for `ROW_FORMAT=REDUNDANT`, `CHAR(N)` columns occupy the maximum character byte length  $\times N$ .

InnoDB encodes fixed-length fields greater than or equal to 768 bytes in length as variable-length fields, which can be stored off-page. For example, a `CHAR(255)` column can exceed 768 bytes if the maximum byte length of the character set is greater than 3, as it is with `utf8mb4`.

`ROW_FORMAT=DYNAMIC` and `ROW_FORMAT=COMPRESSED` handle `CHAR` storage in the same way as `ROW_FORMAT=COMPACT`.

## DYNAMIC and COMPRESSED Row Formats

`DYNAMIC` and `COMPRESSED` row formats are variations of the `COMPACT` row format. For information about these row formats, see [Section 15.11.3, “DYNAMIC and COMPRESSED Row Formats”](#).

## 15.8.4 Moving or Copying InnoDB Tables to Another Machine

This section describes techniques for moving or copying some or all InnoDB tables to a different server. For example, you might move an entire MySQL instance to a larger, faster server; you might clone an entire MySQL instance to a new replication slave server; you might copy individual tables to another server to develop and test an application, or to a data warehouse server to produce reports.

Techniques for moving or copying InnoDB tables include:

- [Transportable Tablespaces](#)
- [MySQL Enterprise Backup](#)
- [Copying Data Files \(Cold Backup Method\)](#)
- [Export and Import \(mysqldump\)](#)

## Using Lowercase Names for Cross-Platform Moving or Copying

On Windows, InnoDB always stores database and table names internally in lowercase. To move databases in a binary format from Unix to Windows or from Windows to Unix, create all databases and tables using lowercase names. A convenient way to accomplish this is to add the following line to the `[mysqld]` section of your `my.cnf` or `my.ini` file before creating any databases or tables:

```
[mysqld]
```

```
lower_case_table_names=1
```

## Transportable Tablespaces

Introduced in MySQL 5.6.6, the transportable tablespaces feature uses `FLUSH TABLES ... FOR EXPORT` to ready `InnoDB` tables for copying from one server instance to another. To use this feature, `InnoDB` tables must be created with `innodb_file_per_table` set to `ON` so that each `InnoDB` table has its own tablespace. For usage information, see [Section 15.7.6, “Copying File-Per-Table Tablespaces to Another Server”](#).

## MySQL Enterprise Backup

The MySQL Enterprise Backup product lets you back up a running MySQL database, including `InnoDB` and `MyISAM` tables, with minimal disruption to operations while producing a consistent snapshot of the database. When MySQL Enterprise Backup is copying `InnoDB` tables, reads and writes to both `InnoDB` and `MyISAM` tables can continue. During the copying of `MyISAM` and other non-`InnoDB` tables, reads (but not writes) to those tables are permitted. In addition, MySQL Enterprise Backup can create compressed backup files, and back up subsets of `InnoDB` tables. In conjunction with the MySQL binary log, you can perform point-in-time recovery. MySQL Enterprise Backup is included as part of the MySQL Enterprise subscription.

For more details about MySQL Enterprise Backup, see [Section 28.2, “MySQL Enterprise Backup Overview”](#).

## Copying Data Files (Cold Backup Method)

You can move an `InnoDB` database simply by copying all the relevant files listed under “Cold Backups” in [Section 15.18, “InnoDB Backup and Recovery”](#).

Like `MyISAM` data files, `InnoDB` data and log files are binary-compatible on all platforms having the same floating-point number format. If the floating-point formats differ but you have not used `FLOAT` or `DOUBLE` data types in your tables, then the procedure is the same: simply copy the relevant files.

## Portability Considerations for File-Per-Table .ibd Files

When you move or copy file-per-table `.ibd` files, the database directory name must be the same on the source and destination systems. The table definition stored in the `InnoDB` shared tablespace includes the database name. The transaction IDs and log sequence numbers stored in the tablespace files also differ between databases.

To move an `.ibd` file and the associated table from one database to another, use a `RENAME TABLE` statement:

```
RENAME TABLE db1.tbl_name TO db2.tbl_name;
```

If you have a “clean” backup of an `.ibd` file, you can restore it to the MySQL installation from which it originated as follows:

1. The table must not have been dropped or truncated since you copied the `.ibd` file, because doing so changes the table ID stored inside the tablespace.
2. Issue this `ALTER TABLE` statement to delete the current `.ibd` file:

```
ALTER TABLE tbl_name DISCARD TABLESPACE;
```

3. Copy the backup `.ibd` file to the proper database directory.
4. Issue this `ALTER TABLE` statement to tell `InnoDB` to use the new `.ibd` file for the table:

```
ALTER TABLE tbl_name IMPORT TABLESPACE;
```

#### Note

The `ALTER TABLE ... IMPORT TABLESPACE` feature does not enforce foreign key constraints on imported data.

In this context, a “clean” `.ibd` file backup is one for which the following requirements are satisfied:

- There are no uncommitted modifications by transactions in the `.ibd` file.
- There are no unmerged insert buffer entries in the `.ibd` file.
- Purge has removed all delete-marked index records from the `.ibd` file.
- `mysqld` has flushed all modified pages of the `.ibd` file from the buffer pool to the file.

You can make a clean backup `.ibd` file using the following method:

1. Stop all activity from the `mysqld` server and commit all transactions.
2. Wait until `SHOW ENGINE INNODB STATUS` shows that there are no active transactions in the database, and the main thread status of InnoDB is `Waiting for server activity`. Then you can make a copy of the `.ibd` file.

Another method for making a clean copy of an `.ibd` file is to use the MySQL Enterprise Backup product:

1. Use MySQL Enterprise Backup to back up the InnoDB installation.
2. Start a second `mysqld` server on the backup and let it clean up the `.ibd` files in the backup.

## Export and Import (mysqldump)

You can use `mysqldump` to dump your tables on one machine and then import the dump files on the other machine. Using this method, it does not matter whether the formats differ or if your tables contain floating-point data.

One way to increase the performance of this method is to switch off `autocommit` mode when importing data, assuming that the tablespace has enough space for the big rollback segment that the import transactions generate. Do the commit only after importing a whole table or a segment of a table.

## 15.8.5 Converting Tables from MyISAM to InnoDB

If you have `MyISAM` tables that you want to convert to `InnoDB` for better reliability and scalability, review the following guidelines and tips before making the conversion.

- [Reduce Memory Usage for MyISAM, Increase Memory Usage for InnoDB](#)
- [Watch Out for Too-Long Or Too-Short Transactions](#)
- [Don't Worry Too Much About Deadlocks](#)
- [Plan the Storage Layout](#)
- [Converting an Existing Table](#)
- [Cloning the Structure of a Table](#)
- [Transferring Existing Data](#)
- [Storage Requirements](#)

- [Carefully Choose a PRIMARY KEY for Each Table](#)
- [Application Performance Considerations](#)
- [Understand Files Associated with InnoDB Tables](#)

## Reduce Memory Usage for MyISAM, Increase Memory Usage for InnoDB

As you transition away from [MyISAM](#) tables, lower the value of the [key\\_buffer\\_size](#) configuration option to free memory no longer needed for caching results. Increase the value of the [innodb\\_buffer\\_pool\\_size](#) configuration option, which performs a similar role of allocating cache memory for [InnoDB](#) tables. The [InnoDB buffer pool](#) caches both table data and index data, so it does double duty in speeding up lookups for queries and keeping query results in memory for reuse. For guidance regarding buffer pool size configuration, see [Section 9.12.4.1, “How MySQL Uses Memory”](#).

On a busy server, run benchmarks with the Query Cache turned off. The [InnoDB](#) buffer pool provides similar benefits, so the Query Cache might be tying up memory unnecessarily.

## Watch Out for Too-Long Or Too-Short Transactions

Because [MyISAM](#) tables do not support [transactions](#), you might not have paid much attention to the [autocommit](#) configuration option and the [COMMIT](#) and [ROLLBACK](#) statements. These keywords are important to allow multiple sessions to read and write [InnoDB](#) tables concurrently, providing substantial scalability benefits in write-heavy workloads.

While a transaction is open, the system keeps a snapshot of the data as seen at the beginning of the transaction, which can cause substantial overhead if the system inserts, updates, and deletes millions of rows while a stray transaction keeps running. Thus, take care to avoid transactions that run for too long:

- If you are using a [mysql](#) session for interactive experiments, always [COMMIT](#) (to finalize the changes) or [ROLLBACK](#) (to undo the changes) when finished. Close down interactive sessions rather than leaving them open for long periods, to avoid keeping transactions open for long periods by accident.
- Make sure that any error handlers in your application also [ROLLBACK](#) incomplete changes or [COMMIT](#) completed changes.
- [ROLLBACK](#) is a relatively expensive operation, because [INSERT](#), [UPDATE](#), and [DELETE](#) operations are written to [InnoDB](#) tables prior to the [COMMIT](#), with the expectation that most changes will be committed successfully and rollbacks will be rare. When experimenting with large volumes of data, avoid making changes to large numbers of rows and then rolling back those changes.
- When loading large volumes of data with a sequence of [INSERT](#) statements, periodically [COMMIT](#) the results to avoid having transactions that last for hours. In typical load operations for data warehousing, if something goes wrong, you truncate the table (using [TRUNCATE TABLE](#)) and start over from the beginning rather than doing a [ROLLBACK](#).

The preceding tips save memory and disk space that can be wasted during too-long transactions. When transactions are shorter than they should be, the problem is excessive I/O. With each [COMMIT](#), MySQL makes sure each change is safely recorded to disk, which involves some I/O.

- For most operations on [InnoDB](#) tables, you should use the setting [autocommit=0](#). From an efficiency perspective, this avoids unnecessary I/O when you issue large numbers of consecutive [INSERT](#), [UPDATE](#), or [DELETE](#) statements. From a safety perspective, this allows you to issue a [ROLLBACK](#) statement to recover lost or garbled data if you make a mistake on the [mysql](#) command line, or in an exception handler in your application.
- The time when [autocommit=1](#) is suitable for [InnoDB](#) tables is when running a sequence of queries for generating reports or analyzing statistics. In this situation, there is no I/O penalty related to [COMMIT](#) or [ROLLBACK](#), and [InnoDB](#) can [automatically optimize the read-only workload](#).

- If you make a series of related changes, finalize all those changes at once with a single `COMMIT` at the end. For example, if you insert related pieces of information into several tables, do a single `COMMIT` after making all the changes. Or if you run many consecutive `INSERT` statements, do a single `COMMIT` after all the data is loaded; if you are doing millions of `INSERT` statements, perhaps split up the huge transaction by issuing a `COMMIT` every ten thousand or hundred thousand records, so the transaction does not grow too large.
- Remember that even a `SELECT` statement opens a transaction, so after running some report or debugging queries in an interactive `mysql` session, either issue a `COMMIT` or close the `mysql` session.

### Don't Worry Too Much About Deadlocks

You might see warning messages referring to “deadlocks” in the MySQL error log, or the output of `SHOW ENGINE INNODB STATUS`. Despite the scary-sounding name, a `deadlock` is not a serious issue for `InnoDB` tables, and often does not require any corrective action. When two transactions start modifying multiple tables, accessing the tables in a different order, they can reach a state where each transaction is waiting for the other and neither can proceed. When `deadlock detection` is enabled (the default), MySQL immediately detects this condition and cancels (`rolls back`) the “smaller” transaction, allowing the other to proceed. If deadlock detection is disabled using the `innodb_deadlock_detect` configuration option, `InnoDB` relies on the `innodb_lock_wait_timeout` setting to roll back transactions in case of a deadlock.

Either way, your applications need error-handling logic to restart a transaction that is forcibly cancelled due to a deadlock. When you re-issue the same SQL statements as before, the original timing issue no longer applies: either the other transaction has already finished and yours can proceed, or the other transaction is still in progress and your transaction waits until it finishes.

If deadlock warnings occur constantly, you might review the application code to reorder the SQL operations in a consistent way, or to shorten the transactions. You can test with the `innodb_print_all_deadlocks` option enabled to see all deadlock warnings in the MySQL error log, rather than only the last warning in the `SHOW ENGINE INNODB STATUS` output.

For more information, see [Section 15.5.5, “Deadlocks in InnoDB”](#).

### Plan the Storage Layout

To get the best performance from `InnoDB` tables, you can adjust a number of parameters related to storage layout.

When you convert `MyISAM` tables that are large, frequently accessed, and hold vital data, investigate and consider the `innodb_file_per_table`, `innodb_file_format`, and `innodb_page_size` configuration options, and the `ROW_FORMAT` and `KEY_BLOCK_SIZE` clauses of the `CREATE TABLE` statement.

During your initial experiments, the most important setting is `innodb_file_per_table`. When this setting is enabled, which is the default as of MySQL 5.6.6, new `InnoDB` tables are implicitly created in `file-per-table` tablespaces. In contrast with the `InnoDB` system tablespace, file-per-table tablespaces allow disk space to be reclaimed by the operating system when a table is truncated or dropped. File-per-table tablespaces also support the `Barracuda` file format and associated features such as table compression and off-page storage for long variable-length columns. For more information, see [Section 15.7.4, “InnoDB File-Per-Table Tablespaces”](#).

As of MySQL 5.7.6, you can also store `InnoDB` tables in a shared general tablespace. General tablespaces support the `Barracuda` file format and can contain multiple tables. For more information, see [Section 15.7.9, “InnoDB General Tablespaces”](#).

### Converting an Existing Table

To convert a non-`InnoDB` table to use `InnoDB` use `ALTER TABLE`:

```
ALTER TABLE table_name ENGINE=InnoDB;
```

### Important

Do not convert MySQL system tables in the `mysql` database from `MyISAM` to the `InnoDB` type. This is an unsupported operation. type.

## Cloning the Structure of a Table

You might make an `InnoDB` table that is a clone of a `MyISAM` table, rather than doing the `ALTER TABLE` conversion, to test the old and new table side-by-side before switching.

Create an empty `InnoDB` table with identical column and index definitions. Use `show create table table_name\G` to see the full `CREATE TABLE` statement to use. Change the `ENGINE` clause to `ENGINE=INNODB`.

## Transferring Existing Data

To transfer a large volume of data into an empty `InnoDB` table created as shown in the previous section, insert the rows with `INSERT INTO innodb_table SELECT * FROM myisam_table ORDER BY primary_key_columns`.

You can also create the indexes for the `InnoDB` table after inserting the data. Historically, creating new secondary indexes was a slow operation for `InnoDB`, but now you can create the indexes after the data is loaded with relatively little overhead from the index creation step.

If you have `UNIQUE` constraints on secondary keys, you can speed up a table import by turning off the uniqueness checks temporarily during the import operation:

```
SET unique_checks=0;
... import operation ...
SET unique_checks=1;
```

For big tables, this saves disk I/O because `InnoDB` can use its `change buffer` to write secondary index records as a batch. Be certain that the data contains no duplicate keys. `unique_checks` permits but does not require storage engines to ignore duplicate keys.

To get better control over the insertion process, you might insert big tables in pieces:

```
INSERT INTO newtable SELECT * FROM oldtable
WHERE yourkey > something AND yourkey <= somethingelse;
```

After all records have been inserted, you can rename the tables.

During the conversion of big tables, increase the size of the `InnoDB` buffer pool to reduce disk I/O, to a maximum of 80% of physical memory. You can also increase the sizes of the `InnoDB` log files.

## Storage Requirements

If you intend to make several temporary copies of your data in `InnoDB` tables during the conversion process, it is recommended that you create the tables in file-per-table tablespaces so that you can reclaim the disk space when you drop the tables. As mentioned previously, when the `innodb_file_per_table` option is enabled (the default), newly created `InnoDB` tables are implicitly created in file-per-table tablespaces.

Whether you convert the `MyISAM` table directly or create a cloned `InnoDB` table, make sure that you have sufficient disk space to hold both the old and new tables during the process. **InnoDB tables require more disk space than MyISAM tables.** If an `ALTER TABLE` operation runs out of space, it starts a rollback, and that can take hours if it is disk-bound. For inserts, `InnoDB` uses the insert buffer

to merge secondary index records to indexes in batches. That saves a lot of disk I/O. For rollback, no such mechanism is used, and the rollback can take 30 times longer than the insertion.

In the case of a runaway rollback, if you do not have valuable data in your database, it may be advisable to kill the database process rather than wait for millions of disk I/O operations to complete. For the complete procedure, see [Section 15.21.2, “Forcing InnoDB Recovery”](#).

## Carefully Choose a PRIMARY KEY for Each Table

The `PRIMARY KEY` clause is a critical factor affecting the performance of MySQL queries and the space usage for tables and indexes. Perhaps you have phoned a financial institution where you are asked for an account number. If you do not have the number, you are asked for a dozen different pieces of information to “uniquely identify” yourself. The primary key is like that unique account number that lets you get straight down to business when querying or modifying the information in a table. Every row in the table must have a primary key value, and no two rows can have the same primary key value.

Here are guidelines for the primary key, followed by more detailed explanations.

- Declare a `PRIMARY KEY` for each table. Typically, it is the most important column that you refer to in `WHERE` clauses when looking up a single row.
- Declare the `PRIMARY KEY` clause in the original `CREATE TABLE` statement, rather than adding it later through an `ALTER TABLE` statement.
- Choose the column and its data type carefully. Prefer numeric columns over character or string ones.
- Consider using an auto-increment column if there is not another stable, unique, non-null, numeric column to use.
- An auto-increment column is also a good choice if there is any doubt whether the value of the primary key column could ever change. Changing the value of a primary key column is an expensive operation, possibly involving rearranging data within the table and within each secondary index.

Consider adding a `primary key` to any table that does not already have one. Use the smallest practical numeric type based on the maximum projected size of the table. This can make each row slightly more compact, which can yield substantial space savings for large tables. The space savings are multiplied if the table has any `secondary indexes`, because the primary key value is repeated in each secondary index entry. In addition to reducing data size on disk, a small primary key also lets more data fit into the `buffer pool`, speeding up all kinds of operations and improving concurrency.

If the table already has a primary key on some longer column, such as a `VARCHAR`, consider adding a new unsigned `AUTO_INCREMENT` column and switching the primary key to that, even if that column is not referenced in queries. This design change can produce substantial space savings in the secondary indexes. You can designate the former primary key columns as `UNIQUE NOT NULL` to enforce the same constraints as the `PRIMARY KEY` clause, that is, to prevent duplicate or null values across all those columns.

If you spread related information across multiple tables, typically each table uses the same column for its primary key. For example, a personnel database might have several tables, each with a primary key of employee number. A sales database might have some tables with a primary key of customer number, and other tables with a primary key of order number. Because lookups using the primary key are very fast, you can construct efficient join queries for such tables.

If you leave the `PRIMARY KEY` clause out entirely, MySQL creates an invisible one for you. It is a 6-byte value that might be longer than you need, thus wasting space. Because it is hidden, you cannot refer to it in queries.

## Application Performance Considerations

The extra reliability and scalability features of `InnoDB` do require more disk storage than equivalent `MyISAM` tables. You might change the column and index definitions slightly, for better space utilization,

reduced I/O and memory consumption when processing result sets, and better query optimization plans making efficient use of index lookups.

If you do set up a numeric ID column for the primary key, use that value to cross-reference with related values in any other tables, particularly for [join](#) queries. For example, rather than accepting a country name as input and doing queries searching for the same name, do one lookup to determine the country ID, then do other queries (or a single join query) to look up relevant information across several tables. Rather than storing a customer or catalog item number as a string of digits, potentially using up several bytes, convert it to a numeric ID for storing and querying. A 4-byte unsigned [INT](#) column can index over 4 billion items (with the US meaning of billion: 1000 million). For the ranges of the different integer types, see [Section 12.2.1, “Integer Types \(Exact Value\) - INTEGER, INT, SMALLINT, TINYINT, MEDIUMINT, BIGINT”](#).

## Understand Files Associated with InnoDB Tables

[InnoDB](#) files require more care and planning than [MyISAM](#) files do:

- You must not delete the [ibdata files](#) that represent the [InnoDB system tablespace](#).
- Copying [InnoDB](#) tables from one server to another requires issuing the `FLUSH TABLES ... FOR EXPORT` statement first, and copying the `table_name.cfg` file along with the `table_name.ibd` file.

## 15.8.6 AUTO\_INCREMENT Handling in InnoDB

[InnoDB](#) provides a configurable locking mechanism that can significantly improve scalability and performance of SQL statements that add rows to tables with [AUTO\\_INCREMENT](#) columns. To use the [AUTO\\_INCREMENT](#) mechanism with an [InnoDB](#) table, an [AUTO\\_INCREMENT](#) column must be defined as part of an index such that it is possible to perform the equivalent of an indexed `SELECT MAX(ai_col)` lookup on the table to obtain the maximum column value. Typically, this is achieved by making the column the first column of some table index.

This section describes the behavior of [AUTO\\_INCREMENT](#) lock modes, usage implications for different [AUTO\\_INCREMENT](#) lock mode settings, and how [InnoDB](#) initializes the [AUTO\\_INCREMENT](#) counter.

- [InnoDB AUTO\\_INCREMENT Lock Modes](#)
- [InnoDB AUTO\\_INCREMENT Lock Mode Usage Implications](#)
- [InnoDB AUTO\\_INCREMENT Counter Initialization](#)

### InnoDB AUTO\_INCREMENT Lock Modes

This section describes the behavior of [AUTO\\_INCREMENT](#) lock modes used to generate auto-increment values, and how each lock mode affects replication. Auto-increment lock modes are configured at startup using the `innodb_autoinc_lock_mode` configuration parameter.

The following terms are used in describing `innodb_autoinc_lock_mode` settings:

- “[INSERT-like](#)” statements

All statements that generate new rows in a table, including [INSERT](#), [INSERT ... SELECT](#), [REPLACE](#), [REPLACE ... SELECT](#), and [LOAD DATA](#). Includes “simple-inserts”, “bulk-inserts”, and “mixed-mode” inserts.

- “Simple inserts”

Statements for which the number of rows to be inserted can be determined in advance (when the statement is initially processed). This includes single-row and multiple-row [INSERT](#) and [REPLACE](#) statements that do not have a nested subquery, but not [INSERT ... ON DUPLICATE KEY UPDATE](#).

- “Bulk inserts”

Statements for which the number of rows to be inserted (and the number of required auto-increment values) is not known in advance. This includes `INSERT ... SELECT`, `REPLACE ... SELECT`, and `LOAD DATA` statements, but not plain `INSERT`. InnoDB assigns new values for the `AUTO_INCREMENT` column one at a time as each row is processed.

- “Mixed-mode inserts”

These are “simple insert” statements that specify the auto-increment value for some (but not all) of the new rows. An example follows, where `c1` is an `AUTO_INCREMENT` column of table `t1`:

```
INSERT INTO t1 (c1,c2) VALUES (1,'a'), (NULL,'b'), (5,'c'), (NULL,'d');
```

Another type of “mixed-mode insert” is `INSERT ... ON DUPLICATE KEY UPDATE`, which in the worst case is in effect an `INSERT` followed by a `UPDATE`, where the allocated value for the `AUTO_INCREMENT` column may or may not be used during the update phase.

There are three possible settings for the `innodb_autoinc_lock_mode` configuration parameter. The settings are 0, 1, or 2, for “traditional”, “consecutive”, or “interleaved” lock mode, respectively.

- `innodb_autoinc_lock_mode = 0` (“traditional” lock mode)

The traditional lock mode provides the same behavior that existed before the `innodb_autoinc_lock_mode` configuration parameter was introduced in MySQL 5.1. The traditional lock mode option is provided for backward compatibility, performance testing, and working around issues with “mixed-mode inserts”, due to possible differences in semantics.

In this lock mode, all “INSERT-like” statements obtain a special table-level `AUTO-INC` lock for inserts into tables with `AUTO_INCREMENT` columns. This lock is normally held to the end of the statement (not to the end of the transaction) to ensure that auto-increment values are assigned in a predictable and repeatable order for a given sequence of `INSERT` statements, and to ensure that auto-increment values assigned by any given statement are consecutive.

In the case of statement-based replication, this means that when an SQL statement is replicated on a slave server, the same values are used for the auto-increment column as on the master server. The result of execution of multiple `INSERT` statements is deterministic, and the slave reproduces the same data as on the master. If auto-increment values generated by multiple `INSERT` statements were interleaved, the result of two concurrent `INSERT` statements would be nondeterministic, and could not reliably be propagated to a slave server using statement-based replication.

To make this clear, consider an example that uses this table:

```
CREATE TABLE t1 (
  c1 INT(11) NOT NULL AUTO_INCREMENT,
  c2 VARCHAR(10) DEFAULT NULL,
  PRIMARY KEY (c1)
) ENGINE=InnoDB;
```

Suppose that there are two transactions running, each inserting rows into a table with an `AUTO_INCREMENT` column. One transaction is using an `INSERT ... SELECT` statement that inserts 1000 rows, and another is using a simple `INSERT` statement that inserts one row:

```
Tx1: INSERT INTO t1 (c2) SELECT 1000 rows from another table ...
Tx2: INSERT INTO t1 (c2) VALUES ('xxx');
```

InnoDB cannot tell in advance how many rows will be retrieved from the `SELECT` in the `INSERT` statement in Tx1, and it assigns the auto-increment values one at a time as the statement proceeds. With a table-level lock, held to the end of the statement, only one `INSERT` statement referring to table `t1` can execute at a time, and the generation of auto-increment numbers by different

statements is not interleaved. The auto-increment value generated by the Tx1 `INSERT ... SELECT` statement will be consecutive, and the (single) auto-increment value used by the `INSERT` statement in Tx2 will either be smaller or larger than all those used for Tx1, depending on which statement executes first.

As long as the SQL statements execute in the same order when replayed from the binary log (when using statement-based replication, or in recovery scenarios), the results will be the same as they were when Tx1 and Tx2 first ran. Thus, table-level locks held until the end of a statement make `INSERT` statements using auto-increment safe for use with statement-based replication. However, those table-level locks limit concurrency and scalability when multiple transactions are executing insert statements at the same time.

In the preceding example, if there were no table-level lock, the value of the auto-increment column used for the `INSERT` in Tx2 depends on precisely when the statement executes. If the `INSERT` of Tx2 executes while the `INSERT` of Tx1 is running (rather than before it starts or after it completes), the specific auto-increment values assigned by the two `INSERT` statements are nondeterministic, and may vary from run to run.

Under the `consecutive` lock mode, InnoDB can avoid using table-level `AUTO-INC` locks for “simple insert” statements where the number of rows is known in advance, and still preserve deterministic execution and safety for statement-based replication.

If you are not using the binary log to replay SQL statements as part of recovery or replication, the `interleaved` lock mode can be used to eliminate all use of table-level `AUTO-INC` locks for even greater concurrency and performance, at the cost of permitting gaps in auto-increment numbers assigned by a statement and potentially having the numbers assigned by concurrently executing statements interleaved.

- `innodb_autoinc_lock_mode = 1` (“consecutive” lock mode)

This is the default lock mode. In this mode, “bulk inserts” use the special `AUTO-INC` table-level lock and hold it until the end of the statement. This applies to all `INSERT ... SELECT`, `REPLACE ... SELECT`, and `LOAD DATA` statements. Only one statement holding the `AUTO-INC` lock can execute at a time.

“Simple inserts” (for which the number of rows to be inserted is known in advance) avoid table-level `AUTO-INC` locks by obtaining the required number of auto-increment values under the control of a mutex (a light-weight lock) that is only held for the duration of the allocation process, *not* until the statement completes. No table-level `AUTO-INC` lock is used unless an `AUTO-INC` lock is held by another transaction. If another transaction holds an `AUTO-INC` lock, a “simple insert” waits for the `AUTO-INC` lock, as if it were a “bulk insert”.

This lock mode ensures that, in the presence of `INSERT` statements where the number of rows is not known in advance (and where auto-increment numbers are assigned as the statement progresses), all auto-increment values assigned by any “`INSERT`-like” statement are consecutive, and operations are safe for statement-based replication.

Simply put, this lock mode significantly improves scalability while being safe for use with statement-based replication. Further, as with “traditional” lock mode, auto-increment numbers assigned by any given statement are *consecutive*. There is *no change* in semantics compared to “traditional” mode for any statement that uses auto-increment, with one important exception.

The exception is for “mixed-mode inserts”, where the user provides explicit values for an `AUTO_INCREMENT` column for some, but not all, rows in a multiple-row “simple insert”. For such inserts, InnoDB allocates more auto-increment values than the number of rows to be inserted. However, all values automatically assigned are consecutively generated (and thus higher than) the auto-increment value generated by the most recently executed previous statement. “Excess” numbers are lost.

- `innodb_autoinc_lock_mode = 2` (“interleaved” lock mode)

In this lock mode, no “[INSERT-like](#)” statements use the table-level [AUTO-INC](#) lock, and multiple statements can execute at the same time. This is the fastest and most scalable lock mode, but it is *not safe* when using statement-based replication or recovery scenarios when SQL statements are replayed from the binary log.

In this lock mode, auto-increment values are guaranteed to be unique and monotonically increasing across all concurrently executing “[INSERT-like](#)” statements. However, because multiple statements can be generating numbers at the same time (that is, allocation of numbers is *interleaved* across statements), the values generated for the rows inserted by any given statement may not be consecutive.

If the only statements executing are “simple inserts” where the number of rows to be inserted is known ahead of time, there will be no gaps in the numbers generated for a single statement, except for “mixed-mode inserts”. However, when “bulk inserts” are executed, there may be gaps in the auto-increment values assigned by any given statement.

## InnoDB AUTO\_INCREMENT Lock Mode Usage Implications

- Using auto-increment with replication

If you are using statement-based replication, set `innodb_autoinc_lock_mode` to 0 or 1 and use the same value on the master and its slaves. Auto-increment values are not ensured to be the same on the slaves as on the master if you use `innodb_autoinc_lock_mode = 2` (“interleaved”) or configurations where the master and slaves do not use the same lock mode.

If you are using row-based or mixed-format replication, all of the auto-increment lock modes are safe, since row-based replication is not sensitive to the order of execution of the SQL statements (and the mixed format uses row-based replication for any statements that are unsafe for statement-based replication).

- “Lost” auto-increment values and sequence gaps

In all lock modes (0, 1, and 2), if a transaction that generated auto-increment values rolls back, those auto-increment values are “lost”. Once a value is generated for an auto-increment column, it cannot be rolled back, whether or not the “[INSERT-like](#)” statement is completed, and whether or not the containing transaction is rolled back. Such lost values are not reused. Thus, there may be gaps in the values stored in an [AUTO\\_INCREMENT](#) column of a table.

- Specifying NULL or 0 for the [AUTO\\_INCREMENT](#) column

In all lock modes (0, 1, and 2), if a user specifies NULL or 0 for the [AUTO\\_INCREMENT](#) column in an [INSERT](#), InnoDB treats the row as if the value was not specified and generates a new value for it.

- Assigning a negative value to the [AUTO\\_INCREMENT](#) column

In all lock modes (0, 1, and 2), the behavior of the auto-increment mechanism is not defined if you assign a negative value to the [AUTO\\_INCREMENT](#) column.

- If the [AUTO\\_INCREMENT](#) value becomes larger than the maximum integer for the specified integer type

In all lock modes (0, 1, and 2), the behavior of the auto-increment mechanism is not defined if the value becomes larger than the maximum integer that can be stored in the specified integer type.

- Gaps in auto-increment values for “bulk inserts”

With `innodb_autoinc_lock_mode` set to 0 (“traditional”) or 1 (“consecutive”), the auto-increment values generated by any given statement are consecutive, without gaps, because the table-level [AUTO-INC](#) lock is held until the end of the statement, and only one such statement can execute at a time.

With `innodb_autoinc_lock_mode` set to 2 (“interleaved”), there may be gaps in the auto-increment values generated by “bulk inserts,” but only if there are concurrently executing “`INSERT`-like” statements.

For lock modes 1 or 2, gaps may occur between successive statements because for bulk inserts the exact number of auto-increment values required by each statement may not be known and overestimation is possible.

- Auto-increment values assigned by “mixed-mode inserts”

Consider a “mixed-mode insert,” where a “simple insert” specifies the auto-increment value for some (but not all) resulting rows. Such a statement behaves differently in lock modes 0, 1, and 2. For example, assume `c1` is an `AUTO_INCREMENT` column of table `t1`, and that the most recent automatically generated sequence number is 100.

```
mysql> CREATE TABLE t1 (
  -> c1 INT UNSIGNED NOT NULL AUTO_INCREMENT PRIMARY KEY,
  -> c2 CHAR(1)
  -> ) ENGINE = INNODB;

mysql> INSERT INTO t1 VALUES(1,'a'),(101,'b'),(5,'c'),(102,'d');
```

Now, consider the following “mixed-mode insert” statement:

```
mysql> INSERT INTO t1 (c1,c2) VALUES (1,'a'), (NULL,'b'), (5,'c'), (NULL,'d');
```

With `innodb_autoinc_lock_mode` set to 0 (“traditional”), the four new rows are:

```
mysql> SELECT c1, c2 FROM t1 ORDER BY c2;
+-----+-----+
| c1 | c2 |
+-----+-----+
| 1 | a |
| 101 | b |
| 5 | c |
| 102 | d |
+-----+-----+
```

The next available auto-increment value is 103 because the auto-increment values are allocated one at a time, not all at once at the beginning of statement execution. This result is true whether or not there are concurrently executing “`INSERT`-like” statements (of any type).

With `innodb_autoinc_lock_mode` set to 1 (“consecutive”), the four new rows are also:

```
mysql> SELECT c1, c2 FROM t1 ORDER BY c2;
+-----+-----+
| c1 | c2 |
+-----+-----+
| 1 | a |
| 101 | b |
| 5 | c |
| 102 | d |
+-----+-----+
```

However, in this case, the next available auto-increment value is 105, not 103 because four auto-increment values are allocated at the time the statement is processed, but only two are used. This result is true whether or not there are concurrently executing “`INSERT`-like” statements (of any type).

With `innodb_autoinc_lock_mode` set to mode 2 (“interleaved”), the four new rows are:

```
mysql> SELECT c1, c2 FROM t1 ORDER BY c2;
+-----+-----+
```

| c1       | c2 |
|----------|----|
| 1        | a  |
| <i>x</i> | b  |
| 5        | c  |
| <i>y</i> | d  |

The values of *x* and *y* are unique and larger than any previously generated rows. However, the specific values of *x* and *y* depend on the number of auto-increment values generated by concurrently executing statements.

Finally, consider the following statement, issued when the most-recently generated sequence number was the value 4:

```
mysql> INSERT INTO t1 (c1,c2) VALUES (1,'a'), (NULL,'b'), (5,'c'), (NULL,'d');
```

With any `innodb_autoinc_lock_mode` setting, this statement generates a duplicate-key error 23000 (Can't write; duplicate key in table) because 5 is allocated for the row (NULL, 'b') and insertion of the row (5, 'c') fails.

- Modifying `AUTO_INCREMENT` column values in the middle of a sequence of `INSERT` statements

In all lock modes (0, 1, and 2), modifying an `AUTO_INCREMENT` column value in the middle of a sequence of `INSERT` statements could lead to “Duplicate entry” errors. For example, if you perform an `UPDATE` operation that changes an `AUTO_INCREMENT` column value to a value larger than the current maximum auto-increment value, subsequent `INSERT` operations that do not specify an unused auto-increment value could encounter “Duplicate entry” errors. This behavior is demonstrated in the following example.

```
mysql> CREATE TABLE t1 (
-> c1 INT NOT NULL AUTO_INCREMENT,
-> PRIMARY KEY (c1)
-> ) ENGINE = InnoDB;

mysql> INSERT INTO t1 VALUES(0), (0), (3);

mysql> SELECT c1 FROM t1;
+-----+
| c1 |
+-----+
| 1 |
| 2 |
| 3 |
+-----+

mysql> UPDATE t1 SET c1 = 4 WHERE c1 = 1;

mysql> SELECT c1 FROM t1;
+-----+
| c1 |
+-----+
| 2 |
| 3 |
| 4 |
+-----+

mysql> INSERT INTO t1 VALUES(0);
ERROR 1062 (23000): Duplicate entry '4' for key 'PRIMARY'
```

## InnoDB AUTO\_INCREMENT Counter Initialization

This section describes how InnoDB initializes `AUTO_INCREMENT` counters.

If you specify an `AUTO_INCREMENT` column for an `InnoDB` table, the table handle in the `InnoDB` data dictionary contains a special counter called the auto-increment counter that is used in assigning new values for the column. This counter is stored only in main memory, not on disk.

To initialize an auto-increment counter after a server restart, `InnoDB` executes the equivalent of the following statement on the first insert into a table containing an `AUTO_INCREMENT` column.

```
SELECT MAX(ai_col) FROM table_name FOR UPDATE;
```

`InnoDB` increments the value retrieved by the statement and assigns it to the column and to the auto-increment counter for the table. By default, the value is incremented by 1. This default can be overridden by the `auto_increment_increment` configuration setting.

If the table is empty, `InnoDB` uses the value 1. This default can be overridden by the `auto_increment_offset` configuration setting.

If a `SHOW TABLE STATUS` statement examines the table before the auto-increment counter is initialized, `InnoDB` initializes but does not increment the value. The value is stored for use by later inserts. This initialization uses a normal exclusive-locking read on the table and the lock lasts to the end of the transaction. `InnoDB` follows the same procedure for initializing the auto-increment counter for a newly created table.

After the auto-increment counter has been initialized, if you do not explicitly specify a value for an `AUTO_INCREMENT` column, `InnoDB` increments the counter and assigns the new value to the column. If you insert a row that explicitly specifies the column value, and the value is greater than the current counter value, the counter is set to the specified column value.

`InnoDB` uses the in-memory auto-increment counter as long as the server runs. When the server is stopped and restarted, `InnoDB` reinitializes the counter for each table for the first `INSERT` to the table, as described earlier.

A server restart also cancels the effect of the `AUTO_INCREMENT = N` table option in `CREATE TABLE` and `ALTER TABLE` statements, which you can use with `InnoDB` tables to set the initial counter value or alter the current counter value.

## 15.8.7 InnoDB and FOREIGN KEY Constraints

This section describes differences in the `InnoDB` storage engine's handling of foreign keys as compared with that of the MySQL Server.

For foreign key usage information and examples, see [Section 14.1.18.5, “Using FOREIGN KEY Constraints”](#).

### Foreign Key Definitions

Foreign key definitions for `InnoDB` tables are subject to the following conditions:

- `InnoDB` permits a foreign key to reference any index column or group of columns. However, in the referenced table, there must be an index where the referenced columns are listed as the *first* columns in the same order.
- `InnoDB` does not currently support foreign keys for tables with user-defined partitioning. This means that no user-partitioned `InnoDB` table may contain foreign key references or columns referenced by foreign keys.
- `InnoDB` allows a foreign key constraint to reference a non-unique key. *This is an `InnoDB` extension to standard SQL.*

### Referential Actions

Referential actions for foreign keys of `InnoDB` tables are subject to the following conditions:

- While `SET DEFAULT` is allowed by the MySQL Server, it is rejected as invalid by InnoDB. `CREATE TABLE` and `ALTER TABLE` statements using this clause are not allowed for InnoDB tables.
- If there are several rows in the parent table that have the same referenced key value, InnoDB acts in foreign key checks as if the other parent rows with the same key value do not exist. For example, if you have defined a `RESTRICT` type constraint, and there is a child row with several parent rows, InnoDB does not permit the deletion of any of those parent rows.
- InnoDB performs cascading operations through a depth-first algorithm, based on records in the indexes corresponding to the foreign key constraints.
- If `ON UPDATE CASCADE` or `ON UPDATE SET NULL` recurses to update the *same table* it has previously updated during the cascade, it acts like `RESTRICT`. This means that you cannot use self-referential `ON UPDATE CASCADE` or `ON UPDATE SET NULL` operations. This is to prevent infinite loops resulting from cascaded updates. A self-referential `ON DELETE SET NULL`, on the other hand, is possible, as is a self-referential `ON DELETE CASCADE`. Cascading operations may not be nested more than 15 levels deep.
- Like MySQL in general, in an SQL statement that inserts, deletes, or updates many rows, InnoDB checks `UNIQUE` and `FOREIGN KEY` constraints row-by-row. When performing foreign key checks, InnoDB sets shared row-level locks on child or parent records it has to look at. InnoDB checks foreign key constraints immediately; the check is not deferred to transaction commit. According to the SQL standard, the default behavior should be deferred checking. That is, constraints are only checked after the *entire SQL statement* has been processed. Until InnoDB implements deferred constraint checking, some things are impossible, such as deleting a record that refers to itself using a foreign key.

## Foreign Key Restrictions for Generated Columns and Virtual Indexes

- A foreign key constraint on a [generated stored column](#) cannot use `ON UPDATE CASCADE`, `ON DELETE SET NULL`, `ON UPDATE SET NULL`, `ON DELETE SET DEFAULT`, or `ON UPDATE SET DEFAULT`.
- A foreign key constraint cannot reference a [generated virtual column](#).
- Prior to 5.7.16, a foreign key constraint cannot reference a secondary index defined on a generated virtual column.
- In MySQL 5.7.13 and earlier, InnoDB does not permit defining a foreign key constraint with a cascading referential action on the [base column](#) of an indexed generated virtual column. This restriction is lifted in MySQL 5.7.14.
- In MySQL 5.7.13 and earlier, InnoDB does not permit defining cascading referential actions on non-virtual foreign key columns that are explicitly included in a [virtual index](#). This restriction is lifted in MySQL 5.7.14.

## Foreign Key Usage and Error Information

You can obtain general information about foreign keys and their usage from querying the `INFORMATION_SCHEMA.KEY_COLUMN_USAGE` table, and more information more specific to InnoDB tables can be found in the `INNODB_SYS_FOREIGN` and `INNODB_SYS_FOREIGN_COLS` tables, also in the `INFORMATION_SCHEMA` database.

In addition to `SHOW ERRORS`, in the event of a foreign key error involving InnoDB tables (usually Error 150 in the MySQL Server), you can obtain a detailed explanation of the most recent InnoDB foreign key error by checking the output of `SHOW ENGINE INNODB STATUS`.

## 15.8.8 Limits on InnoDB Tables

**Warning**

Do *not* convert MySQL system tables in the `mysql` database from `MyISAM` to `InnoDB` tables. This is an unsupported operation. If you do this, MySQL does not restart until you restore the old system tables from a backup or regenerate them by reinitializing the data directory (see [Section 2.10.1, “Initializing the Data Directory”](#)).

**Warning**

It is not a good idea to configure `InnoDB` to use data files or log files on NFS volumes. Otherwise, the files might be locked by other processes and become unavailable for use by MySQL.

**Maximums and Minimums**

- A table can contain a maximum of 1017 columns (raised in MySQL 5.6.9 from the earlier limit of 1000). Virtual generated columns are included in this limit.
- A table can contain a maximum of 64 [secondary indexes](#).
- If `innodb_large_prefix` is enabled (the default in MySQL 5.7.7), the index key prefix limit is 3072 bytes for `InnoDB` tables that use `DYNAMIC` or `COMPRESSED` row format. If `innodb_large_prefix` is disabled, the index key prefix limit is 767 bytes for tables of any row format.

`innodb_large_prefix` is deprecated in MySQL 5.7.7 and will be removed in a future release. `innodb_large_prefix` was introduced in MySQL 5.5 to disable large index key prefixes for compatibility with earlier versions of `InnoDB` that do not support large index key prefixes.

The index key prefix length limit is 767 bytes for `InnoDB` tables that use the `REDUNDANT` or `COMPACT` row format. For example, you might hit this limit with a [column prefix](#) index of more than 255 characters on a `TEXT` or `VARCHAR` column, assuming a `utf8mb3` character set and the maximum of 3 bytes for each character.

Attempting to use an index key prefix length that exceeds the limit returns an error. To avoid such errors in replication configurations, avoid enabling `innodb_large_prefix` on the master if it cannot also be enabled on slaves.

The limits that apply to index key prefixes also apply to full-column index keys.

- If you reduce the [InnoDB page size](#) to 8KB or 4KB by specifying the `innodb_page_size` option when creating the MySQL instance, the maximum length of the index key is lowered proportionally, based on the limit of 3072 bytes for a 16KB page size. That is, the maximum index key length is 1536 bytes when the page size is 8KB, and 768 bytes when the page size is 4KB.
- A maximum of 16 columns is permitted for multicolumn indexes. Exceeding the limit returns an error.

```
ERROR 1070 (42000): Too many key parts specified; max 16 parts allowed
```

- The maximum row length, except for variable-length columns (`VARBINARY`, `VARCHAR`, `BLOB` and `TEXT`), is slightly less than half of a page for 4KB, 8KB, 16KB, and 32KB page sizes. For example, the maximum row length for the default `innodb_page_size` of 16KB is about 8000 bytes. For an `InnoDB` page size of 64KB, the maximum row length is about 16000 bytes. `LONGBLOB` and `LONGTEXT` columns must be less than 4GB, and the total row length, including `BLOB` and `TEXT` columns, must be less than 4GB.

If a row is less than half a page long, all of it is stored locally within the page. If it exceeds half a page, variable-length columns are chosen for external off-page storage until the row fits within half a page, as described in [Section 15.12.2, “File Space Management”](#).

- Although [InnoDB](#) supports row sizes larger than 65,535 bytes internally, MySQL itself imposes a row-size limit of 65,535 for the combined size of all columns:

```
mysql> CREATE TABLE t (a VARCHAR(8000), b VARCHAR(10000),
-> c VARCHAR(10000), d VARCHAR(10000), e VARCHAR(10000),
-> f VARCHAR(10000), g VARCHAR(10000)) ENGINE=InnoDB;
ERROR 1118 (42000): Row size too large. The maximum row size for the
used table type, not counting BLOBs, is 65535. You have to change some
columns to TEXT or BLOBs
```

See [Section C.10.4, “Limits on Table Column Count and Row Size”](#).

- On some older operating systems, files must be less than 2GB. This is not a limitation of [InnoDB](#) itself, but if you require a large tablespace, configure it using several smaller data files rather than one large data file.
- The combined size of the [InnoDB](#) log files can be up to 512GB.
- The minimum tablespace size is slightly larger than 10MB. The maximum tablespace size depends on the [InnoDB](#) page size.

**Table 15.6 InnoDB Maximum Tablespace Size**

| InnoDB Page Size | Maximum Tablespace Size |
|------------------|-------------------------|
| 4KB              | 16TB                    |
| 8KB              | 32TB                    |
| 16KB             | 64TB                    |
| 32KB             | 128TB                   |
| 64KB             | 256TB                   |

The maximum tablespace size is also the maximum size for a table.

- The default page size in [InnoDB](#) is 16KB. You can increase or decrease the page size by configuring the `innodb_page_size` option when creating the MySQL instance.

Prior to MySQL 5.7.6, increasing the page size is not a supported operation, and there is no guarantee that [InnoDB](#) functions normally with a page size greater than 16KB. Problems compiling or running [InnoDB](#) may occur. In particular, `ROW_FORMAT=COMPRESSED` in the [Barracuda](#) file format assumes that the page size is at most 16KB and uses 14-bit pointers.

As of MySQL 5.7.6, 32KB and 64KB page sizes are supported, but `ROW_FORMAT=COMPRESSED` is unsupported for page sizes greater than 16KB. For both 32KB and 64KB page sizes, the maximum record size is 16KB. For `innodb_page_size=32k`, extent size is 2MB. For `innodb_page_size=64k`, extent size is 4MB.

A MySQL instance using a particular [InnoDB](#) page size cannot use data files or log files from an instance that uses a different page size.

## Restrictions on InnoDB Tables

- `ANALYZE TABLE` determines index cardinality (as displayed in the `Cardinality` column of `SHOW INDEX` output) by doing [random dives](#) to each of the index trees and updating index cardinality estimates accordingly. Because these are only estimates, repeated runs of `ANALYZE TABLE` could produce different numbers. This makes `ANALYZE TABLE` fast on [InnoDB](#) tables but not 100% accurate because it does not take all rows into account.

You can make the [statistics](#) collected by `ANALYZE TABLE` more precise and more stable by turning on the `innodb_stats_persistent` configuration option, as explained in [Section 15.6.11.1, “Configuring Persistent Optimizer Statistics Parameters”](#). When that setting is enabled, it is important

to run `ANALYZE TABLE` after major changes to indexed column data, because the statistics are not recalculated periodically (such as after a server restart) as they traditionally have been.

You can change the number of random dives by modifying the `innodb_stats_persistent_sample_pages` system variable (if the persistent statistics setting is turned on), or the `innodb_stats_transient_sample_pages` system variable (if the persistent statistics setting is turned off).

MySQL uses index cardinality estimates only in join optimization. If some join is not optimized in the right way, you can try using `ANALYZE TABLE`. In the few cases that `ANALYZE TABLE` does not produce values good enough for your particular tables, you can use `FORCE INDEX` with your queries to force the use of a particular index, or set the `max_seeks_for_key` system variable to ensure that MySQL prefers index lookups over table scans. See [Section 6.1.5, “Server System Variables”](#), and [Section B.5.5, “Optimizer-Related Issues”](#).

- If statements or transactions are running on a table and `ANALYZE TABLE` is run on the same table followed by a second `ANALYZE TABLE` operation, the second `ANALYZE TABLE` operation is blocked until the statements or transactions are completed. This behavior occurs because `ANALYZE TABLE` marks the currently loaded table definition as obsolete when `ANALYZE TABLE` is finished running. New statements or transactions (including a second `ANALYZE TABLE` statement) must load the new table definition into the table cache, which cannot occur until currently running statements or transactions are completed and the old table definition is purged. Loading multiple concurrent table definitions is not supported.
- `SHOW TABLE STATUS` does not give accurate statistics on InnoDB tables, except for the physical size reserved by the table. The row count is only a rough estimate used in SQL optimization.
- InnoDB does not keep an internal count of rows in a table because concurrent transactions might “see” different numbers of rows at the same time. Consequently, `SELECT COUNT(*) FROM t` statements only count rows visible to the current transaction.

To process a `SELECT COUNT(*) FROM t` statement, InnoDB scans the clustered index, which takes some time if clustered index records are not entirely in the buffer pool. For a faster count, you can create a counter table and let your application update it according to the inserts and deletes it does. However, this method may not scale well in situations where thousands of concurrent transactions are initiating updates to the same counter table. If an approximate row count is sufficient, `SHOW TABLE STATUS` can be used.

`SELECT COUNT(*) FROM t` statements invoke a single handler call to the storage engine to scan the clustered index and return the row count to the optimizer. In MySQL 5.7.1 and earlier, a row count was typically performed by traversing a smaller secondary index and invoking a handler call for each record. A single handler call to the storage engine to count rows in the clustered index improves `SELECT COUNT(*) FROM t` performance in most cases. However, in the case of large clustered index and a much smaller secondary index, a single handler call to the storage engine to count rows in the clustered index may be slower than the previous implementation that could perform a row count by traversing a smaller secondary index.

InnoDB handles `SELECT COUNT(*)` and `SELECT COUNT(1)` operations in the same way. There is no performance difference.

- On Windows, InnoDB always stores database and table names internally in lowercase. To move databases in a binary format from Unix to Windows or from Windows to Unix, create all databases and tables using lowercase names.
- An `AUTO_INCREMENT` column `ai_col` must be defined as part of an index such that it is possible to perform the equivalent of an indexed `SELECT MAX(ai_col)` lookup on the table to obtain the maximum column value. Typically, this is achieved by making the column the first column of some table index.

- [InnoDB](#) sets an exclusive lock on the end of the index associated with the [AUTO\\_INCREMENT](#) column while initializing a previously specified [AUTO\\_INCREMENT](#) column on a table.

With `innodb_autoinc_lock_mode=0`, [InnoDB](#) uses a special [AUTO-INC](#) table lock mode where the lock is obtained and held to the end of the current SQL statement while accessing the auto-increment counter. Other clients cannot insert into the table while the [AUTO-INC](#) table lock is held. The same behavior occurs for “bulk inserts” with `innodb_autoinc_lock_mode=1`. Table-level [AUTO-INC](#) locks are not used with `innodb_autoinc_lock_mode=2`. For more information, See [Section 15.8.6, “AUTO\\_INCREMENT Handling in InnoDB”](#).

- When you restart the MySQL server, [InnoDB](#) may reuse an old value that was generated for an [AUTO\\_INCREMENT](#) column but never stored (that is, a value that was generated during an old transaction that was rolled back).
- When an [AUTO\\_INCREMENT](#) integer column runs out of values, a subsequent [INSERT](#) operation returns a duplicate-key error. This is general MySQL behavior, similar to how [MyISAM](#) works.
- `DELETE FROM tbl_name` does not regenerate the table but instead deletes all rows, one by one.
- Cascaded foreign key actions do not activate triggers.
- You cannot create a table with a column name that matches the name of an internal [InnoDB](#) column (including `DB_ROW_ID`, `DB_TRX_ID`, `DB_ROLL_PTR`, and `DB_MIX_ID`). This restriction applies to use of the names in any letter case.

```
mysql> CREATE TABLE t1 (c1 INT, db_row_id INT) ENGINE=INNODB;
ERROR 1166 (42000): Incorrect column name 'db_row_id'
```

## Locking and Transactions

- `LOCK TABLES` acquires two locks on each table if `innodb_table_locks=1` (the default). In addition to a table lock on the MySQL layer, it also acquires an [InnoDB](#) table lock. Versions of MySQL before 4.1.2 did not acquire [InnoDB](#) table locks; the old behavior can be selected by setting `innodb_table_locks=0`. If no [InnoDB](#) table lock is acquired, `LOCK TABLES` completes even if some records of the tables are being locked by other transactions.

In MySQL 5.7, `innodb_table_locks=0` has no effect for tables locked explicitly with `LOCK TABLES ... WRITE`. It does have an effect for tables locked for read or write by `LOCK TABLES ... WRITE` implicitly (for example, through triggers) or by `LOCK TABLES ... READ`.

- All [InnoDB](#) locks held by a transaction are released when the transaction is committed or aborted. Thus, it does not make much sense to invoke `LOCK TABLES` on [InnoDB](#) tables in `autocommit=1` mode because the acquired [InnoDB](#) table locks would be released immediately.
- You cannot lock additional tables in the middle of a transaction because `LOCK TABLES` performs an implicit `COMMIT` and `UNLOCK TABLES`.
- The limit on data-modifying transactions is now  $96 * 1023$  concurrent transactions that generate undo records. As of MySQL 5.7.2, 32 of 128 rollback segments are assigned to non-redo logs for transactions that modify temporary tables and related objects. This reduces the maximum number of concurrent data-modifying transactions from 128K to 96K. The 96K limit assumes that transactions do not modify temporary tables. If all data-modifying transactions also modify temporary tables, the limit is 32K concurrent transactions.

## 15.8.9 Clustered and Secondary Indexes

Every [InnoDB](#) table has a special index called the [clustered index](#) where the data for the rows is stored. Typically, the clustered index is synonymous with the [primary key](#). To get the best performance from queries, inserts, and other database operations, you must understand how [InnoDB](#) uses the clustered index to optimize the most common lookup and DML operations for each table.

- When you define a [PRIMARY KEY](#) on your table, [InnoDB](#) uses it as the clustered index. Define a primary key for each table that you create. If there is no logical unique and non-null column or set of columns, add a new [auto-increment](#) column, whose values are filled in automatically.
- If you do not define a [PRIMARY KEY](#) for your table, MySQL locates the first [UNIQUE](#) index where all the key columns are [NOT NULL](#) and [InnoDB](#) uses it as the clustered index.
- If the table has no [PRIMARY KEY](#) or suitable [UNIQUE](#) index, [InnoDB](#) internally generates a hidden clustered index on a synthetic column containing row ID values. The rows are ordered by the ID that [InnoDB](#) assigns to the rows in such a table. The row ID is a 6-byte field that increases monotonically as new rows are inserted. Thus, the rows ordered by the row ID are physically in insertion order.

## How the Clustered Index Speeds Up Queries

Accessing a row through the clustered index is fast because the index search leads directly to the page with all the row data. If a table is large, the clustered index architecture often saves a disk I/O operation when compared to storage organizations that store row data using a different page from the index record. (For example, [MyISAM](#) uses one file for data rows and another for index records.)

## How Secondary Indexes Relate to the Clustered Index

All indexes other than the clustered index are known as [secondary indexes](#). In [InnoDB](#), each record in a secondary index contains the primary key columns for the row, as well as the columns specified for the secondary index. [InnoDB](#) uses this primary key value to search for the row in the clustered index.

If the primary key is long, the secondary indexes use more space, so it is advantageous to have a short primary key.

For coding guidelines to take advantage of [InnoDB](#) clustered and secondary indexes, see [Section 9.3.2, “Using Primary Keys”](#) [Section 9.3, “Optimization and Indexes”](#) [Section 9.5, “Optimizing for InnoDB Tables”](#) [Section 9.3.2, “Using Primary Keys”](#).

### 15.8.10 InnoDB FULLTEXT Indexes

[FULLTEXT](#) indexes are created on text-based columns ([CHAR](#), [VARCHAR](#), or [TEXT](#) columns) to help speed up queries and DML operations on data contained within those columns, omitting any words that are defined as stopwords.

A [FULLTEXT](#) index can be defined as part of a [CREATE TABLE](#) statement, or added later using [ALTER TABLE](#) or [CREATE INDEX](#).

Full-text searching is performed using [MATCH\( \) . . . AGAINST](#) syntax. For usage information, see [Section 13.9, “Full-Text Search Functions”](#).

## InnoDB Full-Text Index Design

[InnoDB FULLTEXT](#) indexes have an inverted index design. Inverted indexes store a list of words, and for each word, a list of documents that the word appears in. To support proximity search, position information for each word is also stored, as a byte offset.

## InnoDB Full-text Index Tables

For each [InnoDB FULLTEXT](#) index, a set of index tables is created, as shown in the following example:

```
CREATE TABLE opening_lines (
  id INT UNSIGNED AUTO_INCREMENT NOT NULL PRIMARY KEY,
  opening_line TEXT(500),
  author VARCHAR(200),
  title VARCHAR(200),
  FULLTEXT idx (opening_line)
) ENGINE=InnoDB;
```

```
mysql> SELECT table_id, name, space from INFORMATION_SCHEMA.INNODB_SYS_TABLES
WHERE name LIKE 'test/%';
```

| table_id | name   | space |
|----------|--|-------|
| 333      | test/FTS_0000000000000147_00000000000001c9_INDEX_1 | 289   |
| 334      | test/FTS_0000000000000147_00000000000001c9_INDEX_2 | 290   |
| 335      | test/FTS_0000000000000147_00000000000001c9_INDEX_3 | 291   |
| 336      | test/FTS_0000000000000147_00000000000001c9_INDEX_4 | 292   |
| 337      | test/FTS_0000000000000147_00000000000001c9_INDEX_5 | 293   |
| 338      | test/FTS_0000000000000147_00000000000001c9_INDEX_6 | 294   |
| 330      | test/FTS_0000000000000147_BEING_DELETED            | 286   |
| 331      | test/FTS_0000000000000147_BEING_DELETED_CACHE      | 287   |
| 332      | test/FTS_0000000000000147_CONFIG                   | 288   |
| 328      | test/FTS_0000000000000147_DELETED                  | 284   |
| 329      | test/FTS_0000000000000147_DELETED_CACHE            | 285   |
| 327      | test/opening_lines                                 | 283   |

The first six tables represent the inverted index and are referred to as auxiliary index tables. When incoming documents are tokenized, the individual words (also referred to as “tokens”) are inserted into the index tables along with position information and the associated Document ID (`DOC_ID`). The words are fully sorted and partitioned among the six index tables based on the character set sort weight of the word's first character.

The inverted index is partitioned into six auxiliary index tables to support parallel index creation. By default, two threads tokenize, sort, and insert words and associated data into the index tables. The number of threads is configurable using the `innodb_ft_sort_pll_degree` option. When creating `FULLTEXT` indexes on large tables, consider increasing the number of threads.

Auxiliary index table names are prefixed with `FTS_` and postfixed with `INDEX_*`. Each index table is associated with the indexed table by a hex value in the index table name that matches the `table_id` of the indexed table. For example, the `table_id` of the `test/opening_lines` table is 327, for which the hex value is 0x147. As shown in the preceding example, the “147” hex value appears in the names of index tables that are associated with the `test/opening_lines` table.

A hex value representing the `index_id` of the `FULLTEXT` index also appears in auxiliary index table names. For example, in the auxiliary table name `test/FTS_0000000000000147_00000000000001c9_INDEX_1`, the hex value `1c9` has a decimal value of 457. The index defined on the `opening_lines` table (`idx`) can be identified by querying the `INFORMATION_SCHEMA.INNODB_SYS_INDEXES` table for this value (457).

```
mysql> SELECT index_id, name, table_id, space from INFORMATION_SCHEMA.INNODB_SYS_INDEXES
WHERE index_id=457;
```

| index_id | name | table_id | space |
|----------|------|----------|-------|
| 457      | idx  | 327      | 283   |

Index tables are stored in their own tablespace if the primary table is created in a file-per-table tablespace.

#### Note

Due to a bug introduced in MySQL 5.6.5, index tables were created in the `InnoDB` system tablespace (space 0) even though the primary table was created in a file-per-table tablespace. The bug is fixed in MySQL 5.6.20 and MySQL 5.7.5 (Bug#18635485). As of MySQL 5.7.8, auxiliary index tables are always stored in the same tablespace as the primary table and have the same row format as the primary table (MySQL Bug #75869).

The other index tables shown in the preceding example are used for deletion handling and for storing the internal state of the `FULLTEXT` index.

- `FTS_*_DELETED` and `FTS_*_DELETED_CACHE`: Contain the document IDs (`DOC_ID`) for documents that are deleted but whose data is not yet removed from the full-text index. The `FTS_*_DELETED_CACHE` is the in-memory version of the `FTS_*_DELETED` table.
- `FTS_*_BEING_DELETED` and `FTS_*_BEING_DELETED_CACHE`: Contain the document IDs (`DOC_ID`) for documents that are deleted and whose data is currently in the process of being removed from the full-text index. The `FTS_*_BEING_DELETED_CACHE` table is the in-memory version of the `FTS_*_BEING_DELETED` table.
- `FTS_*_CONFIG`: Stores information about the internal state of the `FULLTEXT` index. Most importantly, it stores the `FTS_SYNCED_DOC_ID`, which identifies documents that have been parsed and flushed to disk. In case of crash recovery, `FTS_SYNCED_DOC_ID` values are used to identify documents that have not been flushed to disk so that the documents can be re-parsed and added back to the `FULLTEXT` index cache. To view the data in this table, query the `INFORMATION_SCHEMA.INNODB_FT_CONFIG` table.

## InnoDB Full-Text Index Cache

When a document is inserted, it is tokenized, and the individual words and associated data are inserted into the `FULLTEXT` index. This process, even for small documents, could result in numerous small insertions into the auxiliary index tables, making concurrent access to these tables a point of contention. To avoid this problem, InnoDB uses a `FULLTEXT` index cache to temporarily cache index table insertions for recently inserted rows. This in-memory cache structure holds insertions until the cache is full and then batch flushes them to disk (to the auxiliary index tables). You can query the `INFORMATION_SCHEMA.INNODB_FT_INDEX_CACHE` table to view tokenized data for recently inserted rows.

The caching and batch flushing behavior avoids frequent updates to auxiliary index tables, which could result in concurrent access issues during busy insert and update times. The batching technique also avoids multiple insertions for the same word, and minimizes duplicate entries. Instead of flushing each word individually, insertions for the same word are merged and flushed to disk as a single entry, improving insertion efficiency while keeping auxiliary index tables as small as possible.

The `innodb_ft_cache_size` variable is used to configure the full-text index cache size (on a per-table basis), which affects how often the full-text index cache is flushed. You can also define a global full-text index cache size limit for all tables in a given instance using the `innodb_ft_total_cache_size` option.

The full-text index cache stores the same information as auxiliary index tables. However, the full-text index cache only caches tokenized data for recently inserted rows. The data that is already flushed to disk (to the full-text auxiliary tables) is not brought back into the full-text index cache when queried. The data in auxiliary index tables is queried directly, and results from the auxiliary index tables are merged with results from the full-text index cache before being returned.

## InnoDB Full-Text Document ID and FTS\_DOC\_ID Column

InnoDB uses a unique document identifier referred to as a Document ID (`DOC_ID`) to map words in the full-text index to document records where the word appears. The mapping requires an `FTS_DOC_ID` column on the indexed table. If an `FTS_DOC_ID` column is not defined, InnoDB automatically adds a hidden `FTS_DOC_ID` column when the full-text index is created. The following example demonstrates this behavior.

The following table definition does not include an `FTS_DOC_ID` column:

```
CREATE TABLE opening_lines (  
  id INT UNSIGNED AUTO_INCREMENT NOT NULL PRIMARY KEY,  
  opening_line TEXT(500),  
  author VARCHAR(200),  
  title VARCHAR(200)  
) ENGINE=InnoDB;
```

When you create a full-text index on the table using `CREATE FULLTEXT INDEX` syntax, a warning is returned which reports that InnoDB is rebuilding the table to add the `FTS_DOC_ID` column.

```
mysql> CREATE FULLTEXT INDEX idx ON opening_lines(opening_line);
Query OK, 0 rows affected, 1 warning (0.19 sec)
Records: 0 Duplicates: 0 Warnings: 1

mysql> SHOW WARNINGS;
+-----+-----+-----+
| Level | Code | Message                                     |
+-----+-----+-----+
| Warning | 124 | InnoDB rebuilding table to add column FTS_DOC_ID |
+-----+-----+-----+
```

The same warning is returned when using `ALTER TABLE` to add a full-text index to a table that does not have an `FTS_DOC_ID` column. If you create a full-text index at `CREATE TABLE` time and do not specify an `FTS_DOC_ID` column, InnoDB adds a hidden `FTS_DOC_ID` column, without warning.

Defining an `FTS_DOC_ID` column at `CREATE TABLE` time reduces the time required to create a full-text index on a table that is already loaded with data. If an `FTS_DOC_ID` column is defined on a table prior to loading data, the table and its indexes do not have to be rebuilt to add the new column. If you are not concerned with `CREATE FULLTEXT INDEX` performance, leave out the `FTS_DOC_ID` column to have InnoDB create it for you. InnoDB creates a hidden `FTS_DOC_ID` column along with a unique index (`FTS_DOC_ID_INDEX`) on the `FTS_DOC_ID` column. If you want to create your own `FTS_DOC_ID` column, the column must be defined as `BIGINT UNSIGNED NOT NULL` and named `FTS_DOC_ID` (all upper case), as in the following example:

#### Note

The `FTS_DOC_ID` column does not need to be defined as an `AUTO_INCREMENT` column but `AUTO_INCREMENT` could make loading data easier.

```
CREATE TABLE opening_lines (
  FTS_DOC_ID BIGINT UNSIGNED AUTO_INCREMENT NOT NULL PRIMARY KEY,
  opening_line TEXT(500),
  author VARCHAR(200),
  title VARCHAR(200)
) ENGINE=InnoDB;
```

If you choose to define the `FTS_DOC_ID` column yourself, you are responsible for managing the column to avoid empty or duplicate values. `FTS_DOC_ID` values cannot be reused, which means `FTS_DOC_ID` values must be ever increasing.

Optionally, you can create the required unique `FTS_DOC_ID_INDEX` (all upper case) on the `FTS_DOC_ID` column.

```
CREATE UNIQUE INDEX FTS_DOC_ID_INDEX on opening_lines(FTS_DOC_ID);
```

If you do not create the `FTS_DOC_ID_INDEX`, InnoDB creates it automatically.

Before MySQL 5.7.13, the permitted gap between the largest used `FTS_DOC_ID` value and new `FTS_DOC_ID` value is 10000. In MySQL 5.7.13 and later, the permitted gap is 65535.

## InnoDB Full-Text Index Deletion Handling

Deleting a record that has a full-text index column could result in numerous small deletions in the auxiliary index tables, making concurrent access to these tables a point of contention. To avoid this problem, the Document ID (`DOC_ID`) of a deleted document is logged in a special `FTS_*_DELETED` table whenever a record is deleted from an indexed table, and the indexed record remains in the full-text index. Before returning query results, information in the `FTS_*_DELETED` table is used to filter out deleted Document IDs. The benefit of this design is that deletions are fast and inexpensive. The drawback is that the size of the index is not immediately reduced after deleting records. To remove

full-text index entries for deleted records, you must run `OPTIMIZE TABLE` on the indexed table with `innodb_optimize_fulltext_only=ON` to rebuild the full-text index. For more information, see [Optimizing InnoDB Full-Text Indexes](#).

## InnoDB Full-Text Index Transaction Handling

`InnoDB FULLTEXT` indexes have special transaction handling characteristics due its caching and batch processing behavior. Specifically, updates and insertions on a `FULLTEXT` index are processed at transaction commit time, which means that a `FULLTEXT` search can only see committed data. The following example demonstrates this behavior. The `FULLTEXT` search only returns a result after the inserted lines are committed.

```
mysql> CREATE TABLE opening_lines (
  id INT UNSIGNED AUTO_INCREMENT NOT NULL PRIMARY KEY,
  opening_line TEXT(500),
  author VARCHAR(200),
  title VARCHAR(200),
  FULLTEXT idx (opening_line)
) ENGINE=InnoDB;

mysql> BEGIN;
Query OK, 0 rows affected (0.00 sec)

mysql> INSERT INTO opening_lines(opening_line,author,title) VALUES
('Call me Ishmael.','Herman Melville','Moby-Dick'),
('A screaming comes across the sky.','Thomas Pynchon','Gravity\'s Rainbow'),
('I am an invisible man.','Ralph Ellison','Invisible Man'),
('Where now? Who now? When now?','Samuel Beckett','The Unnamable'),
('It was love at first sight.','Joseph Heller','Catch-22'),
('All this happened, more or less.','Kurt Vonnegut','Slaughterhouse-Five'),
('Mrs. Dalloway said she would buy the flowers herself.','Virginia Woolf','Mrs. Dalloway'),
('It was a pleasure to burn.','Ray Bradbury','Fahrenheit 451');
Query OK, 8 rows affected (0.00 sec)
Records: 8  Duplicates: 0  Warnings: 0

mysql> SELECT COUNT(*) FROM opening_lines WHERE MATCH(opening_line) AGAINST('Ishmael');
+-----+
| COUNT(*) |
+-----+
|         0 |
+-----+

mysql> COMMIT;
Query OK, 0 rows affected (0.00 sec)

mysql> SELECT COUNT(*) FROM opening_lines WHERE MATCH(opening_line) AGAINST('Ishmael');
+-----+
| COUNT(*) |
+-----+
|         1 |
+-----+
```

## Monitoring InnoDB Full-Text Indexes

You can monitor and examine the special text-processing aspects of `InnoDB FULLTEXT` indexes by querying the following `INFORMATION_SCHEMA` tables:

- `INNODB_FT_CONFIG`
- `INNODB_FT_INDEX_TABLE`
- `INNODB_FT_INDEX_CACHE`
- `INNODB_FT_DEFAULT_STOPWORD`
- `INNODB_FT_DELETED`
- `INNODB_FT_BEING_DELETED`

You can also view basic information for [FULLTEXT](#) indexes and tables by querying [INNODB\\_SYS\\_INDEXES](#) and [INNODB\\_SYS\\_TABLES](#).

See [Section 15.15.4, “InnoDB INFORMATION\\_SCHEMA FULLTEXT Index Tables”](#) for more information.

## 15.8.11 Physical Structure of an InnoDB Index

With the exception of spatial indexes, [InnoDB](#) indexes are [B-tree](#) data structures. Spatial indexes use [R-trees](#), which are specialized data structures for indexing multi-dimensional data. Index records are stored in the leaf pages of their B-tree or R-tree data structure. The default size of an index page is 16KB.

When new records are inserted into an [InnoDB clustered index](#), [InnoDB](#) tries to leave 1/16 of the page free for future insertions and updates of the index records. If index records are inserted in a sequential order (ascending or descending), the resulting index pages are about 15/16 full. If records are inserted in a random order, the pages are from 1/2 to 15/16 full.

As of MySQL 5.7.5, [InnoDB](#) performs a bulk load when creating or rebuilding B-tree indexes. This method of index creation is known as a sorted index build. [innodb\\_fill\\_factor](#) defines the percentage of space on each B-tree page that is filled during a sorted index build, with the remaining space reserved for future index growth. Sorted index builds are not supported for spatial indexes. For more information, see [Section 15.8.12, “Sorted Index Builds”](#). As of MySQL 5.7.8, an [innodb\\_fill\\_factor](#) setting of 100 leaves 1/16 of the space in clustered index pages free for future index growth.

If the fill factor of an [InnoDB](#) index page drops below the [MERGE\\_THRESHOLD](#), which is 50% by default if not specified, [InnoDB](#) tries to contract the index tree to free the page. The [MERGE\\_THRESHOLD](#) setting applies to both B-tree and R-tree indexes. For more information, see [Section 15.6.12, “Configuring the Merge Threshold for Index Pages”](#).

You can configure the [page size](#) for all [InnoDB](#) tablespaces in a MySQL instance by setting the [innodb\\_page\\_size](#) configuration option before creating the instance. Once the page size for an instance is set, you cannot change it. Supported sizes are 64KB, 32KB, 16KB (default), 8KB, and 4KB, corresponding to the option values [64k](#), [32k](#), [16k](#), [8k](#), and [4k](#).

Support for 32KB and 64KB pages sizes was added in MySQL 5.7.6. For more information, refer to the [innodb\\_page\\_size](#) documentation.

A MySQL instance using a particular [InnoDB](#) page size cannot use data files or log files from an instance that uses a different page size.

## 15.8.12 Sorted Index Builds

As of MySQL 5.7.5, [InnoDB](#) performs a bulk load instead of inserting one index record at a time when creating or rebuilding indexes. This method of index creation is also known as a sorted index build. Sorted index builds are not supported for spatial indexes.

There are three phases to an index build. In the first phase, the [clustered index](#) is scanned, and index entries are generated and added to the sort buffer. When the [sort buffer](#) becomes full, entries are sorted and written out to a temporary intermediate file. This process is also known as a “run”. In the second phase, with one or more runs written to the temporary intermediate file, a merge sort is performed on all entries in the file. In the third and final phase, the sorted entries are inserted into the [B-tree](#).

Prior to the introduction of sorted index builds, index entries were inserted into the B-tree one record at a time using insert APIs. This method involved opening a B-tree [cursor](#) to find the insert position and then inserting entries into a B-tree page using an [optimistic](#) insert. If an insert failed due to a page being full, a [pessimistic](#) insert would be performed, which involves opening a B-tree cursor and splitting and merging B-tree nodes as necessary to find space for the entry. The drawbacks of this “top-down”

method of building an index are the cost of searching for an insert position and the constant splitting and merging of B-tree nodes.

Sorted index builds use a bottom up approach to building an index. With this approach, a reference to the right-most leaf page is held at all levels of the B-tree. The right-most leaf page at the necessary B-tree depth is allocated and entries are inserted according to their sorted order. Once a leaf page is full, a node pointer is appended to the parent page and a sibling leaf page is allocated for the next insert. This process continues until all entries are inserted, which may result in inserts up to the root level. When a sibling page is allocated, the reference to the previously pinned leaf page is released, and the newly allocated leaf page becomes the right-most leaf page and new default insert location.

## Reserving B-tree Page Space for Future Index Growth

To set aside space for future index growth, you can use the `innodb_fill_factor` configuration option to reserve a percentage of B-tree page space. For example, setting `innodb_fill_factor` to 80 reserves 20 percent of the space in B-tree pages during a sorted index build. This setting applies to both B-tree leaf and non-leaf pages. It does not apply to external pages used for `TEXT` or `BLOB` entries. The amount of space that is reserved may not be exactly as configured, as the `innodb_fill_factor` value is interpreted as a hint rather than a hard limit.

## Sorted Index Builds and Fulltext Index Support

Sorted index builds are supported for [fulltext indexes](#). Previously, SQL was used to insert entries into a fulltext index.

## Sorted Index Builds and Compressed Tables

For [compressed tables](#), the previous index creation method appended entries to both compressed and uncompressed pages. When the modification log (representing free space on the compressed page) became full, the compressed page would be recompressed. If compression failed due to a lack of space, the page would be split. With sorted index builds, entries are only appended to uncompressed pages. When an uncompressed page becomes full, it is compressed. Adaptive padding is used to ensure that compression succeeds in most cases, but if compression fails, the page is split and compression is attempted again. This process continues until compression is successful. For additional information about compression of B-Tree pages, see [Section 15.9.1.5, “How Compression Works for InnoDB Tables”](#).

## Sorted Index Builds and Redo Logging

[Redo logging](#) is turned off during a sorted index build. Instead, there is a [checkpoint](#) to ensure that the index build can withstand a crash or failure. The checkpoint forces a write of all dirty pages to disk. During a sorted index build, the [page cleaner](#) thread is signaled periodically to flush [dirty pages](#) to ensure that the checkpoint operation can be processed quickly. Normally, the page cleaner thread flushes dirty pages when the number of clean pages falls below a set threshold. For sorted index builds, dirty pages are flushed promptly to reduce checkpoint overhead and to parallelize IO and CPU activity.

## Sorted Index Builds and Optimizer Statistics

Sorted index builds may result in [optimizer](#) statistics that differ from those generated by the previous method of index creation. The difference in statistics, which is not expected to affect workload performance, is due to the different algorithm that is used to populate the index.

# 15.9 InnoDB Table and Page Compression

This section provides information about the [InnoDB](#) table compression and [InnoDB](#) page compression features. The page compression feature, referred to as [transparent page compression](#), was introduced in MySQL 5.7.8.

Using the compression features of [InnoDB](#), you can create tables where the data is stored in compressed form. Compression can help to improve both raw performance and scalability. The

compression means less data is transferred between disk and memory, and takes up less space on disk and in memory. The benefits are amplified for tables with [secondary indexes](#), because index data is compressed also. Compression can be especially important for [SSD](#) storage devices, because they tend to have lower capacity than [HDD](#) devices.

## 15.9.1 InnoDB Table Compression

This section describes [InnoDB](#) table compression, which is supported with [InnoDB](#) tables that reside in [file\\_per\\_table](#) tablespaces or [general tablespaces](#). Table compression is enabled using the [ROW\\_FORMAT=COMPRESSED](#) attribute with [CREATE TABLE](#) or [ALTER TABLE](#).

### 15.9.1.1 Overview of Table Compression

Because processors and cache memories have increased in speed more than disk storage devices, many workloads are [disk-bound](#). Data [compression](#) enables smaller database size, reduced I/O, and improved throughput, at the small cost of increased CPU utilization. Compression is especially valuable for read-intensive applications, on systems with enough RAM to keep frequently used data in memory.

An [InnoDB](#) table created with [ROW\\_FORMAT=COMPRESSED](#) can use a smaller [page size](#) on disk than the configured [innodb\\_page\\_size](#) value. Smaller pages require less I/O to read from and write to disk, which is especially valuable for [SSD](#) devices.

The compressed page size is specified through the [CREATE TABLE](#) or [ALTER TABLE](#) [KEY\\_BLOCK\\_SIZE](#) parameter. The different page size requires that the table be placed in a [file-per-table](#) tablespace or [general tablespace](#) rather than in the [system tablespace](#), as the system tablespace cannot store compressed tables. For more information, see [Section 15.7.4, “InnoDB File-Per-Table Tablespaces”](#), and [Section 15.7.9, “InnoDB General Tablespaces”](#).

The level of compression is the same regardless of the [KEY\\_BLOCK\\_SIZE](#) value. As you specify smaller values for [KEY\\_BLOCK\\_SIZE](#), you get the I/O benefits of increasingly smaller pages. But if you specify a value that is too small, there is additional overhead to reorganize the pages when data values cannot be compressed enough to fit multiple rows in each page. There is a hard limit on how small [KEY\\_BLOCK\\_SIZE](#) can be for a table, based on the lengths of the key columns for each of its indexes. Specify a value that is too small, and the [CREATE TABLE](#) or [ALTER TABLE](#) statement fails.

In the buffer pool, the compressed data is held in small pages, with a page size based on the [KEY\\_BLOCK\\_SIZE](#) value. For extracting or updating the column values, MySQL also creates an uncompressed page in the buffer pool with the uncompressed data. Within the buffer pool, any updates to the uncompressed page are also re-written back to the equivalent compressed page. You might need to size your buffer pool to accommodate the additional data of both compressed and uncompressed pages, although the uncompressed pages are [evicted](#) from the buffer pool when space is needed, and then uncompressed again on the next access.

### 15.9.1.2 Creating Compressed Tables

Compressed tables can be created in [file-per-table](#) tablespaces or in [general tablespaces](#). Table compression is not available for the [InnoDB system tablespace](#). The system tablespace (space 0, the [.ibdata files](#)) can contain user-created tables, but it also contains internal system data, which is never compressed. Thus, compression applies only to tables (and indexes) stored in file-per-table or general tablespaces.

#### Creating a Compressed Table in File-Per-Table Tablespace

To create a compressed table in a file-per-table tablespace, [innodb\\_file\\_per\\_table](#) must be enabled (the default in MySQL 5.6.6) and [innodb\\_file\\_format](#) must be set to [Barracuda](#). You can set these parameters in the MySQL configuration file ([my.cnf](#) or [my.ini](#)) or dynamically, using a [SET](#) statement.

After the [innodb\\_file\\_per\\_table](#) and [innodb\\_file\\_format](#) options are configured, specify the [ROW\\_FORMAT=COMPRESSED](#) clause or [KEY\\_BLOCK\\_SIZE](#) clause, or both, in a [CREATE TABLE](#) or [ALTER TABLE](#) statement to create a compressed table in a file-per-table tablespace.

For example, you might use the following statements:

```
SET GLOBAL innodb_file_per_table=1;
SET GLOBAL innodb_file_format=Barracuda;
CREATE TABLE t1
(c1 INT PRIMARY KEY)
ROW_FORMAT=COMPRESSED
KEY_BLOCK_SIZE=8;
```

## Creating a Compressed Table in a General Tablespace

To create a compressed table in a general tablespace, `FILE_BLOCK_SIZE` must be defined for the general tablespace, which is specified when the tablespace is created. The `FILE_BLOCK_SIZE` value must be a valid compressed page size in relation to the `innodb_page_size` value, and the page size of the compressed table, defined by the `CREATE TABLE` or `ALTER TABLE KEY_BLOCK_SIZE` clause, must be equal to `FILE_BLOCK_SIZE/1024`. For example, if `innodb_page_size=16384` and `FILE_BLOCK_SIZE=8192`, the `KEY_BLOCK_SIZE` of the table must be 8. For more information, see [Section 15.7.9, “InnoDB General Tablespace”](#).

The following example demonstrates creating a general tablespace and adding a compressed table. The example assumes a default `innodb_page_size` of 16K. The `FILE_BLOCK_SIZE` of 8192 requires that the compressed table have a `KEY_BLOCK_SIZE` of 8.

```
mysql> CREATE TABLESPACE `ts2` ADD DATAFILE 'ts2.ibd' FILE_BLOCK_SIZE = 8192 Engine=InnoDB;
Query OK, 0 rows affected (0.01 sec)

mysql> CREATE TABLE t4 (c1 INT PRIMARY KEY) TABLESPACE ts2 ROW_FORMAT=COMPRESSED KEY_BLOCK_SIZE=8;
Query OK, 0 rows affected (0.00 sec)
```

## Notes

- If you specify `ROW_FORMAT=COMPRESSED`, you can omit `KEY_BLOCK_SIZE`; the `KEY_BLOCK_SIZE` setting defaults to half the `innodb_page_size` value.
- If you specify a valid `KEY_BLOCK_SIZE` value, you can omit `ROW_FORMAT=COMPRESSED`; compression is enabled automatically.
- To determine the best value for `KEY_BLOCK_SIZE`, typically you create several copies of the same table with different values for this clause, then measure the size of the resulting `.ibd` files and see how well each performs with a realistic [workload](#). For general tablespaces, keep in mind that dropping a table does not reduce the size of the general tablespace `.ibd` file, nor does it return disk space to the operating system. For more information, see [Section 15.7.9, “InnoDB General Tablespace”](#).
- The `KEY_BLOCK_SIZE` value is treated as a hint; a different size could be used by InnoDB if necessary. For file-per-table tablespaces, the `KEY_BLOCK_SIZE` can only be less than or equal to the `innodb_page_size` value. If you specify a value greater than the `innodb_page_size` value, the specified value is ignored, a warning is issued, and `KEY_BLOCK_SIZE` is set to half of the `innodb_page_size` value. If `innodb_strict_mode=ON`, specifying an invalid `KEY_BLOCK_SIZE` value returns an error. For general tablespaces, valid `KEY_BLOCK_SIZE` values depend on the `FILE_BLOCK_SIZE` setting of the tablespace. For more information, see [Section 15.7.9, “InnoDB General Tablespace”](#).
- Support for 32k and 64k page sizes was added in MySQL 5.7.6 but these page sizes do not support compression. For more information, refer to the `innodb_page_size` documentation.
- The default uncompressed size of InnoDB data [pages](#) is 16KB. Depending on the combination of option values, MySQL uses a page size of 1KB, 2KB, 4KB, 8KB, or 16KB for the tablespace data file (`.ibd` file). The actual compression algorithm is not affected by the `KEY_BLOCK_SIZE` value; the value determines how large each compressed chunk is, which in turn affects how many rows can be packed into each compressed page.
- When creating a compressed table in a file-per-table tablespace, setting `KEY_BLOCK_SIZE` equal to the InnoDB [page size](#) does not typically result in much compression. For example, setting

`KEY_BLOCK_SIZE=16` typically would not result in much compression, since the normal InnoDB page size is 16KB. This setting may still be useful for tables with many long `BLOB`, `VARCHAR` or `TEXT` columns, because such values often do compress well, and might therefore require fewer [overflow pages](#) as described in [Section 15.9.1.5, “How Compression Works for InnoDB Tables”](#). For general tablespaces, a `KEY_BLOCK_SIZE` value equal to the InnoDB page size is not permitted. For more information, see [Section 15.7.9, “InnoDB General Tablespaces”](#).

- All indexes of a table (including the [clustered index](#)) are compressed using the same page size, as specified in the `CREATE TABLE` or `ALTER TABLE` statement. Table attributes such as `ROW_FORMAT` and `KEY_BLOCK_SIZE` are not part of the `CREATE INDEX` syntax for InnoDB tables, and are ignored if they are specified (although, if specified, they will appear in the output of the `SHOW CREATE TABLE` statement).
- For performance-related configuration options, see [Section 15.9.1.3, “Tuning Compression for InnoDB Tables”](#).

## Restrictions on Compressed Tables

- MySQL versions prior to 5.1 cannot process compressed tables.
- Compressed tables cannot be stored in the InnoDB system tablespace.
- General tablespaces can contain multiple tables, but compressed and uncompressed tables cannot coexist within the same general tablespace.
- Compression applies to an entire table and all its associated indexes, not to individual rows, despite the clause name `ROW_FORMAT`.

### 15.9.1.3 Tuning Compression for InnoDB Tables

Most often, the internal optimizations described in [InnoDB Data Storage and Compression](#) ensure that the system runs well with compressed data. However, because the efficiency of compression depends on the nature of your data, you can make decisions that affect the performance of compressed tables:

- Which tables to compress.
- What compressed page size to use.
- Whether to adjust the size of the buffer pool based on run-time performance characteristics, such as the amount of time the system spends compressing and uncompressing data. Whether the workload is more like a [data warehouse](#) (primarily queries) or an [OLTP](#) system (mix of queries and [DML](#)).
- If the system performs DML operations on compressed tables, and the way the data is distributed leads to expensive [compression failures](#) at runtime, you might adjust additional advanced configuration options.

Use the guidelines in this section to help make those architectural and configuration choices. When you are ready to conduct long-term testing and put compressed tables into production, see [Section 15.9.1.4, “Monitoring Compression at Runtime”](#) for ways to verify the effectiveness of those choices under real-world conditions.

## When to Use Compression

In general, compression works best on tables that include a reasonable number of character string columns and where the data is read far more often than it is written. Because there are no guaranteed ways to predict whether or not compression benefits a particular situation, always test with a specific [workload](#) and data set running on a representative configuration. Consider the following factors when deciding which tables to compress.

## Data Characteristics and Compression

A key determinant of the efficiency of compression in reducing the size of data files is the nature of the data itself. Recall that compression works by identifying repeated strings of bytes in a block of data. Completely randomized data is the worst case. Typical data often has repeated values, and so compresses effectively. Character strings often compress well, whether defined in [CHAR](#), [VARCHAR](#), [TEXT](#) or [BLOB](#) columns. On the other hand, tables containing mostly binary data (integers or floating point numbers) or data that is previously compressed (for example JPEG or PNG images) may not generally compress well, significantly or at all.

You choose whether to turn on compression for each InnoDB table. A table and all of its indexes use the same (compressed) [page size](#). It might be that the [primary key](#) (clustered) index, which contains the data for all columns of a table, compresses more effectively than the secondary indexes. For those cases where there are long rows, the use of compression might result in long column values being stored “off-page”, as discussed in [Section 15.11.3, “DYNAMIC and COMPRESSED Row Formats”](#). Those overflow pages may compress well. Given these considerations, for many applications, some tables compress more effectively than others, and you might find that your workload performs best only with a subset of tables compressed.

To determine whether or not to compress a particular table, conduct experiments. You can get a rough estimate of how efficiently your data can be compressed by using a utility that implements LZ77 compression (such as [gzip](#) or WinZip) on a copy of the [.ibd file](#) for an uncompressed table. You can expect less compression from a MySQL compressed table than from file-based compression tools, because MySQL compresses data in chunks based on the [page size](#), 16KB by default. In addition to user data, the page format includes some internal system data that is not compressed. File-based compression utilities can examine much larger chunks of data, and so might find more repeated strings in a huge file than MySQL can find in an individual page.

Another way to test compression on a specific table is to copy some data from your uncompressed table to a similar, compressed table (having all the same indexes) in a [file-per-table](#) tablespace and look at the size of the resulting [.ibd file](#). For example:

```
use test;
set global innodb_file_per_table=1;
set global innodb_file_format=Barracuda;
set global autocommit=0;

-- Create an uncompressed table with a million or two rows.
create table big_table as select * from information_schema.columns;
insert into big_table select * from big_table;
insert into big_table select * from big_table;
insert into big_table select * from big_table;
insert into big_table select * from big_table;
insert into big_table select * from big_table;
insert into big_table select * from big_table;
insert into big_table select * from big_table;
insert into big_table select * from big_table;
insert into big_table select * from big_table;
commit;
alter table big_table add id int unsigned not null primary key auto_increment;

show create table big_table\G

select count(id) from big_table;

-- Check how much space is needed for the uncompressed table.
\! ls -l data/test/big_table.ibd

create table key_block_size_4 like big_table;
alter table key_block_size_4 key_block_size=4 row_format=compressed;

insert into key_block_size_4 select * from big_table;
commit;

-- Check how much space is needed for a compressed table
-- with particular compression settings.
```

```
\! ls -l data/test/key_block_size_4.ibd
```

This experiment produced the following numbers, which of course could vary considerably depending on your table structure and data:

```
-rw-rw---- 1 cirrus staff 310378496 Jan  9 13:44 data/test/big_table.ibd
-rw-rw---- 1 cirrus staff 83886080 Jan  9 15:10 data/test/key_block_size_4.ibd
```

To see whether compression is efficient for your particular [workload](#):

- For simple tests, use a MySQL instance with no other compressed tables and run queries against the `INFORMATION_SCHEMA.INNODB_CMP` table.
- For more elaborate tests involving workloads with multiple compressed tables, run queries against the `INFORMATION_SCHEMA.INNODB_CMP_PER_INDEX` table. Because the statistics in the `INNODB_CMP_PER_INDEX` table are expensive to collect, you must enable the configuration option `innodb_cmp_per_index_enabled` before querying that table, and you might restrict such testing to a development server or a non-critical [slave server](#).
- Run some typical SQL statements against the compressed table you are testing.
- Examine the ratio of successful compression operations to overall compression operations by querying the `INFORMATION_SCHEMA.INNODB_CMP` or `INFORMATION_SCHEMA.INNODB_CMP_PER_INDEX` table, and comparing `COMPRESS_OPS` to `COMPRESS_OPS_OK`.
- If a high percentage of compression operations complete successfully, the table might be a good candidate for compression.
- If you get a high proportion of [compression failures](#), you can adjust `innodb_compression_level`, `innodb_compression_failure_threshold_pct`, and `innodb_compression_pad_pct_max` options as described in [Section 15.9.1.6, “Compression for OLTP Workloads”](#), and try further tests.

## Database Compression versus Application Compression

Decide whether to compress data in your application or in the table; do not use both types of compression for the same data. When you compress the data in the application and store the results in a compressed table, extra space savings are extremely unlikely, and the double compression just wastes CPU cycles.

### Compressing in the Database

When enabled, MySQL table compression is automatic and applies to all columns and index values. The columns can still be tested with operators such as `LIKE`, and sort operations can still use indexes even when the index values are compressed. Because indexes are often a significant fraction of the total size of a database, compression could result in significant savings in storage, I/O or processor time. The compression and decompression operations happen on the database server, which likely is a powerful system that is sized to handle the expected load.

### Compressing in the Application

If you compress data such as text in your application, before it is inserted into the database, You might save overhead for data that does not compress well by compressing some columns and not others. This approach uses CPU cycles for compression and uncompression on the client machine rather than the database server, which might be appropriate for a distributed application with many clients, or where the client machine has spare CPU cycles.

### Hybrid Approach

Of course, it is possible to combine these approaches. For some applications, it may be appropriate to use some compressed tables and some uncompressed tables. It may be best to externally compress some data (and store it in uncompressed tables) and allow MySQL to compress (some of) the other

tables in the application. As always, up-front design and real-life testing are valuable in reaching the right decision.

## Workload Characteristics and Compression

In addition to choosing which tables to compress (and the page size), the workload is another key determinant of performance. If the application is dominated by reads, rather than updates, fewer pages need to be reorganized and recompressed after the index page runs out of room for the per-page “modification log” that MySQL maintains for compressed data. If the updates predominantly change non-indexed columns or those containing [BLOBs](#) or large strings that happen to be stored “off-page”, the overhead of compression may be acceptable. If the only changes to a table are [INSERTs](#) that use a monotonically increasing primary key, and there are few secondary indexes, there is little need to reorganize and recompress index pages. Since MySQL can “delete-mark” and delete rows on compressed pages “in place” by modifying uncompressed data, [DELETE](#) operations on a table are relatively efficient.

For some environments, the time it takes to load data can be as important as run-time retrieval. Especially in data warehouse environments, many tables may be read-only or read-mostly. In those cases, it might or might not be acceptable to pay the price of compression in terms of increased load time, unless the resulting savings in fewer disk reads or in storage cost is significant.

Fundamentally, compression works best when the CPU time is available for compressing and uncompressing data. Thus, if your workload is I/O bound, rather than CPU-bound, you might find that compression can improve overall performance. When you test your application performance with different compression configurations, test on a platform similar to the planned configuration of the production system.

## Configuration Characteristics and Compression

Reading and writing database [pages](#) from and to disk is the slowest aspect of system performance. Compression attempts to reduce I/O by using CPU time to compress and uncompress data, and is most effective when I/O is a relatively scarce resource compared to processor cycles.

This is often especially the case when running in a multi-user environment with fast, multi-core CPUs. When a page of a compressed table is in memory, MySQL often uses additional memory, typically 16KB, in the [buffer pool](#) for an uncompressed copy of the page. The adaptive LRU algorithm attempts to balance the use of memory between compressed and uncompressed pages to take into account whether the workload is running in an I/O-bound or CPU-bound manner. Still, a configuration with more memory dedicated to the buffer pool tends to run better when using compressed tables than a configuration where memory is highly constrained.

## Choosing the Compressed Page Size

The optimal setting of the compressed page size depends on the type and distribution of data that the table and its indexes contain. The compressed page size should always be bigger than the maximum record size, or operations may fail as noted in [Compression of B-Tree Pages](#).

Setting the compressed page size too large wastes some space, but the pages do not have to be compressed as often. If the compressed page size is set too small, inserts or updates may require time-consuming recompression, and the [B-tree](#) nodes may have to be split more frequently, leading to bigger data files and less efficient indexing.

Typically, you set the compressed page size to 8K or 4K bytes. Given that the maximum row size for an InnoDB table is around 8K, [KEY\\_BLOCK\\_SIZE=8](#) is usually a safe choice.

### 15.9.1.4 Monitoring Compression at Runtime

Overall application performance, CPU and I/O utilization and the size of disk files are good indicators of how effective compression is for your application. This section builds on the performance tuning advice from [Section 15.9.1.3, “Tuning Compression for InnoDB Tables”](#), and shows how to find problems that might not turn up during initial testing.

To dig deeper into performance considerations for compressed tables, you can monitor compression performance at runtime using the [Information Schema](#) tables described in [Example 15.10, “Using the Compression Information Schema Tables”](#). These tables reflect the internal use of memory and the rates of compression used overall.

The [INNODB\\_CMP](#) table reports information about compression activity for each compressed page size ([KEY\\_BLOCK\\_SIZE](#)) in use. The information in these tables is system-wide: it summarizes the compression statistics across all compressed tables in your database. You can use this data to help decide whether or not to compress a table by examining these tables when no other compressed tables are being accessed. It involves relatively low overhead on the server, so you might query it periodically on a production server to check the overall efficiency of the compression feature.

The [INNODB\\_CMP\\_PER\\_INDEX](#) table reports information about compression activity for individual tables and indexes. This information is more targeted and more useful for evaluating compression efficiency and diagnosing performance issues one table or index at a time. (Because that each [InnoDB](#) table is represented as a clustered index, MySQL does not make a big distinction between tables and indexes in this context.) The [INNODB\\_CMP\\_PER\\_INDEX](#) table does involve substantial overhead, so it is more suitable for development servers, where you can compare the effects of different [workloads](#), data, and compression settings in isolation. To guard against imposing this monitoring overhead by accident, you must enable the [innodb\\_cmp\\_per\\_index\\_enabled](#) configuration option before you can query the [INNODB\\_CMP\\_PER\\_INDEX](#) table.

The key statistics to consider are the number of, and amount of time spent performing, compression and uncompression operations. Since MySQL splits [B-tree](#) nodes when they are too full to contain the compressed data following a modification, compare the number of “successful” compression operations with the number of such operations overall. Based on the information in the [INNODB\\_CMP](#) and [INNODB\\_CMP\\_PER\\_INDEX](#) tables and overall application performance and hardware resource utilization, you might make changes in your hardware configuration, adjust the size of the buffer pool, choose a different page size, or select a different set of tables to compress.

If the amount of CPU time required for compressing and uncompressing is high, changing to faster or multi-core CPUs can help improve performance with the same data, application workload and set of compressed tables. Increasing the size of the buffer pool might also help performance, so that more uncompressed pages can stay in memory, reducing the need to uncompress pages that exist in memory only in compressed form.

A large number of compression operations overall (compared to the number of [INSERT](#), [UPDATE](#) and [DELETE](#) operations in your application and the size of the database) could indicate that some of your compressed tables are being updated too heavily for effective compression. If so, choose a larger page size, or be more selective about which tables you compress.

If the number of “successful” compression operations ([COMPRESS\\_OPS\\_OK](#)) is a high percentage of the total number of compression operations ([COMPRESS\\_OPS](#)), then the system is likely performing well. If the ratio is low, then MySQL is reorganizing, recompressing, and splitting B-tree nodes more often than is desirable. In this case, avoid compressing some tables, or increase [KEY\\_BLOCK\\_SIZE](#) for some of the compressed tables. You might turn off compression for tables that cause the number of “compression failures” in your application to be more than 1% or 2% of the total. (Such a failure ratio might be acceptable during a temporary operation such as a data load).

### 15.9.1.5 How Compression Works for InnoDB Tables

This section describes some internal implementation details about [compression](#) for InnoDB tables. The information presented here may be helpful in tuning for performance, but is not necessary to know for basic use of compression.

#### Compression Algorithms

Some operating systems implement compression at the file system level. Files are typically divided into fixed-size blocks that are compressed into variable-size blocks, which easily leads into fragmentation. Every time something inside a block is modified, the whole block is recompressed before it is written

to disk. These properties make this compression technique unsuitable for use in an update-intensive database system.

MySQL implements compression with the help of the well-known [zlib library](#), which implements the LZ77 compression algorithm. This compression algorithm is mature, robust, and efficient in both CPU utilization and in reduction of data size. The algorithm is “lossless”, so that the original uncompressed data can always be reconstructed from the compressed form. LZ77 compression works by finding sequences of data that are repeated within the data to be compressed. The patterns of values in your data determine how well it compresses, but typical user data often compresses by 50% or more.

Unlike compression performed by an application, or compression features of some other database management systems, InnoDB compression applies both to user data and to indexes. In many cases, indexes can constitute 40-50% or more of the total database size, so this difference is significant. When compression is working well for a data set, the size of the InnoDB data files (the [file-per-table](#) tablespace or [general tablespace](#) `.ibd` files) is 25% to 50% of the uncompressed size or possibly smaller. Depending on the [workload](#), this smaller database can in turn lead to a reduction in I/O, and an increase in throughput, at a modest cost in terms of increased CPU utilization. You can adjust the balance between compression level and CPU overhead by modifying the [innodb\\_compression\\_level](#) configuration option.

## InnoDB Data Storage and Compression

All user data in InnoDB tables is stored in pages comprising a [B-tree](#) index (the [clustered index](#)). In some other database systems, this type of index is called an “index-organized table”. Each row in the index node contains the values of the (user-specified or system-generated) [primary key](#) and all the other columns of the table.

[Secondary indexes](#) in InnoDB tables are also B-trees, containing pairs of values: the index key and a pointer to a row in the clustered index. The pointer is in fact the value of the primary key of the table, which is used to access the clustered index if columns other than the index key and primary key are required. Secondary index records must always fit on a single B-tree page.

The compression of B-tree nodes (of both clustered and secondary indexes) is handled differently from compression of [overflow pages](#) used to store long [VARCHAR](#), [BLOB](#), or [TEXT](#) columns, as explained in the following sections.

## Compression of B-Tree Pages

Because they are frequently updated, B-tree pages require special treatment. It is important to minimize the number of times B-tree nodes are split, as well as to minimize the need to uncompress and recompress their content.

One technique MySQL uses is to maintain some system information in the B-tree node in uncompressed form, thus facilitating certain in-place updates. For example, this allows rows to be delete-marked and deleted without any compression operation.

In addition, MySQL attempts to avoid unnecessary uncompression and recompression of index pages when they are changed. Within each B-tree page, the system keeps an uncompressed “modification log” to record changes made to the page. Updates and inserts of small records may be written to this modification log without requiring the entire page to be completely reconstructed.

When the space for the modification log runs out, InnoDB uncompresses the page, applies the changes and recompresses the page. If recompression fails (a situation known as a [compression failure](#)), the B-tree nodes are split and the process is repeated until the update or insert succeeds.

To avoid frequent compression failures in write-intensive workloads, such as for [OLTP](#) applications, MySQL sometimes reserves some empty space (padding) in the page, so that the modification log fills up sooner and the page is recompressed while there is still enough room to avoid splitting it. The amount of padding space left in each page varies as the system keeps track of the frequency of page splits. On a busy server doing frequent writes to compressed tables, you can adjust the

`innodb_compression_failure_threshold_pct`, and `innodb_compression_pad_pct_max` configuration options to fine-tune this mechanism.

Generally, MySQL requires that each B-tree page in an InnoDB table can accommodate at least two records. For compressed tables, this requirement has been relaxed. Leaf pages of B-tree nodes (whether of the primary key or secondary indexes) only need to accommodate one record, but that record must fit, in uncompressed form, in the per-page modification log. If `innodb_strict_mode` is `ON`, MySQL checks the maximum row size during `CREATE TABLE` or `CREATE INDEX`. If the row does not fit, the following error message is issued: `ERROR HY000: Too big row`.

If you create a table when `innodb_strict_mode` is `OFF`, and a subsequent `INSERT` or `UPDATE` statement attempts to create an index entry that does not fit in the size of the compressed page, the operation fails with `ERROR 42000: Row size too large`. (This error message does not name the index for which the record is too large, or mention the length of the index record or the maximum record size on that particular index page.) To solve this problem, rebuild the table with `ALTER TABLE` and select a larger compressed page size (`KEY_BLOCK_SIZE`), shorten any column prefix indexes, or disable compression entirely with `ROW_FORMAT=DYNAMIC` or `ROW_FORMAT=COMPACT`.

`innodb_strict_mode` is not applicable to general tablespaces, which also support compressed tables. Tablespace management rules for general tablespaces are strictly enforced independently of `innodb_strict_mode`. For more information, see [Section 14.1.19, “CREATE TABLESPACE Syntax”](#).

## Compressing BLOB, VARCHAR, and TEXT Columns

In an InnoDB table, `BLOB`, `VARCHAR`, and `TEXT` columns that are not part of the primary key may be stored on separately allocated [overflow pages](#). We refer to these columns as [off-page columns](#). Their values are stored on singly-linked lists of overflow pages.

For tables created in `ROW_FORMAT=DYNAMIC` or `ROW_FORMAT=COMPRESSED`, the values of `BLOB`, `TEXT`, or `VARCHAR` columns may be stored fully off-page, depending on their length and the length of the entire row. For columns that are stored off-page, the clustered index record only contains 20-byte pointers to the overflow pages, one per column. Whether any columns are stored off-page depends on the page size and the total size of the row. When the row is too long to fit entirely within the page of the clustered index, MySQL chooses the longest columns for off-page storage until the row fits on the clustered index page. As noted above, if a row does not fit by itself on a compressed page, an error occurs.

### Note

For tables created in `ROW_FORMAT=DYNAMIC` or `ROW_FORMAT=COMPRESSED`, `TEXT` and `BLOB` columns that are less than or equal to 40 bytes are always stored in-line.

Tables created in older versions of MySQL use the [Antelope](#) file format, which supports only `ROW_FORMAT=REDUNDANT` and `ROW_FORMAT=COMPACT`. In these formats, MySQL stores the first 768 bytes of `BLOB`, `VARCHAR`, and `TEXT` columns in the clustered index record along with the primary key. The 768-byte prefix is followed by a 20-byte pointer to the overflow pages that contain the rest of the column value.

When a table is in `COMPRESSED` format, all data written to overflow pages is compressed “as is”; that is, MySQL applies the zlib compression algorithm to the entire data item. Other than the data, compressed overflow pages contain an uncompressed header and trailer comprising a page checksum and a link to the next overflow page, among other things. Therefore, very significant storage savings can be obtained for longer `BLOB`, `TEXT`, or `VARCHAR` columns if the data is highly compressible, as is often the case with text data. Image data, such as `JPEG`, is typically already compressed and so does not benefit much from being stored in a compressed table; the double compression can waste CPU cycles for little or no space savings.

The overflow pages are of the same size as other pages. A row containing ten columns stored off-page occupies ten overflow pages, even if the total length of the columns is only 8K bytes. In an

uncompressed table, ten uncompressed overflow pages occupy 160K bytes. In a compressed table with an 8K page size, they occupy only 80K bytes. Thus, it is often more efficient to use compressed table format for tables with long column values.

For [file-per-table](#) tablespaces, using a 16K compressed page size can reduce storage and I/O costs for [BLOB](#), [VARCHAR](#), or [TEXT](#) columns, because such data often compress well, and might therefore require fewer overflow pages, even though the B-tree nodes themselves take as many pages as in the uncompressed form. General tablespaces do not support a 16K compressed page size ([KEY\\_BLOCK\\_SIZE](#)). For more information, see [Section 15.7.9, “InnoDB General Tablespaces”](#).

## Compression and the InnoDB Buffer Pool

In a compressed [InnoDB](#) table, every compressed page (whether 1K, 2K, 4K or 8K) corresponds to an uncompressed page of 16K bytes (or a smaller size if [innodb\\_page\\_size](#) is set). To access the data in a page, MySQL reads the compressed page from disk if it is not already in the [buffer pool](#), then uncompresses the page to its original form. This section describes how [InnoDB](#) manages the buffer pool with respect to pages of compressed tables.

To minimize I/O and to reduce the need to uncompress a page, at times the buffer pool contains both the compressed and uncompressed form of a database page. To make room for other required database pages, MySQL can [evict](#) from the buffer pool an uncompressed page, while leaving the compressed page in memory. Or, if a page has not been accessed in a while, the compressed form of the page might be written to disk, to free space for other data. Thus, at any given time, the buffer pool might contain both the compressed and uncompressed forms of the page, or only the compressed form of the page, or neither.

MySQL keeps track of which pages to keep in memory and which to evict using a least-recently-used (LRU) list, so that [hot](#) (frequently accessed) data tends to stay in memory. When compressed tables are accessed, MySQL uses an adaptive LRU algorithm to achieve an appropriate balance of compressed and uncompressed pages in memory. This adaptive algorithm is sensitive to whether the system is running in an [I/O-bound](#) or [CPU-bound](#) manner. The goal is to avoid spending too much processing time uncompressing pages when the CPU is busy, and to avoid doing excess I/O when the CPU has spare cycles that can be used for uncompressing compressed pages (that may already be in memory). When the system is I/O-bound, the algorithm prefers to evict the uncompressed copy of a page rather than both copies, to make more room for other disk pages to become memory resident. When the system is CPU-bound, MySQL prefers to evict both the compressed and uncompressed page, so that more memory can be used for “hot” pages and reducing the need to uncompress data in memory only in compressed form.

## Compression and the InnoDB Redo Log Files

Before a compressed page is written to a [data file](#), MySQL writes a copy of the page to the redo log (if it has been recompressed since the last time it was written to the database). This is done to ensure that redo logs are usable for [crash recovery](#), even in the unlikely case that the [zlib](#) library is upgraded and that change introduces a compatibility problem with the compressed data. Therefore, some increase in the size of [log files](#), or a need for more frequent [checkpoints](#), can be expected when using compression. The amount of increase in the log file size or checkpoint frequency depends on the number of times compressed pages are modified in a way that requires reorganization and recompression.

Compressed tables require the [Barracuda](#) file format. To create a compressed table in a file-per-table tablespace, [innodb\\_file\\_per\\_table](#) must be enabled and [innodb\\_file\\_format](#) must be set to [Barracuda](#). There is no dependence on the [innodb\\_file\\_format](#) setting when creating a compressed table in a general tablespace. For more information, see [Section 15.7.9, “InnoDB General Tablespaces”](#). The [MySQL Enterprise Backup](#) product supports the [Barracuda](#) file format.

### 15.9.1.6 Compression for OLTP Workloads

Traditionally, the [InnoDB compression](#) feature was recommended primarily for read-only or read-mostly [workloads](#), such as in a [data warehouse](#) configuration. The rise of [SSD](#) storage devices, which

are fast but relatively small and expensive, makes compression attractive also for OLTP workloads: high-traffic, interactive web sites can reduce their storage requirements and their I/O operations per second (IOPS) by using compressed tables with applications that do frequent INSERT, UPDATE, and DELETE operations.

Configuration options introduced in MySQL 5.6 let you adjust the way compression works for a particular MySQL instance, with an emphasis on performance and scalability for write-intensive operations:

- `innodb_compression_level` lets you turn the degree of compression up or down. A higher value lets you fit more data onto a storage device, at the expense of more CPU overhead during compression. A lower value lets you reduce CPU overhead when storage space is not critical, or you expect the data is not especially compressible.
- `innodb_compression_failure_threshold_pct` specifies a cutoff point for compression failures during updates to a compressed table. When this threshold is passed, MySQL begins to leave additional free space within each new compressed page, dynamically adjusting the amount of free space up to the percentage of page size specified by `innodb_compression_pad_pct_max`.
- `innodb_compression_pad_pct_max` lets you adjust the maximum amount of space reserved within each page to record changes to compressed rows, without needing to compress the entire page again. The higher the value, the more changes can be recorded without recompressing the page. MySQL uses a variable amount of free space for the pages within each compressed table, only when a designated percentage of compression operations “fail” at runtime, requiring an expensive operation to split the compressed page.
- `innodb_log_compressed_pages` lets you disable writing of images of re-compressed pages to the redo log. Re-compression may occur when changes are made to compressed data. This option is enabled by default to prevent corruption that could occur if a different version of the `zlib` compression algorithm is used during recovery. If you are certain that the `zlib` version will not change, disable `innodb_log_compressed_pages` to reduce redo log generation for workloads that modify compressed data.

Because working with compressed data sometimes involves keeping both compressed and uncompressed versions of a page in memory at the same time, when using compression with an OLTP-style workload, be prepared to increase the value of the `innodb_buffer_pool_size` configuration option.

### 15.9.1.7 SQL Compression Syntax Warnings and Errors

This section describes syntax warnings and errors that you may encounter when using the table compression feature with `file-per-table` tablespaces and `general tablespaces`.

#### SQL Compression Syntax Warnings and Errors for File-Per-Table Tablespaces

When `innodb_strict_mode` is enabled (the default as of MySQL 5.7.7), specifying `ROW_FORMAT=COMPRESSED` or `KEY_BLOCK_SIZE` in `CREATE TABLE` or `ALTER TABLE` statements produces the following error if `innodb_file_per_table` is disabled or if `innodb_file_format` is set to `Antelope` rather than `Barracuda`.

```
ERROR 1031 (HY000): Table storage engine for 't1' doesn't have this option
```

#### Note

The table is not created if the current configuration does not permit using compressed tables.

When `innodb_strict_mode` is disabled, specifying `ROW_FORMAT=COMPRESSED` or `KEY_BLOCK_SIZE` in `CREATE TABLE` or `ALTER TABLE` statements produces the following warnings if `innodb_file_per_table` is disabled.

```
mysql> SHOW WARNINGS;
```

| Level   | Code | Message   |
|---------|------|---|
| Warning | 1478 | InnoDB: KEY_BLOCK_SIZE requires innodb_file_per_table.        |
| Warning | 1478 | InnoDB: ignoring KEY_BLOCK_SIZE=4.                            |
| Warning | 1478 | InnoDB: ROW_FORMAT=COMPRESSED requires innodb_file_per_table. |
| Warning | 1478 | InnoDB: assuming ROW_FORMAT=DYNAMIC.                          |

Similar warnings are issued if `innodb_file_format` is set to `Antelope` rather than `Barracuda`.

#### Note

These messages are only warnings, not errors, and the table is created without compression, as if the options were not specified.

The “non-strict” behavior lets you import a `mysqldump` file into a database that does not support compressed tables, even if the source database contained compressed tables. In that case, MySQL creates the table in `ROW_FORMAT=COMPACT` instead of preventing the operation.

To import the dump file into a new database, and have the tables re-created as they exist in the original database, ensure the server has the proper settings for the configuration parameters `innodb_file_format` and `innodb_file_per_table`.

The attribute `KEY_BLOCK_SIZE` is permitted only when `ROW_FORMAT` is specified as `COMPRESSED` or is omitted. Specifying a `KEY_BLOCK_SIZE` with any other `ROW_FORMAT` generates a warning that you can view with `SHOW WARNINGS`. However, the table is non-compressed; the specified `KEY_BLOCK_SIZE` is ignored).

| Level   | Code | Message   |
|---------|------|---|
| Warning | 1478 | InnoDB: ignoring KEY_BLOCK_SIZE= <i>n</i> unless ROW_FORMAT=COMPRESSED. |

If you are running with `innodb_strict_mode` enabled, the combination of a `KEY_BLOCK_SIZE` with any `ROW_FORMAT` other than `COMPRESSED` generates an error, not a warning, and the table is not created.

Table 15.7, “`ROW_FORMAT` and `KEY_BLOCK_SIZE` Options” provides an overview the `ROW_FORMAT` and `KEY_BLOCK_SIZE` options that are used with `CREATE TABLE` or `ALTER TABLE`.

**Table 15.7 `ROW_FORMAT` and `KEY_BLOCK_SIZE` Options**

| Option                               | Usage Notes  | Description   |
|--------------------------------------|--|---|
| <code>ROW_FORMAT=REDUNDANT</code>    | Storage format used prior to MySQL 5.0.3                                     | Less efficient than <code>ROW_FORMAT=COMPACT</code> ; for backward compatibility  |
| <code>ROW_FORMAT=COMPACT</code>      | Default storage format since MySQL 5.0.3                                     | Stores a prefix of 768 bytes of long column values in the clustered index page, with the remaining bytes stored in an overflow page   |
| <code>ROW_FORMAT=DYNAMIC</code>      | File-per-table tablespaces require <code>innodb_file_format=Barracuda</code> | Store values within the clustered index page if they fit; if not, stores only a 20-byte pointer to an overflow page (no prefix)   |
| <code>ROW_FORMAT=COMPRESSED</code>   | File-per-table tablespaces require <code>innodb_file_format=Barracuda</code> | Compresses the table and indexes using zlib   |
| <code>KEY_BLOCK_SIZE=<i>n</i></code> | File-per-table tablespaces require <code>innodb_file_format=Barracuda</code> | Specifies compressed page size of 1, 2, 4, 8 or 16 kilobytes; implies <code>ROW_FORMAT=COMPRESSED</code> . For general tablespaces, a <code>KEY_BLOCK_SIZE</code> value equal to the InnoDB page size is not permitted. |

Table 15.8, “`CREATE/ALTER TABLE` Warnings and Errors when InnoDB Strict Mode is OFF” summarizes error conditions that occur with certain combinations of configuration parameters and

options on the `CREATE TABLE` or `ALTER TABLE` statements, and how the options appear in the output of `SHOW TABLE STATUS`.

When `innodb_strict_mode` is `OFF`, MySQL creates or alters the table, but ignores certain settings as shown below. You can see the warning messages in the MySQL error log. When `innodb_strict_mode` is `ON`, these specified combinations of options generate errors, and the table is not created or altered. To see the full description of the error condition, issue the `SHOW ERRORS` statement: example:

```
mysql> CREATE TABLE x (id INT PRIMARY KEY, c INT)
-> ENGINE=INNODB KEY_BLOCK_SIZE=33333;

ERROR 1005 (HY000): Can't create table 'test.x' (errno: 1478)

mysql> SHOW ERRORS;
+-----+-----+-----+
| Level | Code | Message                                     |
+-----+-----+-----+
| Error | 1478 | InnoDB: invalid KEY_BLOCK_SIZE=33333.      |
| Error | 1005 | Can't create table 'test.x' (errno: 1478) |
+-----+-----+-----+
```

**Table 15.8 CREATE/ALTER TABLE Warnings and Errors when InnoDB Strict Mode is OFF**

| Syntax  | Warning or Error Condition  | Resulting <code>ROW_FORMAT</code> , as shown in <code>SHOW TABLE STATUS</code>                          |
|---|---|---|
| <code>ROW_FORMAT=REDUNDANT</code>   | None  | <code>REDUNDANT</code>  |
| <code>ROW_FORMAT=COMPACT</code>   | None  | <code>COMPACT</code>  |
| <code>ROW_FORMAT=COMPRESSED</code> or <code>ROW_FORMAT=DYNAMIC</code> or <code>KEY_BLOCK_SIZE</code> is specified                     | Ignored for file-per-table tablespaces unless both <code>innodb_file_format=Barracuda</code> and <code>innodb_file_per_table</code> are enabled. General tablespaces support all row formats (with some restrictions) regardless of <code>innodb_file_format</code> and <code>innodb_file_per_table</code> settings. See <a href="#">Section 15.7.9, “InnoDB General Tablespaces”</a> . | the default row format for file-per-table tablespaces; the specified row format for general tablespaces |
| Invalid <code>KEY_BLOCK_SIZE</code> is specified (not 1, 2, 4, 8 or 16)   | <code>KEY_BLOCK_SIZE</code> is ignored  | the specified row format, or the default row format   |
| <code>ROW_FORMAT=COMPRESSED</code> and valid <code>KEY_BLOCK_SIZE</code> are specified  | None; <code>KEY_BLOCK_SIZE</code> specified is used   | <code>COMPRESSED</code>   |
| <code>KEY_BLOCK_SIZE</code> is specified with <code>REDUNDANT</code> , <code>COMPACT</code> or <code>DYNAMIC</code> row format        | <code>KEY_BLOCK_SIZE</code> is ignored  | <code>REDUNDANT</code> , <code>COMPACT</code> or <code>DYNAMIC</code>                                   |
| <code>ROW_FORMAT</code> is not one of <code>REDUNDANT</code> , <code>COMPACT</code> , <code>DYNAMIC</code> or <code>COMPRESSED</code> | Ignored if recognized by the MySQL parser. Otherwise, an error is issued.   | the default row format or N/A   |

When `innodb_strict_mode` is `ON`, MySQL rejects invalid `ROW_FORMAT` or `KEY_BLOCK_SIZE` parameters and issues errors. When `innodb_strict_mode` is `OFF`, MySQL issues warnings instead of errors for ignored invalid parameters. `innodb_strict_mode` is `ON` by default as of MySQL 5.7.7.

When `innodb_strict_mode` is `ON`, MySQL rejects invalid `ROW_FORMAT` or `KEY_BLOCK_SIZE` parameters. For compatibility with earlier versions of MySQL, strict mode is not enabled by default; instead, MySQL issues warnings (not errors) for ignored invalid parameters.

It is not possible to see the chosen `KEY_BLOCK_SIZE` using `SHOW TABLE STATUS`. The statement `SHOW CREATE TABLE` displays the `KEY_BLOCK_SIZE` (even if it was ignored when creating the table). The real compressed page size of the table cannot be displayed by MySQL.

## SQL Compression Syntax Warnings and Errors for General Tablespaces

- If `FILE_BLOCK_SIZE` was not defined for the general tablespace when the tablespace was created, the tablespace cannot contain compressed tables. If you attempt to add a compressed table, an error is returned, as shown in the following example:

```
mysql> CREATE TABLESPACE `ts1` ADD DATAFILE 'ts1.ibd' Engine=InnoDB;
Query OK, 0 rows affected (0.01 sec)

mysql> CREATE TABLE t1 (c1 INT PRIMARY KEY) TABLESPACE ts1 ROW_FORMAT=COMPRESSED
KEY_BLOCK_SIZE=8;
ERROR 1478 (HY000): InnoDB: Tablespace `ts1` cannot contain a COMPRESSED table
```

- Attempting to add a table with an invalid `KEY_BLOCK_SIZE` to a general tablespace returns an error, as shown in the following example:

```
mysql> CREATE TABLESPACE `ts2` ADD DATAFILE 'ts2.ibd' FILE_BLOCK_SIZE = 8192 Engine=InnoDB;
Query OK, 0 rows affected (0.01 sec)

mysql> CREATE TABLE t2 (c1 INT PRIMARY KEY) TABLESPACE ts2 ROW_FORMAT=COMPRESSED
KEY_BLOCK_SIZE=4;
ERROR 1478 (HY000): InnoDB: Tablespace `ts2` uses block size 8192 and cannot
contain a table with physical page size 4096
```

For general tablespaces, the `KEY_BLOCK_SIZE` of the table must be equal to the `FILE_BLOCK_SIZE` of the tablespace divided by 1024. For example, if the `FILE_BLOCK_SIZE` of the tablespace is 8192, the `KEY_BLOCK_SIZE` of the table must be 8.

- Attempting to add a table with an uncompressed row format to a general tablespace configured to store compressed tables returns an error, as shown in the following example:

```
mysql> CREATE TABLESPACE `ts3` ADD DATAFILE 'ts3.ibd' FILE_BLOCK_SIZE = 8192 Engine=InnoDB;
Query OK, 0 rows affected (0.01 sec)

mysql> CREATE TABLE t3 (c1 INT PRIMARY KEY) TABLESPACE ts3 ROW_FORMAT=COMPACT;
ERROR 1478 (HY000): InnoDB: Tablespace `ts3` uses block size 8192 and cannot
contain a table with physical page size 16384
```

`innodb_strict_mode` is not applicable to general tablespaces. Tablespace management rules for general tablespaces are strictly enforced independently of `innodb_strict_mode`. For more information, see [Section 14.1.19, “CREATE TABLESPACE Syntax”](#).

For more information about using compressed tables with general tablespaces, see [Section 15.7.9, “InnoDB General Tablespaces”](#).

## 15.9.2 InnoDB Page Compression

As of MySQL 5.7.8, InnoDB supports page-level compression for tables that reside in [file-per-table](#) tablespaces. This feature is referred to as *Transparent Page Compression*. Page compression is enabled by specifying the `COMPRESSION` attribute with `CREATE TABLE` or `ALTER TABLE`. Supported compression algorithms include `Zlib` and `LZ4`.

### Supported Platforms

Page compression requires sparse file and hole punching support. Page compression is supported on Windows with NTFS, and on the following subset of MySQL-supported Linux platforms where the kernel level provides hole punching support:

- RHEL 7 and derived distributions that use kernel version 3.10.0-123 or higher
- OEL 5.10 (UEK2) kernel version 2.6.39 or higher
- OEL 6.5 (UEK3) kernel version 3.8.13 or higher
- OEL 7.0 kernel version 3.8.13 or higher
- SLE11 kernel version 3.0-x
- SLE12 kernel version 3.12-x
- OES11 kernel version 3.0-x
- Ubuntu 14.0.4 LTS kernel version 3.13 or higher
- Ubuntu 12.0.4 LTS kernel version 3.2 or higher
- Debian 7 kernel version 3.2 or higher

**Note**

All of the available file systems for a given Linux distribution may not support hole punching.

## How Page Compression Works

When a page is written, it is compressed using the specified compression algorithm. The compressed data is written to disk, where the hole punching mechanism releases empty blocks from the end of the page. If compression fails, data is written out as-is.

## Hole Punch Size on Linux

On Linux systems, the file system block size is the unit size used for hole punching. Therefore, page compression only works if page data can be compressed to a size that is less than or equal to the [InnoDB](#) page size minus the file system block size. For example, if `innodb_page_size=16K` and the file system block size is 4K, page data must compress to less than or equal to 12K to make hole punching possible.

## Hole Punch Size on Windows

On Windows systems, the underlying infrastructure for sparse files is based on NTFS compression. Hole punching size is the NTFS compression unit, which is 16 times the NTFS cluster size. Cluster sizes and their compression units are shown in the following table:

**Table 15.9 Windows NTFS Cluster Size and Compression Units**

| Cluster Size | Compression Unit |
|--------------|------------------|
| 512 Bytes    | 8 KB             |
| 1 KB         | 16 KB            |
| 2 KB         | 32 KB            |
| 4 KB         | 64 KB            |

Page compression on Windows systems only works if page data can be compressed to a size that is less than or equal to the [InnoDB](#) page size minus the compression unit size.

The default NTFS cluster size is 4K, for which the compression unit size is 64K. This means that page compression has no benefit for an out-of-the box Windows NTFS configuration, as the maximum `innodb_page_size` is also 64K.

For page compression to work on Windows, the file system must be created with a cluster size smaller than 4K, and the `innodb_page_size` must be at least twice the size of the compression

unit. For example, for page compression to work on Windows, you could build the file system with a cluster size of 512 Bytes (which has a compression unit of 8KB) and initialize [InnoDB](#) with an [innodb\\_page\\_size](#) value of 16K or greater.

## Enabling Page Compression

To enable page compression, specify the [COMPRESSION](#) attribute in the [CREATE TABLE](#) statement. For example:

```
CREATE TABLE t1 (c1 INT) COMPRESSION="zlib";
```

You can also enable page compression in an [ALTER TABLE](#) statement. However, [ALTER TABLE ... COMPRESSION](#) only updates the tablespace compression attribute. Writes to the tablespace that occur after setting the new compression algorithm use the new setting, but to apply the new compression algorithm to existing pages, you must rebuild the table using [OPTIMIZE TABLE](#).

```
ALTER TABLE t1 COMPRESSION="zlib";
OPTIMIZE TABLE t1;
```

## Disabling Page Compression

To disable page compression, set [COMPRESSION=None](#) using [ALTER TABLE](#). Writes to the tablespace that occur after setting [COMPRESSION=None](#) no longer use page compression. To uncompress existing pages, you must rebuild the table using [OPTIMIZE TABLE](#) after setting [COMPRESSION=None](#).

```
ALTER TABLE t1 COMPRESSION="None";
OPTIMIZE TABLE t1;
```

## Page Compression Metadata

Page compression metadata is found in the [INFORMATION\\_SCHEMA.INNODB\\_SYS\\_TABLESPACES](#) table, in the following columns:

- [FS\\_BLOCK\\_SIZE](#): The file system block size, which is the unit size used for hole punching.
- [FILE\\_SIZE](#): The apparent size of the file, which represents the maximum size of the file, uncompressed.
- [ALLOCATED\\_SIZE](#): The actual size of the file, which is the amount of space allocated on disk.

### Note

On Unix-like systems, `ls -l tablespace_name.ibd` shows the apparent file size (equivalent to [FILE\\_SIZE](#)) in bytes. To view the actual amount of space allocated on disk (equivalent to [ALLOCATED\\_SIZE](#)), use `du --block-size=1 tablespace_name.ibd`. The `--block-size=1` option prints the allocated space in bytes instead of blocks, so that it can be compared to `ls -l` output.

Use [SHOW CREATE TABLE](#) to view the current page compression setting ([Zlib](#), [Lz4](#), or [None](#)). A table may contain a mix of pages with different compression settings.

In the following example, page compression metadata for the employees table is retrieved from the [INFORMATION\\_SCHEMA.INNODB\\_SYS\\_TABLESPACES](#) table.

```
# Create the employees table with Zlib page compression

CREATE TABLE employees (
  emp_no      INT          NOT NULL,
  birth_date  DATE         NOT NULL,
  first_name  VARCHAR(14)  NOT NULL,
  last_name   VARCHAR(16)  NOT NULL,
  gender      ENUM ('M','F') NOT NULL,
  hire_date   DATE         NOT NULL,
  PRIMARY KEY (emp_no)
```

```

) COMPRESSION="zlib";

# Insert data (not shown)

# Query page compression metadata in INFORMATION_SCHEMA.INNODB_SYS_TABLESPACES

mysql> SELECT SPACE, NAME, FS_BLOCK_SIZE, FILE_SIZE, ALLOCATED_SIZE FROM
INFORMATION_SCHEMA.INNODB_SYS_TABLESPACES WHERE NAME='employees/employees'\G
***** 1. row *****
SPACE: 45
NAME: employees/employees
FS_BLOCK_SIZE: 4096
FILE_SIZE: 23068672
ALLOCATED_SIZE: 19415040

```

Page compression metadata for the employees table shows that the apparent file size is 23068672 bytes while the actual file size (with page compression) is 19415040 bytes. The file system block size is 4096 bytes, which is the block size used for hole punching.

## Page Compression Limitations and Usage Notes

- Page compression is disabled if the file system block size (or compression unit size on Windows) \* 2 > [innodb\\_page\\_size](#).
- Page compression is not supported for tables that reside in shared tablespaces, which include the system tablespace, the temporary tablespace, and general tablespaces.
- Page compression is not supported for undo log tablespaces.
- Page compression is not supported for redo log pages.
- R-tree pages, which are used for spatial indexes, are not compressed.
- Pages that belong to compressed tables ([ROW\\_FORMAT=COMPRESSED](#)) are left as-is.
- During recovery, updated pages are written out in an uncompressed form.
- Loading a page-compressed tablespace on a server that does not support the compression algorithm that was used causes an I/O error.
- Before downgrading to an earlier version of MySQL that does not support page compression, uncompress the tables that use the page compression feature. To uncompress a table, run [ALTER TABLE ... COMPRESSION=None](#) and [OPTIMIZE TABLE](#).
- Page-compressed tablespaces can be copied between Linux and Windows servers if the compression algorithm that was used is available on both servers.
- Preserving page compression when moving a page-compressed tablespace file from one host to another requires a utility that preserves sparse files.
- Better page compression may be achieved on Fusion-io hardware with NVMFS than on other platforms, as NVMFS is designed to take advantage of punch hole functionality.
- Using the page compression feature with a large [InnoDB](#) page size and relatively small file system block size could result in write amplification. For example, a maximum [InnoDB](#) page size of 64KB with a 4KB file system block size may improve compression but may also increase demand on the buffer pool, leading to increased I/O and potential write amplification.

## 15.10 InnoDB File-Format Management

As [InnoDB](#) evolves, data file formats that are not compatible with prior versions of [InnoDB](#) are sometimes required to support new features. To help manage compatibility in upgrade and downgrade situations, and systems that run different versions of MySQL, [InnoDB](#) uses named file formats. [InnoDB](#) currently supports two named file formats, [Antelope](#) and [Barracuda](#).

- [Antelope](#) is the original [InnoDB](#) file format, which previously did not have a name. It supports the [COMPACT](#) and [REDUNDANT](#) row formats for [InnoDB](#) tables.
- [Barracuda](#) is the newest file format. It supports all [InnoDB](#) row formats including the newer [COMPRESSED](#) and [DYNAMIC](#) row formats. The features associated with [COMPRESSED](#) and [DYNAMIC](#) row formats include compressed tables, efficient storage of off-page columns, and index key prefixes up to 3072 bytes ([innodb\\_large\\_prefix](#)). See [Section 15.11, “InnoDB Row Storage and Row Formats”](#).

This section discusses enabling [InnoDB](#) file formats for new [InnoDB](#) tables, verifying compatibility of different file formats between MySQL releases, and identifying the file format in use.

InnoDB file format settings do not apply to tables stored in [general tablespaces](#) (introduced in MySQL 5.7.6). General tablespaces provide support for all row formats and associated features. For more information, see [Section 15.7.9, “InnoDB General Tablespaces”](#).

#### Note

The following file format configuration parameters have new default values as of MySQL 5.7.7:

- The [innodb\\_file\\_format](#) default value was changed to [Barracuda](#). The previous default value was [Antelope](#).
- The [innodb\\_large\\_prefix](#) default value was changed to [ON](#). The previous default was [OFF](#).

The following file format configuration parameters are deprecated in MySQL 5.7.7 and may be removed in a future release:

- [innodb\\_file\\_format](#)
- [innodb\\_file\\_format\\_check](#)
- [innodb\\_file\\_format\\_max](#)
- [innodb\\_large\\_prefix](#)

The file format configuration parameters were provided for creating tables compatible with earlier versions of [InnoDB](#) in MySQL 5.1. Now that MySQL 5.1 has reached the end of its product lifecycle, the parameters are no longer required. Future removal of the [innodb\\_file\\_format](#) parameter will require a new mechanism for managing compatibility of [InnoDB](#) tables and tablespaces among different versions of MySQL.

## 15.10.1 Enabling File Formats

The [innodb\\_file\\_format](#) configuration option enables an [InnoDB](#) file format for [file-per-table](#) tablespaces.

[Barracuda](#) is the default [innodb\\_file\\_format](#) setting as of MySQL 5.7.7. Prior to MySQL 5.7.7, the default file format is [Antelope](#).

#### Note

The [innodb\\_file\\_format](#) configuration option is deprecated and may be removed in a future release. For more information, see [Section 15.10, “InnoDB File-Format Management”](#).

You can set the value of [innodb\\_file\\_format](#) on the command line when you start [mysqld](#), or in the option file ([my.cnf](#) on Unix, [my.ini](#) on Windows). You can also change it dynamically with a [SET GLOBAL](#) statement.

```
SET GLOBAL innodb_file_format=Barracuda;
```

## Usage notes

- InnoDB file format settings do not apply to tables stored in [general tablespaces](#). General tablespaces provide support for all row formats and associated features. For more information, see [Section 15.7.9, “InnoDB General Tablespaces”](#).
- As of MySQL 5.7.6, the `innodb_file_format` setting is not applicable when using the `TABLESPACE [=] innodb_system` table option with `CREATE TABLE` or `ALTER TABLE` to store a `DYNAMIC` table in the system tablespace.
- As of MySQL 5.7.9, the `innodb_file_format` setting is ignored when creating tables that use the `DYNAMIC` row format. For more information, see [Section 15.11.3, “DYNAMIC and COMPRESSED Row Formats”](#).

## 15.10.2 Verifying File Format Compatibility

InnoDB incorporates several checks to guard against the possible crashes and data corruptions that might occur if you run an old release of the MySQL server on InnoDB data files that use a newer file format. These checks take place when the server is started, and when you first access a table. This section describes these checks, how you can control them, and error and warning conditions that might arise.

### Backward Compatibility

You only need to consider backward file format compatibility when using a recent version of InnoDB (MySQL 5.5 and higher with InnoDB) alongside an older version (MySQL 5.1 or earlier, with the built-in InnoDB rather than the InnoDB Plugin). To minimize the chance of compatibility issues, you can standardize on the InnoDB Plugin for all your MySQL 5.1 and earlier database servers.

In general, a newer version of InnoDB may create a table or index that cannot safely be read or written with an older version of InnoDB without risk of crashes, hangs, wrong results or corruptions. InnoDB includes a mechanism to guard against these conditions, and to help preserve compatibility among database files and versions of InnoDB. This mechanism lets you take advantage of some new features of an InnoDB release (such as performance improvements and bug fixes), and still preserve the option of using your database with an old version of InnoDB, by preventing accidental use of new features that create downward-incompatible disk files.

If a version of InnoDB supports a particular file format (whether or not that format is the default), you can query and update any table that requires that format or an earlier format. Only the creation of new tables using new features is limited based on the particular file format enabled. Conversely, if a tablespace contains a table or index that uses a file format that is not supported, it cannot be accessed at all, even for read access.

The only way to “downgrade” an InnoDB tablespace to the earlier Antelope file format is to copy the data to a new table, in a tablespace that uses the earlier format.

The easiest way to determine the file format of an existing InnoDB tablespace is to examine the properties of the table it contains, using the `SHOW TABLE STATUS` command or querying the table `INFORMATION_SCHEMA.TABLES`. If the `Row_format` of the table is reported as `'Compressed'` or `'Dynamic'`, the tablespace containing the table supports the Barracuda format.

### Internal Details

Every InnoDB file-per-table tablespace (represented by a `*.ibd` file) is labeled with a file format identifier. The system tablespace (represented by the `ibdata` files) is tagged with the “highest” file format in use in a group of InnoDB database files, and this tag is checked when the files are opened.

Creating a compressed table, or a table with `ROW_FORMAT=DYNAMIC`, updates the file header of the corresponding file-per-table `.ibd` file and the table type in the InnoDB data dictionary with the identifier for the Barracuda file format. From that point forward, the table cannot be used with a version of InnoDB that does not support the Barracuda file format. To protect against anomalous behavior, InnoDB performs a compatibility check when the table is opened. (In many cases, the `ALTER TABLE` statement recreates a table and thus changes its properties. The special case of adding or dropping indexes without rebuilding the table is described in [Section 15.13.1, “Overview of Online DDL”](#).)

General tablespaces, which are also represented by a `*.ibd` file, support both Antelope and Barracuda file formats. For more information about general tablespaces, see [Section 15.7.9, “InnoDB General Tablespaces”](#).

## Definition of ib-file set

To avoid confusion, for the purposes of this discussion we define the term “ib-file set” to mean the set of operating system files that InnoDB manages as a unit. The ib-file set includes the following files:

- The system tablespace (one or more `ibdata` files) that contain internal system information (including internal catalogs and undo information) and may include user data and indexes.
- Zero or more single-table tablespaces (also called “file per table” files, named `*.ibd` files).
- InnoDB log files; usually two, `ib_logfile0` and `ib_logfile1`. Used for crash recovery and in backups.

An “ib-file set” does not include the corresponding `.frm` files that contain metadata about InnoDB tables. The `.frm` files are created and managed by MySQL, and can sometimes get out of sync with the internal metadata in InnoDB.

Multiple tables, even from more than one database, can be stored in a single “ib-file set”. (In MySQL, a “database” is a logical collection of tables, what other systems refer to as a “schema” or “catalog”.)

### 15.10.2.1 Compatibility Check When InnoDB Is Started

To prevent possible crashes or data corruptions when InnoDB opens an ib-file set, it checks that it can fully support the file formats in use within the ib-file set. If the system is restarted following a crash, or a “fast shutdown” (i.e., `innodb_fast_shutdown` is greater than zero), there may be on-disk data structures (such as redo or undo entries, or doublewrite pages) that are in a “too-new” format for the current software. During the recovery process, serious damage can be done to your data files if these data structures are accessed. The startup check of the file format occurs before any recovery process begins, thereby preventing consistency issues with the new tables or startup problems for the MySQL server.

Beginning with version InnoDB 1.0.1, the system tablespace records an identifier or tag for the “highest” file format used by any table in any of the tablespaces that is part of the ib-file set. Checks against this file format tag are controlled by the configuration parameter `innodb_file_format_check`, which is `ON` by default.

If the file format tag in the system tablespace is newer or higher than the highest version supported by the particular currently executing software and if `innodb_file_format_check` is `ON`, the following error is issued when the server is started:

```
InnoDB: Error: the system tablespace is in a
file format that this version doesn't support
```

You can also set `innodb_file_format` to a file format name. Doing so prevents InnoDB from starting if the current software does not support the file format specified. It also sets the “high water mark” to the value you specify. The ability to set `innodb_file_format_check` will be useful (with future releases of InnoDB) if you manually “downgrade” all of the tables in an ib-file set (as described in [Downgrading the InnoDB Storage Engine](#)). You can then rely on the file format check at startup if you subsequently use an older version of InnoDB to access the ib-file set.

In some limited circumstances, you might want to start the server and use an ib-file set that is in a new file format that is not supported by the software you are using. If you set the configuration parameter `innodb_file_format_check` to `OFF`, InnoDB opens the database, but issues this warning message in the error log:

```
InnoDB: Warning: the system tablespace is in a
file format that this version doesn't support
```

#### Note

This is a dangerous setting, as it permits the recovery process to run, possibly corrupting your database if the previous shutdown was a crash or “fast shutdown”. You should only set `innodb_file_format_check` to `OFF` if you are sure that the previous shutdown was done with `innodb_fast_shutdown=0`, so that essentially no recovery process occurs.

The parameter `innodb_file_format_check` affects only what happens when a database is opened, not subsequently. Conversely, the parameter `innodb_file_format` (which enables a specific format) only determines whether or not a new table can be created in the enabled format and has no effect on whether or not a database can be opened.

The file format tag is a “high water mark”, and as such it is increased after the server is started, if a table in a “higher” format is created or an existing table is accessed for read or write (assuming its format is supported). If you access an existing table in a format higher than the format the running software supports, the system tablespace tag is not updated, but table-level compatibility checking applies (and an error is issued), as described in [Section 15.10.2.2, “Compatibility Check When a Table Is Opened”](#). Any time the high water mark is updated, the value of `innodb_file_format_check` is updated as well, so the command `SELECT @@innodb_file_format_check;` displays the name of the latest file format known to be used by tables in the currently open ib-file set and supported by the currently executing software.

### 15.10.2.2 Compatibility Check When a Table Is Opened

When a table is first accessed, InnoDB (including some releases prior to InnoDB 1.0) checks that the file format of the tablespace in which the table is stored is fully supported. This check prevents crashes or corruptions that would otherwise occur when tables using a “too new” data structure are encountered.

All tables using any file format supported by a release can be read or written (assuming the user has sufficient privileges). The setting of the system configuration parameter `innodb_file_format` can prevent creating a new table that uses a specific file format, even if the file format is supported by a given release. Such a setting might be used to preserve backward compatibility, but it does not prevent accessing any table that uses a supported format.

Versions of MySQL older than 5.0.21 cannot reliably use database files created by newer versions if a new file format was used when a table was created. To prevent various error conditions or corruptions, InnoDB checks file format compatibility when it opens a file (for example, upon first access to a table). If the currently running version of InnoDB does not support the file format identified by the table type in the InnoDB data dictionary, MySQL reports the following error:

```
ERROR 1146 (42S02): Table 'test.t1' doesn't exist
```

InnoDB also writes a message to the error log:

```
InnoDB: table test/t1: unknown table type 33
```

The table type should be equal to the tablespace flags, which contains the file format version as discussed in [Section 15.10.3, “Identifying the File Format in Use”](#).

Versions of InnoDB prior to MySQL 4.1 did not include table format identifiers in the database files, and versions prior to MySQL 5.0.21 did not include a table format compatibility check. Therefore, there is no way to ensure proper operations if a table in a newer file format is used with versions of InnoDB prior to 5.0.21.

The file format management capability in InnoDB 1.0 and higher (tablespace tagging and run-time checks) allows InnoDB to verify as soon as possible that the running version of software can properly process the tables existing in the database.

If you permit InnoDB to open a database containing files in a format it does not support (by setting the parameter `innodb_file_format_check` to `OFF`), the table-level checking described in this section still applies.

Users are *strongly* urged not to use database files that contain Barracuda file format tables with releases of InnoDB older than the MySQL 5.1 with the InnoDB Plugin. It may be possible to rebuild such tables to use the Antelope format.

### 15.10.3 Identifying the File Format in Use

If you enable a different [file format](#) using the `innodb_file_format` configuration option, the change only applies to newly created tables. Also, when you create a new table, the tablespace containing the table is tagged with the “earliest” or “simplest” file format that is required to support the table's features. For example, if you enable the [Barracuda](#) file format, and create a new table that does not use the Dynamic or Compressed row format, the new tablespace that contains the table is tagged as using the [Antelope](#) file format .

It is easy to identify the file format used by a given table. The table uses the [Antelope](#) file format if the row format reported by `SHOW TABLE STATUS` is either [Compact](#) or [Redundant](#). The table uses the [Barracuda](#) file format if the row format reported by `SHOW TABLE STATUS` is either [Compressed](#) or [Dynamic](#).

```
mysql> SHOW TABLE STATUS\G
***** 1. row *****
      Name: t1
      Engine: InnoDB
      Version: 10
      Row_format: Compact
      Rows: 0
      Avg_row_length: 0
      Data_length: 16384
      Max_data_length: 0
      Index_length: 16384
      Data_free: 0
      Auto_increment: 1
      Create_time: 2014-11-03 13:32:10
      Update_time: NULL
      Check_time: NULL
      Collation: latin1_swedish_ci
      Checksum: NULL
      Create_options:
      Comment:
```

You can also identify the file format used by a given table or tablespace using [InnoDB INFORMATION\\_SCHEMA](#) tables. For example:

```
mysql> SELECT * FROM INFORMATION_SCHEMA.INNODB_SYS_TABLES WHERE NAME='test/t1'\G
***** 1. row *****
      TABLE_ID: 44
      NAME: test/t1
      FLAG: 1
      N_COLS: 6
      SPACE: 30
      FILE_FORMAT: Antelope
      ROW_FORMAT: Compact
      ZIP_PAGE_SIZE: 0
```

```
mysql> SELECT * FROM INFORMATION_SCHEMA.INNODB_SYS_TABLESPACES WHERE NAME='test/t1'\G
***** 1. row *****
SPACE: 30
NAME: test/t1
FLAG: 0
FILE_FORMAT: Antelope
ROW_FORMAT: Compact or Redundant
PAGE_SIZE: 16384
ZIP_PAGE_SIZE: 0
```

## 15.10.4 Modifying the File Format

Each InnoDB tablespace file (with a name matching `*.ibd`) is tagged with the file format used to create its table and indexes. The way to modify the file format is to re-create the table and its indexes. The easiest way to recreate a table and its indexes is to use the following command on each table that you want to modify:

```
ALTER TABLE t ROW_FORMAT=format_name;
```

If you are modifying the file format to downgrade to an older MySQL version, there may be incompatibilities in table storage formats that require additional steps. For information about downgrading to a previous MySQL version, see [Section 2.11.2, “Downgrading MySQL”](#).

## 15.11 InnoDB Row Storage and Row Formats

This section discusses how InnoDB features such as table [compression](#), off-page storage of long variable-length column values, and large index key prefixes (`innodb_large_prefix`) are controlled by the row format of an [InnoDB](#) table. It also discusses considerations for choosing the right row format, and compatibility of row formats between MySQL releases.

### 15.11.1 Overview of InnoDB Row Storage

The storage for rows and associated columns affects performance for queries and DML operations. As more rows fit into a single disk [page](#), queries and index lookups can work faster, less cache memory is required in the InnoDB buffer pool, and less I/O is required to write out updated values for the numeric and short string columns.

The data in each InnoDB table is divided into [pages](#). The pages that make up each table are arranged in a tree data structure called a [B-tree index](#). Table data and [secondary indexes](#) both use this type of structure. The B-tree index that represents an entire table is known as the [clustered index](#), which is organized according to the [primary key](#) columns. The nodes of the index data structure contain the values of all the columns in that row (for the clustered index) or the index columns and the primary key columns (for secondary indexes).

Variable-length columns are an exception to this rule. Columns such as [BLOB](#) and [VARCHAR](#) that are too long to fit on a B-tree page are stored on separately allocated disk pages called [overflow pages](#). We call such columns [off-page columns](#). The values of these columns are stored in singly-linked lists of overflow pages, and each such column has its own list of one or more overflow pages. In some cases, all or a prefix of the long column value is stored in the B-tree, to avoid wasting storage and eliminating the need to read a separate page.

The following sections describe how to configure the row format of [InnoDB](#) tables to control how variable-length columns values are stored. Row format configuration also determines the availability of the [table compression](#) feature and the large index key prefix feature (`innodb_large_prefix`).

### 15.11.2 Specifying the Row Format for a Table

In MySQL 5.7.8 and earlier, rows are stored in [COMPACT](#) format by default. As of MySQL 5.7.9, the default row format is defined by `innodb_default_row_format`, which has a default value of

**DYNAMIC**. The default row format is used when the **ROW\_FORMAT** table option is not defined explicitly or when **ROW\_FORMAT=DEFAULT** is specified.

The row format of a table can be defined explicitly using the **ROW\_FORMAT** table option in a **CREATE TABLE** or **ALTER TABLE** statement. For example:

```
CREATE TABLE t1 (c1 INT) ROW_FORMAT=DYNAMIC;
```

An explicitly defined **ROW\_FORMAT** setting overrides the implicit default. Specifying **ROW\_FORMAT=DEFAULT** is equivalent to using the implicit default.

The **innodb\_default\_row\_format** option, introduced in MySQL 5.7.9, can be set dynamically:

```
mysql> SET GLOBAL innodb_default_row_format=DYNAMIC;
```

Valid **innodb\_default\_row\_format** options include **DYNAMIC**, **COMPACT**, and **REDUNDANT**. The **COMPRESSED** row format, which is not supported for use in the system tablespace, cannot be defined as the default. It can only be specified explicitly in a **CREATE TABLE** or **ALTER TABLE** statement. Attempting to set **innodb\_default\_row\_format** to **COMPRESSED** returns an error:

```
mysql> SET GLOBAL innodb_default_row_format=COMPRESSED;
ERROR 1231 (42000): Variable 'innodb_default_row_format'
can't be set to the value of 'COMPRESSED'
```

Newly created tables use the row format defined by **innodb\_default\_row\_format** when a **ROW\_FORMAT** option is not specified explicitly or when **ROW\_FORMAT=DEFAULT** is used. For example, the following **CREATE TABLE** statements use the row format defined by **innodb\_default\_row\_format**.

```
CREATE TABLE t1 (c1 INT);
```

```
CREATE TABLE t2 (c1 INT) ROW_FORMAT=DEFAULT;
```

When a **ROW\_FORMAT** option is not specified explicitly or when **ROW\_FORMAT=DEFAULT** is used, any operation that rebuilds a table also silently changes the row format of the table to the format defined by **innodb\_default\_row\_format**.

Table-rebuilding operations include **ALTER TABLE** operations that use **ALGORITHM=COPY** or **ALTER TABLE** operations that use **ALGORITHM=INPLACE** where table rebuilding is required. See [Table 15.10, “Summary of Online Status for DDL Operations”](#) for an overview of the online status of DDL operations. **OPTIMIZE TABLE** is also a table-rebuilding operation.

The following example demonstrates a table-rebuilding operation that silently changes the row format of a table created without an explicitly defined row format.

```
mysql> SELECT @@innodb_default_row_format;
+-----+
| @@innodb_default_row_format |
+-----+
| dynamic                      |
+-----+

mysql> CREATE TABLE t1 (c1 INT);

mysql> SELECT * FROM INFORMATION_SCHEMA.INNODB_SYS_TABLES WHERE NAME LIKE 'test/t1' \G
***** 1. row *****
      TABLE_ID: 54
        NAME: test/t1
        FLAG: 33
      N_COLS: 4
        SPACE: 35
    FILE_FORMAT: Barracuda
      ROW_FORMAT: Dynamic
ZIP_PAGE_SIZE: 0
    SPACE_TYPE: Single

mysql> SET GLOBAL innodb_default_row_format=COMPACT;
```

```
mysql> ALTER TABLE t1 ADD COLUMN (c2 INT);

mysql> SELECT * FROM INFORMATION_SCHEMA.INNODB_SYS_TABLES WHERE NAME LIKE 'test/t1' \G
***** 1. row *****
      TABLE_ID: 55
        NAME: test/t1
         FLAG: 1
        N_COLS: 5
         SPACE: 36
    FILE_FORMAT: Antelope
    ROW_FORMAT: Compact
ZIP_PAGE_SIZE: 0
    SPACE_TYPE: Single
```

Consider the following potential issues before changing the row format of existing tables from [REDUNDANT](#) or [COMPACT](#) to [DYNAMIC](#).

- The [REDUNDANT](#) and [COMPACT](#) row format supports a maximum index key prefix length of 767 bytes whereas [DYNAMIC](#) and [COMPRESSED](#) row formats support an index key prefix length of 3072 bytes if the `innodb_large_prefix` configuration option is enabled. In a replication environment, if `innodb_default_row_format` is set to [DYNAMIC](#) on the master and set to [COMPACT](#) on the slave, the following DDL statement, which does not explicitly define a row format, succeeds on the master but fails on the slave:

```
CREATE TABLE t1 (c1 INT PRIMARY KEY, c2 VARCHAR(5000), KEY i1(c2(3070)));
```

For related information, see [Section 15.8.8, “Limits on InnoDB Tables”](#).

- Importing a table that does not explicitly define a row format results in a schema mismatch error if the `innodb_default_row_format` setting on the source server differs from the setting on the destination server. For more information, refer to the limitations outlined in [Section 15.7.6, “Copying File-Per-Table Tablespace to Another Server”](#).

To view the row format of a table, issue a `SHOW TABLE STATUS` statement or query `INFORMATION_SCHEMA.TABLES`.

```
SELECT * FROM INFORMATION_SCHEMA.INNODB_SYS_TABLES WHERE NAME LIKE 'test/t1' \G
```

The row format of an [InnoDB](#) table determines its physical row structure. See [Section 15.8.3, “Physical Row Structure of InnoDB Tables”](#) for more information.

### 15.11.3 DYNAMIC and COMPRESSED Row Formats

When a table is created with `ROW_FORMAT=DYNAMIC` or `ROW_FORMAT=COMPRESSED`, [InnoDB](#) can store long variable-length column values (for [VARCHAR](#), [VARBINARY](#), and [BLOB](#) and [TEXT](#) types) fully off-page, with the clustered index record containing only a 20-byte pointer to the overflow page. [InnoDB](#) also encodes fixed-length fields greater than or equal to 768 bytes in length as variable-length fields. For example, a `CHAR(255)` column can exceed 768 bytes if the maximum byte length of the character set is greater than 3, as it is with `utf8mb4`.

Whether any columns are stored off-page depends on the page size and the total size of the row. When the row is too long, [InnoDB](#) chooses the longest columns for off-page storage until the clustered index record fits on the [B-tree](#) page. [TEXT](#) and [BLOB](#) columns that are less than or equal to 40 bytes are always stored in-line.

The [DYNAMIC](#) row format maintains the efficiency of storing the entire row in the index node if it fits (as do the [COMPACT](#) and [REDUNDANT](#) formats), but the [DYNAMIC](#) row format avoids the problem of filling B-tree nodes with a large number of data bytes of long columns. The [DYNAMIC](#) format is based on the idea that if a portion of a long data value is stored off-page, it is usually most efficient to store all of the value off-page. With [DYNAMIC](#) format, shorter columns are likely to remain in the B-tree node, minimizing the number of overflow pages needed for any given row.

The [COMPRESSED](#) row format uses similar internal details for off-page storage as the [DYNAMIC](#) row format, with additional storage and performance considerations from the table and index data being

compressed and using smaller page sizes. With the `COMPRESSED` row format, the `KEY_BLOCK_SIZE` option controls how much column data is stored in the clustered index, and how much is placed on overflow pages. For full details about the `COMPRESSED` row format, see [Section 15.9, “InnoDB Table and Page Compression”](#).

Both `DYNAMIC` and `COMPRESSED` row formats support index key prefixes up to 3072 bytes. This feature is controlled by the `innodb_large_prefix` configuration option, which is enabled by default as of MySQL 5.7.7. See the `innodb_large_prefix` option description for more information.

Tables that use the `COMPRESSED` row format can be created in [file-per-table](#) tablespaces or [general tablespaces](#) (introduced in MySQL 5.7.6). The system tablespace does not support the `COMPRESSED` row format. To store a `COMPRESSED` table in a file-per-table tablespace, `innodb_file_per_table` must be enabled and `innodb_file_format` must be set to `Barracuda`. The `innodb_file_per_table` and `innodb_file_format` configuration options are not applicable to general tablespaces. General tablespaces support all row formats with the caveat that compressed and uncompressed tables cannot coexist in the same general tablespace due to different physical page sizes. For more information about general tablespaces, see [Section 15.7.9, “InnoDB General Tablespaces”](#).

In MySQL 5.7.5 and earlier, tables that use the `DYNAMIC` row format can only be stored in [file-per-table](#) tablespaces, requiring that `innodb_file_per_table` be enabled and `innodb_file_format` be set to `Barracuda`.

As of MySQL 5.7.6, `DYNAMIC` tables can be stored in file-per-table tablespaces, general tablespaces, and the system tablespace. To store `DYNAMIC` tables in the system tablespace, you must use the `TABLESPACE [=] innodb_system` table option with `CREATE TABLE` or `ALTER TABLE`. The `innodb_file_per_table` and `innodb_file_format` configuration options are not applicable to general tablespaces, nor are they applicable when using the `TABLESPACE [=] innodb_system` table option to store `DYNAMIC` tables in the system tablespace.

As of MySQL 5.7.9, you can add a `DYNAMIC` table to the system tablespace by disabling `innodb_file_per_table` and using a regular `CREATE TABLE` or `ALTER TABLE` statement. The `innodb_file_format` setting is ignored. A `DYNAMIC` table always uses the `Barracuda` file format.

`DYNAMIC` and `COMPRESSED` row formats are variations of the `COMPACT` row format and therefore handle `CHAR` storage in the same way as the `COMPACT` row format. For more information, see [Section 15.8.3, “Physical Row Structure of InnoDB Tables”](#).

## 15.11.4 COMPACT and REDUNDANT Row Formats

Early versions of InnoDB used an unnamed file format (now called [Antelope](#)) for database files. With that file format, tables are defined with `ROW_FORMAT=COMPACT` or `ROW_FORMAT=REDUNDANT`. With these row formats, InnoDB stores up to the first 768 bytes of variable-length columns (`VARCHAR`, `VARBINARY`, and `BLOB` and `TEXT` types) in the index record within the B-tree node, with the remainder stored on the overflow pages. InnoDB also encodes fixed-length fields greater than or equal to 768 bytes in length as variable-length fields, which can be stored off-page. For example, a `CHAR(255)` column can exceed 768 bytes if the maximum byte length of the character set is greater than 3, as it is with `utf8mb4`.

With the Antelope file format, if the value of a column is 768 bytes or less, no overflow page is needed, and some savings in I/O may result, since the value is in the B-tree node. This works well for relatively short `BLOB`s, but may cause B-tree nodes to fill with data rather than key values, reducing their efficiency. Tables with many `BLOB` columns could cause B-tree nodes to become too full of data, and contain too few rows, making the entire index less efficient than if the rows were shorter or if the column values were stored off-page.

To preserve compatibility with earlier versions of InnoDB, `COMPACT` remained the default row format up to MySQL 5.7.8. As of MySQL 5.7.9, the default row format is `DYNAMIC`, as defined by the `innodb_default_row_format` configuration option. See [Section 15.11.3, “DYNAMIC and COMPRESSED Row Formats”](#) for more information.

For information about the physical row structure of tables that use the [REDUNDANT](#) or [COMPACT](#) row format, see [Section 15.8.3, “Physical Row Structure of InnoDB Tables”](#).

## 15.12 InnoDB Disk I/O and File Space Management

As a DBA, you must manage disk I/O to keep the I/O subsystem from becoming saturated, and manage disk space to avoid filling up storage devices. The [ACID](#) design model requires a certain amount of I/O that might seem redundant, but helps to ensure data reliability. Within these constraints, [InnoDB](#) tries to optimize the database work and the organization of disk files to minimize the amount of disk I/O. Sometimes, I/O is postponed until the database is not busy, or until everything needs to be brought to a consistent state, such as during a database restart after a [fast shutdown](#).

This section discusses the main considerations for I/O and disk space with the default kind of MySQL tables (also known as [InnoDB](#) tables):

- Controlling the amount of background I/O used to improve query performance.
- Enabling or disabling features that provide extra durability at the expense of additional I/O.
- Organizing tables into many small files, a few larger files, or a combination of both.
- Balancing the size of redo log files against the I/O activity that occurs when the log files become full.
- How to reorganize a table for optimal query performance.

### 15.12.1 InnoDB Disk I/O

[InnoDB](#) uses asynchronous disk I/O where possible, by creating a number of threads to handle I/O operations, while permitting other database operations to proceed while the I/O is still in progress. On Linux and Windows platforms, [InnoDB](#) uses the available OS and library functions to perform “native” asynchronous I/O. On other platforms, [InnoDB](#) still uses I/O threads, but the threads may actually wait for I/O requests to complete; this technique is known as “simulated” asynchronous I/O.

#### Read-Ahead

If [InnoDB](#) can determine there is a high probability that data might be needed soon, it performs read-ahead operations to bring that data into the buffer pool so that it is available in memory. Making a few large read requests for contiguous data can be more efficient than making several small, spread-out requests. There are two read-ahead heuristics in [InnoDB](#):

- In sequential read-ahead, if [InnoDB](#) notices that the access pattern to a segment in the tablespace is sequential, it posts in advance a batch of reads of database pages to the I/O system.
- In random read-ahead, if [InnoDB](#) notices that some area in a tablespace seems to be in the process of being fully read into the buffer pool, it posts the remaining reads to the I/O system.

For information about configuring read-ahead heuristics, see [Section 15.6.3.5, “Configuring InnoDB Buffer Pool Prefetching \(Read-Ahead\)”](#).

#### Doublewrite Buffer

[InnoDB](#) uses a novel file flush technique involving a structure called the [doublewrite buffer](#), which is enabled by default in most cases (`innodb_doublewrite=ON`). It adds safety to recovery following a crash or power outage, and improves performance on most varieties of Unix by reducing the need for `fsync()` operations.

Before writing pages to a data file, [InnoDB](#) first writes them to a contiguous tablespace area called the doublewrite buffer. Only after the write and the flush to the doublewrite buffer has completed does [InnoDB](#) write the pages to their proper positions in the data file. If there is an operating system, storage subsystem, or `mysqld` process crash in the middle of a page write (causing a [torn page](#) condition), [InnoDB](#) can later find a good copy of the page from the doublewrite buffer during recovery.

As of MySQL 5.7.4, if system tablespace files (“ibdata files”) are located on Fusion-io devices that support atomic writes, doublewrite buffering is automatically disabled and Fusion-io atomic writes are used for all data files. Because the doublewrite buffer setting is global, doublewrite buffering is also disabled for data files residing on non-Fusion-io hardware. This feature is only supported on Fusion-io hardware and is only enabled for Fusion-io NVMFS on Linux. To take full advantage of this feature, an `innodb_flush_method` setting of `O_DIRECT` is recommended.

## 15.12.2 File Space Management

The data files that you define in the configuration file using the `innodb_data_file_path` configuration option form the **InnoDB system tablespace**. The files are logically concatenated to form the system tablespace. There is no striping in use. You cannot define where within the system tablespace your tables are allocated. In a newly created system tablespace, **InnoDB** allocates space starting from the first data file.

To avoid the issues that come with storing all tables and indexes inside the system tablespace, you can enable the `innodb_file_per_table` configuration option (the default), which stores each newly created table in a separate tablespace file (with extension `.ibd`). For tables stored this way, there is less fragmentation within the disk file, and when the table is truncated, the space is returned to the operating system rather than still being reserved by **InnoDB** within the system tablespace. For more information, see [Section 15.7.4, “InnoDB File-Per-Table Tablespaces”](#).

As of MySQL 5.7.6, you can also store tables in **general tablespaces**. General tablespaces are shared tablespaces created using `CREATE TABLESPACE` syntax. They can be created outside of the MySQL data directory, are capable of holding multiple tables, and support tables of all row formats. For more information, see [Section 15.7.9, “InnoDB General Tablespaces”](#).

## Pages, Extents, Segments, and Tablespaces

Each tablespace consists of database **pages**. Every tablespace in a MySQL instance has the same **page size**. By default, all tablespaces have a page size of 16KB; you can reduce the page size to 8KB or 4KB by specifying the `innodb_page_size` option when you create the MySQL instance. As of MySQL 5.7.6, you can also increase the page size to 32KB or 64KB. For more information, refer to the `innodb_page_size` documentation.

The pages are grouped into **extents** of size 1MB for pages up to 16KB in size (64 consecutive 16KB pages, or 128 8KB pages, or 256 4KB pages). For a page size of 32KB, extent size is 2MB. For page size of 64KB, extent size is 4MB. The “files” inside a tablespace are called **segments** in **InnoDB**. (These segments are different from the **rollback segment**, which actually contains many tablespace segments.)

When a segment grows inside the tablespace, **InnoDB** allocates the first 32 pages to it one at a time. After that, **InnoDB** starts to allocate whole extents to the segment. **InnoDB** can add up to 4 extents at a time to a large segment to ensure good sequentiality of data.

Two segments are allocated for each index in **InnoDB**. One is for nonleaf nodes of the **B-tree**, the other is for the leaf nodes. Keeping the leaf nodes contiguous on disk enables better sequential I/O operations, because these leaf nodes contain the actual table data.

Some pages in the tablespace contain bitmaps of other pages, and therefore a few extents in an **InnoDB** tablespace cannot be allocated to segments as a whole, but only as individual pages.

When you ask for available free space in the tablespace by issuing a `SHOW TABLE STATUS` statement, **InnoDB** reports the extents that are definitely free in the tablespace. **InnoDB** always reserves some extents for cleanup and other internal purposes; these reserved extents are not included in the free space.

When you delete data from a table, **InnoDB** contracts the corresponding B-tree indexes. Whether the freed space becomes available for other users depends on whether the pattern of deletes frees individual pages or extents to the tablespace. Dropping a table or deleting all rows from it is guaranteed

to release the space to other users, but remember that deleted rows are physically removed only by the [purge](#) operation, which happens automatically some time after they are no longer needed for transaction rollbacks or consistent reads. (See [Section 15.3, “InnoDB Multi-Versioning”](#).)

## How Pages Relate to Table Rows

The maximum row length is slightly less than half a database page for 4KB, 8KB, 16KB, and 32KB [innodb\\_page\\_size](#) settings. For example, the maximum row length is slightly less than 8KB for the default 16KB InnoDB page size. For 64KB pages, the maximum row length is slightly less than 16KB.

If a row does not exceed the maximum row length, all of it is stored locally within the page. If a row exceeds the maximum row length, [variable-length columns](#) are chosen for external off-page storage until the row fits within the maximum row length limit. External off-page storage for variable-length columns differs by row format:

- *COMPACT and REDUNDANT Row Formats*

When a variable-length column is chosen for external off-page storage, InnoDB stores the first 768 bytes locally in the row, and the rest externally into overflow pages. Each such column has its own list of overflow pages. The 768-byte prefix is accompanied by a 20-byte value that stores the true length of the column and points into the overflow list where the rest of the value is stored. See [Section 15.11.4, “COMPACT and REDUNDANT Row Formats”](#).

- *DYNAMIC and COMPRESSED Row Formats*

When a variable-length column is chosen for external off-page storage, InnoDB stores a 20-byte pointer locally in the row, and the rest externally into overflow pages. See [Section 15.11.3, “DYNAMIC and COMPRESSED Row Formats”](#).

[LONGBLOB](#) and [LONGTEXT](#) columns must be less than 4GB, and the total row length, including [BLOB](#) and [TEXT](#) columns, must be less than 4GB.

## 15.12.3 InnoDB Checkpoints

Making your [log files](#) very large may reduce disk I/O during [checkpointing](#). It often makes sense to set the total size of the log files as large as the buffer pool or even larger. Although in the past large log files could make crash recovery take excessive time, starting with MySQL 5.5, performance enhancements to crash recovery make it possible to use large log files with fast startup after a crash. (Strictly speaking, this performance improvement is available for MySQL 5.1 with the InnoDB Plugin 1.0.7 and higher. It is with MySQL 5.5 that this improvement is available in the default InnoDB storage engine.)

## How Checkpoint Processing Works

InnoDB implements a [checkpoint](#) mechanism known as [fuzzy checkpointing](#). InnoDB flushes modified database pages from the buffer pool in small batches. There is no need to flush the buffer pool in one single batch, which would disrupt processing of user SQL statements during the checkpointing process.

During [crash recovery](#), InnoDB looks for a checkpoint label written to the log files. It knows that all modifications to the database before the label are present in the disk image of the database. Then InnoDB scans the log files forward from the checkpoint, applying the logged modifications to the database.

## 15.12.4 Defragmenting a Table

Random insertions into or deletions from a secondary index can cause the index to become fragmented. Fragmentation means that the physical ordering of the index pages on the disk is not close to the index ordering of the records on the pages, or that there are many unused pages in the 64-page blocks that were allocated to the index.

One symptom of fragmentation is that a table takes more space than it “should” take. How much that is exactly, is difficult to determine. All [InnoDB](#) data and indexes are stored in [B-trees](#), and their [fill factor](#) may vary from 50% to 100%. Another symptom of fragmentation is that a table scan such as this takes more time than it “should” take:

```
SELECT COUNT(*) FROM t WHERE non\_indexed\_column <> 12345;
```

The preceding query requires MySQL to perform a full table scan, the slowest type of query for a large table.

To speed up index scans, you can periodically perform a “null” [ALTER TABLE](#) operation, which causes MySQL to rebuild the table:

```
ALTER TABLE tbl\_name ENGINE=INNODB
```

You can also use [ALTER TABLE \*tbl\\_name\* FORCE](#) to perform a “null” alter operation that rebuilds the table.

As of MySQL 5.7.4, both [ALTER TABLE \*tbl\\_name\* ENGINE=INNODB](#) and [ALTER TABLE \*tbl\\_name\* FORCE](#) use [online DDL](#) ([ALGORITHM=COPY](#)). For more information, see [Section 15.13.1](#), “[Overview of Online DDL](#)”.

Another way to perform a defragmentation operation is to use [mysqldump](#) to dump the table to a text file, drop the table, and reload it from the dump file.

If the insertions into an index are always ascending and records are deleted only from the end, the [InnoDB](#) filesystem management algorithm guarantees that fragmentation in the index does not occur.

## 15.12.5 Reclaiming Disk Space with TRUNCATE TABLE

To reclaim operating system disk space when [truncating](#) an [InnoDB](#) table, the table must be stored in its own [.ibd](#) file. For a table to be stored in its own [.ibd](#) file, [innodb\\_file\\_per\\_table](#) must be enabled when the table is created. Additionally, there cannot be a [foreign key](#) constraint between the table being truncated and other tables, otherwise the [TRUNCATE TABLE](#) operation fails. A foreign key constraint between two columns in the same table, however, is permitted.

When a table is truncated, it is dropped and re-created in a new [.ibd](#) file, and the freed space is returned to the operating system. This is in contrast to truncating [InnoDB](#) tables that are stored within the [InnoDB system tablespace](#) (tables created when [innodb\\_file\\_per\\_table=OFF](#)) and tables stored in shared [general tablespaces](#), where only [InnoDB](#) can use the freed space after the table is truncated.

The ability to truncate tables and return disk space to the operating system also means that [physical backups](#) can be smaller. Truncating tables that are stored in the system tablespace (tables created when [innodb\\_file\\_per\\_table=OFF](#)) or in a general tablespace leaves blocks of unused space in the tablespace.

## 15.13 InnoDB and Online DDL

The [online DDL](#) feature enhances many types of [ALTER TABLE](#) operations to avoid table copying or blocking of [DML](#) operations while [DDL](#) is in progress, or both.

The [online DDL](#) feature has the following benefits:

- It improves responsiveness and availability in busy production environments, where making a table unavailable for minutes or hours is not practical.
- It lets you adjust the balance between performance and concurrency during the DDL operation, by choosing whether to block access to the table entirely ([LOCK=EXCLUSIVE](#) clause), allow queries but not DML ([LOCK=SHARED](#) clause), or allow full query and DML access to the table ([LOCK=NONE](#) clause).

clause). When you omit the `LOCK` clause or specify `LOCK=DEFAULT`, MySQL allows as much concurrency as possible depending on the type of operation.

- Performing changes in-place where possible, rather than creating a new copy of the table, avoids temporary increases in disk space usage and I/O overhead associated with copying the table and reconstructing secondary indexes.

### 15.13.1 Overview of Online DDL

Historically, many DDL operations on InnoDB tables were expensive. Many `ALTER TABLE` operations worked by creating a new, empty table defined with the requested table options and indexes, then copying the existing rows to the new table one-by-one, updating the indexes as the rows were inserted. After all rows from the original table were copied, the old table was dropped and the copy was renamed with the name of the original table.

MySQL 5.5, and MySQL 5.1 with the InnoDB Plugin, optimized `CREATE INDEX` and `DROP INDEX` to avoid the table-copying behavior. That feature was known as **Fast Index Creation**. MySQL 5.6 enhanced many other types of `ALTER TABLE` operations to avoid copying the table. Another enhancement allowed `SELECT` queries and `INSERT`, `UPDATE`, and `DELETE` (DML) statements to proceed while the table is being altered. In MySQL 5.7, `ALTER TABLE RENAME INDEX` was also enhanced to avoid table copying. This combination of features is now known as **online DDL**.

This mechanism also means that you can generally speed the overall process of creating and loading a table and associated indexes by creating the table without any secondary indexes, then adding the secondary indexes after the data is loaded.

Although no syntax changes are required in the `CREATE INDEX` or `DROP INDEX` commands, some factors affect the performance, space usage, and semantics of this operation (see [Section 15.13.9, “Limitations of Online DDL”](#)).

The online DDL enhancements in MySQL 5.6 improved many DDL operations that formerly required a table copy or blocked DML operations on the table, or both. [Table 15.10, “Summary of Online Status for DDL Operations”](#) shows the variations of the `ALTER TABLE` statement and shows how the online DDL feature applies to each.

With the exception of `ALTER TABLE` partitioning clauses, online DDL operations for partitioned InnoDB tables follow the same rules that apply to regular InnoDB tables. For more information, see [Section 15.13.8, “Online DDL for Partitioned InnoDB Tables”](#).

- The “In-Place?” column shows which operations allow the `ALGORITHM=INPLACE` clause; the preferred value is “Yes”.
- The “Copies Table?” column shows which operations are able to avoid the expensive table-copying operation; the preferred value is “No”. This column is mostly the reverse of the “In-Place?” column, except that a few operations allow `ALGORITHM=INPLACE` but still involve some amount of table copying.
- The “Allows Concurrent DML?” column shows which operations can be performed fully online; the preferred value is “Yes”. You can specify `LOCK=NONE` to assert that full concurrency is allowed during the DDL, but MySQL automatically allows this level of concurrency when possible. When concurrent DML is allowed, concurrent queries are also always allowed.
- The “Allows Concurrent Queries?” column shows which DDL operations allow queries on the table while the operation is in progress; the preferred value is “Yes”. Concurrent query is allowed during all online DDL operations. It is shown with “Yes” listed for all cells, for reference purposes. You can specify `LOCK=SHARED` to assert that concurrent queries are allowed during the DDL, but MySQL automatically allows this level of concurrency when possible.
- The “Notes” column explains any exceptions to the “Yes/No” values of the other columns, such as when the answer depends on the setting of a configuration option or some other clause in the DDL statement. The values “Yes\*” and “No\*” indicate that an answer depends on these additional notes.

Table 15.10 Summary of Online Status for DDL Operations

| Operation                                | In-Place? | Copies Table? | Allows Concurrent DML? | Allows Concurrent Query? | Notes   |
|--|-----------|---------------|------------------------|--------------------------|---|
| CREATE INDEX, ADD INDEX                  | Yes*      | No*           | Yes                    | Yes                      | Some restrictions for FULLTEXT index; see next row.   |
| ADD FULLTEXT INDEX                       | Yes       | No*           | No                     | Yes                      | Creating the first FULLTEXT index for a table involves a table copy, unless there is a user-supplied FTS_DOC_ID column. Subsequent FULLTEXT indexes on the same table can be created in-place.  |
| ADD SPATIAL INDEX                        | Yes       | No            | No                     | Yes                      | In-place support was added in MySQL 5.7.5. Bulk load is not supported.  |
| RENAME INDEX                             | Yes       | No            | Yes                    | Yes                      | Only modifies table metadata.   |
| DROP INDEX                               | Yes       | No            | Yes                    | Yes                      | Only modifies table metadata.   |
| OPTIMIZE TABLE                           | Yes       | Yes           | Yes                    | Yes                      | Uses ALGORITHM=INPLACE as of MySQL 5.7.4. ALGORITHM=COPY is used if old_alter_table=1 or mysqld --skip-new option is enabled. OPTIMIZE TABLE using online DDL (ALGORITHM=INPLACE) is not supported for tables with FULLTEXT indexes.  |
| Set default value for a column           | Yes       | No            | Yes                    | Yes                      | Only modifies table metadata.   |
| Change auto-increment value for a column | Yes       | No            | Yes                    | Yes                      | Modifies a value stored in memory, not the data file.   |
| Add a foreign key constraint             | Yes*      | No*           | Yes                    | Yes                      | To avoid copying the table, disable foreign_key_checks during constraint creation.  |
| Drop a foreign key constraint            | Yes       | No            | Yes                    | Yes                      | The foreign_key_checks option can be enabled or disabled.   |
| Rename a column                          | Yes*      | No*           | Yes*                   | Yes                      | To allow concurrent DML, keep the same data type and only change the column name. Prior to MySQL 5.7.8, ALGORITHM=INPLACE is supported for renaming a generated virtual column but not for renaming a generated stored column. As of MySQL 5.7.8, ALGORITHM=INPLACE is not supported for renaming a generated column. |
| Add a column                             | Yes*      | Yes*          | Yes*                   | Yes                      | Concurrent DML is not allowed when adding an auto-increment column. Although ALGORITHM=INPLACE is   |

| Operation                                      | In-Place? | Copies Table? | Allows Concurrent DML? | Allows Concurrent Query? | Notes   |
|--|-----------|---------------|------------------------|--------------------------|---|
|  |           |               |                        |                          | allowed, the data is reorganized substantially, so it is still an expensive operation. <a href="#">ALGORITHM=INPLACE</a> is supported for adding a <a href="#">generated virtual column</a> but not for adding a <a href="#">generated stored column</a> . Adding a generated virtual column does not require a table copy.   |
| Drop a column                                  | Yes       | Yes*          | Yes                    | Yes                      | Although <a href="#">ALGORITHM=INPLACE</a> is allowed, the data is reorganized substantially, so it is still an expensive operation. <a href="#">ALGORITHM=INPLACE</a> is supported for dropping a generated column. Dropping a <a href="#">generated virtual column</a> does not require a table copy.   |
| Reorder columns                                | Yes       | Yes           | Yes                    | Yes                      | Although <a href="#">ALGORITHM=INPLACE</a> is allowed, the data is reorganized substantially, so it is still an expensive operation.  |
| Change <a href="#">ROW_FORMAT</a> property     | Yes       | Yes           | Yes                    | Yes                      | Although <a href="#">ALGORITHM=INPLACE</a> is allowed, the data is reorganized substantially, so it is still an expensive operation.  |
| Change <a href="#">KEY_BLOCK_SIZE</a> property | Yes       | Yes           | Yes                    | Yes                      | Although <a href="#">ALGORITHM=INPLACE</a> is allowed, the data is reorganized substantially, so it is still an expensive operation.  |
| Make column <a href="#">NULL</a>               | Yes       | Yes           | Yes                    | Yes                      | Although <a href="#">ALGORITHM=INPLACE</a> is allowed, the data is reorganized substantially, so it is still an expensive operation.  |
| Make column <a href="#">NOT NULL</a>           | Yes*      | Yes           | Yes                    | Yes                      | <a href="#">STRICT_ALL_TABLES</a> or <a href="#">STRICT_TRANS_TABLES SQL_MODE</a> is required for the operation to succeed. The operation fails if the column contains NULL values. The server prohibits changes to foreign key columns that have the potential to cause loss of referential integrity. For more information, see <a href="#">Section 14.1.8, "ALTER TABLE Syntax"</a> . Although <a href="#">ALGORITHM=INPLACE</a> is allowed, the data is reorganized substantially, so it is still an expensive operation. |
| Change data type of column                     | No*       | Yes*          | No                     | Yes                      | Exception: <a href="#">VARCHAR</a> size may be increased using online <a href="#">ALTER</a>   |

| Operation   | In-Place? | Copies Table? | Allows Concurrent DML? | Allows Concurrent Query? | Notes   |
|---|-----------|---------------|------------------------|--------------------------|---|
|   |           |               |                        |                          | <a href="#">TABLE</a> . See <a href="#">InnoDB Online DDL Column Properties</a> for more information.   |
| Add <a href="#">primary key</a>   | Yes*      | Yes           | Yes                    | Yes                      | Although <a href="#">ALGORITHM=INPLACE</a> is allowed, the data is reorganized substantially, so it is still an expensive operation. <a href="#">ALGORITHM=INPLACE</a> is not allowed under certain conditions if columns have to be converted to <code>NOT NULL</code> . See <a href="#">Example 15.9, “Creating and Dropping the Primary Key”</a> . |
| Drop <a href="#">primary key</a> and add another  | Yes       | Yes           | Yes                    | Yes                      | <a href="#">ALGORITHM=INPLACE</a> is only allowed when you add a new primary key in the same <a href="#">ALTER TABLE</a> ; the data is reorganized substantially, so it is still an expensive operation.  |
| Drop <a href="#">primary key</a>  | No        | Yes           | No                     | Yes                      | Restrictions apply when you drop a primary key without adding a new one in the same <a href="#">ALTER TABLE</a> statement.  |
| Convert character set   | No        | Yes           | No                     | Yes                      | Rebuilds the table if the new character encoding is different.  |
| Specify character set   | No        | Yes           | No                     | Yes                      | Rebuilds the table if the new character encoding is different.  |
| Rebuild with <a href="#">FORCE</a> option   | Yes       | Yes           | Yes                    | Yes                      | Uses <a href="#">ALGORITHM=INPLACE</a> as of MySQL 5.7.4. <a href="#">ALGORITHM=COPY</a> is used if <code>old_alter_table=1</code> or <code>mysqld --skip-new</code> option is enabled. Table rebuild using online DDL ( <a href="#">ALGORITHM=INPLACE</a> ) is not supported for tables with FULLTEXT indexes.                                       |
| Rebuild with “null”<br><a href="#">ALTER TABLE ... ENGINE=INNODB</a>                                  | Yes       | Yes           | Yes                    | Yes                      | Uses <a href="#">ALGORITHM=INPLACE</a> as of MySQL 5.7.4. <a href="#">ALGORITHM=COPY</a> is used if <code>old_alter_table=1</code> or <code>mysqld --skip-new</code> option is enabled. Table rebuild using online DDL ( <a href="#">ALGORITHM=INPLACE</a> ) is not supported for tables with FULLTEXT indexes.                                       |
| Set table-level <a href="#">persistent statistics</a> options<br>( <a href="#">STATS_PERSISTENT</a> , | Yes       | No            | Yes                    | Yes                      | Only modifies table metadata.   |

| Operation   | In-Place? | Copies Table? | Allows Concurrent DML? | Allows Concurrent Query? | Notes |
|---|-----------|---------------|------------------------|--------------------------|-------|
| <code>STATS_AUTO_RECALC</code><br><code>STATS_SAMPLE_PAGES</code> ) |           |               |                        |                          |       |

The following sections shows the basic syntax, and usage notes related to online DDL, for each of the major operations that can be performed with concurrent DML, in-place, or both:

## Secondary Indexes

- Create **secondary indexes**: `CREATE INDEX name ON table (col_list)` or `ALTER TABLE table ADD INDEX name (col_list)`. (Creating a `FULLTEXT` index still requires locking the table.)
- Drop **secondary indexes**: `DROP INDEX name ON table;` or `ALTER TABLE table DROP INDEX name`

Creating and dropping secondary indexes on `InnoDB` tables skips the table-copying behavior.

In MySQL 5.6 and higher, the table remains available for read and write operations while the index is being created or dropped. The `CREATE INDEX` or `DROP INDEX` statement only finishes after all transactions that are accessing the table are completed, so that the initial state of the index reflects the most recent contents of the table. Previously, modifying the table while an index is being created or dropped typically resulted in a **deadlock** that cancelled the `INSERT`, `UPDATE`, or `DELETE` statement on the table.

## Column Properties

- Set a default value for a column: `ALTER TABLE tbl ALTER COLUMN col SET DEFAULT literal` or `ALTER TABLE tbl ALTER COLUMN col DROP DEFAULT`

The default values for columns are stored in the `.frm` file for the table, not the `InnoDB` data dictionary.

- Changing the **auto-increment** value for a column: `ALTER TABLE table AUTO_INCREMENT=next_value;`

Especially in a distributed system using replication or sharding, you sometimes reset the auto-increment counter for a table to a specific value. The next row inserted into the table uses the specified value for its auto-increment column. You might also use this technique in a data warehousing environment where you periodically empty all the tables and reload them, and you can restart the auto-increment sequence from 1.

- Renaming a column: `ALTER TABLE tbl CHANGE old_col_name new_col_name datatype`

When you keep the same data type and `[NOT] NULL` attribute, only changing the column name, this operation can always be performed online.

You can also rename a column that is part of a foreign key constraint. The foreign key definition is automatically updated to use the new column name. Renaming a column participating in a foreign key only works with the in-place mode of `ALTER TABLE`. If you use the `ALGORITHM=COPY` clause, or some other condition causes the command to use `ALGORITHM=COPY` behind the scenes, the `ALTER TABLE` statement will fail.

- Extending `VARCHAR` size using an in-place `ALTER TABLE` statement, as in this example:

```
ALTER TABLE t1 ALGORITHM=INPLACE, CHANGE COLUMN c1 c1 VARCHAR(255);
```

The number of length bytes required by a `VARCHAR` column must remain the same. For `VARCHAR` values of 0 to 255, one length byte is required to encode the value. For `VARCHAR` values of 256 bytes

or more, two length bytes are required. As a result, in-place `ALTER TABLE` only supports increasing `VARCHAR` size from 0 to 255 bytes or increasing `VARCHAR` size from a value equal to or greater than 256 bytes. In-place `ALTER TABLE` does not support increasing `VARCHAR` size from less than 256 bytes to a value equal to or greater than 256 bytes. In this case, the number of required length bytes would change from 1 to 2, which is only supported by a table copy (`ALGORITHM=COPY`). For example, attempting to change `VARCHAR` column size from 255 to 256 using in-place `ALTER TABLE` would return an error:

```
ALTER TABLE t1 ALGORITHM=INPLACE, CHANGE COLUMN c1 c1 VARCHAR(256);
ERROR 0A000: ALGORITHM=INPLACE is not supported. Reason: Cannot change
column type INPLACE. Try ALGORITHM=COPY.
```

Decreasing `VARCHAR` size using in-place `ALTER TABLE` is not supported. Decreasing `VARCHAR` size requires a table copy (`ALGORITHM=COPY`).

## Foreign Keys

- Adding or dropping a [foreign key constraint](#):

```
ALTER TABLE tbl1 ADD CONSTRAINT fk_name FOREIGN KEY index (col1) REFERENCES tbl2(col2) referential_ac
ALTER TABLE tbl1 DROP FOREIGN KEY fk_name;
```

Dropping a foreign key can be performed online with the `foreign_key_checks` option enabled or disabled. Creating a foreign key online requires `foreign_key_checks` to be disabled.

If you do not know the names of the foreign key constraints on a particular table, issue the following statement and find the constraint name in the `CONSTRAINT` clause for each foreign key:

```
show create table table\G
```

Or, query the `information_schema.table_constraints` table and use the `constraint_name` and `constraint_type` columns to identify the foreign key names.

You can also drop a foreign key and its associated index in a single statement:

```
ALTER TABLE table DROP FOREIGN KEY constraint, DROP INDEX index;
```

If [foreign keys](#) are already present in the table being altered (that is, it is a [child table](#) containing any `FOREIGN KEY ... REFERENCE` clauses), additional restrictions apply to online DDL operations, even those not directly involving the foreign key columns:

- An `ALTER TABLE` on the child table could wait for another transaction to commit, if a change to the parent table caused associated changes in the child table through an `ON UPDATE` or `ON DELETE` clause using the `CASCADE` or `SET NULL` parameters.
- In the same way, if a table is the [parent table](#) in a foreign key relationship, even though it does not contain any `FOREIGN KEY` clauses, it could wait for the `ALTER TABLE` to complete if an `INSERT`, `UPDATE`, or `DELETE` statement caused an `ON UPDATE` or `ON DELETE` action in the child table.

## Notes on `ALGORITHM=COPY`

Any `ALTER TABLE` operation run with the `ALGORITHM=COPY` clause prevents concurrent DML operations. Concurrent queries are still allowed. That is, a table-copying operation always includes at least the concurrency restrictions of `LOCK=SHARED` (allow queries but not DML). You can further restrict concurrency for such operations by specifying `LOCK=EXCLUSIVE`, which prevents DML and queries.

## Concurrent DML but Table Copy Still Required

Some other `ALTER TABLE` operations allow concurrent DML but still require a table copy. However, the table copy for these operations is faster than it was in MySQL 5.5 and prior.

- Adding, dropping, or reordering columns.
- Adding or dropping a `primary key`.
- Changing the `ROW_FORMAT` or `KEY_BLOCK_SIZE` properties for a table.
- Changing the nullable status for a column.
- `OPTIMIZE TABLE`
- Rebuilding a table with the `FORCE` option
- Rebuilding a table using a “null” `ALTER TABLE ... ENGINE=INNODB` statement

## Maintaining CREATE TABLE Statements

As your database schema evolves with new columns, data types, constraints, indexes, and so on, keep your `CREATE TABLE` statements up to date with the latest table definitions. Even with the performance improvements of online DDL, it is more efficient to create stable database structures at the beginning, rather than creating part of the schema and then issuing `ALTER TABLE` statements afterward.

The main exception to this guideline is for `secondary indexes` on tables with large numbers of rows. It is typically most efficient to create the table with all details specified except the secondary indexes, load the data, then create the secondary indexes. You can use the same technique with `foreign keys` (load the data first, then set up the foreign keys) if you know the initial data is clean and do not need consistency checks during the loading process.

Whatever sequence of `CREATE TABLE`, `CREATE INDEX`, `ALTER TABLE`, and similar statements went into putting a table together, you can capture the SQL needed to reconstruct the current form of the table by issuing the statement `SHOW CREATE TABLE table\G` (uppercase `\G` required for tidy formatting). This output shows clauses such as numeric precision, `NOT NULL`, and `CHARACTER SET` that are sometimes added behind the scenes, which you may want to leave out when cloning the table on a new system or setting up foreign key columns with identical type.

## 15.13.2 Performance and Concurrency Considerations for Online DDL

`Online DDL` improves several aspects of MySQL operation, such as performance, concurrency, availability, and scalability:

- Because queries and `DML` operations on the table can proceed while the DDL is in progress, applications that access the table are more responsive. Reduced `locking` and waiting for other resources throughout the MySQL server leads to greater scalability, even for operations not involving the table being altered.
- For in-place operations, by avoiding the disk I/O and CPU cycles to rebuild the table, you minimize the overall load on the database and maintain good performance and high throughput during the DDL operation.
- For in-place operations, because less data is read into the `buffer pool` than if all the data was copied, you avoid purging frequently accessed data from memory, which formerly could cause a temporary performance dip after a DDL operation.

If an online operation requires temporary sort files, `InnoDB` creates them in the temporary file directory by default, not the directory containing the original table. If this directory is not large enough to hold such files, you may need to set the `tmpdir` system variable to a different directory. Alternatively, you can define a separate temporary directory for `InnoDB` online `ALTER TABLE` operations using the

`innodb_tmpdir` configuration option. This option was introduced in MySQL 5.7.11 to help avoid temporary directory overflows that could occur as a result of large temporary sort files created during online `ALTER TABLE` operations. For more information, see [Section B.5.3.5, “Where MySQL Stores Temporary Files”](#).

## Locking Options for Online DDL

While an InnoDB table is being changed by a DDL operation, the table may or may not be [locked](#), depending on the internal workings of that operation and the `LOCK` clause of the `ALTER TABLE` statement. By default, MySQL uses as little locking as possible during a DDL operation; you specify the clause either to make the locking more restrictive than it normally would be (thus limiting concurrent DML, or DML and queries), or to ensure that some expected degree of locking is allowed for an operation. If the `LOCK` clause specifies a level of locking that is not available for that specific kind of DDL operation, such as `LOCK=SHARED` or `LOCK=NONE` while creating or dropping a primary key, the clause works like an assertion, causing the statement to fail with an error. The following list shows the different possibilities for the `LOCK` clause, from the most permissive to the most restrictive:

- For DDL operations with `LOCK=NONE`, both queries and concurrent DML are allowed. This clause makes the `ALTER TABLE` fail if the kind of DDL operation cannot be performed with the requested type of locking, so specify `LOCK=NONE` if keeping the table fully available is vital and it is OK to cancel the DDL if that is not possible. For example, you might use this clause in DDLs for tables involving customer signups or purchases, to avoid making those tables unavailable by mistakenly issuing an expensive `ALTER TABLE` statement.
- For DDL operations with `LOCK=SHARED`, any writes to the table (that is, DML operations) are blocked, but the data in the table can be read. This clause makes the `ALTER TABLE` fail if the kind of DDL operation cannot be performed with the requested type of locking, so specify `LOCK=SHARED` if keeping the table available for queries is vital and it is OK to cancel the DDL if that is not possible. For example, you might use this clause in DDLs for tables in a data warehouse, where it is OK to delay data load operations until the DDL is finished, but queries cannot be delayed for long periods.
- For DDL operations with `LOCK=DEFAULT`, or with the `LOCK` clause omitted, MySQL uses the lowest level of locking that is available for that kind of operation, allowing concurrent queries, DML, or both wherever possible. This is the setting to use when making pre-planned, pre-tested changes that you know will not cause any availability problems based on the workload for that table.
- For DDL operations with `LOCK=EXCLUSIVE`, both queries and DML operations are blocked. This clause makes the `ALTER TABLE` fail if the kind of DDL operation cannot be performed with the requested type of locking, so specify `LOCK=EXCLUSIVE` if the primary concern is finishing the DDL in the shortest time possible, and it is OK to make applications wait when they try to access the table. You might also use `LOCK=EXCLUSIVE` if the server is supposed to be idle, to avoid unexpected accesses to the table.

Depending on the internal workings of the online DDL operation and the `LOCK` clause of the `ALTER TABLE` statement, an online DDL operation may wait for currently executing transactions that are accessing the table to [commit](#) or [roll back](#) before completing because exclusive access to the table is required for a brief time during the initial and final phases of the DDL operation. These online DDL statements also wait for table-accessing transactions started while the DDL is in progress to commit or roll back before completing. Consequently, in the case of long running transactions performing inserts, updates, deletes, or `SELECT ... FOR UPDATE` on the table, an online `ALTER TABLE` operation can time out as it waits for exclusive access to the table. DML operations that are run on the table while the online `ALTER TABLE` operation waits for an exclusive table lock may also be blocked.

Because there is some processing work involved with recording the changes made by concurrent DML operations, then applying those changes at the end, an online DDL operation could take longer overall than the old-style mechanism that blocks table access from other sessions. The reduction in raw performance is balanced against better responsiveness for applications that use the table. When evaluating the ideal techniques for changing table structure, consider end-user perception of performance, based on factors such as load times for web pages.

A newly created InnoDB secondary index contains only the committed data in the table at the time the `CREATE INDEX` or `ALTER TABLE` statement finishes executing. It does not contain any uncommitted values, old versions of values, or values marked for deletion but not yet removed from the old index.

## Performance of In-Place versus Table-Copying DDL Operations

The raw performance of an online DDL operation is largely determined by whether the operation is performed in-place, or requires copying and rebuilding the entire table. See [Table 15.10, “Summary of Online Status for DDL Operations”](#) to see what kinds of operations can be performed in-place, and any requirements for avoiding table-copy operations.

The performance speedup from in-place DDL applies to operations on secondary indexes, not to the primary key index. The rows of an InnoDB table are stored in a [clustered index](#) organized based on the [primary key](#), forming what some database systems call an “index-organized table”. Because the table structure is closely tied to the primary key, redefining the primary key still requires copying the data.

When an operation on the primary key uses `ALGORITHM=INPLACE`, even though the data is still copied, it is more efficient than using `ALGORITHM=COPY` because:

- No undo logging or associated redo logging is required for `ALGORITHM=INPLACE`. These operations add overhead to DDL statements that use `ALGORITHM=COPY`.
- The secondary index entries are pre-sorted, and so can be loaded in order.
- The change buffer is not used, because there are no random-access inserts into the secondary indexes.

To judge the relative performance of online DDL operations, you can run such operations on a big [InnoDB](#) table using current and earlier versions of MySQL. You can also run all the performance tests under the latest MySQL version, simulating the previous DDL behavior for the “before” results, by setting the `old_alter_table` system variable. Issue the statement `set old_alter_table=1` in the session, and measure DDL performance to record the “before” figures. Then `set old_alter_table=0` to re-enable the newer, faster behavior, and run the DDL operations again to record the “after” figures.

For a basic idea of whether a DDL operation does its changes in-place or performs a table copy, look at the “rows affected” value displayed after the command finishes. For example, here are lines you might see after doing different types of DDL operations:

- Changing the default value of a column (super-fast, does not affect the table data at all):

```
Query OK, 0 rows affected (0.07 sec)
```

- Adding an index (takes time, but `0 rows affected` shows that the table is not copied):

```
Query OK, 0 rows affected (21.42 sec)
```

- Changing the data type of a column (takes substantial time and does require rebuilding all the rows of the table):

```
Query OK, 1671168 rows affected (1 min 35.54 sec)
```

### Note

Changing the data type of a column requires rebuilding all the rows of the table with the exception of changing `VARCHAR` size, which may be performed using online `ALTER TABLE`. See [InnoDB Online DDL Column Properties](#) for more information.

For example, before running a DDL operation on a big table, you might check whether the operation will be fast or slow as follows:

1. Clone the table structure.
2. Populate the cloned table with a tiny amount of data.
3. Run the DDL operation on the cloned table.
4. Check whether the “rows affected” value is zero or not. A non-zero value means the operation will require rebuilding the entire table, which might require special planning. For example, you might do the DDL operation during a period of scheduled downtime, or on each replication slave server one at a time.

For a deeper understanding of the reduction in MySQL processing, examine the [performance\\_schema](#) and [INFORMATION\\_SCHEMA](#) tables related to [InnoDB](#) before and after DDL operations, to see the number of physical reads, writes, memory allocations, and so on.

### 15.13.3 SQL Syntax for Online DDL

Typically, you do not need to do anything special to enable [online DDL](#) when using the [ALTER TABLE](#) statement for [InnoDB](#) tables. See [Table 15.10, “Summary of Online Status for DDL Operations”](#) for the kinds of DDL operations that can be performed in-place, allowing concurrent DML, or both. Some variations require particular combinations of configuration settings or [ALTER TABLE](#) clauses.

You can control the various aspects of a particular online DDL operation by using the [LOCK](#) and [ALGORITHM](#) clauses of the [ALTER TABLE](#) statement. These clauses come at the end of the statement, separated from the table and column specifications by commas. The [LOCK](#) clause is useful for fine-tuning the degree of concurrent access to the table. The [ALGORITHM](#) clause is primarily intended for performance comparisons and as a fallback to the older table-copying behavior in case you encounter any issues with existing DDL code. For example:

- To avoid accidentally making the table unavailable for reads, writes, or both, specify a clause on the [ALTER TABLE](#) statement such as [LOCK=NONE](#) (allow both reads and writes) or [LOCK=SHARED](#) (allow reads). The operation halts immediately if the requested level of concurrency is not available.
- To compare performance, run one statement with [ALGORITHM=INPLACE](#) and another with [ALGORITHM=COPY](#), as an alternative to setting the [old\\_alter\\_table](#) configuration option.
- To avoid tying up the server with an [ALTER TABLE](#) operation that copies the table, include [ALGORITHM=INPLACE](#). The statement halts immediately if it cannot use the in-place mechanism. See [Table 15.10, “Summary of Online Status for DDL Operations”](#) for a list of the DDL operations that can or cannot be performed in-place.

See [Section 15.13.2, “Performance and Concurrency Considerations for Online DDL”](#) for more details about the [LOCK](#) clause. For full examples of using online DDL, see [Section 15.13.5, “Examples of Online DDL”](#).

### 15.13.4 Combining or Separating DDL Statements

Before the introduction of [online DDL](#), it was common practice to combine many DDL operations into a single [ALTER TABLE](#) statement. Because each [ALTER TABLE](#) statement involved copying and rebuilding the table, it was more efficient to make several changes to the same table at once, since those changes could all be done with a single rebuild operation for the table. The downside was that SQL code involving DDL operations was harder to maintain and to reuse in different scripts. If the specific changes were different each time, you might have to construct a new complex [ALTER TABLE](#) for each slightly different scenario.

For DDL operations that can be done in-place, as shown in [Table 15.10, “Summary of Online Status for DDL Operations”](#), now you can separate them into individual [ALTER TABLE](#) statements for easier scripting and maintenance, without sacrificing efficiency. For example, you might take a complicated statement such as:

```
ALTER TABLE t1 ADD INDEX i1(c1), ADD UNIQUE INDEX i2(c2),
```

```
CHANGE c4_old_name c4_new_name INTEGER UNSIGNED;
```

and break it down into simpler parts that can be tested and performed independently, such as:

```
ALTER TABLE t1 ADD INDEX i1(c1);
ALTER TABLE t1 ADD UNIQUE INDEX i2(c2);
ALTER TABLE t1 CHANGE c4_old_name c4_new_name INTEGER UNSIGNED NOT NULL;
```

You might still use multi-part `ALTER TABLE` statements for:

- Operations that must be performed in a specific sequence, such as creating an index followed by a foreign key constraint that uses that index.
- Operations all using the same specific `LOCK` clause, that you want to either succeed or fail as a group.
- Operations that cannot be performed in-place, that is, that still copy and rebuild the table.
- Operations for which you specify `ALGORITHM=COPY` or `old_alter_table=1`, to force the table-copying behavior if needed for precise backward-compatibility in specialized scenarios.

### 15.13.5 Examples of Online DDL

Here are code examples showing some operations whose performance, concurrency, and scalability are improved by the latest [online DDL](#) enhancements.

- [Example 15.1, “Schema Setup Code for Online DDL Experiments”](#) sets up tables named `BIG_TABLE` and `SMALL_TABLE` used in the subsequent examples.
- [Example 15.2, “Speed and Efficiency of CREATE INDEX and DROP INDEX”](#) illustrates the performance aspects of creating and dropping indexes.
- [Example 15.3, “Concurrent DML During CREATE INDEX and DROP INDEX”](#) shows queries and DML statements running during a `DROP INDEX` operation.
- [Example 15.4, “Renaming a Column”](#) demonstrates the speed improvement for renaming a column, and shows the care needed to keep the data type precisely the same when doing the rename operation.
- [Example 15.5, “Dropping Foreign Keys”](#) demonstrates how foreign keys work with online DDL. Because two tables are involved in foreign key operations, there are extra locking considerations. Thus, tables with foreign keys sometimes have restrictions for online DDL operations.
- [Example 15.6, “Changing Auto-Increment Value”](#) demonstrates how auto-increment columns work with online DDL. Tables with auto-increment columns sometimes have restrictions for online DDL operations.
- [Example 15.7, “Controlling Concurrency with the LOCK Clause”](#) demonstrates the options to permit or restrict concurrent queries and DML operations while an online DDL operation is in progress. It shows the situations when the DDL statement might wait, or the concurrent transaction might wait, or the concurrent transaction might cancel a DML statement due to a deadlock error.
- [Example 15.8, “Schema Setup Code for Online DDL Experiments”](#) demonstrates creating and dropping multiple indexes in a single statement, which can be more efficient than using a separate statement for each index operation.
- [Example 15.9, “Creating and Dropping the Primary Key”](#) demonstrates how it is more efficient to define a [primary key](#) when creating the table, and relatively expensive to add one later.

#### Example 15.1 Schema Setup Code for Online DDL Experiments

Here is the code that sets up the initial tables used in these demonstrations:

```

/*
Setup code for the online DDL demonstration:
- Set up some config variables.
- Create 2 tables that are clones of one of the INFORMATION_SCHEMA tables
  that always has some data. The "small" table has a couple of thousand rows.
  For the "big" table, keep doubling the data until it reaches over a million rows.
- Set up a primary key for the sample tables, since we are demonstrating InnoDB aspects.
*/

set autocommit = 0;
set foreign_key_checks = 1;
set global innodb_file_per_table = 1;
set old_alter_table=0;
prompt mysql:

use test;

\! echo "Setting up 'small' table:"
drop table if exists small_table;
create table small_table as select * from information_schema.columns;
alter table small_table add id int unsigned not null primary key auto_increment;
select count(id) from small_table;

\! echo "Setting up 'big' table:"
drop table if exists big_table;
create table big_table as select * from information_schema.columns;
show create table big_table\G

insert into big_table select * from big_table;
insert into big_table select * from big_table;
insert into big_table select * from big_table;
insert into big_table select * from big_table;
insert into big_table select * from big_table;
insert into big_table select * from big_table;
insert into big_table select * from big_table;
insert into big_table select * from big_table;
insert into big_table select * from big_table;
insert into big_table select * from big_table;
commit;

alter table big_table add id int unsigned not null primary key auto_increment;
select count(id) from big_table;

```

Running this code gives this output, condensed for brevity and with the most important points bolded:

```

Setting up 'small' table:
Query OK, 0 rows affected (0.01 sec)

Query OK, 1678 rows affected (0.13 sec)
Records: 1678 Duplicates: 0 Warnings: 0

Query OK, 1678 rows affected (0.07 sec)
Records: 1678 Duplicates: 0 Warnings: 0

+-----+
| count(id) |
+-----+
|      1678 |
+-----+
1 row in set (0.00 sec)

Setting up 'big' table:
Query OK, 0 rows affected (0.16 sec)

Query OK, 1678 rows affected (0.17 sec)
Records: 1678 Duplicates: 0 Warnings: 0

***** 1. row *****
      Table: big_table
Create Table: CREATE TABLE `big_table` (
  `TABLE_CATALOG` varchar(512) CHARACTER SET utf8 NOT NULL DEFAULT '',

```

```

`TABLE_SCHEMA` varchar(64) CHARACTER SET utf8 NOT NULL DEFAULT '',

### Example 15.2 Speed and Efficiency of CREATE INDEX and DROP INDEX

Here is a sequence of statements demonstrating the relative speed of `CREATE INDEX` and `DROP INDEX` statements. For a small table, the elapsed time is less than a second whether we use the fast or slow technique, so we look at the “rows affected” output to verify which operations can avoid the table rebuild. For a large table, the difference in efficiency is obvious because skipping the table rebuild saves substantial time.

```

\! clear

\! echo "=== Create and drop index (small table, new/fast technique) ==="
\! echo
\! echo "Data size (kilobytes) before index created: "
\! du -k data/test/small_table.ibd
create index i_dtyp_small on small_table (data_type), algorithm=inplace;
\! echo "Data size after index created: "
\! du -k data/test/small_table.ibd
drop index i_dtyp_small on small_table, algorithm=inplace;

-- Compare against the older slower DDL.

\! echo "=== Create and drop index (small table, old/slow technique) ==="
\! echo
\! echo "Data size (kilobytes) before index created: "
\! du -k data/test/small_table.ibd
create index i_dtyp_small on small_table (data_type), algorithm=copy;
\! echo "Data size after index created: "
\! du -k data/test/small_table.ibd
drop index i_dtyp_small on small_table, algorithm=copy;

-- In the above example, we examined the "rows affected" number,
-- ideally looking for a zero figure. Let's try again with a larger
-- sample size, where we'll see that the actual time taken can
-- vary significantly.

\! echo "=== Create and drop index (big table, new/fast technique) ==="
\! echo
\! echo "Data size (kilobytes) before index created: "
\! du -k data/test/big_table.ibd
create index i_dtyp_big on big_table (data_type), algorithm=inplace;
\! echo "Data size after index created: "
\! du -k data/test/big_table.ibd
drop index i_dtyp_big on big_table, algorithm=inplace;

\! echo "=== Create and drop index (big table, old/slow technique) ==="
\! echo
\! echo "Data size (kilobytes) before index created: "
\! du -k data/test/big_table.ibd
create index i_dtyp_big on big_table (data_type), algorithm=copy;
\! echo "Data size after index created: "
\! du -k data/test/big_table.ibd
drop index i_dtyp_big on big_table, algorithm=copy;

```

Running this code gives this output, condensed for brevity and with the most important points bolded:

```

Query OK, 0 rows affected (0.00 sec)

=== Create and drop index (small table, new/fast technique) ===

Data size (kilobytes) before index created:
384 data/test/small_table.ibd

Data size after index created:
348160 data/test/big_table.ibd
Query OK, 1718272 rows affected (46.59 sec)
Records: 1718272 Duplicates: 0 Warnings: 0

```

### Example 15.3 Concurrent DML During CREATE INDEX and DROP INDEX

Here are some snippets of code that are run in separate [mysql](#) sessions connected to the same database, to illustrate DML statements (insert, update, or delete) running at the same time as [CREATE INDEX](#) and [DROP INDEX](#).

```

/*
CREATE INDEX statement to run against a table while
insert/update/delete statements are modifying the
column being indexed.
*/

-- Run this script in one session, while simultaneously creating and dropping
-- an index on test/big_table.table_name in another session.

use test;
create index i_concurrent on big_table(table_name);

```

```

/*
DROP INDEX statement to run against a table while
insert/update/delete statements are modifying the
column being indexed.
*/

-- Run this script in one session, while simultaneously creating and dropping
-- an index on test/big_table.table_name in another session.

use test;
drop index i_concurrent on big_table;

```

```

/*
Some queries and insert/update/delete statements to run against a table
while an index is being created or dropped. Previously, these operations
would have stalled during the index create/drop period and possibly
timed out or deadlocked.
*/

```

```
-- Run this script in one session, while simultaneously creating and dropping
-- an index on test/big_table.table_name in another session.

-- In the test instance, that column has about 1.7M rows, with 136 different values.
-- Sample values: COLUMNS (20480), ENGINES (6144), EVENTS (24576), FILES (38912),
-- TABLES (21504), VIEWS (10240).

set autocommit = 0;
use test;

select distinct character_set_name from big_table where table_name = 'FILES';
delete from big_table where table_name = 'FILES';
select distinct character_set_name from big_table where table_name = 'FILES';

-- I'll issue the final rollback interactively, not via script,
-- the better to control the timing.
-- rollback;
```

Running this code gives this output, condensed for brevity and with the most important points bolded:

```
mysql: source concurrent_ddl_create.sql
Database changed
Query OK, 0 rows affected (1 min 25.15 sec)
Records: 0 Duplicates: 0 Warnings: 0

mysql: source concurrent_ddl_drop.sql
Database changed
Query OK, 0 rows affected (24.98 sec)
Records: 0 Duplicates: 0 Warnings: 0

mysql: source concurrent_dml.sql
Query OK, 0 rows affected (0.00 sec)

Database changed
+-----+
| character_set_name |
+-----+
| NULL              |
| utf8              |
+-----+
2 rows in set (0.32 sec)

Query OK, 38912 rows affected (1.84 sec)

Empty set (0.01 sec)

mysql: rollback;
Query OK, 0 rows affected (1.05 sec)
```

#### Example 15.4 Renaming a Column

Here is a demonstration of using `ALTER TABLE` to rename a column. We use the new, fast DDL mechanism to change the name, then the old, slow DDL mechanism (with `old_alter_table=1`) to restore the original column name.

Notes:

- Because the syntax for renaming a column also involves re-specifying the data type, be careful to specify exactly the same data type to avoid a costly table rebuild. In this case, we checked the output of `show create table table\G` and copied any clauses such as `CHARACTER SET` and `NOT NULL` from the original column definition.
- Again, renaming a column for a small table is fast enough that we need to examine the “rows affected” number to verify that the new DDL mechanism is more efficient than the old one. With a big table, the difference in elapsed time makes the improvement obvious.

```
/*
```

```

Run through a sequence of 'rename column' statements.
Because this operation involves only metadata, not table data,
it is fast for big and small tables, with new or old DDL mechanisms.
*/

\! clear

\! echo "Rename column (fast technique, small table):"
alter table small_table change `IS_NULLABLE` `NULLABLE` varchar(3) character
    set utf8 not null, algorithm=inplace;
\! echo "Rename back to original name (slow technique):"
alter table small_table change `NULLABLE` `IS_NULLABLE` varchar(3) character
    set utf8 not null, algorithm=copy;

\! echo "Rename column (fast technique, big table):"
alter table big_table change `IS_NULLABLE` `NULLABLE` varchar(3) character
    set utf8 not null, algorithm=inplace;
\! echo "Rename back to original name (slow technique):"
alter table big_table change `NULLABLE` `IS_NULLABLE` varchar(3) character
    set utf8 not null, algorithm=copy;

```

Running this code gives this output, condensed for brevity and with the most important points bolded:

```

Rename column (fast technique, small table):
Query OK, 0 rows affected (0.05 sec)

Query OK, 0 rows affected (0.13 sec)
Records: 0 Duplicates: 0 Warnings: 0

Rename back to original name (slow technique):
Query OK, 0 rows affected (0.00 sec)

Query OK, 1678 rows affected (0.35 sec)
Records: 1678 Duplicates: 0 Warnings: 0

Rename column (fast technique, big table):
Query OK, 0 rows affected (0.00 sec)

Query OK, 0 rows affected (0.11 sec)
Records: 0 Duplicates: 0 Warnings: 0

Rename back to original name (slow technique):
Query OK, 0 rows affected (0.00 sec)

Query OK, 1718272 rows affected (1 min 0.00 sec)
Records: 1718272 Duplicates: 0 Warnings: 0

Query OK, 0 rows affected (0.00 sec)

```

### Example 15.5 Dropping Foreign Keys

Here is a demonstration of foreign keys, including improvement to the speed of dropping a foreign key constraint.

```

/*
Demonstrate aspects of foreign keys that are or aren't affected by the DDL improvements.
- Create a new table with only a few values to serve as the parent table.
- Set up the 'small' and 'big' tables as child tables using a foreign key.
- Verify that the ON DELETE CASCADE clause makes changes ripple from parent to child tables.
- Drop the foreign key constraints, and optionally associated indexes. (This is the operation that is sped
*/

\! clear

-- Make sure foreign keys are being enforced, and allow
-- rollback after doing some DELETES that affect both
-- parent and child tables.
set foreign_key_checks = 1;
set autocommit = 0;

```

```

-- Create a parent table, containing values that we know are already present
-- in the child tables.
drop table if exists schema_names;
create table schema_names (id int unsigned not null primary key auto_increment, schema_name
    varchar(64) character set utf8 not null, index i_schema (schema_name)) as select distinct
    table_schema schema_name from small_table;

show create table schema_names\G
show create table small_table\G
show create table big_table\G

-- Creating the foreign key constraint still involves a table rebuild when foreign_key_checks=1,
-- as illustrated by the "rows affected" figure.
alter table small_table add constraint small_fk foreign key i_table_schema (table_schema)
    references schema_names(schema_name) on delete cascade;
alter table big_table add constraint big_fk foreign key i_table_schema (table_schema)
    references schema_names(schema_name) on delete cascade;

show create table small_table\G
show create table big_table\G

select schema_name from schema_names order by schema_name;
select count(table_schema) howmany, table_schema from small_table group by table_schema;
select count(table_schema) howmany, table_schema from big_table group by table_schema;

-- big_table is the parent table.
-- schema_names is the parent table.
-- big_table is the child table.
-- (One row in the parent table can have many "children" in the child table.)
-- Changes to the parent table can ripple through to the child table.
-- For example, removing the value 'test' from schema_names.schema_name will
-- result in the removal of 20K or so rows from big_table.

delete from schema_names where schema_name = 'test';

select schema_name from schema_names order by schema_name;
select count(table_schema) howmany, table_schema from small_table group by table_schema;
select count(table_schema) howmany, table_schema from big_table group by table_schema;

-- Because we've turned off autocommit, we can still get back those deleted rows
-- if the DELETE was issued by mistake.
rollback;

select schema_name from schema_names order by schema_name;
select count(table_schema) howmany, table_schema from small_table group by table_schema;
select count(table_schema) howmany, table_schema from big_table group by table_schema;

-- All of the cross-checking between parent and child tables would be
-- deadly slow if there wasn't the requirement for the corresponding
-- columns to be indexed!

-- But we can get rid of the foreign key using a fast operation
-- that doesn't rebuild the table.
-- If we didn't specify a constraint name when setting up the foreign key, we would
-- have to find the auto-generated name such as 'big_table_ibfk_1' in the
-- output from 'show create table'.

-- For the small table, drop the foreign key and the associated index.
-- Having an index on a small table is less critical.

\! echo "DROP FOREIGN KEY and INDEX from small_table:"
alter table small_table drop foreign key small_fk, drop index small_fk;

-- For the big table, drop the foreign key and leave the associated index.
-- If we are still doing queries that reference the indexed column, the index is
-- very important to avoid a full table scan of the big table.
\! echo "DROP FOREIGN KEY from big_table:"
alter table big_table drop foreign key big_fk;

show create table small_table\G

```

```
show create table big_table\G
```

Running this code gives this output, condensed for brevity and with the most important points bolded:

### Example 15.6 Changing Auto-Increment Value

Here is an illustration of increasing the [auto-increment](#) lower limit for a table column, demonstrating how this operation now avoids a table rebuild, plus other facts about [InnoDB](#) auto-increment columns.

```

/*
If this script is run after foreign_key.sql, the schema_names table is
already set up. But to allow this script to run multiple times without
running into duplicate ID errors, we set up the schema_names table
all over again.
*/

\! clear

\! echo "=== Adjusting the Auto-Increment Limit for a Table ==="
\! echo

drop table if exists schema_names;
create table schema_names (id int unsigned not null primary key auto_increment,
  schema_name varchar(64) character set utf8 not null, index i_schema (schema_name))
  as select distinct table_schema schema_name from small_table;

\! echo "Initial state of schema_names table."
\! echo "AUTO_INCREMENT is included in SHOW CREATE TABLE output."
\! echo "Note how MySQL reserved a block of IDs."
\! echo "Only 4 IDs are needed in this transaction. The next inserted values get IDs 8 and 9."
show create table schema_names\G
select * from schema_names order by id;

\! echo "Inserting even a tiny amount of data can produce gaps in the ID sequence."
insert into schema_names (schema_name) values ('eight'), ('nine');

\! echo "Bumping auto-increment lower limit to 20 (fast mechanism):"
alter table schema_names auto_increment=20, algorithm=inplace;

\! echo "Inserting 2 rows that should get IDs 20 and 21:"
insert into schema_names (schema_name) values ('foo'), ('bar');
commit;

\! echo "Bumping auto-increment lower limit to 30 (slow mechanism):"
alter table schema_names auto_increment=30, algorithm=copy;

\! echo "Inserting 2 rows that should get IDs 30 and 31:"
insert into schema_names (schema_name) values ('bletch'),('baz');
commit;

select * from schema_names order by id;

\! echo "Final state of schema_names table."
\! echo "AUTO_INCREMENT value shows the next inserted row would get ID=32."
show create table schema_names\G

```

Running this code gives this output, condensed for brevity and with the most important points bolded:

```

=== Adjusting the Auto-Increment Limit for a Table ===

Query OK, 0 rows affected (0.01 sec)

### Example 15.7 Controlling Concurrency with the LOCK Clause

This example shows how to use the `LOCK` clause of the `ALTER TABLE` statement to allow or deny concurrent access to the table while an online DDL operation is in progress. The clause has settings that allow queries and DML statements (`LOCK=NONE`), just queries (`LOCK=SHARED`), or no concurrent access at all (`LOCK=EXCLUSIVE`).

In one session, we run a succession of `ALTER TABLE` statements to create and drop an index, using different values for the `LOCK` clause to see what happens with waiting or deadlocking in either session. We are using the same `BIG_TABLE` table as in previous examples, starting with approximately 1.7 million rows. For illustration purposes, we will index and query the `IS_NULLABLE` column. (Although in real life it would be silly to make an index for a tiny column with only 2 distinct values.)

```
mysql: desc big_table;
+-----+-----+-----+-----+-----+-----+
| Field | Type | Null | Key | Default | Extra |
+-----+-----+-----+-----+-----+-----+
| TABLE_CATALOG | varchar(512) | NO | | | |
| TABLE_SCHEMA | varchar(64) | NO | | | |
| TABLE_NAME | varchar(64) | NO | | | |
| COLUMN_NAME | varchar(64) | NO | | | |
| ORDINAL_POSITION | bigint(21) unsigned | NO | | 0 | |
| COLUMN_DEFAULT | longtext | YES | | NULL | |
| IS_NULLABLE | varchar(3) | NO | | | |
...
+-----+-----+-----+-----+-----+-----+
21 rows in set (0.14 sec)

mysql: alter table big_table add index i1(is_nullable);
Query OK, 0 rows affected (20.71 sec)

mysql: alter table big_table drop index i1;
Query OK, 0 rows affected (0.02 sec)

mysql: alter table big_table add index i1(is_nullable), lock=exclusive;
Query OK, 0 rows affected (19.44 sec)

mysql: alter table big_table drop index i1;
Query OK, 0 rows affected (0.03 sec)

mysql: alter table big_table add index i1(is_nullable), lock=shared;
Query OK, 0 rows affected (16.71 sec)

mysql: alter table big_table drop index i1;
Query OK, 0 rows affected (0.05 sec)

mysql: alter table big_table add index i1(is_nullable), lock=none;
Query OK, 0 rows affected (12.26 sec)

mysql: alter table big_table drop index i1;
```

```
Query OK, 0 rows affected (0.01 sec)
```

```
... repeat statements like the above while running queries ...
... and DML statements at the same time in another session ...
```

Nothing dramatic happens in the session running the DDL statements. Sometimes, an [ALTER TABLE](#) takes unusually long because it is waiting for another transaction to finish, when that transaction modified the table during the DDL or queried the table before the DDL:

```
mysql: alter table big_table add index i1(is_nullable), lock=none;
```

```
Query OK, 0 rows affected (59.27 sec)
```

```
mysql: -- The previous ALTER took so long because it was waiting for all the concurrent
mysql: -- transactions to commit or roll back.
```

```
mysql: alter table big_table drop index i1;
```

```
Query OK, 0 rows affected (41.05 sec)
```

```
mysql: -- Even doing a SELECT on the table in the other session first causes
mysql: -- the ALTER TABLE above to stall until the transaction
mysql: -- surrounding the SELECT is committed or rolled back.
```

Here is the log from another session running concurrently, where we issue queries and DML statements against the table before, during, and after the DDL operations shown in the previous listings. This first listing shows queries only. We expect the queries to be allowed during DDL operations using [LOCK=NONE](#) or [LOCK=SHARED](#), and for the query to wait until the DDL is finished if the [ALTER TABLE](#) statement includes [LOCK=EXCLUSIVE](#).

```
mysql: show variables like 'autocommit';
```

```
+-----+
| Variable_name | Value |
+-----+
| autocommit    | ON    |
+-----+
1 row in set (0.01 sec)
```

```
mysql: -- A trial query before any ADD INDEX in the other session:
```

```
mysql: -- Note: because autocommit is enabled, each
mysql: -- transaction finishes immediately after the query.
mysql: select distinct is_nullable from big_table;
```

```
+-----+
| is_nullable |
+-----+
| NO          |
| YES         |
+-----+
2 rows in set (4.49 sec)
```

```
mysql: -- Index is being created with LOCK=EXCLUSIVE on the ALTER statement.
```

```
mysql: -- The query waits until the DDL is finished before proceeding.
```

```
mysql: select distinct is_nullable from big_table;
```

```
+-----+
| is_nullable |
+-----+
| NO          |
| YES         |
+-----+
```

```
2 rows in set (17.26 sec)
```

```
mysql: -- Index is being created with LOCK=SHARED on the ALTER statement.
```

```
mysql: -- The query returns its results while the DDL is in progress.
```

```
mysql: -- The same thing happens with LOCK=NONE on the ALTER statement.
```

```
mysql: select distinct is_nullable from big_table;
```

```
+-----+
| is_nullable |
+-----+
| NO          |
```

```

| YES |
+-----+
2 rows in set (3.11 sec)

mysql: -- Once the index is created, and with no DDL in progress,
mysql: -- queries referencing the indexed column are very fast:
mysql: select count(*) from big_table where is_nullable = 'YES';
+-----+
| count(*) |
+-----+
| 411648 |
+-----+
1 row in set (0.20 sec)

mysql: select distinct is_nullable from big_table;
+-----+
| is_nullable |
+-----+
| NO |
| YES |
+-----+
2 rows in set (0.00 sec)

```

Now in this concurrent session, we run some transactions including DML statements, or a combination of DML statements and queries. We use [DELETE](#) statements to illustrate predictable, verifiable changes to the table. Because the transactions in this part can span multiple statements, we run these tests with [autocommit](#) turned off.

```

mysql: set global autocommit = off;
Query OK, 0 rows affected (0.00 sec)

mysql: -- Count the rows that will be involved in our DELETE statements:
mysql: select count(*) from big_table where is_nullable = 'YES';
+-----+
| count(*) |
+-----+
| 411648 |
+-----+
1 row in set (0.95 sec)

mysql: -- After this point, any DDL statements back in the other session
mysql: -- stall until we commit or roll back.

mysql: delete from big_table where is_nullable = 'YES' limit 11648;
Query OK, 11648 rows affected (0.14 sec)

mysql: select count(*) from big_table where is_nullable = 'YES';
+-----+
| count(*) |
+-----+
| 400000 |
+-----+
1 row in set (1.04 sec)

mysql: rollback;
Query OK, 0 rows affected (0.09 sec)

mysql: select count(*) from big_table where is_nullable = 'YES';
+-----+
| count(*) |
+-----+
| 411648 |
+-----+
1 row in set (0.93 sec)

mysql: -- OK, now we're going to try that during index creation with LOCK=NONE.
mysql: delete from big_table where is_nullable = 'YES' limit 11648;
Query OK, 11648 rows affected (0.21 sec)

mysql: -- We expect that now there will be 400000 'YES' rows left:

```

```

mysql: select count(*) from big_table where is_nullable = 'YES';
+-----+
| count(*) |
+-----+
| 400000 |
+-----+
1 row in set (1.25 sec)

mysql: -- In the other session, the ALTER TABLE is waiting before finishing,
mysql: -- because _this_ transaction hasn't committed or rolled back yet.
mysql: rollback;
Query OK, 0 rows affected (0.11 sec)

mysql: select count(*) from big_table where is_nullable = 'YES';
+-----+
| count(*) |
+-----+
| 411648 |
+-----+
1 row in set (0.19 sec)

mysql: -- The ROLLBACK left the table in the same state we originally found it.
mysql: -- Now let's make a permanent change while the index is being created,
mysql: -- again with ALTER TABLE ... , LOCK=NONE.
mysql: -- First, commit so the DROP INDEX in the other shell can finish;
mysql: -- the previous SELECT started a transaction that accessed the table.
mysql: commit;
Query OK, 0 rows affected (0.00 sec)

mysql: -- Now we add the index back in the other shell, then issue DML in this one
mysql: -- while the DDL is running.
mysql: delete from big_table where is_nullable = 'YES' limit 11648;
Query OK, 11648 rows affected (0.23 sec)

mysql: commit;
Query OK, 0 rows affected (0.01 sec)

mysql: -- In the other shell, the ADD INDEX has finished.
mysql: select count(*) from big_table where is_nullable = 'YES';
+-----+
| count(*) |
+-----+
| 400000 |
+-----+
1 row in set (0.19 sec)

mysql: -- At the point the new index is finished being created, it contains entries
mysql: -- only for the 400000 'YES' rows left when all concurrent transactions are finished.
mysql:
mysql: -- Now we will run a similar test, while ALTER TABLE ... , LOCK=SHARED is running.
mysql: -- We expect a query to complete during the ALTER TABLE, but for the DELETE
mysql: -- to run into some kind of issue.
mysql: commit;
Query OK, 0 rows affected (0.00 sec)

mysql: -- As expected, the query returns results while the LOCK=SHARED DDL is running:
mysql: select count(*) from big_table where is_nullable = 'YES';
+-----+
| count(*) |
+-----+
| 400000 |
+-----+
1 row in set (2.07 sec)

mysql: -- The DDL in the other session is not going to finish until this transaction
mysql: -- is committed or rolled back. If we tried a DELETE now and it waited because
mysql: -- of LOCK=SHARED on the DDL, both transactions would wait forever (deadlock).
mysql: -- MySQL detects this condition and cancels the attempted DML statement.
mysql: delete from big_table where is_nullable = 'YES' limit 100000;
ERROR 1213 (40001): Deadlock found when trying to get lock; try restarting transaction
mysql: -- The transaction here is still going, so in the other shell, the ADD INDEX operation
mysql: -- is waiting for this transaction to commit or roll back.

```

```

mysql: rollback;
Query OK, 0 rows affected (0.00 sec)

mysql: -- Now let's try issuing a query and some DML, on one line, while running
mysql: -- ALTER TABLE ... , LOCK=EXCLUSIVE in the other shell.
mysql: -- Notice how even the query is held up until the DDL is finished.
mysql: -- By the time the DELETE is issued, there is no conflicting access
mysql: -- to the table and we avoid the deadlock error.
mysql: select count(*) from big_table where is_nullable = 'YES'; delete from big_table
      where is_nullable = 'YES' limit 100000;
+-----+
| count(*) |
+-----+
|   400000 |
+-----+

1 row in set (15.98 sec)

Query OK, 100000 rows affected (2.81 sec)

mysql: select count(*) from big_table where is_nullable = 'YES';
+-----+
| count(*) |
+-----+
|   300000 |
+-----+
1 row in set (0.17 sec)

mysql: rollback;
Query OK, 0 rows affected (1.36 sec)

mysql: select count(*) from big_table where is_nullable = 'YES';
+-----+
| count(*) |
+-----+
|   400000 |
+-----+
1 row in set (0.19 sec)

mysql: commit;
Query OK, 0 rows affected (0.00 sec)

mysql: -- Next, we try ALTER TABLE ... , LOCK=EXCLUSIVE in the other session
mysql: -- and only issue DML, not any query, in the concurrent transaction here.
mysql: delete from big_table where is_nullable = 'YES' limit 100000;
Query OK, 100000 rows affected (16.37 sec)

mysql: -- That was OK because the ALTER TABLE did not have to wait for the transaction
mysql: -- here to complete. The DELETE in this session waited until the index was ready.
mysql: select count(*) from big_table where is_nullable = 'YES';
+-----+
| count(*) |
+-----+
|   300000 |
+-----+
1 row in set (0.16 sec)

mysql: commit;
Query OK, 0 rows affected (0.00 sec)

```

In the preceding example listings, we learned that:

- The **LOCK** clause for **ALTER TABLE** is set off from the rest of the statement by a comma.
- Online DDL operations might wait before starting, until any prior transactions that access the table are committed or rolled back.
- Online DDL operations might wait before completing, until any concurrent transactions that access the table are committed or rolled back.

- While an online DDL operation is running, concurrent queries are relatively straightforward, as long as the `ALTER TABLE` statement uses `LOCK=NONE` or `LOCK=SHARED`.
- Pay attention to whether `autocommit` is turned on or off. If it is turned off, be careful to end transactions in other sessions (even just queries) before performing DDL operations on the table.
- With `LOCK=SHARED`, concurrent transactions that mix queries and DML could encounter deadlock errors and have to be restarted after the DDL is finished.
- With `LOCK=NONE`, concurrent transactions can freely mix queries and DML. The DDL operation waits until the concurrent transactions are committed or rolled back.
- With `LOCK=EXCLUSIVE`, concurrent transactions can freely mix queries and DML, but those transactions wait until the DDL operation is finished before they can access the table.

### Example 15.8 Schema Setup Code for Online DDL Experiments

You can create multiple indexes on a table with one `ALTER TABLE` statement. This is relatively efficient, because the clustered index of the table needs to be scanned only once (although the data is sorted separately for each new index). For example:

```
CREATE TABLE T1(A INT PRIMARY KEY, B INT, C CHAR(1)) ENGINE=InnoDB;
INSERT INTO T1 VALUES (1,2,'a'), (2,3,'b'), (3,2,'c'), (4,3,'d'), (5,2,'e');
COMMIT;
ALTER TABLE T1 ADD INDEX (B), ADD UNIQUE INDEX (C);
```

The above statements create table `T1` with the primary key on column `A`, insert several rows, then build two new indexes on columns `B` and `C`. If there were many rows inserted into `T1` before the `ALTER TABLE` statement, this approach is much more efficient than creating all the secondary indexes before loading the data.

Because dropping InnoDB secondary indexes also does not require any copying of table data, it is equally efficient to drop multiple indexes with a single `ALTER TABLE` statement or multiple `DROP INDEX` statements:

```
ALTER TABLE T1 DROP INDEX B, DROP INDEX C;
```

or:

```
DROP INDEX B ON T1;
DROP INDEX C ON T1;
```

### Example 15.9 Creating and Dropping the Primary Key

Restructuring the `clustered index` for an InnoDB table always requires copying the table data. Thus, it is best to define the `primary key` when you create a table, rather than issuing `ALTER TABLE ... ADD PRIMARY KEY` later, to avoid rebuilding the table.

Defining a `PRIMARY KEY` later causes the data to be copied, as in the following example:

```
CREATE TABLE T2 (A INT, B INT);
INSERT INTO T2 VALUES (NULL, 1);
ALTER TABLE T2 ADD PRIMARY KEY (B);
```

When you create a `UNIQUE` or `PRIMARY KEY` index, MySQL must do some extra work. For `UNIQUE` indexes, MySQL checks that the table contains no duplicate values for the key. For a `PRIMARY KEY` index, MySQL also checks that none of the `PRIMARY KEY` columns contains a `NULL`.

When you add a primary key using the `ALGORITHM=COPY` clause, MySQL actually converts `NULL` values in the associated columns to default values: 0 for numbers, the empty string for character-based

columns and BLOBs, and 0000-00-00 00:00:00 for `DATETIME`. This is a non-standard behavior that Oracle recommends you not rely on. Adding a primary key using `ALGORITHM=INPLACE` is only allowed when the `SQL_MODE` setting includes the `strict_trans_tables` or `strict_all_tables` flags; when the `SQL_MODE` setting is strict, `ADD PRIMARY KEY ... , ALGORITHM=INPLACE` is allowed, but the statement can still fail if the requested primary key columns contain any `NULL` values. The `ALGORITHM=INPLACE` behavior is more standard-compliant.

The following examples show the different possibilities for the `ADD PRIMARY KEY` clause. With the `ALGORITHM=COPY` clause, the operation succeeds despite the presence of `NULL` values in the primary key columns; the data is silently changed, which could cause problems.

```
mysql> CREATE TABLE add_pk_via_copy (c1 INT, c2 VARCHAR(10), c3 DATETIME);
Query OK, 0 rows affected (0.03 sec)

mysql> INSERT INTO add_pk_via_copy VALUES (1,'a','2014-11-03 11:01:37'),(NULL,NULL,NULL);
Query OK, 2 rows affected (0.00 sec)
Records: 2  Duplicates: 0  Warnings: 0

mysql> SET sql_mode = '';
Query OK, 0 rows affected (0.00 sec)

mysql> ALTER TABLE add_pk_via_copy ADD PRIMARY KEY (c1,c2,c3), ALGORITHM=COPY;
Query OK, 2 rows affected, 3 warnings (0.07 sec)
Records: 2  Duplicates: 0  Warnings: 3

mysql> SHOW WARNINGS;
+-----+-----+-----+
| Level | Code | Message                                     |
+-----+-----+-----+
| Warning | 1265 | Data truncated for column 'c1' at row 2 |
| Warning | 1265 | Data truncated for column 'c2' at row 2 |
| Warning | 1265 | Data truncated for column 'c3' at row 2 |
+-----+-----+-----+
3 rows in set (0.00 sec)

mysql> SELECT * FROM add_pk_via_copy;
+----+-----+-----+
| c1 | c2 | c3                                     |
+----+-----+-----+
| 0 |  | 0000-00-00 00:00:00 |
| 1 | a | 2014-11-03 11:01:37 |
+----+-----+-----+
2 rows in set (0.00 sec)
```

With the `ALGORITHM=INPLACE` clause, the operation could fail for different reasons, because this setting considers data integrity a high priority: the statement gives an error if the `SQL_MODE` setting is not “strict” enough, or if the primary key columns contain any `NULL` values. Once we address both of those requirements, the `ALTER TABLE` operation succeeds.

```
mysql> CREATE TABLE add_pk_via_inplace (c1 INT, c2 VARCHAR(10), c3 DATETIME);
Query OK, 0 rows affected (0.02 sec)

```

If you create a table without a primary key, InnoDB chooses one for you, which can be the first [UNIQUE](#) key defined on [NOT NULL](#) columns, or a system-generated key. To avoid any uncertainty and the potential space requirement for an extra hidden column, specify the [PRIMARY KEY](#) clause as part of the [CREATE TABLE](#) statement.

### 15.13.6 Implementation Details of Online DDL

Each [ALTER TABLE](#) operation for an [InnoDB](#) table is governed by several aspects:

- Whether there is any change to the physical representation of the table, or whether it purely a change to metadata that can be done without touching the table itself.
- Whether the volume of data in the table stays the same, increases, or decreases.
- Whether a change in table data involves the clustered index, secondary indexes, or both.
- Whether there are any [foreign key](#) relationships between the table being altered and some other table. The mechanics differ depending on whether the [foreign\\_key\\_checks](#) configuration option is enabled or disabled.
- Whether the table is partitioned. Partitioning clauses of [ALTER TABLE](#) are turned into low-level operations involving one or more tables, and those operations follow the regular rules for online DDL.
- Whether the table data must be copied, whether the table can be reorganized “in-place”, or a combination of both.
- Whether the table contains any [auto-increment](#) columns.
- What degree of [locking](#) is required, either by the nature of the underlying database operations, or a [LOCK](#) clause that you specify in the [ALTER TABLE](#) statement.

This section explains how these factors affect the different kinds of [ALTER TABLE](#) operations on [InnoDB](#) tables.

### Error Conditions for Online DDL

Here are the primary reasons why an online DDL operation could fail:

- If a [LOCK](#) clause specifies a low degree of locking ([SHARED](#) or [NONE](#)) that is not compatible with the particular type of DDL operation.

- If a timeout occurs while waiting to get an [exclusive lock](#) on the table, which may be needed briefly during the initial and final phases of the DDL operation.
- If the `tmpdir` or `innodb_tmpdir` file system runs out of disk space, while MySQL writes temporary sort files on disk during index creation. For more information, see [Section B.5.3.5, “Where MySQL Stores Temporary Files”](#).
- If the `ALTER TABLE` takes so long, and concurrent DML modifies the table so much, that the size of the temporary online log exceeds the value of the `innodb_online_alter_log_max_size` configuration option. This condition causes a `DB_ONLINE_LOG_TOO_BIG` error.
- If concurrent DML makes changes to the table that are allowed with the original table definition, but not with the new one. The operation only fails at the very end, when MySQL tries to apply all the changes from concurrent DML statements. For example, you might insert duplicate values into a column while a unique index is being created, or you might insert `NULL` values into a column while creating a [primary key](#) index on that column. The changes made by the concurrent DML take precedence, and the `ALTER TABLE` operation is effectively [rolled back](#).

Although the configuration option `innodb_file_per_table` has a dramatic effect on the representation for an [InnoDB](#) table, all online DDL operations work equally well whether that option is enabled or disabled, and whether the table is physically located in its own `.ibd` file or inside the [system tablespace](#).

InnoDB has two types of indexes: the [clustered index](#) representing all the data in the table, and optional [secondary indexes](#) to speed up queries. Since the clustered index contains the data values in its B-tree nodes, adding or dropping a clustered index does involve copying the data, and creating a new copy of the table. A secondary index, however, contains only the index key and the value of the primary key. This type of index can be created or dropped without copying the data in the clustered index. Because each secondary index contains copies of the primary key values (used to access the clustered index when needed), when you change the definition of the primary key, all secondary indexes are recreated as well.

Dropping a secondary index is simple. Only the internal InnoDB system tables and the MySQL data dictionary tables are updated to reflect the fact that the index no longer exists. InnoDB returns the storage used for the index to the tablespace that contained it, so that new indexes or additional table rows can use the space.

To add a secondary index to an existing table, InnoDB scans the table, and sorts the rows using memory buffers and temporary files in order by the values of the secondary index key columns. The B-tree is then built in key-value order, which is more efficient than inserting rows into an index in random order. Because the B-tree nodes are split when they fill, building the index in this way results in a higher fill-factor for the index, making it more efficient for subsequent access.

## Primary Key and Secondary Key Indexes

Historically, the MySQL server and [InnoDB](#) have each kept their own metadata about table and index structures. The MySQL server stores this information in `.frm` files that are not protected by a transactional mechanism, while [InnoDB](#) has its own [data dictionary](#) as part of the [system tablespace](#). If a DDL operation was interrupted by a crash or other unexpected event partway through, the metadata could be left inconsistent between these two locations, causing problems such as startup errors or inability to access the table that was being altered. Now that [InnoDB](#) is the default storage engine, addressing such issues is a high priority. These enhancements to DDL operations reduce the window of opportunity for such issues to occur.

### 15.13.7 How Crash Recovery Works with Online DDL

Although no data is lost if the server crashes while an `ALTER TABLE` statement is executing, the [crash recovery](#) process is different for [clustered indexes](#) and [secondary indexes](#).

If the server crashes while creating an InnoDB secondary index, upon recovery, MySQL drops any partially created indexes. You must re-run the `ALTER TABLE` or `CREATE INDEX` statement.

When a crash occurs during the creation of an InnoDB clustered index, recovery is more complicated, because the data in the table must be copied to an entirely new clustered index. Remember that all InnoDB tables are stored as clustered indexes.

MySQL creates the new clustered index by copying the existing data from the original InnoDB table to a temporary table that has the desired index structure. Once the data is completely copied to this temporary table, the original table is renamed with a different temporary table name. The temporary table comprising the new clustered index is renamed with the name of the original table, and the original table is dropped from the database.

If a system crash occurs while creating a new clustered index, no data is lost, but you must complete the recovery process using the temporary tables that exist during the process. Since it is rare to re-create a clustered index or re-define primary keys on large tables, or to encounter a system crash during this operation, this manual does not provide information on recovering from this scenario.

### 15.13.8 Online DDL for Partitioned InnoDB Tables

With the exception of `ALTER TABLE` partitioning clauses, online DDL operations for partitioned InnoDB tables follow the same rules that apply to regular InnoDB tables. Online DDL rules are outlined in [Table 15.10, “Summary of Online Status for DDL Operations”](#).

`ALTER TABLE` partitioning clauses do not go through the same internal online DDL API as regular non-partitioned InnoDB tables, and are only allowed in conjunction with `ALGORITHM=DEFAULT` and `LOCK=DEFAULT`.

If you use an `ALTER TABLE` partitioning clause in an `ALTER TABLE` statement, the partitioned table will be “re-partitioned” using the `ALTER TABLE COPY` algorithm. In other words, a new partitioned table is created with the new partitioning scheme. The newly created table will include any changes applied by the `ALTER TABLE` statement and the table data will be copied into the new table structure.

If you do not change the table's partitioning using `ALTER TABLE` partitioning clauses or perform any other partition management in your `ALTER TABLE` statement, `ALTER TABLE` will use the `INPLACE` algorithm on each table partition. Be aware, however, that when `INPLACE ALTER TABLE` operations are performed on each partition, there will be increased demand on system resources due to operations being performed on multiple partitions.

Even though partitioning clauses of the `ALTER TABLE` statement do not go through the same internal online DDL API as regular non-partitioned InnoDB tables, MySQL still attempts to minimize data copying and locking where possible:

- `ADD PARTITION` and `DROP PARTITION` for tables partitioned by `RANGE` or `LIST` do not copy any existing data.
- `TRUNCATE PARTITION` does not copy any existing data, for all types of partitioned tables.
- Concurrent queries are allowed during `ADD PARTITION` and `COALESCE PARTITION` for tables partitioned by `HASH` or `LIST`. MySQL copies the data while holding a shared lock.
- For `REORGANIZE PARTITION`, `REBUILD PARTITION`, or `ADD PARTITION` or `COALESCE PARTITION` for a table partitioned by `LINEAR HASH` or `LIST`, concurrent queries are allowed. Data from the affected partitions is copied while holding a shared metadata (read) lock at the table level.

#### Note

Full-text search (FTS) and foreign keys are not supported by InnoDB partitioned tables. For more information, see [Section 13.9.5, “Full-Text Restrictions”](#) and [Section 21.6.2, “Partitioning Limitations Relating to Storage Engines”](#).

### 15.13.9 Limitations of Online DDL

Take the following limitations into account when running online DDL operations:

- An online DDL operation that copies the table can cause an error if the operation uses all of the available disk space on the file system where the data directory (`datadir`) resides. To avoid this problem, ensure that there is enough disk space to accommodate online `ALTER TABLE` operations that copy the table. During these operations, MySQL writes temporary sort files to the MySQL temporary directory (`$TMPDIR` on Unix, `%TEMP%` on Windows, or the directory specified by the `--tmpdir` configuration variable). Each temporary file is large enough to hold one column in the new table or index, and each one is removed as soon as it is merged into the final table or index. Such operations may require temporary space equal to the amount of data in the table plus indexes.

As of MySQL 5.7.11, you can use the `innodb_tmpdir` configuration option to define a separate temporary directory for online DDL operations. The `innodb_tmpdir` option was introduced to help avoid temporary directory overflows that could occur as a result of large temporary sort files created during online `ALTER TABLE` operations that rebuild the table.

- The table is copied, rather than using Fast Index Creation when you create an index on a `TEMPORARY TABLE`. This has been reported as MySQL Bug #39833.
- InnoDB handles error cases when users attempt to drop indexes needed for foreign keys. See [Section B.3, “Server Error Codes and Messages”](#) for information related to error 1553.
- The `ALTER TABLE` clause `LOCK=NONE` is not allowed if there are `ON...CASCADE` or `ON...SET NULL` constraints on the table.
- Depending on the internal workings of the online DDL operation and the `LOCK` clause of the `ALTER TABLE` statement, an online DDL operation may require exclusive access to the table for a brief time during the initial and final phases of the DDL operation. Thus, an online DDL operation might wait before finishing if there is a long-running transaction performing inserts, updates, deletes, or `SELECT ... FOR UPDATE` on the table; and an online DDL operation might wait before finishing if a similar long-running transaction is started while the `ALTER TABLE` is in progress.
- When running an online DDL operation, the thread that runs the `ALTER TABLE` statement will apply an “online log” of DML operations that were run concurrently on the same table from other connection threads. When the DML operations are applied, it is possible to encounter a duplicate key entry error (`ERROR 1062 (23000): Duplicate entry`), even if the duplicate entry is only temporary and would be reverted by a later entry in the “online log”. This is similar to the idea of a foreign key constraint check in InnoDB in which constraints must hold during a transaction.
- `OPTIMIZE TABLE` for an InnoDB table is mapped to an `ALTER TABLE` operation to rebuild the table and update index statistics and free unused space in the clustered index. Prior to 5.7.4, there is no online DDL support for this operation. Secondary indexes are not created as efficiently because keys are inserted in the order they appeared in the primary key. As of 5.7.4, `OPTIMIZE TABLE` is supported with the addition of online DDL support for rebuilding regular and partitioned InnoDB tables. For additional information, see [Section 15.13.1, “Overview of Online DDL”](#).
- InnoDB tables created before MySQL 5.6 do not support `ALTER TABLE ... ALGORITHM=INPLACE` for tables that include temporal columns (`DATE`, `DATETIME` or `TIMESTAMP`) and have not been rebuilt using `ALTER TABLE ... ALGORITHM=COPY`. In this case, an `ALTER TABLE ... ALGORITHM=INPLACE` operation returns the following error:

```
ERROR 1846 (0A000): ALGORITHM=INPLACE is not supported.
Reason: Cannot change column type INPLACE. Try ALGORITHM=COPY.
```

- These limitations are generally applicable to online DDL operations on large tables where table copying is involved:
  - There is no mechanism to pause an online DDL operation or to throttle I/O or CPU usage for an online DDL operation.
  - Progress monitoring capability for online DDL operations is limited until MySQL 5.7.6, which introduces Performance Schema stage events for monitoring `ALTER TABLE` progress. See

[Section 15.16.1, “Monitoring ALTER TABLE Progress for InnoDB Tables Using Performance Schema”](#).

- Rollback of an online DDL operation can be expensive should the operation fail.
- Long running online DDL operations can cause replication lag. An online DDL operation must finish running on the master before it is run on the slave. Also, DML that was processed concurrently on the master is only processed on the slave after the DDL operation on the slave is completed (Bug #73196).

For additional information related to running online DDL operations on large tables, see [Section 15.13.2, “Performance and Concurrency Considerations for Online DDL”](#).

## 15.14 InnoDB Startup Options and System Variables

- System variables that are true or false can be enabled at server startup by naming them, or disabled by using a `--skip-` prefix. For example, to enable or disable the `InnoDB` adaptive hash index, you can use `--innodb_adaptive_hash_index` or `--skip-innodb_adaptive_hash_index` on the command line, or `innodb_adaptive_hash_index` or `skip-innodb_adaptive_hash_index` in an option file.
- System variables that take a numeric value can be specified as `--var_name=value` on the command line or as `var_name=value` in option files.
- Many system variables can be changed at runtime (see [Section 6.1.6.2, “Dynamic System Variables”](#)).
- For information about `GLOBAL` and `SESSION` variable scope modifiers, refer to the `SET` statement documentation.
- Certain options control the locations and layout of the `InnoDB` data files. [Section 15.6.1, “InnoDB Startup Configuration”](#) explains how to use these options.
- Some options, which you might not use initially, help tune `InnoDB` performance characteristics based on machine capacity and your database workload.
- For more information on specifying options and system variables, see [Section 5.2.3, “Specifying Program Options”](#).

**Table 15.11 InnoDB Option/Variable Reference**

| Name   | Cmd-Line | Option File | System Var | Status Var | Var Scope | Dynamic |
|--|----------|-------------|------------|------------|-----------|---------|

## InnoDB Command Options

- `--ignore-builtin-innodb`

|                            |                                      |                                    |
|----------------------------|--------------------------------------|------------------------------------|
| <b>Deprecated</b>          | 5.5.22                               |                                    |
| <b>Command-Line Format</b> | <code>--ignore-builtin-innodb</code> |                                    |
| <b>System Variable</b>     | <b>Name</b>                          | <code>ignore_builtin_innodb</code> |
|                            | <b>Variable Scope</b>                | Global                             |
|                            | <b>Dynamic Variable</b>              | No                                 |
| <b>Permitted Values</b>    | <b>Type</b>                          | boolean                            |

In MySQL 5.1, this option caused the server to behave as if the built-in `InnoDB` were not present, which enabled the `InnoDB Plugin` to be used instead. In MySQL 5.7, `InnoDB` is the default storage engine and `InnoDB Plugin` is not used, so this option is ignored.

- `--innodb[=value]`

|                            |                               |                    |
|----------------------------|-------------------------------|--------------------|
| <b>Deprecated</b>          | 5.7.5                         |                    |
| <b>Command-Line Format</b> | <code>--innodb[=value]</code> |                    |
| <b>Permitted Values</b>    | <b>Type</b>                   | enumeration        |
|                            | <b>Default</b>                | <code>ON</code>    |
|                            | <b>Valid Values</b>           | <code>OFF</code>   |
|                            |                               | <code>ON</code>    |
|                            |                               | <code>FORCE</code> |

Controls loading of the `InnoDB` storage engine, if the server was compiled with `InnoDB` support. This option has a tristate format, with possible values of `OFF`, `ON`, or `FORCE`. See [Section 6.5.2, “Installing and Uninstalling Plugins”](#).

To disable `InnoDB`, use `--innodb=OFF` or `--skip-innodb`. In this case, because the default storage engine is `InnoDB`, the server does not start unless you also use `--default-storage-engine` and `--default-tmp-storage-engine` to set the default to some other engine for both permanent and `TEMPORARY` tables.

As of MySQL 5.7.5, the `InnoDB` storage engine can no longer be disabled, and the `--innodb=OFF` and `--skip-innodb` options are deprecated and have no effect. Their use results in a warning. These options will be removed in a future MySQL release.

- `--innodb-status-file`

|                            |                                   |                  |
|----------------------------|-----------------------------------|------------------|
| <b>Command-Line Format</b> | <code>--innodb-status-file</code> |                  |
| <b>Permitted Values</b>    | <b>Type</b>                       | boolean          |
|                            | <b>Default</b>                    | <code>OFF</code> |

Controls whether `InnoDB` creates a file named `innodb_status.pid` in the MySQL data directory. If enabled, `InnoDB` periodically writes the output of `SHOW ENGINE INNODB STATUS` to this file.

By default, the file is not created. To create it, start `mysqld` with the `--innodb-status-file=1` option. The file is deleted during normal shutdown.

- `--skip-innodb`

Disable the [InnoDB](#) storage engine. See the description of `--innodb`.

## InnoDB System Variables

- [daemon\\_memcached\\_enable\\_binlog](#)

|                            |   |  |
|----------------------------|---|--|
| <b>Command-Line Format</b> | <code>--daemon_memcached_enable_binlog=#</code> |  |
| <b>System Variable</b>     | <b>Name</b>                                     | <a href="#">daemon_memcached_enable_binlog</a> |
|                            | <b>Variable Scope</b>                           | Global   |
|                            | <b>Dynamic Variable</b>                         | No   |
| <b>Permitted Values</b>    | <b>Type</b>                                     | boolean  |
|                            | <b>Default</b>                                  | <a href="#">false</a>                          |

Enable this option on the [master server](#) to use the [InnoDB memcached](#) plugin ([daemon\\_memcached](#)) with the MySQL [binary log](#). This option can only be set at server startup. You must also enable the MySQL binary log on the master server using the `--log-bin` option.

For more information, see [Section 15.20.6, “The InnoDB memcached Plugin and Replication”](#).

- [daemon\\_memcached\\_engine\\_lib\\_name](#)

|                            |   |  |
|----------------------------|---|--|
| <b>Command-Line Format</b> | <code>--daemon_memcached_engine_lib_name=library</code> |  |
| <b>System Variable</b>     | <b>Name</b>   | <a href="#">daemon_memcached_engine_lib_name</a> |
|                            | <b>Variable Scope</b>                                   | Global   |
|                            | <b>Dynamic Variable</b>                                 | No   |
| <b>Permitted Values</b>    | <b>Type</b>   | file name  |
|                            | <b>Default</b>  | <a href="#">innodb_engine.so</a>                 |

Specifies the shared library that implements the [InnoDB memcached](#) plugin.

For more information, see [Section 15.20.3, “Setting Up the InnoDB memcached Plugin”](#).

- [daemon\\_memcached\\_engine\\_lib\\_path](#)

|                            |   |  |
|----------------------------|---|--|
| <b>Command-Line Format</b> | <code>--daemon_memcached_engine_lib_path=directory</code> |  |
| <b>System Variable</b>     | <b>Name</b>   | <a href="#">daemon_memcached_engine_lib_path</a> |
|                            | <b>Variable Scope</b>                                     | Global   |
|                            | <b>Dynamic Variable</b>                                   | No   |
| <b>Permitted Values</b>    | <b>Type</b>   | directory name                                   |
|                            | <b>Default</b>  | <a href="#">NULL</a>                             |

The path of the directory containing the shared library that implements the [InnoDB memcached](#) plugin. The default value is `NULL`, representing the MySQL plugin directory. You should not need to modify this parameter unless specifying a [memcached](#) plugin for a different storage engine that is located outside of the MySQL plugin directory.

For more information, see [Section 15.20.3, “Setting Up the InnoDB memcached Plugin”](#).

- `daemon_memcached_option`

|                            |  |                                      |
|----------------------------|--|--------------------------------------|
| <b>Command-Line Format</b> | <code>--daemon_memcached_option=options</code> |                                      |
| <b>System Variable</b>     | <b>Name</b>                                    | <code>daemon_memcached_option</code> |
|                            | <b>Variable Scope</b>                          | Global                               |
|                            | <b>Dynamic Variable</b>                        | No                                   |
| <b>Permitted Values</b>    | <b>Type</b>                                    | string                               |
|                            | <b>Default</b>                                 |                                      |

Used to pass space-separated memcached options to the underlying `memcached` memory object caching daemon on startup. For example, you might change the port that `memcached` listens on, reduce the maximum number of simultaneous connections, change the maximum memory size for a key/value pair, or enable debugging messages for the error log.

See [Section 15.20.3, “Setting Up the InnoDB memcached Plugin”](#) for usage details. For information about `memcached` options, refer to the `memcached` man page.

- `daemon_memcached_r_batch_size`

|                            |  |  |
|----------------------------|--|--|
| <b>Command-Line Format</b> | <code>--daemon_memcached_r_batch_size=#</code> |  |
| <b>System Variable</b>     | <b>Name</b>                                    | <code>daemon_memcached_r_batch_size</code> |
|                            | <b>Variable Scope</b>                          | Global                                     |
|                            | <b>Dynamic Variable</b>                        | No   |
| <b>Permitted Values</b>    | <b>Type</b>                                    | integer                                    |
|                            | <b>Default</b>                                 | 1  |

Specifies how many `memcached` read operations (`get` operations) to perform before doing a `COMMIT` to start a new transaction. Counterpart of `daemon_memcached_w_batch_size`.

This value is set to 1 by default, so that any changes made to the table through SQL statements are immediately visible to `memcached` operations. You might increase it to reduce the overhead from frequent commits on a system where the underlying table is only being accessed through the `memcached` interface. If you set the value too large, the amount of undo or redo data could impose some storage overhead, as with any long-running transaction.

For more information, see [Section 15.20.3, “Setting Up the InnoDB memcached Plugin”](#).

- `daemon_memcached_w_batch_size`

|                            |  |  |
|----------------------------|--|--|
| <b>Command-Line Format</b> | <code>--daemon_memcached_w_batch_size=#</code> |  |
| <b>System Variable</b>     | <b>Name</b>                                    | <code>daemon_memcached_w_batch_size</code> |
|                            | <b>Variable Scope</b>                          | Global                                     |
|                            | <b>Dynamic Variable</b>                        | No   |
| <b>Permitted Values</b>    | <b>Type</b>                                    | integer                                    |
|                            | <b>Default</b>                                 | 1  |

Specifies how many `memcached` write operations, such as `add`, `set`, and `incr`, to perform before doing a `COMMIT` to start a new transaction. Counterpart of `daemon_memcached_r_batch_size`.

This value is set to 1 by default, on the assumption that data being stored is important to preserve in case of an outage and should immediately be committed. When storing non-critical data, you might increase this value to reduce the overhead from frequent commits; but then the last `N-1` uncommitted write operations could be lost if a crash occurs.

For more information, see [Section 15.20.3, “Setting Up the InnoDB memcached Plugin”](#).

- `ignore_builtin_innodb`

|                            |                                      |                                    |
|----------------------------|--------------------------------------|------------------------------------|
| <b>Deprecated</b>          | 5.5.22                               |                                    |
| <b>Command-Line Format</b> | <code>--ignore-builtin-innodb</code> |                                    |
| <b>System Variable</b>     | <b>Name</b>                          | <code>ignore_builtin_innodb</code> |
|                            | <b>Variable Scope</b>                | Global                             |
|                            | <b>Dynamic Variable</b>              | No                                 |
| <b>Permitted Values</b>    | <b>Type</b>                          | boolean                            |

See the description of `--ignore-builtin-innodb` under “InnoDB Command Options” earlier in this section.

- `innodb_adaptive_flushing`

|                            |   |                                       |
|----------------------------|---|---------------------------------------|
| <b>Command-Line Format</b> | <code>--innodb_adaptive_flushing=#</code> |                                       |
| <b>System Variable</b>     | <b>Name</b>                               | <code>innodb_adaptive_flushing</code> |
|                            | <b>Variable Scope</b>                     | Global                                |
|                            | <b>Dynamic Variable</b>                   | Yes                                   |
| <b>Permitted Values</b>    | <b>Type</b>                               | boolean                               |
|                            | <b>Default</b>                            | <code>ON</code>                       |

Specifies whether to dynamically adjust the rate of flushing `dirty pages` in the `InnoDB buffer pool` based on the workload. Adjusting the flush rate dynamically is intended to avoid bursts of I/O activity. This setting is enabled by default. See [Section 15.6.3.6, “Configuring InnoDB Buffer Pool Flushing”](#) for more information. For general I/O tuning advice, see [Section 9.5.8, “Optimizing InnoDB Disk I/O”](#).

- `innodb_adaptive_flushing_lwm`

|                            |   |   |
|----------------------------|---|---|
| <b>Command-Line Format</b> | <code>--innodb_adaptive_flushing_lwm=#</code> |   |
| <b>System Variable</b>     | <b>Name</b>                                   | <code>innodb_adaptive_flushing_lwm</code> |
|                            | <b>Variable Scope</b>                         | Global                                    |
|                            | <b>Dynamic Variable</b>                       | Yes                                       |
| <b>Permitted Values</b>    | <b>Type</b>                                   | integer                                   |
|                            | <b>Default</b>                                | <code>10</code>                           |

|  |                  |    |
|--|------------------|----|
|  | <b>Min Value</b> | 0  |
|  | <b>Max Value</b> | 70 |

Defines the low water mark representing percentage of [redo log](#) capacity at which [adaptive flushing](#) is enabled. For more information, see [Section 15.6.3.7, “Fine-tuning InnoDB Buffer Pool Flushing”](#).

- [innodb\\_adaptive\\_hash\\_index](#)

|                            |   |  |
|----------------------------|---|--|
| <b>Command-Line Format</b> | <code>--innodb_adaptive_hash_index=#</code> |  |
| <b>System Variable</b>     | <b>Name</b>                                 | <a href="#">innodb_adaptive_hash_index</a> |
|                            | <b>Variable Scope</b>                       | Global                                     |
|                            | <b>Dynamic Variable</b>                     | Yes  |
| <b>Permitted Values</b>    | <b>Type</b>                                 | boolean                                    |
|                            | <b>Default</b>                              | ON   |

Whether the [InnoDB adaptive hash index](#) is enabled or disabled. It may be desirable, depending on your workload, to dynamically enable or disable [adaptive hash indexing](#) to improve query performance. Because the adaptive hash index may not be useful for all workloads, conduct benchmarks with it both enabled and disabled, using realistic workloads. See [Section 15.4.3, “Adaptive Hash Index”](#) for details.

This variable is enabled by default. You can modify this parameter using the `SET GLOBAL` statement, without restarting the server. Changing the setting requires the [SUPER](#) privilege. You can also use `--skip-innodb_adaptive_hash_index` at server startup to disable it.

Disabling the adaptive hash index empties the hash table immediately. Normal operations can continue while the hash table is emptied, and executing queries that were using the hash table access the index B-trees directly instead. When the adaptive hash index is re-enabled, the hash table is populated again during normal operation.

- [innodb\\_adaptive\\_hash\\_index\\_parts](#)

|                            |   |  |
|----------------------------|---|--|
| <b>Introduced</b>          | 5.7.8   |  |
| <b>Command-Line Format</b> | <code>--innodb_adaptive_hash_index_parts=#</code> |  |
| <b>System Variable</b>     | <b>Name</b>                                       | <a href="#">innodb_adaptive_hash_index_parts</a> |
|                            | <b>Variable Scope</b>                             | Global   |
|                            | <b>Dynamic Variable</b>                           | No   |
| <b>Permitted Values</b>    | <b>Type</b>                                       | numeric  |
|                            | <b>Default</b>                                    | 8  |
|                            | <b>Min Value</b>                                  | 1  |
|                            | <b>Max Value</b>                                  | 512  |

Partitions the adaptive hash index search system. Each index is bound to a specific partition, with each partition protected by a separate latch.

Prior to MySQL 5.7.8, the adaptive hash index search system was protected by a single latch (`btr_search_latch`) which could become a point of contention. With the introduction of the `innodb_adaptive_hash_index_parts` option, the search system is partitioned into 8 parts by default. The maximum setting is 512.

For related information, see [Section 15.4.3, “Adaptive Hash Index”](#).

- `innodb_adaptive_max_sleep_delay`

|                            |  |  |
|----------------------------|--|--|
| <b>Command-Line Format</b> | <code>--innodb_adaptive_max_sleep_delay=#</code> |  |
| <b>System Variable</b>     | <b>Name</b>                                      | <code>innodb_adaptive_max_sleep_delay</code> |
|                            | <b>Variable Scope</b>                            | Global                                       |
|                            | <b>Dynamic Variable</b>                          | Yes  |
| <b>Permitted Values</b>    | <b>Type</b>                                      | integer                                      |
|                            | <b>Default</b>                                   | 150000                                       |
|                            | <b>Min Value</b>                                 | 0  |
|                            | <b>Max Value</b>                                 | 1000000                                      |

Permits InnoDB to automatically adjust the value of `innodb_thread_sleep_delay` up or down according to the current workload. Any non-zero value enables automated, dynamic adjustment of the `innodb_thread_sleep_delay` value, up to the maximum value specified in the `innodb_adaptive_max_sleep_delay` option. The value represents the number of microseconds. This option can be useful in busy systems, with greater than 16 InnoDB threads. (In practice, it is most valuable for MySQL systems with hundreds or thousands of simultaneous connections.)

For more information, see [Section 15.6.6, “Configuring Thread Concurrency for InnoDB”](#).

- `innodb_additional_mem_pool_size`

|                            |  |  |
|----------------------------|--|--|
| <b>Deprecated</b>          | 5.6.3  |  |
| <b>Removed</b>             | 5.7.4  |  |
| <b>Command-Line Format</b> | <code>--innodb_additional_mem_pool_size=#</code> |  |

The size in bytes of a memory pool InnoDB uses to store [data dictionary](#) information and other internal data structures. The more tables you have in your application, the more memory you allocate here. If InnoDB runs out of memory in this pool, it starts to allocate memory from the operating system and writes warning messages to the MySQL error log. The default value is 8MB.

This variable relates to the [InnoDB](#) internal memory allocator, which is unused if [innodb\\_use\\_sys\\_malloc](#) is enabled. For more information, see [Section 15.6.4, “Configuring the Memory Allocator for InnoDB”](#).

[innodb\\_additional\\_mem\\_pool\\_size](#) was deprecated in MySQL 5.6.3 and removed in MySQL 5.7.4.

How often to auto-commit idle connections that use the [InnoDB memcached](#) interface, in seconds. For more information, see [Section 15.20.5.4, “Controlling Transactional Behavior of the InnoDB memcached Plugin”](#).

- [innodb\\_api\\_disable\\_rowlock](#)

|                            |   |  |
|----------------------------|---|--|
| <b>Command-Line Format</b> | <code>--innodb_api_disable_rowlock=#</code> |  |
| <b>System Variable</b>     | <b>Name</b>                                 | <a href="#">innodb_api_disable_rowlock</a> |
|                            | <b>Variable Scope</b>                       | Global                                     |
|                            | <b>Dynamic Variable</b>                     | No   |
| <b>Permitted Values</b>    | <b>Type</b>                                 | boolean                                    |
|                            | <b>Default</b>                              | OFF  |

Use this option to disable row locks when [InnoDB memcached](#) performs DML operations. By default, [innodb\\_api\\_disable\\_rowlock](#) is disabled, which means that [memcached](#) requests row locks for [get](#) and [set](#) operations. When [innodb\\_api\\_disable\\_rowlock](#) is enabled, [memcached](#) requests a table lock instead of row locks.

[innodb\\_api\\_disable\\_rowlock](#) is not dynamic. It must be specified on the `mysqld` command line or entered in the MySQL configuration file. Configuration takes effect when the plugin is installed, which occurs when the MySQL server is started.

For more information, see [Section 15.20.5.4, “Controlling Transactional Behavior of the InnoDB memcached Plugin”](#).

|                            | <b>Default</b>                        | OFF                               |

Locks the table used by the [InnoDB memcached](#) plugin, so that it cannot be dropped or altered by DDL through the SQL interface. For more information, see [Section 15.20.5.4, “Controlling Transactional Behavior of the InnoDB memcached Plugin”](#).

- `innodb_api_trx_level`

|                            |                                       |                                   |
|----------------------------|---------------------------------------|-----------------------------------|
| <b>Command-Line Format</b> | <code>--innodb_api_trx_level=#</code> |                                   |
| <b>System Variable</b>     | <b>Name</b>                           | <code>innodb_api_trx_level</code> |
|                            | <b>Variable Scope</b>                 | Global                            |
|                            | <b>Dynamic Variable</b>               | Yes                               |
| <b>Permitted Values</b>    | <b>Type</b>                           | integer                           |
|                            | <b>Default</b>                        | 0                                 |

Controls the transaction [isolation level](#) on queries processed by the [memcached](#) interface. The constants corresponding to the familiar names are:

- 0 = `READ UNCOMMITTED`
- 1 = `READ COMMITTED`
- 2 = `REPEATABLE READ`
- 3 = `SERIALIZABLE`

For more information, see [Section 15.20.5.4, “Controlling Transactional Behavior of the InnoDB memcached Plugin”](#).

- `innodb_autoextend_increment`

|                            |  |  |
|----------------------------|--|--|
| <b>Command-Line Format</b> | <code>--innodb_autoextend_increment=#</code> |  |
| <b>System Variable</b>     | <b>Name</b>                                  | <code>innodb_autoextend_increment</code> |

|                         |                         |         |
|-------------------------|-------------------------|---------|
| <b>Permitted Values</b> | <b>Variable Scope</b>   | Global  |
|                         | <b>Dynamic Variable</b> | Yes     |
|                         | <b>Type</b>             | integer |
|                         | <b>Default</b>          | 64      |
|                         | <b>Min Value</b>        | 1       |
|                         | <b>Max Value</b>        | 1000    |

The increment size (in megabytes) for extending the size of an auto-extending [InnoDB system tablespace](#) file when it becomes full. The default value is 64. For related information, see [System Tablespace Data File Configuration](#), and [Section 15.7.1, “Resizing the InnoDB System Tablespace”](#).

The `innodb_autoextend_increment` setting does not affect [file-per-table](#) tablespace files or [general tablespace](#) files. These files are auto-extending regardless of the `innodb_autoextend_increment` setting. The initial extensions are by small amounts, after which extensions occur in increments of 4MB.

- `innodb_autoinc_lock_mode`

|                            |   |                                       |
|----------------------------|---|---------------------------------------|
| <b>Command-Line Format</b> | <code>--innodb_autoinc_lock_mode=#</code> |                                       |
| <b>System Variable</b>     | <b>Name</b>                               | <code>innodb_autoinc_lock_mode</code> |
|                            | <b>Variable Scope</b>                     | Global                                |
|                            | <b>Dynamic Variable</b>                   | No                                    |
| <b>Permitted Values</b>    | <b>Type</b>                               | integer                               |
|                            | <b>Default</b>                            | 1                                     |
|                            | <b>Valid Values</b>                       | 0                                     |
|                            |   | 1                                     |
|                            |   | 2                                     |

The [lock mode](#) to use for generating [auto-increment](#) values. Permissible values are 0, 1, or 2, for “traditional”, “consecutive”, or “interleaved”, respectively. The default setting is 1 (“consecutive”). For the characteristics of each lock mode, see [InnoDB AUTO\\_INCREMENT Lock Modes](#).

- `innodb_background_drop_list_empty`

|                            |  |  |
|----------------------------|--|--|
| <b>Introduced</b>          | 5.7.10   |  |
| <b>Command-Line Format</b> | <code>--innodb_background_drop_list_empty=#</code> |  |
| <b>System Variable</b>     | <b>Name</b>  | <code>innodb_background_drop_list_empty</code> |
|                            | <b>Variable Scope</b>                              | Global   |
|                            | <b>Dynamic Variable</b>                            | Yes  |
| <b>Permitted Values</b>    | <b>Type</b>  | boolean  |
|                            | <b>Default</b>                                     | OFF  |

Enabling the `innodb_background_drop_list_empty` debug option helps avoid test case failures by delaying table creation until the background drop list is empty. For example, if test case A places table `t1` on the background drop list, test case B waits until the background drop list is empty before creating table `t1`.

- `innodb_buffer_pool_chunk_size`

|                            |  |   |
|----------------------------|--|---|
| <b>Introduced</b>          | 5.7.5  |   |
| <b>Command-Line Format</b> | <code>--innodb_buffer_pool_chunk_size</code> |   |
| <b>System Variable</b>     | <b>Name</b>                                  | <code>innodb_buffer_pool_chunk_size</code>                          |
|                            | <b>Variable Scope</b>                        | Global  |
|                            | <b>Dynamic Variable</b>                      | No  |
| <b>Permitted Values</b>    | <b>Type</b>                                  | integer   |
|                            | <b>Default</b>                               | 134217728   |
|                            | <b>Min Value</b>                             | 1048576   |
|                            | <b>Max Value</b>                             | <code>innodb_buffer_pool_size / innodb_buffer_pool_instances</code> |

`innodb_buffer_pool_chunk_size` defines the chunk size for InnoDB buffer pool resizing operations. The `innodb_buffer_pool_size` parameter is dynamic, which allows you to resize the buffer pool without restarting the server.

To avoid copying all buffer pool pages during resizing operations, the operation is performed in “chunks”. By default, `innodb_buffer_pool_chunk_size` is 128MB (134217728 bytes). The number of pages contained in a chunk depends on the value of `innodb_page_size`. `innodb_buffer_pool_chunk_size` can be increased or decreased in units of 1MB (1048576 bytes).

The following conditions apply when altering the `innodb_buffer_pool_chunk_size` value:

- If `innodb_buffer_pool_chunk_size * innodb_buffer_pool_instances` is larger than the current buffer pool size when the buffer pool is initialized, `innodb_buffer_pool_chunk_size` is truncated to `innodb_buffer_pool_size / innodb_buffer_pool_instances`.
- Buffer pool size must always be equal to or a multiple of `innodb_buffer_pool_chunk_size * innodb_buffer_pool_instances`. If you alter `innodb_buffer_pool_chunk_size`, `innodb_buffer_pool_size` is automatically adjusted to a value that is equal to or a multiple of `innodb_buffer_pool_chunk_size * innodb_buffer_pool_instances` that is not less than the current buffer pool size. The adjustment occurs when the buffer pool is initialized.

#### Important

Care should be taken when changing `innodb_buffer_pool_chunk_size`, as changing this value can automatically increase the size of the buffer pool. Before changing `innodb_buffer_pool_chunk_size`, calculate the effect it will have on `innodb_buffer_pool_size` to ensure that the resulting buffer pool size is acceptable.

To avoid potential performance issues, the number of chunks (`innodb_buffer_pool_size / innodb_buffer_pool_chunk_size`) should not exceed 1000.

See [Section 15.6.3.2, “Configuring InnoDB Buffer Pool Size”](#) for more information.

- `innodb_buffer_pool_dump_at_shutdown`

|                                       |  |  |
|---------------------------------------|--|--|
| <b>Command-Line Format</b>            | <code>--innodb_buffer_pool_dump_at_shutdown=#</code> |  |
| <b>System Variable</b>                | <b>Name</b>  | <code>innodb_buffer_pool_dump_at_shutdown</code> |
|                                       | <b>Variable Scope</b>                                | Global   |
|                                       | <b>Dynamic Variable</b>                              | Yes  |
| <b>Permitted Values (&lt;= 5.7.6)</b> | <b>Type</b>  | boolean  |
|                                       | <b>Default</b>                                       | <code>OFF</code>                                 |
| <b>Permitted Values (&gt;= 5.7.7)</b> | <b>Type</b>  | boolean  |
|                                       | <b>Default</b>                                       | <code>ON</code>                                  |

Specifies whether to record the pages cached in the [InnoDB buffer pool](#) when the MySQL server is shut down, to shorten the [warmup](#) process at the next restart. Typically used in combination with [innodb\\_buffer\\_pool\\_load\\_at\\_startup](#). The [innodb\\_buffer\\_pool\\_dump\\_pct](#) option defines the percentage of most recently used buffer pool pages to dump.

Both [innodb\\_buffer\\_pool\\_dump\\_at\\_shutdown](#) and [innodb\\_buffer\\_pool\\_load\\_at\\_startup](#) are enabled by default as of MySQL 5.7.7.

For more information, see [Section 15.6.3.8, “Saving and Restoring the Buffer Pool State”](#).

- `innodb_buffer_pool_dump_now`

|                            |  |  |
|----------------------------|--|--|
| <b>Command-Line Format</b> | <code>--innodb_buffer_pool_dump_now=#</code> |  |
| <b>System Variable</b>     | <b>Name</b>                                  | <code>innodb_buffer_pool_dump_now</code> |
|                            | <b>Variable Scope</b>                        | Global                                   |
|                            | <b>Dynamic Variable</b>                      | Yes                                      |
| <b>Permitted Values</b>    | <b>Type</b>                                  | boolean                                  |
|                            | <b>Default</b>                               | <code>OFF</code>                         |

Immediately records the pages cached in the [InnoDB buffer pool](#). Typically used in combination with [innodb\\_buffer\\_pool\\_load\\_now](#).

For more information, see [Section 15.6.3.8, “Saving and Restoring the Buffer Pool State”](#).

- `innodb_buffer_pool_dump_pct`

|                                       |  |  |
|---------------------------------------|--|--|
| <b>Introduced</b>                     | 5.7.2  |  |
| <b>Command-Line Format</b>            | <code>--innodb_buffer_pool_dump_pct=#</code> |  |
| <b>System Variable</b>                | <b>Name</b>                                  | <code>innodb_buffer_pool_dump_pct</code> |
|                                       | <b>Variable Scope</b>                        | Global                                   |
|                                       | <b>Dynamic Variable</b>                      | Yes                                      |
| <b>Permitted Values (&lt;= 5.7.6)</b> | <b>Type</b>                                  | integer                                  |

|                                       |                  |         |
|---------------------------------------|------------------|---------|
|                                       | <b>Default</b>   | 100     |
|                                       | <b>Min Value</b> | 1       |
|                                       | <b>Max Value</b> | 100     |
| <b>Permitted Values (&gt;= 5.7.7)</b> | <b>Type</b>      | integer |
|                                       | <b>Default</b>   | 25      |
|                                       | <b>Min Value</b> | 1       |
|                                       | <b>Max Value</b> | 100     |

Specifies the percentage of the most recently used pages for each buffer pool to read out and dump. The range is 1 to 100. Prior to MySQL 5.7.7, the default value is 100 (dump all pages). As of MySQL 5.7.7, the default value is 25. For example, if there are 4 buffer pools with 100 pages each, and `innodb_buffer_pool_dump_pct` is set to 25, the 25 most recently used pages from each buffer pool are dumped.

The change to the `innodb_buffer_pool_dump_pct` default value in MySQL 5.7.7 coincides with default value changes for `innodb_buffer_pool_dump_at_shutdown` and `innodb_buffer_pool_load_at_startup`, which are both enabled by default as of MySQL 5.7.7.

- `innodb_buffer_pool_filename`

|                            |   |  |
|----------------------------|---|--|
| <b>Command-Line Format</b> | <code>--innodb_buffer_pool_filename=file</code> |  |
| <b>System Variable</b>     | <b>Name</b>                                     | <code>innodb_buffer_pool_filename</code> |
|                            | <b>Variable Scope</b>                           | Global                                   |
|                            | <b>Dynamic Variable</b>                         | Yes                                      |
| <b>Permitted Values</b>    | <b>Type</b>                                     | file name                                |
|                            | <b>Default</b>                                  | <code>ib_buffer_pool</code>              |

Specifies the name of the file that holds the list of tablespace IDs and page IDs produced by `innodb_buffer_pool_dump_at_shutdown` or `innodb_buffer_pool_dump_now`. Tablespace IDs and page IDs are saved in the following format: `space, page_id`. By default, the file is named `ib_buffer_pool` and is located in the InnoDB data directory. A non-default location must be specified relative to the data directory.

A file name can be specified at runtime, using a `SET` statement:

```
SET GLOBAL innodb_buffer_pool_filename='file_name';
```

You can also specify a file name at startup, in a startup string or MySQL configuration file. When specifying a file name at startup, the file must exist or InnoDB will return a startup error indicating that there is no such file or directory.

For more information, see [Section 15.6.3.8, “Saving and Restoring the Buffer Pool State”](#).

- `innodb_buffer_pool_instances`

|                            |   |   |
|----------------------------|---|---|
| <b>Command-Line Format</b> | <code>--innodb_buffer_pool_instances=#</code> |   |
| <b>System Variable</b>     | <b>Name</b>                                   | <code>innodb_buffer_pool_instances</code> |

|  |                         |  |
|--|-------------------------|--|
|  | <b>Variable Scope</b>   | Global   |
|  | <b>Dynamic Variable</b> | No   |
| <b>Permitted Values</b><br>(Windows, 32-bit platforms) | <b>Type</b>             | integer  |
|  | <b>Default</b>          | (autosized)  |
|  | <b>Min Value</b>        | 1  |
|  | <b>Max Value</b>        | 64   |
| <b>Permitted Values (Other)</b>                        | <b>Type</b>             | integer  |
|  | <b>Default</b>          | 8 (or 1 if <code>innodb_buffer_pool_size &lt; 1GB</code> ) |
|  | <b>Min Value</b>        | 1  |
|  | <b>Max Value</b>        | 64   |

The number of regions that the [InnoDB buffer pool](#) is divided into. For systems with buffer pools in the multi-gigabyte range, dividing the buffer pool into separate instances can improve concurrency, by reducing contention as different threads read and write to cached pages. Each page that is stored in or read from the buffer pool is assigned to one of the buffer pool instances randomly, using a hashing function. Each buffer pool manages its own free lists, [flush lists](#), [LRUs](#), and all other data structures connected to a buffer pool, and is protected by its own buffer pool [mutex](#).

This option only takes effect when setting `innodb_buffer_pool_size` to 1GB or more. The total buffer pool size is divided among all the buffer pools. For best efficiency, specify a combination of `innodb_buffer_pool_instances` and `innodb_buffer_pool_size` so that each buffer pool instance is at least 1GB.

The default value on 32-bit Windows systems depends on the value of `innodb_buffer_pool_size`, as described below:

- If `innodb_buffer_pool_size` is greater than 1.3GB, the default for `innodb_buffer_pool_instances` is `innodb_buffer_pool_size/128MB`, with individual memory allocation requests for each chunk. 1.3GB was chosen as the boundary at which there is significant risk for 32-bit Windows to be unable to allocate the contiguous address space needed for a single buffer pool.
- Otherwise, the default is 1.

On all other platforms, the default value is 8 when `innodb_buffer_pool_size` is greater than or equal to 1GB. Otherwise, the default is 1.

For related information, see [Section 15.6.3.2, “Configuring InnoDB Buffer Pool Size”](#).

- [innodb\\_buffer\\_pool\\_load\\_abort](#)

|                            |  |  |
|----------------------------|--|--|
| <b>Command-Line Format</b> | <code>--innodb_buffer_pool_load_abort=#</code> |  |
| <b>System Variable</b>     | <b>Name</b>                                    | <code>innodb_buffer_pool_load_abort</code> |
|                            | <b>Variable Scope</b>                          | Global                                     |
|                            | <b>Dynamic Variable</b>                        | Yes  |
| <b>Permitted Values</b>    | <b>Type</b>                                    | boolean                                    |

|  |                |     |
|--|----------------|-----|
|  | <b>Default</b> | OFF |
|--|----------------|-----|

Interrupts the process of restoring [InnoDB buffer pool](#) contents triggered by [innodb\\_buffer\\_pool\\_load\\_at\\_startup](#) or [innodb\\_buffer\\_pool\\_load\\_now](#).

For more information, see [Section 15.6.3.8, “Saving and Restoring the Buffer Pool State”](#).

- [innodb\\_buffer\\_pool\\_load\\_at\\_startup](#)

|                                       |  |  |
|---------------------------------------|--|--|
| <b>Command-Line Format</b>            | <a href="#">--innodb_buffer_pool_load_at_startup=#</a> |  |
| <b>System Variable</b>                | <b>Name</b>  | <a href="#">innodb_buffer_pool_load_at_startup</a> |
|                                       | <b>Variable Scope</b>                                  | Global   |
|                                       | <b>Dynamic Variable</b>                                | No   |
| <b>Permitted Values (&lt;= 5.7.6)</b> | <b>Type</b>  | boolean  |
|                                       | <b>Default</b>   | OFF  |
| <b>Permitted Values (&gt;= 5.7.7)</b> | <b>Type</b>  | boolean  |
|                                       | <b>Default</b>   | ON   |

Specifies that, on MySQL server startup, the [InnoDB buffer pool](#) is automatically [warmed up](#) by loading the same pages it held at an earlier time. Typically used in combination with [innodb\\_buffer\\_pool\\_dump\\_at\\_shutdown](#).

Both [innodb\\_buffer\\_pool\\_dump\\_at\\_shutdown](#) and [innodb\\_buffer\\_pool\\_load\\_at\\_startup](#) are enabled by default as of MySQL 5.7.7.

For more information, see [Section 15.6.3.8, “Saving and Restoring the Buffer Pool State”](#).

- [innodb\\_buffer\\_pool\\_load\\_now](#)

|                            |   |   |
|----------------------------|---|---|
| <b>Command-Line Format</b> | <a href="#">--innodb_buffer_pool_load_now=#</a> |   |
| <b>System Variable</b>     | <b>Name</b>                                     | <a href="#">innodb_buffer_pool_load_now</a> |
|                            | <b>Variable Scope</b>                           | Global                                      |
|                            | <b>Dynamic Variable</b>                         | Yes   |
| <b>Permitted Values</b>    | <b>Type</b>                                     | boolean                                     |
|                            | <b>Default</b>                                  | OFF   |

Immediately [warms up](#) the [InnoDB buffer pool](#) by loading a set of data pages, without waiting for a server restart. Can be useful to bring cache memory back to a known state during benchmarking, or to ready the MySQL server to resume its normal workload after running queries for reports or maintenance.

For more information, see [Section 15.6.3.8, “Saving and Restoring the Buffer Pool State”](#).

- [innodb\\_buffer\\_pool\\_size](#)

|                                      |   |   |
|--------------------------------------|---|---|
| <b>Command-Line Format</b>           | <a href="#">--innodb_buffer_pool_size=#</a> |   |
| <b>System Variable (&lt;= 5.7.4)</b> | <b>Name</b>                                 | <a href="#">innodb_buffer_pool_size</a> |
|                                      | <b>Variable Scope</b>                       | Global                                  |
|                                      |   | 2352                                    |

|  |                         |   |
|--|-------------------------|---|
|  | <b>Dynamic Variable</b> | No                                      |
| <b>System Variable</b> ( $\geq 5.7.5$ )    | <b>Name</b>             | <a href="#">innodb_buffer_pool_size</a> |
|  | <b>Variable Scope</b>   | Global                                  |
|  | <b>Dynamic Variable</b> | Yes                                     |
| <b>Permitted Values</b> (32-bit platforms) | <b>Type</b>             | integer                                 |
|  | <b>Default</b>          | <a href="#">134217728</a>               |
|  | <b>Min Value</b>        | <a href="#">5242880</a>                 |
|  | <b>Max Value</b>        | $2^{32}-1$                              |
| <b>Permitted Values</b> (64-bit platforms) | <b>Type</b>             | integer                                 |
|  | <b>Default</b>          | <a href="#">134217728</a>               |
|  | <b>Min Value</b>        | <a href="#">5242880</a>                 |
|  | <b>Max Value</b>        | $2^{64}-1$                              |

The size in bytes of the [buffer pool](#), the memory area where [InnoDB](#) caches table and index data. The default value is 128MB. The maximum value depends on the CPU architecture; the maximum is 4294967295 ( $2^{32}-1$ ) on 32-bit systems and 18446744073709551615 ( $2^{64}-1$ ) on 64-bit systems. On 32-bit systems, the CPU architecture and operating system may impose a lower practical maximum size than the stated maximum. When the size of the buffer pool is greater than 1GB, setting [innodb\\_buffer\\_pool\\_instances](#) to a value greater than 1 can improve the scalability on a busy server.

A larger buffer pool requires less disk I/O to access the same table data more than once. On a dedicated database server, you might set the buffer pool size to 80% of the machine's physical memory size. Be aware of the following potential issues when configuring buffer pool size, and be prepared to scale back the size of the buffer pool if necessary.

- Competition for physical memory can cause paging in the operating system.
- [InnoDB](#) reserves additional memory for buffers and control structures, so that the total allocated space is approximately 10% greater than the specified buffer pool size.
- Address space for the buffer pool must be contiguous, which can be an issue on Windows systems with DLLs that load at specific addresses.
- The time to initialize the buffer pool is roughly proportional to its size. On instances with large buffer pools, initialization time might be significant. To reduce the initialization period, you can save the buffer pool state at server shutdown and restore it at server startup. See [Section 15.6.3.8, “Saving and Restoring the Buffer Pool State”](#).

When you increase or decrease buffer pool size, the operation is performed in chunks. Chunk size is defined by the [innodb\\_buffer\\_pool\\_chunk\\_size](#) configuration option, which has a default of 128 MB.

Buffer pool size must always be equal to or a multiple of [innodb\\_buffer\\_pool\\_chunk\\_size](#) \* [innodb\\_buffer\\_pool\\_instances](#). If you alter the buffer pool size to a value that is not equal to or a multiple of [innodb\\_buffer\\_pool\\_chunk\\_size](#) \* [innodb\\_buffer\\_pool\\_instances](#), buffer pool size is automatically adjusted to a value that is equal to or a multiple of

`innodb_buffer_pool_chunk_size` \* `innodb_buffer_pool_instances` that is not less than the specified buffer pool size.

`innodb_buffer_pool_size` can be set dynamically, which allows you to resize the buffer pool without restarting the server. The `InnoDB_buffer_pool_resize_status` status variable reports the status of online buffer pool resizing operations. See [Section 15.6.3.2, “Configuring InnoDB Buffer Pool Size”](#) for more information.

- `innodb_change_buffer_max_size`

|                            |  |  |
|----------------------------|--|--|
| <b>Command-Line Format</b> | <code>--innodb_change_buffer_max_size=#</code> |  |
| <b>System Variable</b>     | <b>Name</b>                                    | <code>innodb_change_buffer_max_size</code> |
|                            | <b>Variable Scope</b>                          | Global                                     |
|                            | <b>Dynamic Variable</b>                        | Yes  |
| <b>Permitted Values</b>    | <b>Type</b>                                    | integer                                    |
|                            | <b>Default</b>                                 | 25   |
|                            | <b>Min Value</b>                               | 0  |
|                            | <b>Max Value</b>                               | 50   |

Maximum size for the [InnoDB change buffer](#), as a percentage of the total size of the [buffer pool](#). You might increase this value for a MySQL server with heavy insert, update, and delete activity, or decrease it for a MySQL server with unchanging data used for reporting. For more information, see [Section 15.4.2, “Change Buffer”](#), and [Section 15.6.5, “Configuring InnoDB Change Buffering”](#). For general I/O tuning advice, see [Section 9.5.8, “Optimizing InnoDB Disk I/O”](#).

- `innodb_change_buffering`

|                            |  |                                      |
|----------------------------|--|--------------------------------------|
| <b>Command-Line Format</b> | <code>--innodb_change_buffering=#</code> |                                      |
| <b>System Variable</b>     | <b>Name</b>                              | <code>innodb_change_buffering</code> |
|                            | <b>Variable Scope</b>                    | Global                               |
|                            | <b>Dynamic Variable</b>                  | Yes                                  |
| <b>Permitted Values</b>    | <b>Type</b>                              | enumeration                          |
|                            | <b>Default</b>                           | all                                  |
|                            | <b>Valid Values</b>                      | none                                 |
|                            |  | inserts                              |
|                            |  | deletes                              |
|                            |  | changes                              |
|                            |  | purges                               |
|                            |  | all                                  |

Whether [InnoDB](#) performs [change buffering](#), an optimization that delays write operations to secondary indexes so that the I/O operations can be performed sequentially. Permitted values are described in the following table.

**Table 15.12 Permitted Values for innodb\_change\_buffering**

| Value                | Description  |
|----------------------|--|
| <code>none</code>    | Do not buffer any operations.  |
| <code>inserts</code> | Buffer insert operations.  |
| <code>deletes</code> | Buffer delete marking operations; strictly speaking, the writes that mark index records for later deletion during a purge operation. |
| <code>changes</code> | Buffer inserts and delete-marking operations.  |
| <code>purges</code>  | Buffer the physical deletion operations that happen in the background.   |
| <code>all</code>     | The default. Buffer inserts, delete-marking operations, and purges.  |

For more information, see [Section 15.4.2, “Change Buffer”](#), and [Section 15.6.5, “Configuring InnoDB Change Buffering”](#). For general I/O tuning advice, see [Section 9.5.8, “Optimizing InnoDB Disk I/O”](#).

- `innodb_change_buffering_debug`

|                            |  |  |
|----------------------------|--|--|
| <b>Command-Line Format</b> | <code>--innodb_change_buffering_debug=#</code> |  |
| <b>System Variable</b>     | <b>Name</b>                                    | <code>innodb_change_buffering_debug</code> |
|                            | <b>Variable Scope</b>                          | Global                                     |
|                            | <b>Dynamic Variable</b>                        | Yes  |
| <b>Permitted Values</b>    | <b>Type</b>                                    | integer                                    |
|                            | <b>Default</b>                                 | 0  |
|                            | <b>Max Value</b>                               | 2  |

Sets a debug flag for InnoDB change buffering. A value of 1 forces all changes to the change buffer. A value of 2 causes a crash at merge. A default value of 0 indicates that the change buffering debug flag is not set. This option is only available when debugging support is compiled in using the `WITH_DEBUG` CMake option.

- `innodb_checksum_algorithm`

|                                       |  |  |
|---------------------------------------|--|--|
| <b>Command-Line Format</b>            | <code>--innodb_checksum_algorithm=#</code> |  |
| <b>System Variable</b>                | <b>Name</b>                                | <code>innodb_checksum_algorithm</code> |
|                                       | <b>Variable Scope</b>                      | Global                                 |
|                                       | <b>Dynamic Variable</b>                    | Yes                                    |
| <b>Permitted Values (&lt;= 5.7.6)</b> | <b>Type</b>                                | enumeration                            |
|                                       | <b>Default</b>                             | <code>innodb</code>                    |
|                                       | <b>Valid Values</b>                        | <code>innodb</code>                    |
|                                       |  | <code>crc32</code>                     |
|                                       |  | <code>none</code>                      |
|                                       |  | <code>strict_innodb</code>             |
|                                       |  | <code>strict_crc32</code>              |
|                                       |  | <code>strict_none</code>               |

|                                       |                     |                            |
|---------------------------------------|---------------------|----------------------------|
| <b>Permitted Values (&gt;= 5.7.7)</b> | <b>Type</b>         | enumeration                |
|                                       | <b>Default</b>      | <code>crc32</code>         |
|                                       | <b>Valid Values</b> | <code>innodb</code>        |
|                                       |                     | <code>crc32</code>         |
|                                       |                     | <code>none</code>          |
|                                       |                     | <code>strict_innodb</code> |
|                                       |                     | <code>strict_crc32</code>  |
|                                       |                     | <code>strict_none</code>   |

Specifies how to generate and verify the [checksum](#) stored in the disk blocks of [InnoDB tablespaces](#).

The default value for `innodb_checksum_algorithm` changed from `innodb` to `crc32` in MySQL 5.6.6 but switched back to `innodb` in 5.6.7 for improved compatibility of [InnoDB](#) data files during a downgrade to an earlier MySQL version, and for use with [MySQL Enterprise Backup](#). The limitations encountered included:

- `.ibd` files containing CRC32 checksums could cause problems downgrading to MySQL versions prior to 5.6.3. MySQL 5.6.3 and up recognizes either the new or old checksum values for the block as correct when reading the block from disk, ensuring that data blocks are compatible during upgrade and downgrade regardless of the algorithm setting. If data written with new checksum values is processed by a level of MySQL earlier than 5.6.3, it could be reported as corrupted.
- Versions of [MySQL Enterprise Backup](#) up to 3.8.0 do not support backing up tablespaces that use CRC32 checksums. [MySQL Enterprise Backup](#) adds CRC32 checksum support in 3.8.1, with some limitations. Refer to the [MySQL Enterprise Backup 3.8.1 Change History](#) for more information.

As of MySQL 5.7.7, `crc32` is once again the default value for `innodb_checksum_algorithm`.

`innodb_checksum_algorithm` replaced the `innodb_checksums` option in MySQL 5.6.3. The following values were provided for compatibility, up to and including MySQL 5.7.6:

- `innodb_checksums=ON` is the same as `innodb_checksum_algorithm=innodb`.
- `innodb_checksums=OFF` is the same as `innodb_checksum_algorithm=none`.

As of MySQL 5.7.7, with a default `innodb_checksum_algorithm` value of `crc32`, `innodb_checksums=ON` is now the same as `innodb_checksum_algorithm=crc32`. `innodb_checksums=OFF` is still the same as `innodb_checksum_algorithm=none`.

To avoid conflicts, remove references to `innodb_checksums` from MySQL configuration files and startup scripts.

The value `innodb` is backward-compatible with earlier versions of MySQL. The value `crc32` uses an algorithm that is faster to compute the checksum for every modified block, and to check the checksums for each disk read. It scans blocks 32 bits at a time, which is faster than the `innodb` checksum algorithm, which scans blocks 8 bits at a time. The value `none` writes a constant value in the checksum field rather than computing a value based on the block data. The blocks in a tablespace can use a mix of old, new, and no checksum values, being updated gradually as the data is modified; once blocks in a tablespace are modified to use the `crc32` algorithm, the associated tables cannot be read by earlier versions of MySQL.

The strict form of a checksum algorithm reports an error if it encounters a valid but non-matching checksum value in a tablespace. It is recommended that you only use strict settings in a new instance, to set up tablespaces for the first time. Strict settings are somewhat faster, because they do not need to compute all checksum values during disk reads.

**Note**

Prior to MySQL 5.7.8, a strict mode setting for `innodb_checksum_algorithm` caused InnoDB to halt when encountering a *valid* but non-matching checksum. In MySQL 5.7.8 and later, only an error message is printed, and the page is accepted as valid if it has a valid `innodb`, `crc32` or `none` checksum.

The following table shows the difference between the `none`, `innodb`, and `crc32` option values, and their strict counterparts. `none`, `innodb`, and `crc32` write the specified type of checksum value into each data block, but for compatibility accept other checksum values when verifying a block during a read operation. Strict settings also accept valid checksum values but print an error message when a valid non-matching checksum value is encountered. Using the strict form can make verification faster if all InnoDB data files in an instance are created under an identical `innodb_checksum_algorithm` value.

**Table 15.13 innodb\_checksum\_algorithm Settings**

| Value                      | Generated checksum (when writing)   | Permitted checksums (when reading)  |
|----------------------------|---|---|
| <code>none</code>          | A constant number.  | Any of the checksums generated by <code>none</code> , <code>innodb</code> , or <code>crc32</code> .   |
| <code>innodb</code>        | A checksum calculated in software, using the original algorithm from InnoDB.                        | Any of the checksums generated by <code>none</code> , <code>innodb</code> , or <code>crc32</code> .   |
| <code>crc32</code>         | A checksum calculated using the <code>crc32</code> algorithm, possibly done with a hardware assist. | Any of the checksums generated by <code>none</code> , <code>innodb</code> , or <code>crc32</code> .   |
| <code>strict_none</code>   | A constant number   | Any of the checksums generated by <code>none</code> , <code>innodb</code> , or <code>crc32</code> . InnoDB prints an error message if a valid but non-matching checksum is encountered. |
| <code>strict_innodb</code> | A checksum calculated in software, using the original algorithm from InnoDB.                        | Any of the checksums generated by <code>none</code> , <code>innodb</code> , or <code>crc32</code> . InnoDB prints an error message if a valid but non-matching checksum is encountered. |
| <code>strict_crc32</code>  | A checksum calculated using the <code>crc32</code> algorithm, possibly done with a hardware assist. | Any of the checksums generated by <code>none</code> , <code>innodb</code> , or <code>crc32</code> . InnoDB prints an error message if a valid but non-matching checksum is encountered. |

- `innodb_checksums`

|                            |                                 |                               |
|----------------------------|---------------------------------|-------------------------------|
| <b>Deprecated</b>          | 5.6.3                           |                               |
| <b>Command-Line Format</b> | <code>--innodb_checksums</code> |                               |
| <b>System Variable</b>     | <b>Name</b>                     | <code>innodb_checksums</code> |
|                            | <b>Variable Scope</b>           | Global                        |
|                            | <b>Dynamic Variable</b>         | No                            |

|                         |                |         |
|-------------------------|----------------|---------|
| <b>Permitted Values</b> | <b>Type</b>    | boolean |
|                         | <b>Default</b> | ON      |

InnoDB can use [checksum](#) validation on all tablespace pages read from disk to ensure extra fault tolerance against hardware faults or corrupted data files. This validation is enabled by default. Under specialized circumstances (such as when running benchmarks) this safety feature can be disabled with `--skip-innodb-checksums`. You can specify the method of calculating the checksum using the `innodb_checksum_algorithm` option.

In MySQL 5.6.3 and higher, `innodb_checksums` is deprecated, replaced by `innodb_checksum_algorithm`.

Prior to MySQL 5.7.7, `innodb_checksums=ON` is the same as `innodb_checksum_algorithm=innodb`. As of MySQL 5.7.7, the `innodb_checksum_algorithm` default value is `crc32`, and `innodb_checksums=ON` is the same as `innodb_checksum_algorithm=crc32`. `innodb_checksums=OFF` is the same as `innodb_checksum_algorithm=none`.

Remove any `innodb_checksums` options from your configuration files and startup scripts to avoid conflicts with `innodb_checksum_algorithm`. `innodb_checksums=OFF` automatically sets `innodb_checksum_algorithm=none`. `innodb_checksums=ON` is ignored and overridden by any other setting for `innodb_checksum_algorithm`.

- `innodb_cmp_per_index_enabled`

|                            |   |   |
|----------------------------|---|---|
| <b>Command-Line Format</b> | <code>--innodb_cmp_per_index_enabled=#</code> |   |
| <b>System Variable</b>     | <b>Name</b>                                   | <code>innodb_cmp_per_index_enabled</code> |
|                            | <b>Variable Scope</b>                         | Global                                    |
|                            | <b>Dynamic Variable</b>                       | Yes                                       |
| <b>Permitted Values</b>    | <b>Type</b>                                   | boolean                                   |
|                            | <b>Default</b>                                | OFF                                       |
|                            | <b>Valid Values</b>                           | OFF                                       |
|                            |   | ON  |

Enables per-index compression-related statistics in the `INFORMATION_SCHEMA.INNODB_CMP_PER_INDEX` table. Because these statistics can be expensive to gather, only enable this option on development, test, or slave instances during performance tuning related to [InnoDB compressed](#) tables.

For more information, see [Section 23.31.6, “The INFORMATION\\_SCHEMA INNODB\\_CMP\\_PER\\_INDEX and INNODB\\_CMP\\_PER\\_INDEX\\_RESET Tables”](#), and [Section 15.9.1.4, “Monitoring Compression at Runtime”](#).

- `innodb_commit_concurrency`

|                            |  |  |
|----------------------------|--|--|
| <b>Command-Line Format</b> | <code>--innodb_commit_concurrency=#</code> |  |
| <b>System Variable</b>     | <b>Name</b>                                | <code>innodb_commit_concurrency</code> |
|                            | <b>Variable Scope</b>                      | Global                                 |
|                            | <b>Dynamic Variable</b>                    | Yes                                    |
| <b>Permitted Values</b>    | <b>Type</b>                                | integer                                |

|  |                  |      |
|--|------------------|------|
|  | <b>Default</b>   | 0    |
|  | <b>Min Value</b> | 0    |
|  | <b>Max Value</b> | 1000 |

The number of [threads](#) that can [commit](#) at the same time. A value of 0 (the default) permits any number of [transactions](#) to commit simultaneously.

The value of [innodb\\_commit\\_concurrency](#) cannot be changed at runtime from zero to nonzero or vice versa. The value can be changed from one nonzero value to another.

- [innodb\\_compress\\_debug](#)

|                            |   |                                       |
|----------------------------|---|---------------------------------------|
| <b>Introduced</b>          | 5.7.8                                     |                                       |

|                            | <b>Dynamic Variable</b>                   | Yes                                   |
| <b>Permitted Values</b>    | <b>Type</b>                               | enumeration                           |
|                            | <b>Default</b>                            | <a href="#">none</a>                  |
|                            | <b>Valid Values</b>                       | <a href="#">none</a>                  |
|                            |   | <a href="#">zlib</a>                  |
|                            |   | <a href="#">lz4</a>                   |
|                            |   | <a href="#">lz4hc</a>                 |

Compresses all tables using a specified compression algorithm without having to define a [COMPRESSION](#) attribute for each table. This option is only available if debugging support is compiled in using the [WITH\\_DEBUG CMake](#) option.

For related information, see [Section 15.9.2, “InnoDB Page Compression”](#).

- [innodb\\_compression\\_failure\\_threshold\\_pct](#)

|                            |  |  |
|----------------------------|--|--|
| <b>Command-Line Format</b> | <a href="#">--innodb_compression_failure_threshold_pct=#</a> |  |
| <b>System Variable</b>     | <b>Name</b>  | <a href="#">innodb_compression_failure_threshold_pct</a> |
|                            | <b>Variable Scope</b>  | Global   |
|                            | <b>Dynamic Variable</b>                                      | Yes  |
| <b>Permitted Values</b>    | <b>Type</b>  | integer  |
|                            | <b>Default</b>   | 5  |
|                            | <b>Min Value</b>   | 0  |
|                            | <b>Max Value</b>   | 100  |

Sets the cutoff point at which MySQL begins adding padding within [compressed](#) pages to avoid expensive [compression failures](#). A value of zero disables the mechanism that monitors compression efficiency and dynamically adjusts the padding amount.

For more information, see [Section 15.9.1.6, “Compression for OLTP Workloads”](#).

- [innodb\\_compression\\_level](#)

|                            |   |  |
|----------------------------|---|--|
| <b>Command-Line Format</b> | <code>--innodb_compression_level=#</code> |  |
| <b>System Variable</b>     | <b>Name</b>                               | <a href="#">innodb_compression_level</a> |
|                            | <b>Variable Scope</b>                     | Global                                   |
|                            | <b>Dynamic Variable</b>                   | Yes                                      |
| <b>Permitted Values</b>    | <b>Type</b>                               | integer                                  |
|                            | <b>Default</b>                            | 6  |
|                            | <b>Min Value</b>                          | 0  |
|                            | <b>Max Value</b>                          | 9  |

Specifies the level of zlib compression to use for [InnoDB compressed](#) tables and indexes.

For more information, see [Section 15.9.1.6, “Compression for OLTP Workloads”](#).

- [innodb\\_compression\\_pad\\_pct\\_max](#)

|                            |   |  |
|----------------------------|---|--|
| <b>Command-Line Format</b> | <code>--innodb_compression_pad_pct_max=#</code> |  |
| <b>System Variable</b>     | <b>Name</b>                                     | <a href="#">innodb_compression_pad_pct_max</a> |
|                            | <b>Variable Scope</b>                           | Global   |
|                            | <b>Dynamic Variable</b>                         | Yes  |
| <b>Permitted Values</b>    | <b>Type</b>                                     | integer  |
|                            | <b>Default</b>                                  | 50   |
|                            | <b>Min Value</b>                                | 0  |
|                            | <b>Max Value</b>                                | 75   |

Specifies the maximum percentage that can be reserved as free space within each compressed [page](#), allowing room to reorganize the data and modification log within the page when a [compressed](#) table or index is updated and the data might be recompressed. Only applies when [innodb\\_compression\\_failure\\_threshold\\_pct](#) is set to a non-zero value, and the rate of [compression failures](#) passes the cutoff point.

For more information, see [Section 15.9.1.6, “Compression for OLTP Workloads”](#).

- [innodb\\_concurrency\\_tickets](#)

|                            |   |  |
|----------------------------|---|--|
| <b>Command-Line Format</b> | <code>--innodb_concurrency_tickets=#</code> |  |
| <b>System Variable</b>     | <b>Name</b>                                 | <a href="#">innodb_concurrency_tickets</a> |

|                         |                         |            |
|-------------------------|-------------------------|------------|
| <b>Permitted Values</b> | <b>Variable Scope</b>   | Global     |
|                         | <b>Dynamic Variable</b> | Yes        |
|                         | <b>Type</b>             | integer    |
|                         | <b>Default</b>          | 5000       |
|                         | <b>Min Value</b>        | 1          |
|                         | <b>Max Value</b>        | 4294967295 |

Determines the number of [threads](#) that can enter [InnoDB](#) concurrently. A thread is placed in a queue when it tries to enter [InnoDB](#) if the number of threads has already reached the concurrency limit. When a thread is permitted to enter [InnoDB](#), it is given a number of “tickets” equal to the value of [innodb\\_concurrency\\_tickets](#), and the thread can enter and leave [InnoDB](#) freely until it has used up its tickets. After that point, the thread again becomes subject to the concurrency check (and possible queuing) the next time it tries to enter [InnoDB](#). The default value is 5000.

With a small [innodb\\_concurrency\\_tickets](#) value, small transactions that only need to process a few rows compete fairly with larger transactions that process many rows. The disadvantage of a small [innodb\\_concurrency\\_tickets](#) value is that large transactions must loop through the queue many times before they can complete, which extends the amount of time required to complete their task.

With a large [innodb\\_concurrency\\_tickets](#) value, large transactions spend less time waiting for a position at the end of the queue (controlled by [innodb\\_thread\\_concurrency](#)) and more time retrieving rows. Large transactions also require fewer trips through the queue to complete their task. The disadvantage of a large [innodb\\_concurrency\\_tickets](#) value is that too many large transactions running at the same time can starve smaller transactions by making them wait a longer time before executing.

With a non-zero [innodb\\_thread\\_concurrency](#) value, you may need to adjust the [innodb\\_concurrency\\_tickets](#) value up or down to find the optimal balance between larger and smaller transactions. The `SHOW ENGINE INNODB STATUS` report shows the number of tickets remaining for an executing transaction in its current pass through the queue. This data may also be obtained from the [TRX\\_CONCURRENCY\\_TICKETS](#) column of the [INFORMATION\\_SCHEMA.INNODB\\_TRX](#) table.

For more information, see [Section 15.6.6, “Configuring Thread Concurrency for InnoDB”](#).

- [innodb\\_create\\_intrinsic](#)

|                            |  |   |
|----------------------------|--|---|
| <b>Introduced</b>          | 5.7.5                                    |   |
| <b>Removed</b>             | 5.7.6                                    |   |
| <b>Command-Line Format</b> | <code>--innodb_create_intrinsic=#</code> |   |
| <b>System Variable</b>     | <b>Name</b>                              | <a href="#">innodb_create_intrinsic</a> |
|                            | <b>Variable Scope</b>                    | Session                                 |
|                            | <b>Dynamic Variable</b>                  | Yes                                     |
| <b>Permitted Values</b>    | <b>Type</b>                              | boolean                                 |
|                            | <b>Default</b>                           | OFF                                     |

When `innodb_create_intrinsic` is enabled, `CREATE TEMPORARY TABLE` creates “optimized temporary tables” instead of normal temporary tables.

An optimized temporary table is a lightweight subclass of temporary table that excludes certain functionality and benefits from optimizations that make it faster than a normal temporary table. Like normal temporary tables, optimized temporary tables are only visible to the current connection and are dropped when the connection is terminated. Unlike normal temporary tables, optimized temporary tables are operational when `InnoDB` is in read-only mode.

Row format `COMPRESSED` is not supported. If you attempt to create a compressed optimized temporary table, the `innodb_create_intrinsic=ON` setting is ignored and `InnoDB` creates a normal temporary table.

Metadata for optimized temporary tables is not available in the `INFORMATION_SCHEMA.INNODB_TEMP_TABLE_INFO` table.

Undo logging is disabled for optimized temporary tables, which means that rollback is not supported.

Atomicity for optimized temporary tables is supported at the row-level, not at the statement level.

Statistics generated by the same workload may differ for optimized temporary tables compared to normal temporary tables, as optimized temporary tables may use a different algorithm to complete certain types of operations.

The `innodb_create_intrinsic` option was removed in MySQL 5.7.6.

- `innodb_data_file_path`

|                            |   |                                     |
|----------------------------|---|-------------------------------------|
| <b>Command-Line Format</b> | <code>--innodb_data_file_path=name</code> |                                     |
| <b>System Variable</b>     | <b>Name</b>                               | <code>innodb_data_file_path</code>  |
|                            | <b>Variable Scope</b>                     | Global                              |
|                            | <b>Dynamic Variable</b>                   | No                                  |
| <b>Permitted Values</b>    | <b>Type</b>                               | string                              |
|                            | <b>Default</b>                            | <code>ibdata1:12M:autoextend</code> |

Defines the path and file size for individual `InnoDB system tablespace data files`. The full directory path for system tablespace data files is formed by concatenating path defined by `innodb_data_home_dir` and `innodb_data_file_path`. File sizes are specified KB, MB or GB (1024MB) by appending `K`, `M` or `G` to the size value. If specifying the data file size in kilobytes (KB), do so in multiples of 1024. Otherwise, KB values are rounded to nearest megabyte (MB) boundary. The sum of the sizes of the files must be at least slightly larger than 10MB. If you do not specify `innodb_data_file_path`, the default behavior is to create a single auto-extending data file, slightly larger than 12MB, named `ibdata1`. The size limit of individual files is determined by your operating system. You can set the file size to more than 4GB on operating systems that support large files. You can also [use raw disk partitions as data files](#). For more information about configuring system tablespace data files, see [Section 15.6.1, “InnoDB Startup Configuration”](#).

As of MySQL 5.7.8, the following minimum file sizes are enforced for the *first* system tablespace data file (`ibdata1`) to ensure that there is enough space for doublewrite buffer pages:

- For an `innodb_page_size` value of 16KB or less, the minimum data file size is 3MB.
- For an `innodb_page_size` value of 32KB, the minimum data file size is 6MB.
- For an `innodb_page_size` value of 64KB, the minimum data file size is 12MB.

- `innodb_data_home_dir`

|                            |  |                                   |
|----------------------------|--|-----------------------------------|
| <b>Command-Line Format</b> | <code>--innodb_data_home_dir=dir_name</code> |                                   |
| <b>System Variable</b>     | <b>Name</b>                                  | <code>innodb_data_home_dir</code> |
|                            | <b>Variable Scope</b>                        | Global                            |
|                            | <b>Dynamic Variable</b>                      | No                                |
| <b>Permitted Values</b>    | <b>Type</b>                                  | directory name                    |

The common part of the directory path for [InnoDB system tablespace](#) data files. This setting does not affect the location of [file-per-table](#) tablespaces when `innodb_file_per_table` is enabled. The default value is the MySQL `data` directory. If you specify the value as an empty string, you can specify an absolute file paths for `innodb_data_file_path`.

For related information, see [Section 15.6.1, “InnoDB Startup Configuration”](#).

- `innodb_deadlock_detect`

|                            |                                       |                                     |
|----------------------------|---------------------------------------|-------------------------------------|
| <b>Introduced</b>          | 5.7.15                                |                                     |
| <b>Command-Line Format</b> | <code>--innodb_deadlock_detect</code> |                                     |
| <b>System Variable</b>     | <b>Name</b>                           | <code>innodb_deadlock_detect</code> |
|                            | <b>Variable Scope</b>                 | Global                              |
|                            | <b>Dynamic Variable</b>               | Yes                                 |
| <b>Permitted Values</b>    | <b>Type</b>                           | boolean                             |
|                            | <b>Default</b>                        | <code>ON</code>                     |

This option is used to disable deadlock detection. On high concurrency systems, deadlock detection can cause a slowdown when numerous threads wait for the same lock. At times, it may be more efficient to disable deadlock detection and rely on the `innodb_lock_wait_timeout` setting for transaction rollback when a deadlock occurs.

For related information, see [Section 15.5.5.2, “Deadlock Detection and Rollback”](#).

- `innodb_default_row_format`

|                            |  |  |
|----------------------------|--|--|
| <b>Introduced</b>          | 5.7.9                                      |  |
| <b>Command-Line Format</b> | <code>--innodb_default_row_format=#</code> |  |
| <b>System Variable</b>     | <b>Name</b>                                | <code>innodb_default_row_format</code> |
|                            | <b>Variable Scope</b>                      | Global                                 |
|                            | <b>Dynamic Variable</b>                    | Yes                                    |
| <b>Permitted Values</b>    | <b>Type</b>                                | enumeration                            |
|                            | <b>Default</b>                             | <code>DYNAMIC</code>                   |
|                            | <b>Valid Values</b>                        | <code>DYNAMIC</code>                   |
|                            |  | <code>COMPACT</code>                   |
|                            |  | <code>REDUNDANT</code>                 |

The `innodb_default_row_format` option, introduced in MySQL 5.7.9, defines the default row format for InnoDB tables and user-created temporary tables. The default setting is `DYNAMIC`. Other permitted values are `COMPACT` and `REDUNDANT`. The `COMPRESSED` row format, which is not supported for use in the `system tablespace`, cannot be defined as the default.

Newly created tables use the row format defined by `innodb_default_row_format` when a `ROW_FORMAT` option is not specified explicitly or when `ROW_FORMAT=DEFAULT` is used.

When a `ROW_FORMAT` option is not specified explicitly or when `ROW_FORMAT=DEFAULT` is used, any operation that rebuilds a table also silently changes the row format of the table to the format defined by `innodb_default_row_format`. For more information, see [Section 15.11.2, “Specifying the Row Format for a Table”](#).

Internal InnoDB temporary tables created by the server to process queries use the `DYNAMIC` row format, regardless of the `innodb_default_row_format` setting.

In MySQL 5.7.8 and earlier, the default row format is `COMPACT`.

- `innodb_disable_sort_file_cache`

|                            |   |   |
|----------------------------|---|---|
| <b>Command-Line Format</b> | <code>--innodb_disable_sort_file_cache=#</code> |   |
| <b>System Variable</b>     | <b>Name</b>                                     | <code>innodb_disable_sort_file_cache</code> |
|                            | <b>Variable Scope</b>                           | Global                                      |
|                            | <b>Dynamic Variable</b>                         | Yes   |
| <b>Permitted Values</b>    | <b>Type</b>                                     | boolean                                     |
|                            | <b>Default</b>                                  | <code>OFF</code>                            |

Disables the operating system file system cache for merge-sort temporary files. The effect is to open such files with the equivalent of `O_DIRECT`.

- `innodb_disable_resize_buffer_pool_debug`

|                            |  |  |
|----------------------------|--|--|
| <b>Introduced</b>          | 5.7.6  |  |
| <b>Command-Line Format</b> | <code>--innodb_disable_resize_buffer_pool_debug=#</code> |  |
| <b>System Variable</b>     | <b>Name</b>  | <code>innodb_disable_resize_buffer_pool_debug</code> |
|                            | <b>Variable Scope</b>                                    | Global   |
|                            | <b>Dynamic Variable</b>                                  | Yes  |
| <b>Permitted Values</b>    | <b>Type</b>  | boolean  |
|                            | <b>Default</b>   | <code>ON</code>                                      |

Disables resizing of the InnoDB buffer pool. This option is only available if debugging support is compiled in using the `WITH_DEBUG CMake` option.

- `innodb_doublewrite`

|                            |                                   |                                 |
|----------------------------|-----------------------------------|---------------------------------|
| <b>Command-Line Format</b> | <code>--innodb-doublewrite</code> |                                 |
| <b>System Variable</b>     | <b>Name</b>                       | <code>innodb_doublewrite</code> |
|                            | <b>Variable Scope</b>             | Global                          |

|                         |                         |         |
|-------------------------|-------------------------|---------|
|                         | <b>Dynamic Variable</b> | No      |
| <b>Permitted Values</b> | <b>Type</b>             | boolean |
|                         | <b>Default</b>          | ON      |

When enabled (the default), InnoDB stores all data twice, first to the [doublewrite buffer](#), then to the actual [data files](#). This variable can be turned off with `--skip-innodb_doublewrite` for benchmarks or cases when top performance is needed rather than concern for data integrity or possible failures.

As of MySQL 5.7.4, if system tablespace data files (`ibdata*` files) are located on Fusion-io devices that support atomic writes, doublewrite buffering is automatically disabled and Fusion-io atomic writes are used for all data files. Because the doublewrite buffer setting is global, doublewrite buffering is also disabled for data files residing on non-Fusion-io hardware. This feature is only supported on Fusion-io hardware and only enabled for Fusion-io NVMFS on Linux. To take full advantage of this feature, an `innodb_flush_method` setting of `O_DIRECT` is recommended.

For related information, see [Section 15.4.7, “Doublewrite Buffer”](#).

- [innodb\\_fast\\_shutdown](#)

|                            |   |                                      |
|----------------------------|---|--------------------------------------|
| <b>Command-Line Format</b> | <code>--innodb_fast_shutdown[=#]</code> |                                      |
| <b>System Variable</b>     | <b>Name</b>                             | <a href="#">innodb_fast_shutdown</a> |
|                            | <b>Variable Scope</b>                   | Global                               |
|                            | <b>Dynamic Variable</b>                 | Yes                                  |
| <b>Permitted Values</b>    | <b>Type</b>                             | integer                              |
|                            | <b>Default</b>                          | 1                                    |
|                            | <b>Valid Values</b>                     | 0                                    |
|                            |   | 1                                    |
|                            |   | 2                                    |

The [InnoDB shutdown](#) mode. If the value is 0, InnoDB does a [slow shutdown](#), a full [purge](#) and a change buffer merge before shutting down. If the value is 1 (the default), InnoDB skips these operations at shutdown, a process known as a [fast shutdown](#). If the value is 2, InnoDB flushes its logs and shuts down cold, as if MySQL had crashed; no committed transactions are lost, but the [crash recovery](#) operation makes the next startup take longer.

The slow shutdown can take minutes, or even hours in extreme cases where substantial amounts of data are still buffered. Use the slow shutdown technique before upgrading or downgrading between MySQL major releases, so that all data files are fully prepared in case the upgrade process updates the file format.

Use `innodb_fast_shutdown=2` in emergency or troubleshooting situations, to get the absolute fastest shutdown if data is at risk of corruption.

- [innodb\\_fil\\_make\\_page\\_dirty\\_debug](#)

|                            |   |  |
|----------------------------|---|--|
| <b>Command-Line Format</b> | <code>--innodb_fil_make_page_dirty_debug=#</code> |  |
| <b>System Variable</b>     | <b>Name</b>                                       | <a href="#">innodb_fil_make_page_dirty_debug</a> |
|                            | <b>Variable Scope</b>                             | Global   |

|                         |                         |            |
|-------------------------|-------------------------|------------|
|                         | <b>Dynamic Variable</b> | Yes        |
| <b>Permitted Values</b> | <b>Type</b>             | integer    |
|                         | <b>Default</b>          | 0          |
|                         | <b>Max Value</b>        | $2^{32}-1$ |

By default, setting `innodb_fil_make_page_dirty_debug` to the ID of a tablespace immediately dirties the first page of the tablespace. If `innodb_saved_page_number_debug` is set to a non-default value, setting `innodb_fil_make_page_dirty_debug` dirties the specified page. The `innodb_fil_make_page_dirty_debug` option is only available if debugging support is compiled in using the `WITH_DEBUG` CMake option.

- `innodb_file_format`

|                                       |                                     |                                 |
|---------------------------------------|-------------------------------------|---------------------------------|
| <b>Deprecated</b>                     | 5.7.7                               |                                 |
| <b>Command-Line Format</b>            | <code>--innodb_file_format=#</code> |                                 |
| <b>System Variable</b>                | <b>Name</b>                         | <code>innodb_file_format</code> |
|                                       | <b>Variable Scope</b>               | Global                          |
|                                       | <b>Dynamic Variable</b>             | Yes                             |
| <b>Permitted Values (&lt;= 5.7.6)</b> | <b>Type</b>                         | string                          |
|                                       | <b>Default</b>                      | <code>Antelope</code>           |
|                                       | <b>Valid Values</b>                 | <code>Antelope</code>           |
|                                       |                                     | <code>Barracuda</code>          |
| <b>Permitted Values (&gt;= 5.7.7)</b> | <b>Type</b>                         | string                          |
|                                       | <b>Default</b>                      | <code>Barracuda</code>          |
|                                       | <b>Valid Values</b>                 | <code>Antelope</code>           |
|                                       |                                     | <code>Barracuda</code>          |

Enables an InnoDB file format for `file-per-table` tablespaces. Supported file formats are `Antelope` and `Barracuda`. `Antelope` is the original InnoDB file format, which supports `REDUNDANT` and `COMPACT` row formats. `Barracuda` is the newer file format, which supports `COMPRESSED` and `DYNAMIC` row formats.

`COMPRESSED` and `DYNAMIC` row formats enable important storage features for InnoDB tables. See [Section 15.11, “InnoDB Row Storage and Row Formats”](#).

Changing the `innodb_file_format` setting does not affect the file format of existing InnoDB tablespace files.

The `innodb_file_format` setting does not apply to general tablespaces, which support tables of all row formats. See [Section 15.7.9, “InnoDB General Tablespaces”](#).

The `innodb_file_format` default value was changed to `Barracuda` in MySQL 5.7.7.

As of MySQL 5.7.9, the `innodb_file_format` setting is ignored when creating tables that use the `DYNAMIC` row format. A table created using the `DYNAMIC` row format always uses the `Barracuda` file format, regardless of the `innodb_file_format` setting. To use the `COMPRESSED` row format, `innodb_file_format` must be set to `Barracuda`.

The `innodb_file_format` option is deprecated in MySQL 5.7.7 and will be removed in a future release. The purpose of the `innodb_file_format` option was to allow users to downgrade to the built-in version of InnoDB in MySQL 5.1. Now that MySQL 5.1 has reached the end of its product lifecycle, downgrade support provided by this option is no longer necessary.

For more information, see [Section 15.10, “InnoDB File-Format Management”](#).

- `innodb_file_format_check`

|                            |   |                                       |
|----------------------------|---|---------------------------------------|
| <b>Deprecated</b>          | 5.7.7                                     |                                       |
| <b>Command-Line Format</b> | <code>--innodb_file_format_check=#</code> |                                       |
| <b>System Variable</b>     | <b>Name</b>                               | <code>innodb_file_format_check</code> |
|                            | <b>Variable Scope</b>                     | Global                                |
|                            | <b>Dynamic Variable</b>                   | No                                    |
| <b>Permitted Values</b>    | <b>Type</b>                               | boolean                               |
|                            | <b>Default</b>                            | ON                                    |

This variable can be set to 1 or 0 at server startup to enable or disable whether InnoDB checks the `file format` tag in the `system tablespace` (for example, `Antelope` or `Barracuda`). If the tag is checked and is higher than that supported by the current version of InnoDB, an error occurs and InnoDB does not start. If the tag is not higher, InnoDB sets the value of `innodb_file_format_max` to the file format tag.

#### Note

Despite the default value sometimes being displayed as `ON` or `OFF`, always use the numeric values 1 or 0 to turn this option on or off in your configuration file or command line string.

The `innodb_file_format_check` option is deprecated in MySQL 5.7.7 together with the `innodb_file_format` option. Both options will be removed in a future release.

- `innodb_file_format_max`

|                                       |   |   |
|---------------------------------------|---|---|
| <b>Deprecated</b>                     | 5.7.7                                   |   |
| <b>Command-Line Format</b>            | <code>--innodb_file_format_max=#</code> |   |
| <b>System Variable</b>                | <b>Name</b>                             | <code>innodb_file_format_max</code>             |
|                                       | <b>Variable Scope</b>                   | Global  |
|                                       | <b>Dynamic Variable</b>                 | Yes   |
| <b>Permitted Values (&lt;= 5.7.8)</b> | <b>Type</b>                             | string  |
|                                       | <b>Default</b>                          | <code>Antelope</code>                           |
|                                       | <b>Valid Values</b>                     | <code>Antelope</code><br><code>Barracuda</code> |
| <b>Permitted Values (&gt;= 5.7.9)</b> | <b>Type</b>                             | string  |
|                                       | <b>Default</b>                          | <code>Barracuda</code>                          |
|                                       | <b>Valid Values</b>                     | <code>Antelope</code><br><code>Barracuda</code> |

At server startup, InnoDB sets the value of this variable to the `file format` tag in the `system tablespace` (for example, `Antelope` or `Barracuda`). If the server creates or opens a table with a “higher” file format, it sets the value of `innodb_file_format_max` to that format.

The `innodb_file_format_max` option is deprecated in MySQL 5.7.7 together with the `innodb_file_format` option. Both options will be removed in a future release.

- `innodb_file_per_table`

|                            |                                      |                                    |
|----------------------------|--------------------------------------|------------------------------------|
| <b>Command-Line Format</b> | <code>--innodb_file_per_table</code> |                                    |
| <b>System Variable</b>     | <b>Name</b>                          | <code>innodb_file_per_table</code> |
|                            | <b>Variable Scope</b>                | Global                             |
|                            | <b>Dynamic Variable</b>              | Yes                                |
| <b>Permitted Values</b>    | <b>Type</b>                          | boolean                            |
|                            | <b>Default</b>                       | <code>ON</code>                    |

When `innodb_file_per_table` is enabled (the default in 5.6.6 and higher), InnoDB stores the data and indexes for each newly created table in a separate `.ibd` file, rather than in the system tablespace. The storage for these InnoDB tables is reclaimed when the tables are dropped or truncated. This setting enables several other InnoDB features, such as table `compression`. See [Section 15.7.4, “InnoDB File-Per-Table Tablespaces”](#) for details about such features as well as advantages and disadvantages of using per-table tablespaces.

Be aware that enabling `innodb_file_per_table` also means that an `ALTER TABLE` operation will move InnoDB table from the system tablespace to an individual `.ibd` file in cases where `ALTER TABLE` recreates the table (`ALGORITHM=COPY`). An exception to this rule is for tables that were placed in the system tablespace using the `TABLESPACE=innodb_system` option with `CREATE TABLE` or `ALTER TABLE`. These tables are unaffected by the `innodb_file_per_table` setting and can only be moved to file-per-table tablespaces using `ALTER TABLE ... TABLESPACE=innodb_file_per_table`.

When `innodb_file_per_table` is disabled, InnoDB stores the data for all tables and indexes in the `ibdata` files that make up the `system tablespace`. This setting reduces the performance overhead of filesystem operations for operations such as `DROP TABLE` or `TRUNCATE TABLE`. It is most appropriate for a server environment where entire storage devices are devoted to MySQL data. Because the system tablespace never shrinks, and is shared across all databases in an `instance`, avoid loading huge amounts of temporary data on a space-constrained system when `innodb_file_per_table=OFF`. Set up a separate instance in such cases, so that you can drop the entire instance to reclaim the space.

By default, `innodb_file_per_table` is enabled as of MySQL 5.6.6, disabled before that. Consider disabling it if backward compatibility with MySQL 5.5 or 5.1 is a concern. This will prevent `ALTER TABLE` from moving InnoDB tables from the system tablespace to individual `.ibd` files.

`innodb_file_per_table` is dynamic and can be set `ON` or `OFF` using `SET GLOBAL`. You can also set this parameter in the MySQL `configuration file` (`my.cnf` or `my.ini`) but this requires shutting down and restarting the server.

Dynamically changing the value of this parameter requires the `SUPER` privilege and immediately affects the operation of all connections.

- `innodb_fill_factor`

|                   |       |
|-------------------|-------|
| <b>Introduced</b> | 5.7.5 |
|-------------------|-------|

|                            |                                     |                                 |
|----------------------------|-------------------------------------|---------------------------------|
| <b>Command-Line Format</b> | <code>--innodb_fill_factor=#</code> |                                 |
| <b>System Variable</b>     | <b>Name</b>                         | <code>innodb_fill_factor</code> |
|                            | <b>Variable Scope</b>               | Global                          |
|                            | <b>Dynamic Variable</b>             | Yes                             |
| <b>Permitted Values</b>    | <b>Type</b>                         | integer                         |
|                            | <b>Default</b>                      | 100                             |
|                            | <b>Min Value</b>                    | 10                              |
|                            | <b>Max Value</b>                    | 100                             |

As of MySQL 5.7.5, `InnoDB` performs a bulk load when creating or rebuilding indexes. This method of index creation is known as a “sorted index build”.

`innodb_fill_factor` defines the percentage of space on each B-tree page that is filled during a sorted index build, with the remaining space reserved for future index growth. For example, setting `innodb_fill_factor` to 80 reserves 20 percent of the space on each B-tree page for future index growth. Actual percentages may vary. The `innodb_fill_factor` setting is interpreted as a hint rather than a hard limit.

As of MySQL 5.7.8, an `innodb_fill_factor` setting of 100 leaves 1/16 of the space in clustered index pages free for future index growth (MySQL Bug #74325).

`innodb_fill_factor` applies to both B-tree leaf and non-leaf pages. It does not apply to external pages used for `TEXT` or `BLOB` entries.

For more information, see [Section 15.8.12, “Sorted Index Builds”](#).

- `innodb_flush_log_at_timeout`

|                         |                         |  |
|-------------------------|-------------------------|--|
| <b>System Variable</b>  | <b>Name</b>             | <code>innodb_flush_log_at_timeout</code> |
|                         | <b>Variable Scope</b>   | Global                                   |
|                         | <b>Dynamic Variable</b> | Yes                                      |
| <b>Permitted Values</b> | <b>Type</b>             | integer                                  |
|                         | <b>Default</b>          | 1  |
|                         | <b>Min Value</b>        | 1  |
|                         | <b>Max Value</b>        | 2700                                     |

Write and flush the logs every *N* seconds. `innodb_flush_log_at_timeout` was introduced in MySQL 5.6.6. It allows the timeout period between flushes to be increased in order to reduce flushing and avoid impacting performance of binary log group commit. Prior to MySQL 5.6.6, flushing frequency was once per second. The default setting for `innodb_flush_log_at_timeout` is also once per second.

- `innodb_flush_log_at_trx_commit`

|                            |   |
|----------------------------|---|
| <b>Command-Line Format</b> | <code>--innodb_flush_log_at_trx_commit[=#]</code> |
|----------------------------|---|

|                         |                         |   |
|-------------------------|-------------------------|---|
| <b>System Variable</b>  | <b>Name</b>             | <code>innodb_flush_log_at_trx_commit</code> |
|                         | <b>Variable Scope</b>   | Global                                      |
|                         | <b>Dynamic Variable</b> | Yes   |
| <b>Permitted Values</b> | <b>Type</b>             | enumeration                                 |
|                         | <b>Default</b>          | 1   |
|                         | <b>Valid Values</b>     | 0   |
|                         |                         | 1   |
|                         |                         | 2   |

Controls the balance between strict [ACID](#) compliance for [commit](#) operations, and higher performance that is possible when commit-related I/O operations are rearranged and done in batches. You can achieve better performance by changing the default value, but then you can lose up to a second of transactions in a crash.

- The default value of 1 is required for full ACID compliance. With this value, the contents of the [InnoDB log buffer](#) are written out to the [log file](#) at each transaction commit and the log file is [flushed](#) to disk.
- With a value of 0, the contents of the [InnoDB log buffer](#) are written to the log file approximately once per second and the log file is flushed to disk. No writes from the log buffer to the log file are performed at transaction commit. Once-per-second flushing is not 100% guaranteed to happen every second, due to process scheduling issues. Because the flush to disk operation only occurs approximately once per second, you can lose up to a second of transactions with any [mysqld](#) process crash.
- With a value of 2, the contents of the [InnoDB log buffer](#) are written to the log file after each transaction commit and the log file is flushed to disk approximately once per second. Once-per-second flushing is not 100% guaranteed to happen every second, due to process scheduling issues. Because the flush to disk operation only occurs approximately once per second, you can lose up to a second of transactions in an operating system crash or a power outage.
- As of MySQL 5.6.6, [InnoDB log flushing frequency](#) is controlled by [innodb\\_flush\\_log\\_at\\_timeout](#), which allows you to set log flushing frequency to *N* seconds (where *N* is 1 ... 2700, with a default value of 1). However, any [mysqld](#) process crash can erase up to *N* seconds of transactions.
- DDL changes and other internal [InnoDB](#) activities flush the [InnoDB log](#) independent of the [innodb\\_flush\\_log\\_at\\_trx\\_commit](#) setting.
- [InnoDB's crash recovery](#) works regardless of the [innodb\\_flush\\_log\\_at\\_trx\\_commit](#) setting. Transactions are either applied entirely or erased entirely.

For durability and consistency in a replication setup that uses [InnoDB](#) with transactions:

- If binary logging is enabled, set [sync\\_binlog=1](#).
- Always set [innodb\\_flush\\_log\\_at\\_trx\\_commit=1](#).

### Caution

Many operating systems and some disk hardware fool the flush-to-disk operation. They may tell [mysqld](#) that the flush has taken place, even though it has not. Then the durability of transactions is not guaranteed even with the setting 1, and in the worst case a power outage can even corrupt [InnoDB](#) data. Using a battery-backed disk cache in the SCSI disk controller or in the

disk itself speeds up file flushes, and makes the operation safer. You can also try using the Unix command `hdparm` to disable the caching of disk writes in hardware caches, or use some other command specific to the hardware vendor.

- `innodb_flush_method`

|                                   |   |                                  |
|-----------------------------------|---|----------------------------------|
| <b>Command-Line Format</b>        | <code>--innodb_flush_method=name</code> |                                  |
| <b>System Variable</b>            | <b>Name</b>                             | <code>innodb_flush_method</code> |
|                                   | <b>Variable Scope</b>                   | Global                           |
|                                   | <b>Dynamic Variable</b>                 | No                               |
| <b>Permitted Values (Unix)</b>    | <b>Type</b>                             | string                           |
|                                   | <b>Default</b>                          | <code>NULL</code>                |
|                                   | <b>Valid Values</b>                     | <code>fsync</code>               |
|                                   |   | <code>O_DSYNC</code>             |
|                                   |   | <code>littlesync</code>          |
|                                   |   | <code>nosync</code>              |
|                                   |   | <code>O_DIRECT</code>            |
|                                   |   | <code>O_DIRECT_NO_FSYNC</code>   |
| <b>Permitted Values (Windows)</b> | <b>Type</b>                             | string                           |
|                                   | <b>Default</b>                          | <code>NULL</code>                |
|                                   | <b>Valid Values</b>                     | <code>async_unbuffered</code>    |
|                                   |   | <code>normal</code>              |
|                                   |   | <code>unbuffered</code>          |

Defines the method used to **flush** data to the **InnoDB data files** and **log files**, which can affect I/O throughput.

If `innodb_flush_method=NULL` on a Unix-like system, the `fsync` option is used by default. If `innodb_flush_method=NULL` on Windows, the `async_unbuffered` option is used by default.

The `innodb_flush_method` options for Unix-like systems include:

- **`fsync`:** InnoDB uses the `fsync()` system call to flush both the data and log files. `fsync` is the default setting.
- **`O_DSYNC`:** InnoDB uses `O_SYNC` to open and flush the log files, and `fsync()` to flush the data files. InnoDB does not use `O_DSYNC` directly because there have been problems with it on many varieties of Unix.
- **`littlesync`:** This option is used for internal performance testing and is currently unsupported. Use at your own risk.
- **`nosync`:** This option is used for internal performance testing and is currently unsupported. Use at your own risk.
- **`O_DIRECT`:** InnoDB uses `O_DIRECT` (or `directio()` on Solaris) to open the data files, and uses `fsync()` to flush both the data and log files. This option is available on some GNU/Linux versions, FreeBSD, and Solaris.

- **O\_DIRECT\_NO\_FSYNC**: InnoDB uses **O\_DIRECT** during flushing I/O, but skips the `fsync()` system call afterward. This setting is suitable for some types of file systems but not others. For example, it is not suitable for XFS. If you are not sure whether the file system you use requires an `fsync()`, for example to preserve all file metadata, use **O\_DIRECT** instead. This option was introduced in MySQL 5.6.7 (Bug #11754304, Bug #45892).

The `innodb_flush_method` options for Windows systems include:

- **async\_unbuffered**: InnoDB uses Windows asynchronous I/O and non-buffered I/O. `async_unbuffered` is the default setting on Windows systems.
- **normal**: InnoDB uses a simulated asynchronous I/O and buffered I/O.
- **unbuffered**: InnoDB uses a simulated asynchronous I/O and non-buffered I/O.

How each settings affects performance depends on hardware configuration and workload. Benchmark your particular configuration to decide which setting to use, or whether to keep the default setting. Examine the `InnoDB_data_fsyncs` status variable to see the overall number of `fsync()` calls for each setting. The mix of read and write operations in your workload can affect how a setting performs. For example, on a system with a hardware RAID controller and battery-backed write cache, **O\_DIRECT** can help to avoid double buffering between the InnoDB buffer pool and the operating system's file system cache. On some systems where InnoDB data and log files are located on a SAN, the default value or **O\_DSYNC** might be faster for a read-heavy workload with mostly `SELECT` statements. Always test this parameter with hardware and workload that reflect your production environment. For general I/O tuning advice, see [Section 9.5.8, “Optimizing InnoDB Disk I/O”](#).

- `innodb_flush_neighbors`

|                            |                                       |                                     |
|----------------------------|---------------------------------------|-------------------------------------|
| <b>Command-Line Format</b> | <code>--innodb_flush_neighbors</code> |                                     |
| <b>System Variable</b>     | <b>Name</b>                           | <code>innodb_flush_neighbors</code> |
|                            | <b>Variable Scope</b>                 | Global                              |
|                            | <b>Dynamic Variable</b>               | Yes                                 |
| <b>Permitted Values</b>    | <b>Type</b>                           | enumeration                         |
|                            | <b>Default</b>                        | 1                                   |
|                            | <b>Valid Values</b>                   | 0                                   |
|                            |                                       | 1                                   |
|                            |                                       | 2                                   |

Specifies whether **flushing** a page from the InnoDB **buffer pool** also flushes other **dirty pages** in the same **extent**.

- The default value of 1 flushes contiguous dirty pages in the same extent from the buffer pool.
- A setting of 0 turns `innodb_flush_neighbors` off and no other dirty pages are flushed from the buffer pool.
- A setting of 2 flushes dirty pages in the same extent from the buffer pool.

When the table data is stored on a traditional **HDD** storage device, flushing such **neighbor pages** in one operation reduces I/O overhead (primarily for disk seek operations) compared to flushing individual pages at different times. For table data stored on **SSD**, seek time is not a significant factor and you can turn this setting off to spread out the write operations. For general I/O tuning advice, see [Section 9.5.8, “Optimizing InnoDB Disk I/O”](#).

- `innodb_flush_sync`

|                            |                                    |                                |
|----------------------------|------------------------------------|--------------------------------|
| <b>Introduced</b>          | 5.7.8                              |                                |
| <b>Command-Line Format</b> | <code>--innodb_flush_sync=#</code> |                                |
| <b>System Variable</b>     | <b>Name</b>                        | <code>innodb_flush_sync</code> |
|                            | <b>Variable Scope</b>              | Global                         |
|                            | <b>Dynamic Variable</b>            | Yes                            |
| <b>Permitted Values</b>    | <b>Type</b>                        | boolean                        |
|                            | <b>Default</b>                     | ON                             |

The `innodb_flush_sync` parameter, which is enabled by default, causes the `innodb_io_capacity` setting to be ignored for bursts of I/O activity that occur at [checkpoints](#). To adhere to the limit on InnoDB background I/O activity defined by the `innodb_io_capacity` setting, disable `innodb_flush_sync`.

- `innodb_flushing_avg_loops`

|                            |  |  |
|----------------------------|--|--|
| <b>Command-Line Format</b> | <code>--innodb_flushing_avg_loops=#</code> |  |
| <b>System Variable</b>     | <b>Name</b>                                | <code>innodb_flushing_avg_loops</code> |
|                            | <b>Variable Scope</b>                      | Global                                 |
|                            | <b>Dynamic Variable</b>                    | Yes                                    |
| <b>Permitted Values</b>    | <b>Type</b>                                | integer                                |
|                            | <b>Default</b>                             | 30                                     |
|                            | <b>Min Value</b>                           | 1                                      |
|                            | <b>Max Value</b>                           | 1000                                   |

Number of iterations for which InnoDB keeps the previously calculated snapshot of the flushing state, controlling how quickly [adaptive flushing](#) responds to changing [workloads](#). Increasing the value makes the rate of [flush](#) operations change smoothly and gradually as the workload changes. Decreasing the value makes adaptive flushing adjust quickly to workload changes, which can cause spikes in flushing activity if the workload increases and decreases suddenly.

- `innodb_force_load_corrupted`

|                            |  |  |
|----------------------------|--|--|
| <b>Command-Line Format</b> | <code>--innodb_force_load_corrupted</code> |  |
| <b>System Variable</b>     | <b>Name</b>                                | <code>innodb_force_load_corrupted</code> |
|                            | <b>Variable Scope</b>                      | Global                                   |
|                            | <b>Dynamic Variable</b>                    | No                                       |
| <b>Permitted Values</b>    | <b>Type</b>                                | boolean                                  |
|                            | <b>Default</b>                             | OFF                                      |

Lets InnoDB load tables at startup that are marked as corrupted. Use only during troubleshooting, to recover data that is otherwise inaccessible. When troubleshooting is complete, turn this setting back off and restart the server.

- `innodb_force_recovery`

|                            |  |                                    |
|----------------------------|--|------------------------------------|
| <b>Command-Line Format</b> | <code>--innodb_force_recovery=#</code> |                                    |
| <b>System Variable</b>     | <b>Name</b>                            | <code>innodb_force_recovery</code> |
|                            | <b>Variable Scope</b>                  | Global                             |
|                            | <b>Dynamic Variable</b>                | No                                 |
| <b>Permitted Values</b>    | <b>Type</b>                            | integer                            |
|                            | <b>Default</b>                         | 0                                  |
|                            | <b>Min Value</b>                       | 0                                  |
|                            | <b>Max Value</b>                       | 6                                  |

The `crash recovery` mode, typically only changed in serious troubleshooting situations. Possible values are from 0 to 6. For the meanings of these values and important information about `innodb_force_recovery`, see [Section 15.21.2, “Forcing InnoDB Recovery”](#).

#### Warning

Only set this variable to a value greater than 0 in an emergency situation, so that you can start InnoDB and dump your tables. As a safety measure, InnoDB prevents `INSERT`, `UPDATE`, or `DELETE` operations when `innodb_force_recovery` is greater than 0. Also, as of 5.7.3, an `innodb_force_recovery` setting of 4 or greater places InnoDB into read-only mode.

These restrictions may cause replication administration commands to fail with an error, as replication options such as `--relay-log-info-repository=TABLE` and `--master-info-repository=TABLE` store information in tables in InnoDB.

- `innodb_ft_aux_table`

|                            |   |                                  |
|----------------------------|---|----------------------------------|
| <b>Command-Line Format</b> | <code>--innodb_ft_aux_table=#</code> ( $\geq 5.7.2$ ) |                                  |
| <b>System Variable</b>     | <b>Name</b>   | <code>innodb_ft_aux_table</code> |
|                            | <b>Variable Scope</b>                                 | Global                           |
|                            | <b>Dynamic Variable</b>                               | Yes                              |
| <b>Permitted Values</b>    | <b>Type</b>   | string                           |

Specifies the qualified name of an InnoDB table containing a `FULLTEXT` index. This variable is intended for diagnostic purposes.

After you set this variable to a name in the format `db_name/table_name`, the `INFORMATION_SCHEMA` tables `INNODB_FT_INDEX_TABLE`, `INNODB_FT_INDEX_CACHE`, `INNODB_FT_CONFIG`, `INNODB_FT_DELETED`, and `INNODB_FT_BEING_DELETED` will show information about the search index for the specified table.

- `innodb_ft_cache_size`

|                            |                                       |                                   |
|----------------------------|---------------------------------------|-----------------------------------|
| <b>Command-Line Format</b> | <code>--innodb_ft_cache_size=#</code> |                                   |
| <b>System Variable</b>     | <b>Name</b>                           | <code>innodb_ft_cache_size</code> |
|                            | <b>Variable Scope</b>                 | Global                            |
|                            | <b>Dynamic Variable</b>               | No                                |
| <b>Permitted Values</b>    | <b>Type</b>                           | integer                           |
|                            | <b>Default</b>                        | 8000000                           |
|                            | <b>Min Value</b>                      | 1600000                           |
|                            | <b>Max Value</b>                      | 80000000                          |

The memory allocated, in bytes, for the `InnoDB FULLTEXT` search index cache, which holds a parsed document in memory while creating an `InnoDB FULLTEXT` index. Index inserts and updates are only committed to disk when the `innodb_ft_cache_size` size limit is reached. `innodb_ft_cache_size` defines the cache size on a per table basis. To set a global limit for all tables, see `innodb_ft_total_cache_size`.

- `innodb_ft_enable_diag_print`

|                            |  |  |
|----------------------------|--|--|
| <b>Command-Line Format</b> | <code>--innodb_ft_enable_diag_print=#</code> |  |
| <b>System Variable</b>     | <b>Name</b>                                  | <code>innodb_ft_enable_diag_print</code> |
|                            | <b>Variable Scope</b>                        | Global                                   |
|                            | <b>Dynamic Variable</b>                      | Yes                                      |
| <b>Permitted Values</b>    | <b>Type</b>                                  | boolean                                  |
|                            | <b>Default</b>                               | OFF                                      |

Whether to enable additional full-text search (FTS) diagnostic output. This option is primarily intended for advanced FTS debugging and will not be of interest to most users. Output is printed to the error log and includes information such as:

- FTS index sync progress (when the FTS cache limit is reached). For example:

```
FTS SYNC for table test, deleted count: 100 size: 10000 bytes
SYNC words: 100
```

- FTS optimize progress. For example:

```
FTS start optimize test
FTS_OPTIMIZE: optimize "mysql"
FTS_OPTIMIZE: processed "mysql"
```

- FTS index build progress. For example:

```
Number of doc processed: 1000
```

- For FTS queries, the query parsing tree, word weight, query processing time, and memory usage are printed. For example:

```
FTS Search Processing time: 1 secs: 100 millisec: row(s) 10000
Full Search Memory: 245666 (bytes), Row: 10000
```

- `innodb_ft_enable_stopword`

|                            |  |  |
|----------------------------|--|--|
| <b>Command-Line Format</b> | <code>--innodb_ft_enable_stopword=#</code> |  |
| <b>System Variable</b>     | <b>Name</b>                                | <code>innodb_ft_enable_stopword</code> |
|                            | <b>Variable Scope</b>                      | Global                                 |
|                            | <b>Dynamic Variable</b>                    | Yes                                    |
| <b>Permitted Values</b>    | <b>Type</b>                                | boolean                                |
|                            | <b>Default</b>                             | ON                                     |

Specifies that a set of `stopwords` is associated with an InnoDB `FULLTEXT` index at the time the index is created. If the `innodb_ft_user_stopword_table` option is set, the stopwords are taken from that table. Else, if the `innodb_ft_server_stopword_table` option is set, the stopwords are taken from that table. Otherwise, a built-in set of default stopwords is used.

- `innodb_ft_max_token_size`

|                                       |   |                                       |
|---------------------------------------|---|---------------------------------------|
| <b>Command-Line Format</b>            | <code>--innodb_ft_max_token_size=#</code> |                                       |
| <b>System Variable</b>                | <b>Name</b>                               | <code>innodb_ft_max_token_size</code> |
|                                       | <b>Variable Scope</b>                     | Global                                |
|                                       | <b>Dynamic Variable</b>                   | No                                    |
| <b>Permitted Values</b>               | <b>Type</b>                               | integer                               |
|                                       | <b>Default</b>                            | 84                                    |
|                                       | <b>Min Value</b>                          | 10                                    |
|                                       | <b>Max Value</b>                          | 84                                    |
| <b>Permitted Values (&lt;= 5.7.2)</b> | <b>Type</b>                               | integer                               |
|                                       | <b>Default</b>                            | 84                                    |
|                                       | <b>Min Value</b>                          | 10                                    |
|                                       | <b>Max Value</b>                          | 252                                   |
| <b>Permitted Values (&gt;= 5.7.3)</b> | <b>Type</b>                               | integer                               |
|                                       | <b>Default</b>                            | 84                                    |
|                                       | <b>Min Value</b>                          | 10                                    |
|                                       | <b>Max Value</b>                          | 84                                    |

Maximum character length of words that are stored in an InnoDB `FULLTEXT` index. Setting a limit on this value reduces the size of the index, thus speeding up queries, by omitting long keywords or arbitrary collections of letters that are not real words and are not likely to be search terms.

- `innodb_ft_min_token_size`

|                            |   |                                       |
|----------------------------|---|---------------------------------------|
| <b>Command-Line Format</b> | <code>--innodb_ft_min_token_size=#</code> |                                       |
| <b>System Variable</b>     | <b>Name</b>                               | <code>innodb_ft_min_token_size</code> |
|                            | <b>Variable Scope</b>                     | Global                                |
|                            | <b>Dynamic Variable</b>                   | No                                    |
| <b>Permitted Values</b>    | <b>Type</b>                               | integer                               |
|                            | <b>Default</b>                            | 3                                     |
|                            | <b>Min Value</b>                          | 0                                     |
|                            | <b>Max Value</b>                          | 16                                    |

Minimum length of words that are stored in an InnoDB `FULLTEXT` index. Increasing this value reduces the size of the index, thus speeding up queries, by omitting common word that are unlikely to be significant in a search context, such as the English words “a” and “to”. For content using a CJK (Chinese, Japanese, Korean) character set, specify a value of 1.

- `innodb_ft_num_word_optimize`

|                            |  |  |
|----------------------------|--|--|
| <b>Command-Line Format</b> | <code>--innodb_ft_num_word_optimize=#</code> |  |
| <b>System Variable</b>     | <b>Name</b>                                  | <code>innodb_ft_num_word_optimize</code> |
|                            | <b>Variable Scope</b>                        | Global                                   |
|                            | <b>Dynamic Variable</b>                      | Yes                                      |
| <b>Permitted Values</b>    | <b>Type</b>                                  | integer                                  |
|                            | <b>Default</b>                               | 2000                                     |

Number of words to process during each `OPTIMIZE TABLE` operation on an InnoDB `FULLTEXT` index. Because a bulk insert or update operation to a table containing a full-text search index could require substantial index maintenance to incorporate all changes, you might do a series of `OPTIMIZE TABLE` statements, each picking up where the last left off.

- `innodb_ft_result_cache_limit`

|                                       |   |   |
|---------------------------------------|---|---|
| <b>Introduced</b>                     | 5.7.2   |   |
| <b>Command-Line Format</b>            | <code>--innodb_ft_result_cache_limit=#</code> |   |
| <b>System Variable</b>                | <b>Name</b>                                   | <code>innodb_ft_result_cache_limit</code> |
|                                       | <b>Variable Scope</b>                         | Global                                    |
|                                       | <b>Dynamic Variable</b>                       | Yes                                       |
| <b>Permitted Values (&gt;= 5.7.4)</b> | <b>Type</b>                                   | integer                                   |
|                                       | <b>Default</b>                                | 2000000000                                |
|                                       | <b>Min Value</b>                              | 1000000                                   |
|                                       | <b>Max Value</b>                              | $2^{32}-1$                                |

|  |                  |            |
|--|------------------|------------|
| <b>Permitted Values</b> (Unix, 32-bit platforms, >= 5.7.2, <= 5.7.3) | <b>Type</b>      | integer    |
|  | <b>Default</b>   | 2000000000 |
|  | <b>Min Value</b> | 1000000    |
|  | <b>Max Value</b> | 2**32-1    |
| <b>Permitted Values</b> (Unix, 64-bit platforms, >= 5.7.2, <= 5.7.3) | <b>Type</b>      | integer    |
|  | <b>Default</b>   | 2000000000 |
|  | <b>Min Value</b> | 1000000    |
|  | <b>Max Value</b> | 2**64-1    |
| <b>Permitted Values</b> (Windows, >= 5.7.2, <= 5.7.3)                | <b>Type</b>      | integer    |
|  | <b>Default</b>   | 2000000000 |
|  | <b>Min Value</b> | 1000000    |
|  | <b>Max Value</b> | 2**32-1    |

The [InnoDB FULLTEXT](#) search (FTS) query result cache limit (defined in bytes) per FTS query or per thread. Intermediate and final [InnoDB](#) FTS query results are handled in memory. Use [innodb\\_ft\\_result\\_cache\\_limit](#) to place a size limit on the [InnoDB](#) FTS query result cache to avoid excessive memory consumption in case of very large [InnoDB](#) FTS query results (millions or hundreds of millions of rows, for example). Memory is allocated as required when an FTS query is processed. If the result cache size limit is reached, an error is returned indicating that the query exceeds the maximum allowed memory.

As of MySQL 5.7.4, the maximum value of [innodb\\_ft\\_result\\_cache\\_limit](#) for all platform types and platform bit sizes is 2\*\*32-1. Bug #71554.

- [innodb\\_ft\\_server\\_stopword\\_table](#)

|                            |  |   |
|----------------------------|--|---|
| <b>Command-Line Format</b> | <a href="#">--innodb_ft_server_stopword_table=db_name/table_name</a> |   |
| <b>System Variable</b>     | <b>Name</b>  | <a href="#">innodb_ft_server_stopword_table</a> |
|                            | <b>Variable Scope</b>  | Global  |
|                            | <b>Dynamic Variable</b>  | Yes   |
| <b>Permitted Values</b>    | <b>Type</b>  | string  |
|                            | <b>Default</b>   | NULL  |

This option is used to specify your own [InnoDB FULLTEXT](#) index stopwords list for all [InnoDB](#) tables. To configure your own stopwords list for a specific [InnoDB](#) table, use [innodb\\_ft\\_user\\_stopword\\_table](#).

Set [innodb\\_ft\\_server\\_stopword\\_table](#) to the name of the table containing a list of stopwords, in the format [db\\_name/table\\_name](#).

The stopwords table must exist before you configure [innodb\\_ft\\_server\\_stopword\\_table](#). [innodb\\_ft\\_enable\\_stopword](#) must be enabled and [innodb\\_ft\\_server\\_stopword\\_table](#) option must be configured before you create the [FULLTEXT](#) index.

The stopword table must be an [InnoDB](#) table, containing a single [VARCHAR](#) column named `value`.

For more information, see [Section 13.9.4, “Full-Text Stopwords”](#).

- `innodb_ft_sort_pll_degree`

|                            |  |  |
|----------------------------|--|--|
| <b>Command-Line Format</b> | <code>--innodb_ft_sort_pll_degree=#</code> |  |
| <b>System Variable</b>     | <b>Name</b>                                | <code>innodb_ft_sort_pll_degree</code> |
|                            | <b>Variable Scope</b>                      | Global                                 |
|                            | <b>Dynamic Variable</b>                    | No                                     |
| <b>Permitted Values</b>    | <b>Type</b>                                | integer                                |
|                            | <b>Default</b>                             | 2                                      |
|                            | <b>Min Value</b>                           | 1                                      |
|                            | <b>Max Value</b>                           | 32                                     |

Number of threads used in parallel to index and tokenize text in an [InnoDB FULLTEXT](#) index, when building a [search index](#). See `innodb_sort_buffer_size` for additional usage information.

- `innodb_ft_total_cache_size`

|                            |   |   |
|----------------------------|---|---|
| <b>Introduced</b>          | 5.7.2                                       |   |
| <b>Command-Line Format</b> | <code>--innodb_ft_total_cache_size=#</code> |   |
| <b>System Variable</b>     | <b>Name</b>                                 | <code>innodb_ft_total_cache_size</code> |
|                            | <b>Variable Scope</b>                       | Global                                  |
|                            | <b>Dynamic Variable</b>                     | No                                      |
| <b>Permitted Values</b>    | <b>Type</b>                                 | integer                                 |
|                            | <b>Default</b>                              | 640000000                               |
|                            | <b>Min Value</b>                            | 32000000                                |
|                            | <b>Max Value</b>                            | 1600000000                              |

The total memory allocated, in bytes, for the [InnoDB FULLTEXT](#) search index cache for all tables. Creating numerous tables, each with a full-text search index, could consume a significant portion of available memory. `innodb_ft_total_cache_size`, defines a global memory limit for all full-text search indexes to help avoid excessive memory consumption. If the global limit is reached by an index operation, a force sync is triggered.

- `innodb_ft_user_stopword_table`

|                            |   |  |
|----------------------------|---|--|
| <b>Command-Line Format</b> | <code>--innodb_ft_user_stopword_table=db_name/table_name</code> |  |
| <b>System Variable</b>     | <b>Name</b>   | <code>innodb_ft_user_stopword_table</code> |
|                            | <b>Variable Scope</b>   | Global, Session                            |

|                         |                         |        |
|-------------------------|-------------------------|--------|
|                         | <b>Dynamic Variable</b> | Yes    |
| <b>Permitted Values</b> | <b>Type</b>             | string |
|                         | <b>Default</b>          | NULL   |

This option is used to specify your own [InnoDB FULLTEXT](#) index stopwords list on a specific table. To configure your own stopwords list for all [InnoDB](#) tables, use [innodb\\_ft\\_server\\_stopword\\_table](#).

Set [innodb\\_ft\\_user\\_stopword\\_table](#) to the name of the table containing a list of stopwords, in the format *db\_name/table\_name*.

The stopwords table must exist before you configure [innodb\\_ft\\_user\\_stopword\\_table](#). [innodb\\_ft\\_enable\\_stopword](#) must be enabled and [innodb\\_ft\\_user\\_stopword\\_table](#) must be configured before you create the [FULLTEXT](#) index.

The stopwords table must be an [InnoDB](#) table, containing a single [VARCHAR](#) column named *value*.

For more information, see [Section 13.9.4, “Full-Text Stopwords”](#).

- [innodb\\_io\\_capacity](#)

|  |                                     |                                    |
|--|-------------------------------------|------------------------------------|
| <b>Command-Line Format</b>                 | <code>--innodb_io_capacity=#</code> |                                    |
| <b>System Variable</b>                     | <b>Name</b>                         | <a href="#">innodb_io_capacity</a> |
|  | <b>Variable Scope</b>               | Global                             |
|  | <b>Dynamic Variable</b>             | Yes                                |
| <b>Permitted Values</b> (32-bit platforms) | <b>Type</b>                         | integer                            |
|  | <b>Default</b>                      | <a href="#">200</a>                |
|  | <b>Min Value</b>                    | <a href="#">100</a>                |
|  | <b>Max Value</b>                    | <a href="#">2**32-1</a>            |
| <b>Permitted Values</b> (64-bit platforms) | <b>Type</b>                         | integer                            |
|  | <b>Default</b>                      | <a href="#">200</a>                |
|  | <b>Min Value</b>                    | <a href="#">100</a>                |
|  | <b>Max Value</b>                    | <a href="#">2**64-1</a>            |

The [innodb\\_io\\_capacity](#) parameter sets an upper limit on I/O activity performed by [InnoDB](#) background tasks, such as [flushing](#) pages from the [buffer pool](#) and merging data from the [change buffer](#).

The [innodb\\_io\\_capacity](#) limit is a total limit for all buffer pool instances. When dirty pages are flushed, the limit is divided equally among buffer pool instances.

[innodb\\_io\\_capacity](#) should be set to approximately the number of I/O operations that the system can perform per second. Ideally, keep the setting as low as practical, but not so low that background activities fall behind. If the value is too high, data is removed from the buffer pool and insert buffer too quickly for caching to provide a significant benefit.

The default value is 200. For busy systems capable of higher I/O rates, you can set a higher value to help the server handle the background maintenance work associated with a high rate of row changes.

In general, you can increase the value as a function of the number of drives used for InnoDB I/O. For example, you can increase the value on systems that use multiple disks or solid-state disks (SSD).

The default setting of 200 is generally sufficient for a lower-end SSD. For a higher-end, bus-attached SSD, consider a higher setting such as 1000, for example. For systems with individual 5400 RPM or 7200 RPM drives, you might lower the value to 100, which represents an estimated proportion of the I/O operations per second (IOPS) available to older-generation disk drives that could perform about 100 IOPS.

Although you can specify a very high value such as one million, in practice such large values have little if any benefit. Generally, a value of 20000 or higher is not recommended unless you have proven that lower values are insufficient for your workload.

Consider write workload when tuning `innodb_io_capacity`. Systems with large write workloads are likely to benefit from a higher setting. A lower setting may be sufficient for systems with a small write workload.

You can set `innodb_io_capacity` to any number 100 or greater to a maximum defined by `innodb_io_capacity_max`. `innodb_io_capacity` can be set in the MySQL option file (`my.cnf` or `my.ini`) or changed dynamically using a `SET GLOBAL` statement, which requires the `SUPER` privilege.

The `innodb_flush_sync` configuration option, introduced in MySQL 5.7.8, causes the `innodb_io_capacity` setting to be ignored during bursts of I/O activity that occur at checkpoints. `innodb_flush_sync` is enabled by default.

See [Section 15.6.8, “Configuring the InnoDB Master Thread I/O Rate”](#) for more guidelines about this option. For general information about InnoDB I/O performance, see [Section 9.5.8, “Optimizing InnoDB Disk I/O”](#).

- `innodb_io_capacity_max`

|  |   |                                     |
|--|---|-------------------------------------|
| <b>Command-Line Format</b>                       | <code>--innodb_io_capacity_max=#</code> |                                     |
| <b>System Variable</b>                           | <b>Name</b>                             | <code>innodb_io_capacity_max</code> |
|  | <b>Variable Scope</b>                   | Global                              |
|  | <b>Dynamic Variable</b>                 | Yes                                 |
| <b>Permitted Values</b> (32-bit platforms)       | <b>Type</b>                             | integer                             |
|  | <b>Default</b>                          | <a href="#">see description</a>     |
|  | <b>Min Value</b>                        | 100                                 |
|  | <b>Max Value</b>                        | $2^{32}-1$                          |
| <b>Permitted Values</b> (Unix, 64-bit platforms) | <b>Type</b>                             | integer                             |
|  | <b>Default</b>                          | <a href="#">see description</a>     |
|  | <b>Min Value</b>                        | 100                                 |

|  |                  |                 |
|--|------------------|-----------------|
|  | <b>Max Value</b> | 2**64-1         |
| <b>Permitted Values</b><br>(Windows, 64-bit platforms) | <b>Type</b>      | integer         |
|  | <b>Default</b>   | see description |
|  | <b>Min Value</b> | 100             |
|  | <b>Max Value</b> | 2**32-1         |

If flushing activity falls behind, InnoDB can flush more aggressively than the limit imposed by `innodb_io_capacity`. `innodb_io_capacity_max` defines an upper limit for I/O capacity in such situations.

The `innodb_io_capacity_max` setting is a total limit for all buffer pool instances.

If you specify an `innodb_io_capacity` setting at startup but do not specify a value for `innodb_io_capacity_max`, `innodb_io_capacity_max` defaults to twice the value of `innodb_io_capacity`, with a minimum value of 2000.

When configuring `innodb_io_capacity_max`, twice the `innodb_io_capacity` is often a good starting point. The default value of 2000 is intended for workloads that use a solid-state disk (SSD) or more than one regular disk drive. A setting of 2000 is likely too high for workloads that do not use SSD or multiple disk drives, and could allow too much flushing. For a single regular disk drive, a setting between 200 and 400 is recommended. For a high-end, bus-attached SSD, consider a higher setting such as 2500. As with the `innodb_io_capacity` setting, keep the setting as low as practical, but not so low that InnoDB cannot sufficiently extend beyond the `innodb_io_capacity` limit if necessary.

Consider write workload when tuning `innodb_io_capacity_max`. Systems with large write workloads may benefit from a higher setting. A lower setting may be sufficient for systems with a small write workload.

`innodb_io_capacity_max` cannot be set to a value lower than the `innodb_io_capacity` value.

Setting `innodb_io_capacity_max` to `DEFAULT` using a `SET` statement (`SET GLOBAL innodb_io_capacity_max=DEFAULT`) sets `innodb_io_capacity_max` to the maximum value.

For a brief period during MySQL 5.6 development, this variable was known as `innodb_max_io_capacity`.

For related information, see [Section 15.6.3.7, “Fine-tuning InnoDB Buffer Pool Flushing”](#).

- `innodb_large_prefix`

|                                       |                                    |                                  |

| <b>Command-Line Format</b>            | <code>--innodb_large_prefix</code> |                                  |
| <b>System Variable</b>                | <b>Name</b>                        | <code>innodb_large_prefix</code> |
|                                       | <b>Variable Scope</b>              | Global                           |
|                                       | <b>Dynamic Variable</b>            | Yes                              |
| <b>Permitted Values (&lt;= 5.7.6)</b> | <b>Type</b>                        | boolean                          |
|                                       | <b>Default</b>                     | <code>OFF</code>                 |
| <b>Permitted Values (&gt;= 5.7.7)</b> | <b>Type</b>                        | boolean                          |

|  |                |    |
|--|----------------|----|
|  | <b>Default</b> | ON |
|--|----------------|----|

When this option is enabled, index key prefixes longer than 767 bytes (up to 3072 bytes) are allowed for `InnoDB` tables that use the `DYNAMIC` and `COMPRESSED` row formats. See [Section 15.8.8, “Limits on InnoDB Tables”](#) for the relevant maximums associated with index key prefixes under various settings.

For tables that use the `REDUNDANT` and `COMPACT` row formats, this option does not affect the permitted index key prefix length.

`innodb_large_prefix` is enabled by default in MySQL 5.7.7. This change coincides with the default value change for `innodb_file_format`, which is set to `Barracuda` by default in MySQL 5.7.7. Together, these default value changes allow larger index key prefixes to be created when using `ROW_FORMAT=DYNAMIC` or `ROW_FORMAT=COMPRESSED`. If either option is set to a non-default value, index key prefixes larger than 767 bytes are silently truncated.

`innodb_large_prefix` is deprecated in MySQL 5.7.7 and will be removed in a future release. `innodb_large_prefix` was introduced in MySQL 5.5 to disable large index key prefixes for compatibility with earlier versions of `InnoDB` that do not support large index key prefixes.

- `innodb_limit_optimistic_insert_debug`

|                            |   |   |
|----------------------------|---|---|
| <b>Command-Line Format</b> | <code>--innodb_limit_optimistic_insert_debug=#</code> |   |
| <b>System Variable</b>     | <b>Name</b>   | <code>innodb_limit_optimistic_insert_debug</code> |
|                            | <b>Variable Scope</b>                                 | Global  |
|                            | <b>Dynamic Variable</b>                               | Yes   |
| <b>Permitted Values</b>    | <b>Type</b>   | integer   |
|                            | <b>Default</b>  | 0   |
|                            | <b>Min Value</b>                                      | 0   |
|                            | <b>Max Value</b>                                      | $2^{32}-1$  |

Limits the number of records per `B-tree` page. A default value of 0 means that no limit is imposed. This option is only available if debugging support is compiled in using the `WITH_DEBUG CMake` option.

- `innodb_lock_wait_timeout`

|                            |   |                                       |
|----------------------------|---|---------------------------------------|
| <b>Command-Line Format</b> | <code>--innodb_lock_wait_timeout=#</code> |                                       |
| <b>System Variable</b>     | <b>Name</b>                               | <code>innodb_lock_wait_timeout</code> |
|                            | <b>Variable Scope</b>                     | Global, Session                       |
|                            | <b>Dynamic Variable</b>                   | Yes                                   |
| <b>Permitted Values</b>    | <b>Type</b>                               | integer                               |
|                            | <b>Default</b>                            | 50                                    |
|                            | <b>Min Value</b>                          | 1                                     |
|                            | <b>Max Value</b>                          | 1073741824                            |

The length of time in seconds an [InnoDB transaction](#) waits for a [row lock](#) before giving up. The default value is 50 seconds. A transaction that tries to access a row that is locked by another [InnoDB](#) transaction waits at most this many seconds for write access to the row before issuing the following error:

```
ERROR 1205 (HY000): Lock wait timeout exceeded; try restarting transaction
```

When a lock wait timeout occurs, the current statement is [rolled back](#) (not the entire transaction). To have the entire transaction roll back, start the server with the `--innodb_rollback_on_timeout` option. See also [Section 15.21.4, “InnoDB Error Handling”](#).

You might decrease this value for highly interactive applications or [OLTP](#) systems, to display user feedback quickly or put the update into a queue for processing later. You might increase this value for long-running back-end operations, such as a transform step in a data warehouse that waits for other large insert or update operations to finish.

`innodb_lock_wait_timeout` applies to [InnoDB](#) row locks only. A MySQL [table lock](#) does not happen inside [InnoDB](#) and this timeout does not apply to waits for table locks.

The lock wait timeout value does not apply to [deadlocks](#) when `innodb_deadlock_detect` is enabled (the default) because [InnoDB](#) detects deadlocks immediately and rolls back one of the deadlocked transactions. When `innodb_deadlock_detect` is disabled, [InnoDB](#) relies on `innodb_lock_wait_timeout` for transaction rollback when a deadlock occurs.

`innodb_lock_wait_timeout` can be set at runtime with the `SET GLOBAL` or `SET SESSION` statement. Changing the `GLOBAL` setting requires the [SUPER](#) privilege and affects the operation of all clients that subsequently connect. Any client can change the `SESSION` setting for `innodb_lock_wait_timeout`, which affects only that client.

- [innodb\\_locks\\_unsafe\\_for\\_binlog](#)

|                            | <b>Default</b>                                | <code>OFF</code>                               |

This variable affects how [InnoDB](#) uses [gap locking](#) for searches and index scans. As of MySQL 5.6.3, `innodb_locks_unsafe_for_binlog` is deprecated and will be removed in a future MySQL release.

Normally, [InnoDB](#) uses an algorithm called next-key locking that combines index-row locking with [gap locking](#). [InnoDB](#) performs row-level locking in such a way that when it searches or scans a table index, it sets shared or exclusive locks on the index records it encounters. Thus, the row-level locks are actually index-record locks. In addition, a next-key lock on an index record also affects the “gap” before that index record. That is, a next-key lock is an index-record lock plus a gap lock on the gap preceding the index record. If one session has a shared or exclusive lock on record [R](#) in an index, another session cannot insert a new index record in the gap immediately before [R](#) in the index order. See [Section 15.5.1, “InnoDB Locking”](#).

By default, the value of `innodb_locks_unsafe_for_binlog` is 0 (disabled), which means that gap locking is enabled: InnoDB uses next-key locks for searches and index scans. To enable the variable, set it to 1. This causes gap locking to be disabled: InnoDB uses only index-record locks for searches and index scans.

Enabling `innodb_locks_unsafe_for_binlog` does not disable the use of gap locking for foreign-key constraint checking or duplicate-key checking.

The effects of enabling `innodb_locks_unsafe_for_binlog` are the same as setting the transaction isolation level to `READ COMMITTED`, with these exceptions:

- Enabling `innodb_locks_unsafe_for_binlog` is a global setting and affects all sessions, whereas the isolation level can be set globally for all sessions, or individually per session.
- `innodb_locks_unsafe_for_binlog` can be set only at server startup, whereas the isolation level can be set at startup or changed at runtime.

`READ COMMITTED` therefore offers finer and more flexible control than `innodb_locks_unsafe_for_binlog`. For additional details about the effect of isolation level on gap locking, see [Section 15.5.2.1, “Transaction Isolation Levels”](#).

Enabling `innodb_locks_unsafe_for_binlog` may cause phantom problems because other sessions can insert new rows into the gaps when gap locking is disabled. Suppose that there is an index on the `id` column of the `child` table and that you want to read and lock all rows from the table having an identifier value larger than 100, with the intention of updating some column in the selected rows later:

```
SELECT * FROM child WHERE id > 100 FOR UPDATE;
```

The query scans the index starting from the first record where `id` is greater than 100. If the locks set on the index records in that range do not lock out inserts made in the gaps, another session can insert a new row into the table. Consequently, if you were to execute the same `SELECT` again within the same transaction, you would see a new row in the result set returned by the query. This also means that if new items are added to the database, InnoDB does not guarantee serializability. Therefore, if `innodb_locks_unsafe_for_binlog` is enabled, InnoDB guarantees at most an isolation level of `READ COMMITTED`. (Conflict serializability is still guaranteed.) For additional information about phantoms, see [Section 15.5.4, “Phantom Rows”](#).

Enabling `innodb_locks_unsafe_for_binlog` has additional effects:

- For `UPDATE` or `DELETE` statements, InnoDB holds locks only for rows that it updates or deletes. Record locks for nonmatching rows are released after MySQL has evaluated the `WHERE` condition. This greatly reduces the probability of deadlocks, but they can still happen.
- For `UPDATE` statements, if a row is already locked, InnoDB performs a “semi-consistent” read, returning the latest committed version to MySQL so that MySQL can determine whether the row matches the `WHERE` condition of the `UPDATE`. If the row matches (must be updated), MySQL reads the row again and this time InnoDB either locks it or waits for a lock on it.

Consider the following example, beginning with this table:

```
CREATE TABLE t (a INT NOT NULL, b INT) ENGINE = InnoDB;  
INSERT INTO t VALUES (1,2),(2,3),(3,2),(4,3),(5,2);  
COMMIT;
```

In this case, table has no indexes, so searches and index scans use the hidden clustered index for record locking (see [Section 15.8.9, “Clustered and Secondary Indexes”](#)).

Suppose that one client performs an `UPDATE` using these statements:

```
SET autocommit = 0;
UPDATE t SET b = 5 WHERE b = 3;
```

Suppose also that a second client performs an `UPDATE` by executing these statements following those of the first client:

```
SET autocommit = 0;
UPDATE t SET b = 4 WHERE b = 2;
```

As `InnoDB` executes each `UPDATE`, it first acquires an exclusive lock for each row, and then determines whether to modify it. If `InnoDB` does not modify the row and `innodb_locks_unsafe_for_binlog` is enabled, it releases the lock. Otherwise, `InnoDB` retains the lock until the end of the transaction. This affects transaction processing as follows.

If `innodb_locks_unsafe_for_binlog` is disabled, the first `UPDATE` acquires x-locks and does not release any of them:

```
x-lock(1,2); retain x-lock
x-lock(2,3); update(2,3) to (2,5); retain x-lock
x-lock(3,2); retain x-lock
x-lock(4,3); update(4,3) to (4,5); retain x-lock
x-lock(5,2); retain x-lock
```

The second `UPDATE` blocks as soon as it tries to acquire any locks (because first update has retained locks on all rows), and does not proceed until the first `UPDATE` commits or rolls back:

```
x-lock(1,2); block and wait for first UPDATE to commit or roll back
```

If `innodb_locks_unsafe_for_binlog` is enabled, the first `UPDATE` acquires x-locks and releases those for rows that it does not modify:

```
x-lock(1,2); unlock(1,2)
x-lock(2,3); update(2,3) to (2,5); retain x-lock
x-lock(3,2); unlock(3,2)
x-lock(4,3); update(4,3) to (4,5); retain x-lock
x-lock(5,2); unlock(5,2)
```

For the second `UPDATE`, `InnoDB` does a “semi-consistent” read, returning the latest committed version of each row to MySQL so that MySQL can determine whether the row matches the `WHERE` condition of the `UPDATE`:

```
x-lock(1,2); update(1,2) to (1,4); retain x-lock
x-lock(2,3); unlock(2,3)
x-lock(3,2); update(3,2) to (3,4); retain x-lock
x-lock(4,3); unlock(4,3)
x-lock(5,2); update(5,2) to (5,4); retain x-lock
```

- `innodb_log_buffer_size`

|  | <b>Max Value</b>                      | 4294967295 |
|  | <b>Permitted Values (&gt;= 5.7.6)</b> |            |
|  | <b>Type</b>                           | integer    |
|  | <b>Default</b>                        | 16777216   |
|  | <b>Min Value</b>                      | 1048576    |
|  | <b>Max Value</b>                      | 4294967295 |

The size in bytes of the buffer that InnoDB uses to write to the [log files](#) on disk. The default value changed from 8MB to 16MB in 5.7.6 with the introduction of 32k and 64k [innodb\\_page\\_size](#) values. A large [log buffer](#) enables large [transactions](#) to run without a need to write the log to disk before the transactions [commit](#). Thus, if you have transactions that update, insert, or delete many rows, making the log buffer larger saves disk I/O. For general I/O tuning advice, see [Section 9.5.8](#), “[Optimizing InnoDB Disk I/O](#)”.

- [innodb\\_log\\_checksum\\_algorithm](#)

|                             |  |  |
|-----------------------------|--|--|
| Introduced                  | 5.7.8  |  |
| Removed                     | 5.7.9  |  |
| Command-Line Format         | <code>--innodb_log_checksum_algorithm=#</code> |  |
| System Variable             | Name   | <code>innodb_log_checksum_algorithm</code> |
|                             | Variable Scope                                 | Global                                     |
|                             | Dynamic Variable                               | Yes  |
| Permitted Values (>= 5.7.8) | Type   | enumeration                                |
|                             | Default  | <code>innodb</code>                        |
|                             | Valid Values                                   | <code>innodb</code>                        |
|                             |  | <code>crc32</code>                         |
|                             |  | <code>none</code>                          |
|                             |  | <code>strict_innodb</code>                 |
|                             |  | <code>strict_crc32</code>                  |
|                             |  | <code>strict_none</code>                   |

This configuration option was removed in MySQL 5.7.9 and replaced by [innodb\\_log\\_checksums](#).

Specifies how to generate and verify the [checksum](#) stored in each redo log disk block. [innodb\\_log\\_checksum\\_algorithm](#) supports same algorithms as [innodb\\_checksum\\_algorithm](#). Previously, only the [innodb](#) algorithm was supported for redo log disk blocks. [innodb\\_log\\_checksum\\_algorithm=innodb](#) is the default setting.

The [strict\\_\\*](#) forms work the same as [innodb](#), [crc32](#), and [none](#), except that InnoDB halts if it encounters a mix of checksum values in the same redo log. You can only use these options in a completely new instance. The [strict\\_\\*](#) settings are somewhat faster, because they do not need to compute both new and old checksum values to accept both during disk reads.

The following table illustrates the difference between the `none`, `innodb`, and `crc32` option values, and their `strict_` counterparts. `none`, `innodb`, and `crc32` write the specified type checksum value into each data block, but for compatibility accept any of the other checksum values when verifying a block during a read operation. The `strict_` form of each parameter only recognizes one kind of checksum, which makes verification faster but requires that all InnoDB redo logs in an instance be created under the identical `innodb_log_checksum_algorithm` value.

**Table 15.14 Allowed Settings for `innodb_log_checksum_algorithm`**

| Value                      | Generated checksum (when writing)   | Allowed checksums (when reading)  |
|----------------------------|---|---|
| <code>none</code>          | A constant number.  | Any of the checksums generated by <code>none</code> , <code>innodb</code> , or <code>crc32</code> . |
| <code>innodb</code>        | A checksum calculated in software, using the original algorithm from InnoDB.                        | Any of the checksums generated by <code>none</code> , <code>innodb</code> , or <code>crc32</code> . |
| <code>crc32</code>         | A checksum calculated using the <code>crc32</code> algorithm, possibly done with a hardware assist. | Any of the checksums generated by <code>none</code> , <code>innodb</code> , or <code>crc32</code> . |
| <code>strict_none</code>   | A constant number   | Only the checksum generated by <code>none</code> .  |
| <code>strict_innodb</code> | A checksum calculated in software, using the original algorithm from InnoDB.                        | Only the checksum generated by <code>innodb</code> .  |
| <code>strict_crc32</code>  | A checksum calculated using the <code>crc32</code> algorithm, possibly done with a hardware assist. | Only the checksum generated by <code>crc32</code> .   |

- `innodb_log_checksums`

|                            |                                       |                                   |
|----------------------------|---------------------------------------|-----------------------------------|
| <b>Introduced</b>          | 5.7.9                                 |                                   |
| <b>Command-Line Format</b> | <code>--innodb_log_checksums=#</code> |                                   |
| <b>System Variable</b>     | <b>Name</b>                           | <code>innodb_log_checksums</code> |
|                            | <b>Variable Scope</b>                 | Global                            |
|                            | <b>Dynamic Variable</b>               | Yes                               |
| <b>Permitted Values</b>    | <b>Type</b>                           | boolean                           |
|                            | <b>Default</b>                        | <code>ON</code>                   |

Enables or disables checksums for redo log pages. `innodb_log_checksums` replaces `innodb_log_checksum_algorithm`, which was removed in MySQL 5.7.9.

`innodb_log_checksums=ON` enables the CRC-32C checksum algorithm for redo log pages. When `innodb_log_checksums` is disabled, the contents of the redo log page checksum field are ignored.

Checksums on the redo log header page and redo log checkpoint pages are never disabled.

- `innodb_log_compressed_pages`

|                            |  |  |
|----------------------------|--|--|
| <b>Command-Line Format</b> | <code>--innodb_log_compressed_pages=#</code> |  |
| <b>System Variable</b>     | <b>Name</b>                                  | <code>innodb_log_compressed_pages</code> |
|                            | <b>Variable Scope</b>                        | Global                                   |

|                         |                         |         |
|-------------------------|-------------------------|---------|
|                         | <b>Dynamic Variable</b> | Yes     |
| <b>Permitted Values</b> | <b>Type</b>             | boolean |
|                         | <b>Default</b>          | ON      |

Specifies whether images of [re-compressed pages](#) are written to the [redo log](#). Re-compression may occur when changes are made to compressed data.

[innodb\\_log\\_compressed\\_pages](#) is enabled by default to prevent corruption that could occur if a different version of the [zlib](#) compression algorithm is used during recovery. If you are certain that the [zlib](#) version will not change, you can disable [innodb\\_log\\_compressed\\_pages](#) to reduce redo log generation for workloads that modify compressed data.

To measure the effect of enabling or disabling [innodb\\_log\\_compressed\\_pages](#), compare redo log generation for both settings under the same workload. Options for measuring redo log generation include observing the [Log sequence number](#) (LSN) in the [LOG](#) section of [SHOW ENGINE INNODB STATUS](#) output, or monitoring [Innodb\\_os\\_log\\_written](#) status for the number of bytes written to the redo log files.

- [innodb\\_log\\_file\\_size](#)

|                                     |  |   |

| <b>System Variable</b>              | <b>Name</b>                              | <a href="#">innodb_log_file_size</a>              |
|                                     | <b>Variable Scope</b>                    | Global  |
|                                     | <b>Dynamic Variable</b>                  | No  |
| <b>Permitted Values</b> (<= 5.7.10) | <b>Type</b>                              | integer   |
|                                     | <b>Default</b>                           | <a href="#">50331648</a>                          |
|                                     | <b>Min Value</b>                         | <a href="#">1048576</a>                           |
|                                     | <b>Max Value</b>                         | <a href="#">512GB / innodb_log_files_in_group</a> |
| <b>Permitted Values</b> (>= 5.7.11) | <b>Type</b>                              | integer   |
|                                     | <b>Default</b>                           | <a href="#">50331648</a>                          |
|                                     | <b>Min Value</b>                         | <a href="#">4194304</a>                           |
|                                     | <b>Max Value</b>                         | <a href="#">512GB / innodb_log_files_in_group</a> |

The size in bytes of each [log file](#) in a [log group](#). The combined size of log files ([innodb\\_log\\_file\\_size](#) \* [innodb\\_log\\_files\\_in\\_group](#)) cannot exceed a maximum value that is slightly less than 512GB. A pair of 255 GB log files, for example, would allow you to approach the limit but not exceed it. The default value is 48MB.

Generally, the combined size of the log files should be large enough that the server can smooth out peaks and troughs in workload activity, which often means that there is enough redo log space to handle more than an hour of write activity. The larger the value, the less checkpoint flush activity is needed in the buffer pool, saving disk I/O. Larger log files also make [crash recovery](#) slower, although improvements to recovery performance in MySQL 5.5 and higher make the log file size less of a consideration. For general I/O tuning advice, see [Section 9.5.8, “Optimizing InnoDB Disk I/O”](#).

The minimum [innodb\\_log\\_file\\_size](#) value was increased from 1MB to 4MB in MySQL 5.7.11.

|                            | <b>Variable Scope</b>                      | Global                                 |
|                            | <b>Dynamic Variable</b>                    | No                                     |
| <b>Permitted Values</b>    | <b>Type</b>                                | integer                                |
|                            | <b>Default</b>                             | 2                                      |
|                            | <b>Min Value</b>                           | 2                                      |
|                            | <b>Max Value</b>                           | 100                                    |

The number of [log files](#) in the [log group](#). InnoDB writes to the files in a circular fashion. The default (and recommended) value is 2. The location of these files is specified by [innodb\\_log\\_group\\_home\\_dir](#). The combined size of log files ([innodb\\_log\\_file\\_size](#) \* [innodb\\_log\\_files\\_in\\_group](#)) can be up to 512GB.

- `innodb_log_group_home_dir`

|                            |   |  |
|----------------------------|---|--|
| <b>Command-Line Format</b> | <code>--innodb_log_group_home_dir=dir_name</code> |  |
| <b>System Variable</b>     | <b>Name</b>                                       | <code>innodb_log_group_home_dir</code> |
|                            | <b>Variable Scope</b>                             | Global                                 |
|                            | <b>Dynamic Variable</b>                           | No                                     |
| <b>Permitted Values</b>    | <b>Type</b>                                       | directory name                         |

The directory path to the InnoDB [redo log](#) files, whose number is specified by [innodb\\_log\\_files\\_in\\_group](#). If you do not specify any InnoDB log variables, the default is to create two files named `ib_logfile0` and `ib_logfile1` in the MySQL data directory. Their size is given by the size of the [innodb\\_log\\_file\\_size](#) system variable.

- `innodb_log_write_ahead_size`

|                            |  |   |
|----------------------------|--|---|
| <b>Introduced</b>          | 5.7.4  |   |
| <b>Command-Line Format</b> | <code>--innodb_log_write_ahead_size=#</code> |   |
| <b>System Variable</b>     | <b>Name</b>                                  | <code>innodb_log_write_ahead_size</code>  |
|                            | <b>Variable Scope</b>                        | Global                                    |
|                            | <b>Dynamic Variable</b>                      | Yes                                       |
| <b>Permitted Values</b>    | <b>Type</b>                                  | integer                                   |
|                            | <b>Default</b>                               | 8192                                      |
|                            | <b>Min Value</b>                             | 512 (log file block size)                 |
|                            | <b>Max Value</b>                             | Equal to <a href="#">innodb_page_size</a> |

The write-ahead block size for the redo log, in bytes. To avoid “read-on-write”, set [innodb\\_log\\_write\\_ahead\\_size](#) to match the operating system or file system cache block size. Read-on-write occurs when redo log blocks are not entirely cached to the operating system or file system due to a mismatch between write-ahead block size for redo logs and operating system or file system cache block size.

Valid values for [innodb\\_log\\_write\\_ahead\\_size](#) are multiples of the InnoDB log file block size ( $2^n$ ). The minimum value is the InnoDB log file block size (512). Write-ahead does not occur when the minimum value is specified. The maximum value is equal to [innodb\\_page\\_size](#). If you specify a value for [innodb\\_log\\_write\\_ahead\\_size](#) that is larger than the [innodb\\_page\\_size](#) value, the [innodb\\_log\\_write\\_ahead\\_size](#) value is truncated to the [innodb\\_page\\_size](#) value.

Setting the [innodb\\_log\\_write\\_ahead\\_size](#) value too low in relation to the operating system or file system cache block size will result in “read-on-write”. Setting the value too high may have a slight impact on [fsync](#) performance for log file writes due to several blocks being written at once.

- [innodb\\_lru\\_scan\\_depth](#)

|  |  |                                       |
|--|--|---------------------------------------|
| <b>Command-Line Format</b>                 | <code>--innodb_lru_scan_depth=#</code> |                                       |
| <b>System Variable</b>                     | <b>Name</b>                            | <a href="#">innodb_lru_scan_depth</a> |
|  | <b>Variable Scope</b>                  | Global                                |

| <b>Permitted Values</b> (32-bit platforms) | <b>Type</b>                            | integer                               |
|  | <b>Default</b>                         | <a href="#">1024</a>                  |
|  | <b>Min Value</b>                       | <a href="#">100</a>                   |
|  | <b>Max Value</b>                       | $2^{32}-1$                            |
| <b>Permitted Values</b> (64-bit platforms) | <b>Type</b>                            | integer                               |
|  | <b>Default</b>                         | <a href="#">1024</a>                  |
|  | <b>Min Value</b>                       | <a href="#">100</a>                   |
|  | <b>Max Value</b>                       | $2^{64}-1$                            |

A parameter that influences the algorithms and heuristics for the [flush](#) operation for the [InnoDB buffer pool](#). Primarily of interest to performance experts tuning I/O-intensive workloads. It specifies, per buffer pool instance, how far down the buffer pool LRU list the page cleaner thread scans looking for [dirty pages](#) to flush. This is a background operation performed once a second.

A setting smaller than the default is generally suitable for most workloads. A value that is much higher than necessary may impact performance. Only consider increasing the value if you have spare I/O capacity under a typical workload. Conversely, if a write-intensive workload saturates your I/O capacity, decrease the value, especially in the case of a large buffer pool.

When tuning [innodb\\_lru\\_scan\\_depth](#), start with a low value and configure the setting upward with the goal of rarely seeing zero free pages. Also, consider adjusting [innodb\\_lru\\_scan\\_depth](#) when changing the number of buffer pool instances, since [innodb\\_lru\\_scan\\_depth](#) \* [innodb\\_buffer\\_pool\\_instances](#) defines the amount of work performed by the page cleaner thread each second.

For general I/O tuning advice, see [Section 9.5.8, “Optimizing InnoDB Disk I/O”](#).

- `innodb_max_dirty_pages_pct`

|                                       |   |   |
|---------------------------------------|---|---|
| <b>Command-Line Format</b>            | <code>--innodb_max_dirty_pages_pct=#</code> |   |

|                                       | <b>Dynamic Variable</b>                     | Yes                                     |
| <b>Permitted Values (&lt;= 5.7.4)</b> | <b>Type</b>                                 | numeric                                 |
|                                       | <b>Default</b>                              | 75                                      |
|                                       | <b>Min Value</b>                            | 0                                       |
|                                       | <b>Max Value</b>                            | 99                                      |
| <b>Permitted Values (&gt;= 5.7.5)</b> | <b>Type</b>                                 | numeric                                 |
|                                       | <b>Default</b>                              | 75                                      |
|                                       | <b>Min Value</b>                            | 0                                       |
|                                       | <b>Max Value</b>                            | 99.99                                   |

InnoDB tries to flush data from the buffer pool so that the percentage of dirty pages does not exceed this value. The default value is 75.

The `innodb_max_dirty_pages_pct` setting establishes a target for flushing activity. It does not affect the rate of flushing. For information about managing the rate of flushing, see [Section 15.6.3.6, “Configuring InnoDB Buffer Pool Flushing”](#).

For additional information about this variable, see [Section 15.6.3.7, “Fine-tuning InnoDB Buffer Pool Flushing”](#). For general I/O tuning advice, see [Section 9.5.8, “Optimizing InnoDB Disk I/O”](#).

| <b>System Variable</b>     | <b>Name</b>                           | <a href="#">innodb_max_purge_lag</a> |
|                            | <b>Variable Scope</b>                 | Global                               |
|                            | <b>Dynamic Variable</b>               | Yes                                  |
| <b>Permitted Values</b>    | <b>Type</b>                           | integer                              |
|                            | <b>Default</b>                        | 0                                    |
|                            | <b>Min Value</b>                      | 0                                    |
|                            | <b>Max Value</b>                      | 4294967295                           |

This variable controls how to delay [INSERT](#), [UPDATE](#), and [DELETE](#) operations when [purge](#) operations are lagging (see [Section 15.3, “InnoDB Multi-Versioning”](#)). The default value is 0 (no delays).

The [InnoDB](#) transaction system maintains a list of transactions that have index records delete-marked by [UPDATE](#) or [DELETE](#) operations. The length of this list represents the [purge\\_lag](#) value. When [purge\\_lag](#) exceeds [innodb\\_max\\_purge\\_lag](#), each [INSERT](#), [UPDATE](#), and [DELETE](#) operation is delayed.

To prevent excessive delays in extreme situations where [purge\\_lag](#) becomes huge, you can put a cap on the amount of delay by setting the [innodb\\_max\\_purge\\_lag\\_delay](#) configuration option. The delay is computed at the beginning of a purge batch.

A typical setting for a problematic workload might be 1 million, assuming that transactions are small, only 100 bytes in size, and it is permissible to have 100MB of unpurged [InnoDB](#) table rows.

The lag value is displayed as the history list length in the [TRANSACTIONS](#) section of InnoDB Monitor output. For example, if the output includes the following lines, the lag value is 20:

```
-----
TRANSACTIONS
-----
Trx id counter 0 290328385
Purge done for trx's n:o < 0 290315608 undo n:o < 0 17
History list length 20
```

For general I/O tuning advice, see [Section 9.5.8, “Optimizing InnoDB Disk I/O”](#).

| <b>System Variable</b>     | <b>Name</b>                                 | <a href="#">innodb_max_purge_lag_delay</a> |
|                            | <b>Variable Scope</b>                       | Global                                     |
|                            |   | 2393                                       |

|                         |                         |         |
|-------------------------|-------------------------|---------|
|                         | <b>Dynamic Variable</b> | Yes     |
| <b>Permitted Values</b> | <b>Type</b>             | integer |
|                         | <b>Default</b>          | 0       |
|                         | <b>Min Value</b>        | 0       |

Specifies the maximum delay in milliseconds for the delay imposed by the `innodb_max_purge_lag` configuration option. Any non-zero value represents an upper limit on the delay period computed from the formula based on the value of `innodb_max_purge_lag`. The default of zero means that there is no upper limit imposed on the delay interval.

For general I/O tuning advice, see [Section 9.5.8, “Optimizing InnoDB Disk I/O”](#).

- `innodb_max_undo_log_size`

|                            |   |                                       |
|----------------------------|---|---------------------------------------|
| <b>Introduced</b>          | 5.7.5                                     |                                       |
| <b>Command-Line Format</b> | <code>--innodb_max_undo_log_size=#</code> |                                       |
| <b>System Variable</b>     | <b>Name</b>                               | <code>innodb_max_undo_log_size</code> |
|                            | <b>Variable Scope</b>                     | Global                                |
|                            | <b>Dynamic Variable</b>                   | Yes                                   |
| <b>Permitted Values</b>    | <b>Type</b>                               | integer                               |
|                            | <b>Default</b>                            | 1073741824                            |
|                            | <b>Min Value</b>                          | 10485760                              |
|                            | <b>Max Value</b>                          | $2^{64}-1$                            |

`innodb_max_undo_log_size` defines a threshold size for undo tablespaces. If an undo tablespace exceeds the threshold, it can be marked for truncation when `innodb_undo_log_truncate` is enabled. The default value is 1024 MiB (1073741824 bytes).

For more information, see [Section 15.7.8, “Truncating Undo Logs That Reside in Undo Tablespaces”](#).

- `innodb_merge_threshold_set_all_debug`

|                            |   |   |
|----------------------------|---|---|
| <b>Introduced</b>          | 5.7.6   |   |
| <b>Command-Line Format</b> | <code>--innodb_merge_threshold_set_all_debug=#</code> |   |
| <b>System Variable</b>     | <b>Name</b>   | <code>innodb_merge_threshold_set_all_debug</code> |
|                            | <b>Variable Scope</b>                                 | Global  |
|                            | <b>Dynamic Variable</b>                               | Yes   |
| <b>Permitted Values</b>    | <b>Type</b>   | integer   |
|                            | <b>Default</b>  | 50  |
|                            | <b>Min Value</b>                                      | 1   |

|  |                  |    |
|--|------------------|----|
|  | <b>Max Value</b> | 50 |
|--|------------------|----|

Overrides the current `MERGE_THRESHOLD` setting with the specified value for all indexes that are currently in the dictionary cache. This option is only available if debugging support is compiled in using the `WITH_DEBUG CMake` option. For related information, see [Section 15.6.12, “Configuring the Merge Threshold for Index Pages”](#).

- `innodb_monitor_disable`

|                            |  |                                     |
|----------------------------|--|-------------------------------------|
| <b>Command-Line Format</b> | <code>--innodb_monitor_disable=[counter module pattern all]</code> |                                     |
| <b>System Variable</b>     | <b>Name</b>  | <code>innodb_monitor_disable</code> |
|                            | <b>Variable Scope</b>  | Global                              |
|                            | <b>Dynamic Variable</b>  | Yes                                 |
| <b>Permitted Values</b>    | <b>Type</b>  | string                              |

Turns off one or more [counters](#) in the `INFORMATION_SCHEMA.INNODB_METRICS` table. For usage information, see [Section 23.31.15, “The INFORMATION\\_SCHEMA INNODB\\_METRICS Table”](#).

As of MySQL 5.7.8, `innodb_monitor_disable='latch'` disables statistics collection for `SHOW ENGINE INNODB MUTEX`. For more information, see [Section 14.7.5.15, “SHOW ENGINE Syntax”](#).

- `innodb_monitor_enable`

|                            |   |                                    |
|----------------------------|---|------------------------------------|
| <b>Command-Line Format</b> | <code>--innodb_monitor_enable=[counter module pattern all]</code> |                                    |
| <b>System Variable</b>     | <b>Name</b>   | <code>innodb_monitor_enable</code> |
|                            | <b>Variable Scope</b>   | Global                             |
|                            | <b>Dynamic Variable</b>   | Yes                                |
| <b>Permitted Values</b>    | <b>Type</b>   | string                             |

Turns on one or more [counters](#) in the `INFORMATION_SCHEMA.INNODB_METRICS` table. For usage information, see [Section 23.31.15, “The INFORMATION\\_SCHEMA INNODB\\_METRICS Table”](#).

As of MySQL 5.7.8, `innodb_monitor_enable='latch'` enables statistics collection for `SHOW ENGINE INNODB MUTEX`. For more information, see [Section 14.7.5.15, “SHOW ENGINE Syntax”](#).

- `innodb_monitor_reset`

|                            |  |                                   |
|----------------------------|--|-----------------------------------|
| <b>Command-Line Format</b> | <code>--innodb_monitor_reset=[counter module pattern all]</code> |                                   |
| <b>System Variable</b>     | <b>Name</b>  | <code>innodb_monitor_reset</code> |
|                            | <b>Variable Scope</b>  | Global                            |
|                            | <b>Dynamic Variable</b>  | Yes                               |
| <b>Permitted Values</b>    | <b>Type</b>  | string                            |

Resets to zero the count value for one or more [counters](#) in the `INFORMATION_SCHEMA.INNODB_METRICS` table. For usage information, see [Section 23.31.15, “The INFORMATION\\_SCHEMA INNODB\\_METRICS Table”](#).

As of MySQL 5.7.8, `innodb_monitor_reset='latch'` resets statistics reported by `SHOW ENGINE INNODB MUTEX`. For more information, see [Section 14.7.5.15, “SHOW ENGINE Syntax”](#).

- `innodb_monitor_reset_all`

|                            |  |                                       |
|----------------------------|--|---------------------------------------|
| <b>Command-Line Format</b> | <code>--innodb_monitor_reset_all=[counter module pattern all]</code> |                                       |
| <b>System Variable</b>     | <b>Name</b>  | <code>innodb_monitor_reset_all</code> |
|                            | <b>Variable Scope</b>  | Global                                |
|                            | <b>Dynamic Variable</b>  | Yes                                   |
| <b>Permitted Values</b>    | <b>Type</b>  | string                                |

Resets all values (minimum, maximum, and so on) for one or more [counters](#) in the `INFORMATION_SCHEMA.INNODB_METRICS` table. For usage information, see [Section 23.31.15, “The INFORMATION\\_SCHEMA INNODB\\_METRICS Table”](#).

- `innodb_numa_interleave`

|                            |   |                                     |
|----------------------------|---|-------------------------------------|
| <b>Introduced</b>          | 5.7.9                                   |                                     |
| <b>Command-Line Format</b> | <code>--innodb_numa_interleave=#</code> |                                     |
| <b>System Variable</b>     | <b>Name</b>                             | <code>innodb_numa_interleave</code> |
|                            | <b>Variable Scope</b>                   | Global                              |
|                            | <b>Dynamic Variable</b>                 | No                                  |
| <b>Permitted Values</b>    | <b>Type</b>                             | boolean                             |
|                            | <b>Default</b>                          | <code>OFF</code>                    |

Enables the NUMA interleave memory policy for allocation of the [InnoDB](#) buffer pool. When `innodb_numa_interleave` is enabled, the NUMA memory policy is set to `MPOL_INTERLEAVE` for the `mysqld` process. After the [InnoDB](#) buffer pool is allocated, the NUMA memory policy is set back to `MPOL_DEFAULT`. For the `innodb_numa_interleave` option to be available, MySQL must be compiled on a NUMA-enabled Linux system.

- `innodb_old_blocks_pct`

|                            |  |                                    |
|----------------------------|--|------------------------------------|
| <b>Command-Line Format</b> | <code>--innodb_old_blocks_pct=#</code> |                                    |
| <b>System Variable</b>     | <b>Name</b>                            | <code>innodb_old_blocks_pct</code> |
|                            | <b>Variable Scope</b>                  | Global                             |
|                            | <b>Dynamic Variable</b>                | Yes                                |
| <b>Permitted Values</b>    | <b>Type</b>                            | integer                            |
|                            | <b>Default</b>                         | <code>37</code>                    |
|                            | <b>Min Value</b>                       | <code>5</code>                     |
|                            | <b>Max Value</b>                       | <code>95</code>                    |

Specifies the approximate percentage of the [InnoDB buffer pool](#) used for the old block [sublist](#). The range of values is 5 to 95. The default value is 37 (that is, 3/8 of the pool). Often used in combination with [innodb\\_old\\_blocks\\_time](#). See [Section 15.6.3.4, “Making the Buffer Pool Scan Resistant”](#) for more information. See [Section 15.6.3.1, “The InnoDB Buffer Pool”](#) for information about buffer pool management, such as the [LRU](#) algorithm and [eviction](#) policies.

- [innodb\\_old\\_blocks\\_time](#)

|                            |   |  |
|----------------------------|---|--|
| <b>Command-Line Format</b> | <code>--innodb_old_blocks_time=#</code> |  |
| <b>System Variable</b>     | <b>Name</b>                             | <a href="#">innodb_old_blocks_time</a> |
|                            | <b>Variable Scope</b>                   | Global                                 |
|                            | <b>Dynamic Variable</b>                 | Yes                                    |
| <b>Permitted Values</b>    | <b>Type</b>                             | integer                                |
|                            | <b>Default</b>                          | 1000                                   |
|                            | <b>Min Value</b>                        | 0                                      |
|                            | <b>Max Value</b>                        | $2^{32}-1$                             |

Non-zero values protect against the [buffer pool](#) being filled up by data that is referenced only for a brief period, such as during a [full table scan](#). Increasing this value offers more protection against full table scans interfering with data cached in the buffer pool.

Specifies how long in milliseconds (ms) a block inserted into the old [sublist](#) must stay there after its first access before it can be moved to the new sublist. If the value is 0, a block inserted into the old sublist moves immediately to the new sublist the first time it is accessed, no matter how soon after insertion the access occurs. If the value is greater than 0, blocks remain in the old sublist until an access occurs at least that many ms after the first access. For example, a value of 1000 causes blocks to stay in the old sublist for 1 second after the first access before they become eligible to move to the new sublist.

The default value is 1000.

This variable is often used in combination with [innodb\\_old\\_blocks\\_pct](#). See [Section 15.6.3.4, “Making the Buffer Pool Scan Resistant”](#) for more information. See [Section 15.6.3.1, “The InnoDB Buffer Pool”](#) for information about buffer pool management, such as the [LRU](#) algorithm and [eviction](#) policies.

- [innodb\\_online\\_alter\\_log\\_max\\_size](#)

|                            |   |  |
|----------------------------|---|--|
| <b>Command-Line Format</b> | <code>--innodb_online_alter_log_max_size=#</code> |  |
| <b>System Variable</b>     | <b>Name</b>                                       | <a href="#">innodb_online_alter_log_max_size</a> |
|                            | <b>Variable Scope</b>                             | Global   |
|                            | <b>Dynamic Variable</b>                           | Yes  |
| <b>Permitted Values</b>    | <b>Type</b>                                       | integer  |
|                            | <b>Default</b>                                    | 134217728  |
|                            | <b>Min Value</b>                                  | 65536  |

|  |                  |         |
|--|------------------|---------|
|  | <b>Max Value</b> | 2**64-1 |
|--|------------------|---------|

Specifies an upper limit on the size of the temporary log files used during [online DDL](#) operations for [InnoDB](#) tables. There is one such log file for each index being created or table being altered. This log file stores data inserted, updated, or deleted in the table during the DDL operation. The temporary log file is extended when needed by the value of [innodb\\_sort\\_buffer\\_size](#), up to the maximum specified by [innodb\\_online\\_alter\\_log\\_max\\_size](#). If any temporary log file exceeds the upper size limit, the [ALTER TABLE](#) operation fails and all uncommitted concurrent DML operations are rolled back. Thus, a large value for this option allows more DML to happen during an online DDL operation, but also causes a longer period at the end of the DDL operation when the table is locked to apply the data from the log.

- [innodb\\_open\\_files](#)

|                            |                                       |                                   |
|----------------------------|---------------------------------------|-----------------------------------|
| <b>Command-Line Format</b> | <a href="#">--innodb_open_files=#</a> |                                   |
| <b>System Variable</b>     | <b>Name</b>                           | <a href="#">innodb_open_files</a> |
|                            | <b>Variable Scope</b>                 | Global                            |
|                            | <b>Dynamic Variable</b>               | No                                |
| <b>Permitted Values</b>    | <b>Type</b>                           | integer                           |
|                            | <b>Default</b>                        | -1 (autosized)                    |
|                            | <b>Min Value</b>                      | 10                                |
|                            | <b>Max Value</b>                      | 4294967295                        |

This variable is relevant only if you use multiple [InnoDB tablespaces](#). It specifies the maximum number of [.ibd files](#) that MySQL can keep open at one time. The minimum value is 10. The default value is 300 if [innodb\\_file\\_per\\_table](#) is not enabled, and the higher of 300 and [table\\_open\\_cache](#) otherwise.

The file descriptors used for [.ibd](#) files are for [InnoDB](#) tables only. They are independent of those specified by the [--open-files-limit](#) server option, and do not affect the operation of the table cache. For general I/O tuning advice, see [Section 9.5.8, “Optimizing InnoDB Disk I/O”](#).

- [innodb\\_optimize\\_fulltext\\_only](#)

|                            |   |   |
|----------------------------|---|---|
| <b>Command-Line Format</b> | <a href="#">--innodb_optimize_fulltext_only=#</a> |   |
| <b>System Variable</b>     | <b>Name</b>                                       | <a href="#">innodb_optimize_fulltext_only</a> |
|                            | <b>Variable Scope</b>                             | Global  |
|                            | <b>Dynamic Variable</b>                           | Yes   |
| <b>Permitted Values</b>    | <b>Type</b>                                       | boolean                                       |
|                            | <b>Default</b>                                    | OFF   |

Changes the way the [OPTIMIZE TABLE](#) statement operates on [InnoDB](#) tables. Intended to be enabled temporarily, during maintenance operations for [InnoDB](#) tables with [FULLTEXT](#) indexes.

By default, [OPTIMIZE TABLE](#) reorganizes the data in the [clustered index](#) of the table. When this option is enabled, [OPTIMIZE TABLE](#) skips this reorganization of the table data, and instead processes the newly added, deleted, and updated token data for a [FULLTEXT](#) index. See

Section 15.8.10, “InnoDB FULLTEXT Indexes” for more information about `FULLTEXT` indexes for InnoDB tables.

- `innodb_optimize_point_storage`

|                            |  |  |

The number of page cleaner threads that flush dirty pages from buffer pool instances. The page cleaner threads perform flush list and LRU flushing. A single page cleaner thread was introduced in MySQL 5.6.2 to offload buffer pool flushing work from the InnoDB master thread. As of MySQL 5.7.4, InnoDB provides support for multiple page cleaner threads. A value of 1 maintains the pre-MySQL 5.7.4 configuration in which there is a single page cleaner thread. When there are multiple page cleaner threads, buffer pool flushing tasks for each buffer pool instance are dispatched to idle page cleaner threads. The `innodb_page_cleaners` default value was changed from 1 to 4 in MySQL 5.7.8. If the number of page cleaner threads exceeds the number

of buffer pool instances, `innodb_page_cleaners` is automatically set to the same value as `innodb_buffer_pool_instances`.

If your workload is write-IO bound (when flushing dirty pages from buffer pool instances to data files) and if your system hardware has available capacity, increasing the number of page cleaner threads may help improve write-IO throughput.

Multi-threaded page cleaner support is extended to shutdown and recovery phases in MySQL 5.7.5.

As of MySQL 5.7.6, the `setpriority()` system call is used on Linux platforms (where it is supported and where the `mysqld` execution user is authorized) to give `page_cleaner` threads priority over other MySQL/InnoDB threads to help page flushing keep pace with the current workload. `mysqld` execution user authorization can be configured in `/etc/security/limits.conf`. For example, if `mysqld` is run under the `mysql` user, you might authorize the `mysql` user by adding lines similar to the following to `/etc/security/limits.conf`:

```
mysql          hard    nice    -20
mysql          soft    nice    -20
```

Refer to your Linux operating system documentation for more information.

|                                       |                                    | 8192                          |
|                                       |                                    | 16384                         |
|                                       |                                    | 32768                         |
|                                       |                                    | 65536                         |

Specifies the [page size](#) for all [InnoDB tablespaces](#) in a MySQL [instance](#). You can specify page size using the values 64k, 32k, [16k](#) (the default), [8k](#), or [4k](#). Alternatively, you can specify page size in bytes (65536, 32768, 16384, 8192, 4096).

#### Important

[innodb\\_page\\_size](#) can only be configured prior to initializing the MySQL instance and cannot be changed afterward. If no value is specified, the instance is initialized using the default page size.

Support for 32k and 64k page sizes was added in MySQL 5.7.6. For both 32k and 64k page sizes, the maximum row length is approximately 16000 bytes. [ROW\\_FORMAT=COMPRESSED](#) is not supported when [innodb\\_page\\_size](#) is set to 32KB or 64KB. For [innodb\\_page\\_size=32k](#), extent size is 2MB. For [innodb\\_page\\_size=64k](#), extent size is 4MB. [innodb\\_log\\_buffer\\_size](#) should be set to at least 16M (which is the default as of MySQL 5.7.6) when using 32k or 64k page sizes.

The default page size of 16KB and larger is appropriate for a wide range of [workloads](#), particularly for queries involving table scans and DML operations involving bulk updates. Smaller page sizes might be more efficient for [OLTP](#) workloads involving many small writes, where contention can be an issue when a single page contains many rows. Smaller pages might also be efficient with [SSD](#) storage devices, which typically use small block sizes. Keeping the [InnoDB](#) page size close to the storage device block size minimizes the amount of unchanged data that is rewritten to disk.

The minimum file size for the first system tablespace data file ([ibdata1](#)) differs depending on the [innodb\\_page\\_size](#) value. See the [innodb\\_data\\_file\\_path](#) option description for more information.

For general I/O tuning advice, see [Section 9.5.8, “Optimizing InnoDB Disk I/O”](#).

- [innodb\\_print\\_all\\_deadlocks](#)

|                            |  |  |
|----------------------------|--|--|
| <b>Command-Line Format</b> | <a href="#">--innodb_print_all_deadlocks=#</a> |  |
| <b>System Variable</b>     | <b>Name</b>                                    | <a href="#">innodb_print_all_deadlocks</a> |
|                            | <b>Variable Scope</b>                          | Global                                     |
|                            | <b>Dynamic Variable</b>                        | Yes  |
| <b>Permitted Values</b>    | <b>Type</b>                                    | boolean                                    |
|                            | <b>Default</b>                                 | <a href="#">OFF</a>                        |

When this option is enabled, information about all [deadlocks](#) in [InnoDB](#) user transactions is recorded in the [mysqld error log](#). Otherwise, you see information about only the last deadlock, using the [SHOW ENGINE INNODB STATUS](#) command. An occasional [InnoDB](#) deadlock is not necessarily an issue, because [InnoDB](#) detects the condition immediately, and rolls back one of the transactions automatically. You might use this option to troubleshoot why deadlocks are happening if an application does not have appropriate error-handling logic to detect the rollback and retry its operation. A large number of deadlocks might indicate the need to restructure transactions that issue [DML](#) or [SELECT ... FOR UPDATE](#) statements for multiple tables, so that each transaction accesses the tables in the same order, thus avoiding the deadlock condition.

- [innodb\\_purge\\_batch\\_size](#)

|                            |   |   |
|----------------------------|---|---|
| <b>Command-Line Format</b> | <a href="#">--innodb_purge_batch_size=#</a> |   |
| <b>System Variable</b>     | <b>Name</b>                                 | <a href="#">innodb_purge_batch_size</a> |

|                         |                         |         |
|-------------------------|-------------------------|---------|
|                         | <b>Variable Scope</b>   | Global  |
|                         | <b>Dynamic Variable</b> | Yes     |
| <b>Permitted Values</b> | <b>Type</b>             | integer |
|                         | <b>Default</b>          | 300     |
|                         | <b>Min Value</b>        | 1       |
|                         | <b>Max Value</b>        | 5000    |

Defines the number of undo log pages that purge parses and processes in one batch from the [history list](#). In a multi-threaded purge configuration, the coordinator purge thread divides `innodb_purge_batch_size` by `innodb_purge_threads` and assigns that number of pages to each purge thread. The `innodb_purge_batch_size` option also defines the number of undo log pages that purge frees after every 128 iterations through the undo logs.

The `innodb_purge_batch_size` option is intended for advanced performance tuning in combination with the `innodb_purge_threads` setting. Most MySQL users need not change `innodb_purge_batch_size` from its default value.

- `innodb_purge_threads`

|                                       |                                       |                                   |
|---------------------------------------|---------------------------------------|-----------------------------------|
| <b>Command-Line Format</b>            | <code>--innodb_purge_threads=#</code> |                                   |
| <b>System Variable</b>                | <b>Name</b>                           | <code>innodb_purge_threads</code> |
|                                       | <b>Variable Scope</b>                 | Global                            |
|                                       | <b>Dynamic Variable</b>               | No                                |
| <b>Permitted Values (&lt;= 5.7.7)</b> | <b>Type</b>                           | integer                           |
|                                       | <b>Default</b>                        | 1                                 |
|                                       | <b>Min Value</b>                      | 1                                 |
|                                       | <b>Max Value</b>                      | 32                                |
| <b>Permitted Values (&gt;= 5.7.8)</b> | <b>Type</b>                           | integer                           |
|                                       | <b>Default</b>                        | 4                                 |
|                                       | <b>Min Value</b>                      | 1                                 |
|                                       | <b>Max Value</b>                      | 32                                |

The number of background threads devoted to the [InnoDB purge](#) operation. A minimum value of 1 signifies that the purge operation is always performed by a background thread, never as part of the [master thread](#). Running the purge operation in one or more background threads helps reduce internal contention within [InnoDB](#), improving scalability. Increasing the value to greater than 1 creates that many separate purge threads, which can improve efficiency on systems where [DML](#) operations are performed on multiple tables. The maximum is 32.

The `innodb_purge_threads` default value was changed from 1 to 4 in MySQL 5.7.8.

- `innodb_purge_rseg_truncate_frequency`

|                            |   |   |
|----------------------------|---|---|
| <b>Introduced</b>          | 5.7.5   |   |
| <b>Command-Line Format</b> | <code>--innodb_purge_rseg_truncate_frequency=#</code> |   |
| <b>System Variable</b>     | <b>Name</b>   | <code>innodb_purge_rseg_truncate_frequency</code> |
|                            | <b>Variable Scope</b>                                 | Global  |
|                            | <b>Dynamic Variable</b>                               | Yes   |
| <b>Permitted Values</b>    | <b>Type</b>   | integer   |
|                            | <b>Default</b>  | 128   |
|                            | <b>Min Value</b>                                      | 1   |
|                            | <b>Max Value</b>                                      | 128   |

`innodb_purge_rseg_truncate_frequency` defines the frequency with which the purge system frees rollback segments. An undo tablespace cannot be truncated until its rollback segments are freed. Normally, the purge system frees rollback segments once every 128 times that purge is invoked. Reducing the `innodb_purge_rseg_truncate_frequency` value increases the frequency with which the purge thread frees rollback segments. The default value is 128.

`innodb_purge_rseg_truncate_frequency` is intended for use with `innodb_undo_log_truncate`. For more information, see [Section 15.7.8, “Truncating Undo Logs That Reside in Undo Tablespaces”](#).

- `innodb_random_read_ahead`

|                            |   |                                       |
|----------------------------|---|---------------------------------------|
| <b>Command-Line Format</b> | <code>--innodb_random_read_ahead=#</code> |                                       |
| <b>System Variable</b>     | <b>Name</b>                               | <code>innodb_random_read_ahead</code> |
|                            | <b>Variable Scope</b>                     | Global                                |
|                            | <b>Dynamic Variable</b>                   | Yes                                   |
| <b>Permitted Values</b>    | <b>Type</b>                               | boolean                               |
|                            | <b>Default</b>                            | OFF                                   |

Enables the random [read-ahead](#) technique for optimizing InnoDB I/O.

See [Section 15.6.3.5, “Configuring InnoDB Buffer Pool Prefetching \(Read-Ahead\)”](#) for details about the performance considerations for the different types of read-ahead requests. For general I/O tuning advice, see [Section 9.5.8, “Optimizing InnoDB Disk I/O”](#).

- `innodb_read_ahead_threshold`

|                            |  |  |
|----------------------------|--|--|
| <b>Command-Line Format</b> | <code>--innodb_read_ahead_threshold=#</code> |  |
| <b>System Variable</b>     | <b>Name</b>                                  | <code>innodb_read_ahead_threshold</code> |
|                            | <b>Variable Scope</b>                        | Global                                   |
|                            | <b>Dynamic Variable</b>                      | Yes                                      |
| <b>Permitted Values</b>    | <b>Type</b>                                  | integer                                  |
|                            | <b>Default</b>                               | 56                                       |

|  |                  |    |
|--|------------------|----|
|  | <b>Min Value</b> | 0  |
|  | <b>Max Value</b> | 64 |

Controls the sensitivity of linear [read-ahead](#) that InnoDB uses to prefetch pages into the [buffer pool](#). If InnoDB reads at least [innodb\\_read\\_ahead\\_threshold](#) pages sequentially from an [extent](#) (64 pages), it initiates an asynchronous read for the entire following extent. The permissible range of values is 0 to 64. A value of 0 disables read-ahead. For the default of 56, InnoDB must read at least 56 pages sequentially from an extent to initiate an asynchronous read for the following extent.

Knowing how many pages are read through this read-ahead mechanism, and how many of them are evicted from the buffer pool without ever being accessed, can be useful to help fine-tune the [innodb\\_read\\_ahead\\_threshold](#) parameter. As of MySQL 5.5, [SHOW ENGINE INNODB STATUS](#) output displays counter information from the [Innodb\\_buffer\\_pool\\_read\\_ahead](#) and [Innodb\\_buffer\\_pool\\_read\\_ahead\\_evicted](#) global status variables. These variables indicate the number of pages brought into the [buffer pool](#) by read-ahead requests, and the number of such pages [evicted](#) from the buffer pool without ever being accessed respectively. These counters provide global values since the last server restart.

[SHOW ENGINE INNODB STATUS](#) also shows the rate at which the read-ahead pages are read in and the rate at which such pages are evicted without being accessed. The per-second averages are based on the statistics collected since the last invocation of [SHOW ENGINE INNODB STATUS](#) and are displayed in the [BUFFER POOL AND MEMORY](#) section of the output.

See [Section 15.6.3.5, “Configuring InnoDB Buffer Pool Prefetching \(Read-Ahead\)”](#) for more information. For general I/O tuning advice, see [Section 9.5.8, “Optimizing InnoDB Disk I/O”](#).

- [innodb\\_read\\_io\\_threads](#)

|                            |   |  |
|----------------------------|---|--|
| <b>Command-Line Format</b> | <code>--innodb_read_io_threads=#</code> |  |
| <b>System Variable</b>     | <b>Name</b>                             | <a href="#">innodb_read_io_threads</a> |
|                            | <b>Variable Scope</b>                   | Global                                 |
|                            | <b>Dynamic Variable</b>                 | No                                     |
| <b>Permitted Values</b>    | <b>Type</b>                             | integer                                |
|                            | <b>Default</b>                          | 4                                      |
|                            | <b>Min Value</b>                        | 1                                      |
|                            | <b>Max Value</b>                        | 64                                     |

The number of I/O threads for read operations in InnoDB. The default value is 4. Its counterpart for write threads is [innodb\\_write\\_io\\_threads](#). See [Section 15.6.7, “Configuring the Number of Background InnoDB I/O Threads”](#) for more information. For general I/O tuning advice, see [Section 9.5.8, “Optimizing InnoDB Disk I/O”](#).

#### Note

On Linux systems, running multiple MySQL servers (typically more than 12) with default settings for [innodb\\_read\\_io\\_threads](#), [innodb\\_write\\_io\\_threads](#), and the Linux [aio-max-nr](#) setting can exceed system limits. Ideally, increase the [aio-max-nr](#) setting; as a workaround, you might reduce the settings for one or both of the MySQL configuration options.

- `innodb_read_only`

|                            |                                   |                               |
|----------------------------|-----------------------------------|-------------------------------|
| <b>Command-Line Format</b> | <code>--innodb_read_only=#</code> |                               |
| <b>System Variable</b>     | <b>Name</b>                       | <code>innodb_read_only</code> |
|                            | <b>Variable Scope</b>             | Global                        |
|                            | <b>Dynamic Variable</b>           | No                            |
| <b>Permitted Values</b>    | <b>Type</b>                       | boolean                       |
|                            | <b>Default</b>                    | <code>OFF</code>              |

Starts `InnoDB` in read-only mode. For distributing database applications or data sets on read-only media. Can also be used in data warehouses to share the same data directory between multiple instances. See [Section 15.6.2, “Configuring InnoDB for Read-Only Operation”](#) for usage instructions.

- `innodb_replication_delay`

|                            |   |                                       |
|----------------------------|---|---------------------------------------|
| <b>Command-Line Format</b> | <code>--innodb_replication_delay=#</code> |                                       |
| <b>System Variable</b>     | <b>Name</b>                               | <code>innodb_replication_delay</code> |
|                            | <b>Variable Scope</b>                     | Global                                |
|                            | <b>Dynamic Variable</b>                   | Yes                                   |
| <b>Permitted Values</b>    | <b>Type</b>                               | integer                               |
|                            | <b>Default</b>                            | 0                                     |
|                            | <b>Min Value</b>                          | 0                                     |
|                            | <b>Max Value</b>                          | 4294967295                            |

The replication thread delay (in ms) on a slave server if `innodb_thread_concurrency` is reached.

- `innodb_rollback_on_timeout`

|                            |   |   |
|----------------------------|---|---|
| <b>Command-Line Format</b> | <code>--innodb_rollback_on_timeout</code> |   |
| <b>System Variable</b>     | <b>Name</b>                               | <code>innodb_rollback_on_timeout</code> |
|                            | <b>Variable Scope</b>                     | Global                                  |
|                            | <b>Dynamic Variable</b>                   | No                                      |
| <b>Permitted Values</b>    | <b>Type</b>                               | boolean                                 |
|                            | <b>Default</b>                            | <code>OFF</code>                        |

In MySQL 5.7, `InnoDB` **rolls back** only the last statement on a transaction timeout by default. If `--innodb_rollback_on_timeout` is specified, a transaction timeout causes `InnoDB` to abort and roll back the entire transaction.

- `innodb_rollback_segments`

|                            |   |                                       |
|----------------------------|---|---------------------------------------|
| <b>Command-Line Format</b> | <code>--innodb_rollback_segments=#</code> |                                       |
| <b>System Variable</b>     | <b>Name</b>                               | <code>innodb_rollback_segments</code> |

|                         |                         |         |
|-------------------------|-------------------------|---------|
|                         | <b>Variable Scope</b>   | Global  |
|                         | <b>Dynamic Variable</b> | Yes     |
| <b>Permitted Values</b> | <b>Type</b>             | integer |
|                         | <b>Default</b>          | 128     |
|                         | <b>Min Value</b>        | 1       |
|                         | <b>Max Value</b>        | 128     |

Defines how many of the [rollback segments](#) in the [system tablespace](#) are used for InnoDB [transactions](#). This setting, while still valid, is replaced by [innodb\\_undo\\_logs](#).

- [innodb\\_saved\\_page\\_number\\_debug](#)

|                            |   |  |
|----------------------------|---|--|
| <b>Command-Line Format</b> | <code>--innodb_saved_page_number_debug=#</code> |  |
| <b>System Variable</b>     | <b>Name</b>                                     | <a href="#">innodb_saved_page_number_debug</a> |
|                            | <b>Variable Scope</b>                           | Global   |
|                            | <b>Dynamic Variable</b>                         | Yes  |
| <b>Permitted Values</b>    | <b>Type</b>                                     | integer  |
|                            | <b>Default</b>                                  | 0  |
|                            | <b>Max Value</b>                                | $2^{23}-1$                                     |

Saves a page number. Setting the [innodb\\_fil\\_make\\_page\\_dirty\\_debug](#) option dirties the page defined by [innodb\\_saved\\_page\\_number\\_debug](#). The [innodb\\_saved\\_page\\_number\\_debug](#) option is only available if debugging support is compiled in using the `WITH_DEBUG` CMake option.

- [innodb\\_sort\\_buffer\\_size](#)

|                            |  |   |
|----------------------------|--|---|
| <b>Command-Line Format</b> | <code>--innodb_sort_buffer_size=#</code> |   |
| <b>System Variable</b>     | <b>Name</b>                              | <a href="#">innodb_sort_buffer_size</a> |
|                            | <b>Variable Scope</b>                    | Global                                  |
|                            | <b>Dynamic Variable</b>                  | No                                      |
| <b>Permitted Values</b>    | <b>Type</b>                              | integer                                 |
|                            | <b>Default</b>                           | 1048576                                 |
|                            | <b>Min Value</b>                         | 65536                                   |
|                            | <b>Max Value</b>                         | 67108864                                |

Specifies the size of sort buffers used for sorting data during creation of an [InnoDB](#) index. The size specified defines the amount of data filled in memory for an internal sort and written out to disk, which can be referred to as a “run”. During the merge phase, pairs of buffers of the specified size are “read in” and merged. The larger the setting, the fewer “runs” and merges there are, which is important to understand from a tuning perspective.

This sort area is only used for merge sorts during index creation, not during later index maintenance operations. Buffers are deallocated when index creation completes.

The value of this option also controls the amount by which the temporary log file is extended, to record concurrent DML during [online DDL](#) operations.

Before this setting was made configurable, the size was hardcoded to 1048576 bytes (1MB), and that value remains the default.

During an [ALTER TABLE](#) or [CREATE TABLE](#) statement that creates an index, 3 buffers are allocated, each with a size defined by this option. Additionally, auxiliary pointers are allocated to rows in the sort buffer so that the sort can run on pointers (as opposed to moving rows during the sort operation).

For a typical sort operation, a formula such as this can be used to estimate memory consumption:

```
(6 /*FTS_NUM_AUX_INDEX*/ * (3*@@global.innodb_sort_buffer_size)
+ 2 * number_of_partitions * number_of_secondary_indexes_created
* (@@global.innodb_sort_buffer_size/dict_index_get_min_size(index)*/)
* 8 /*64-bit sizeof *buf->tuples*/)
```

`@@global.innodb_sort_buffer_size/dict_index_get_min_size(index)`  
indicates the maximum tuples held. `2 * (@@global.innodb_sort_buffer_size/  
*dict_index_get_min_size(index)*/) * 8 /*64-bit size of *buf->tuples*/`  
indicates auxiliary pointers allocated.

#### Note

For 32-bit, multiply by 4 instead of 8.

For parallel sorts on a full-text index, multiply by the `innodb_ft_sort_pll_degree` setting:

```
(6 /*FTS_NUM_AUX_INDEX*/ * @@global.innodb_ft_sort_pll_degree)
```

- `innodb_spin_wait_delay`

| Command-Line Format                 | <code>--innodb_spin_wait_delay=#</code> |                                     |

|  |                  |         |
|--|------------------|---------|
|  | <b>Max Value</b> | 2**64-1 |
|--|------------------|---------|

The maximum delay between polls for a [spin](#) lock. The low-level implementation of this mechanism varies depending on the combination of hardware and operating system, so the delay does not correspond to a fixed time interval. The default value is 6. See [Section 15.6.9, “Configuring Spin Lock Polling”](#) for more information.

- [innodb\\_stats\\_auto\\_recalc](#)

|                            |   |  |
|----------------------------|---|--|
| <b>Command-Line Format</b> | <code>--innodb_stats_auto_recalc=#</code> |  |
| <b>System Variable</b>     | <b>Name</b>                               | <a href="#">innodb_stats_auto_recalc</a> |
|                            | <b>Variable Scope</b>                     | Global                                   |
|                            | <b>Dynamic Variable</b>                   | Yes                                      |
| <b>Permitted Values</b>    | <b>Type</b>                               | boolean                                  |
|                            | <b>Default</b>                            | <a href="#">ON</a>                       |

Causes [InnoDB](#) to automatically recalculate [persistent statistics](#) after the data in a table is changed substantially. The threshold value is currently 10% of the rows in the table. This setting applies to tables created when the [innodb\\_stats\\_persistent](#) option is enabled, or where the clause [STATS\\_PERSISTENT=1](#) is enabled by a [CREATE TABLE](#) or [ALTER TABLE](#) statement. The amount of data sampled to produce the statistics is controlled by the [innodb\\_stats\\_persistent\\_sample\\_pages](#) configuration option.

For additional information about [innodb\\_stats\\_auto\\_recalc](#), see [Section 15.6.11.1, “Configuring Persistent Optimizer Statistics Parameters”](#).

- [innodb\\_stats\\_include\\_delete\\_marked](#)

|                            |   |  |
|----------------------------|---|--|
| <b>Introduced</b>          | 5.7.17  |  |
| <b>Command-Line Format</b> | <code>--innodb_stats_include_delete_marked=#</code> |  |
| <b>System Variable</b>     | <b>Name</b>   | <a href="#">innodb_stats_include_delete_marked</a> |
|                            | <b>Variable Scope</b>                               | Global   |
|                            | <b>Dynamic Variable</b>                             | Yes  |
| <b>Permitted Values</b>    | <b>Type</b>   | boolean  |
|                            | <b>Default</b>                                      | <a href="#">OFF</a>                                |

By default, [InnoDB](#) reads uncommitted data when calculating statistics. In the case of an uncommitted transaction that deletes rows from a table, [InnoDB](#) excludes records that are delete-marked when calculating row estimates and index statistics, which can lead to non-optimal execution plans for other transactions that are operating on the table concurrently using a transaction isolation level other than [READ UNCOMMITTED](#). To avoid this scenario, [innodb\\_stats\\_include\\_delete\\_marked](#) can be enabled to ensure that [InnoDB](#) includes delete-marked records when calculating persistent optimizer statistics.

When [innodb\\_stats\\_include\\_delete\\_marked](#) is enabled, [ANALYZE TABLE](#) considers delete-marked records when recalculating statistics.

[innodb\\_stats\\_include\\_delete\\_marked](#) is a global setting that affects all [InnoDB](#) tables, and it is only applicable to persistent optimizer statistics.

For related information, see [Section 15.6.11.1, “Configuring Persistent Optimizer Statistics Parameters”](#).

- `innodb_stats_method`

|                            |   |                                  |
|----------------------------|---|----------------------------------|
| <b>Command-Line Format</b> | <code>--innodb_stats_method=name</code> |                                  |
| <b>System Variable</b>     | <b>Name</b>                             | <code>innodb_stats_method</code> |
|                            | <b>Variable Scope</b>                   | Global                           |
|                            | <b>Dynamic Variable</b>                 | Yes                              |
| <b>Permitted Values</b>    | <b>Type</b>                             | enumeration                      |
|                            | <b>Default</b>                          | <code>nulls_equal</code>         |
|                            | <b>Valid Values</b>                     | <code>nulls_equal</code>         |
|                            |   | <code>nulls_unequal</code>       |
|                            |   | <code>nulls_ignored</code>       |

How the server treats `NULL` values when collecting [statistics](#) about the distribution of index values for InnoDB tables. This variable has three possible values, `nulls_equal`, `nulls_unequal`, and `nulls_ignored`. For `nulls_equal`, all `NULL` index values are considered equal and form a single value group that has a size equal to the number of `NULL` values. For `nulls_unequal`, `NULL` values are considered unequal, and each `NULL` forms a distinct value group of size 1. For `nulls_ignored`, `NULL` values are ignored.

The method that is used for generating table statistics influences how the optimizer chooses indexes for query execution, as described in [Section 9.3.7, “InnoDB and MyISAM Index Statistics Collection”](#).

- `innodb_stats_on_metadata`

|                            |   |                                       |
|----------------------------|---|---------------------------------------|
| <b>Command-Line Format</b> | <code>--innodb_stats_on_metadata</code> |                                       |
| <b>System Variable</b>     | <b>Name</b>                             | <code>innodb_stats_on_metadata</code> |
|                            | <b>Variable Scope</b>                   | Global                                |
|                            | <b>Dynamic Variable</b>                 | Yes                                   |
| <b>Permitted Values</b>    | <b>Type</b>                             | boolean                               |
|                            | <b>Default</b>                          | <code>OFF</code>                      |

When this variable is enabled, InnoDB updates [statistics](#) when metadata statements such as `SHOW TABLE STATUS` or when accessing the `INFORMATION_SCHEMA.TABLES` or `INFORMATION_SCHEMA.STATISTICS` tables. (These updates are similar to what happens for `ANALYZE TABLE`.) When disabled, InnoDB does not update statistics during these operations. Leaving this setting disabled can improve access speed for schemas that have a large number of tables or indexes. It can also improve the stability of [execution plans](#) for queries that involve InnoDB tables.

To change the setting, issue the statement `SET GLOBAL innodb_stats_on_metadata=mode`, where *mode* is either `ON` or `OFF` (or `1` or `0`). Changing this setting requires the `SUPER` privilege and immediately affects the operation of all connections.

This variable is disabled by default.

- `innodb_stats_persistent`

|                            |  |                                      |
|----------------------------|--|--------------------------------------|
| <b>Command-Line Format</b> | <code>--innodb_stats_persistent=setting</code> |                                      |
| <b>System Variable</b>     | <b>Name</b>                                    | <code>innodb_stats_persistent</code> |
|                            | <b>Variable Scope</b>                          | Global                               |
|                            | <b>Dynamic Variable</b>                        | Yes                                  |
| <b>Permitted Values</b>    | <b>Type</b>                                    | boolean                              |
|                            | <b>Default</b>                                 | ON                                   |
|                            | <b>Valid Values</b>                            | OFF                                  |
|                            |  | ON                                   |
|                            |  | 0                                    |
|                            |  | 1                                    |

Specifies whether [InnoDB](#) index statistics are persisted to disk. Otherwise, statistics may be recalculated frequently which can lead to variations in [query execution plans](#). This setting is stored with each table when the table is created. You can set `innodb_stats_persistent` at the global level before creating a table, or use the `STATS_PERSISTENT` clause of the `CREATE TABLE` and `ALTER TABLE` statements to override the system-wide setting and configure persistent statistics for individual tables.

For more information about this option, see [Section 15.6.11.1, “Configuring Persistent Optimizer Statistics Parameters”](#).

- `innodb_stats_persistent_sample_pages`

|                            |   |   |
|----------------------------|---|---|
| <b>Command-Line Format</b> | <code>--innodb_stats_persistent_sample_pages=#</code> |   |
| <b>System Variable</b>     | <b>Name</b>   | <code>innodb_stats_persistent_sample_pages</code> |
|                            | <b>Variable Scope</b>                                 | Global  |
|                            | <b>Dynamic Variable</b>                               | Yes   |
| <b>Permitted Values</b>    | <b>Type</b>   | integer   |
|                            | <b>Default</b>  | 20  |

The number of index [pages](#) to sample when estimating [cardinality](#) and other [statistics](#) for an indexed column, such as those calculated by `ANALYZE TABLE`. Increasing the value improves the accuracy of index statistics, which can improve the [query execution plan](#), at the expense of increased I/O during the execution of `ANALYZE TABLE` for an [InnoDB](#) table. For additional information, see [Section 15.6.11.1, “Configuring Persistent Optimizer Statistics Parameters”](#).

#### Note

Setting a high value for `innodb_stats_persistent_sample_pages` could result in lengthy `ANALYZE TABLE` execution time. To estimate the number of database pages that will be accessed, see [Section 15.6.11.3, “Estimating ANALYZE TABLE Complexity for InnoDB Tables”](#).

This option only applies when the `innodb_stats_persistent` setting is turned on for a table; when that option is turned off for a table, the `innodb_stats_transient_sample_pages` setting applies instead.

- `innodb_stats_sample_pages`

|                            |  |  |
|----------------------------|--|--|
| <b>Deprecated</b>          | 5.6.3                                      |  |
| <b>Command-Line Format</b> | <code>--innodb_stats_sample_pages=#</code> |  |
| <b>System Variable</b>     | <b>Name</b>                                | <code>innodb_stats_sample_pages</code> |
|                            | <b>Variable Scope</b>                      | Global                                 |
|                            | <b>Dynamic Variable</b>                    | Yes                                    |
| <b>Permitted Values</b>    | <b>Type</b>                                | integer                                |
|                            | <b>Default</b>                             | 8                                      |
|                            | <b>Min Value</b>                           | 1                                      |
|                            | <b>Max Value</b>                           | $2^{*}64-1$                            |

Deprecated, use `innodb_stats_transient_sample_pages` instead.

- `innodb_stats_transient_sample_pages`

|                            |  |  |

|                            | <b>Dynamic Variable</b>                              | Yes  |
| <b>Permitted Values</b>    | <b>Type</b>  | integer  |
|                            | <b>Default</b>                                       | 8  |

The number of index [pages](#) to sample when estimating [cardinality](#) and other [statistics](#) for an indexed column, such as those calculated by `ANALYZE TABLE`. The default value is 8. Increasing the value improves the accuracy of index statistics, which can improve the [query execution plan](#), at the expense of increased I/O when opening an [InnoDB](#) table or recalculating statistics. For additional information, see [Section 15.6.11.2, “Configuring Non-Persistent Optimizer Statistics Parameters”](#).

#### Note

Setting a high value for `innodb_stats_transient_sample_pages` could result in lengthy `ANALYZE TABLE` execution time. To estimate the number of database pages that will be accessed, see [Section 15.6.11.3, “Estimating ANALYZE TABLE Complexity for InnoDB Tables”](#).

This option only applies when the `innodb_stats_persistent` setting is turned off for a table; when this option is turned on for a table, the `innodb_stats_persistent_sample_pages` setting applies instead. Takes the place of the `innodb_stats_sample_pages` option. See [Section 15.6.11.2, “Configuring Non-Persistent Optimizer Statistics Parameters”](#) for more information.

- `innodb_status_output`

|                            |                                     |                                   |
|----------------------------|-------------------------------------|-----------------------------------|
| <b>Introduced</b>          | 5.7.4                               |                                   |
| <b>Command-Line Format</b> | <code>--innodb_status_output</code> |                                   |
| <b>System Variable</b>     | <b>Name</b>                         | <code>innodb_status_output</code> |

|                         |                         |         |
|-------------------------|-------------------------|---------|
|                         | <b>Variable Scope</b>   | Global  |
|                         | <b>Dynamic Variable</b> | Yes     |
| <b>Permitted Values</b> | <b>Type</b>             | boolean |
|                         | <b>Default</b>          | OFF     |

Enables or disables periodic output for the standard [InnoDB](#) Monitor. Also used in combination with [innodb\\_status\\_output\\_locks](#) to enable or disable periodic output for the [InnoDB](#) Lock Monitor. See [Section 15.17, “InnoDB Monitors”](#) for additional information.

- [innodb\\_status\\_output\\_locks](#)

|                            |  |  |
|----------------------------|--|--|
| <b>Introduced</b>          | 5.7.4  |  |
| <b>Command-Line Format</b> | <a href="#">--innodb_status_output_locks</a> |  |
| <b>System Variable</b>     | <b>Name</b>                                  | <a href="#">innodb_status_output_locks</a> |
|                            | <b>Variable Scope</b>                        | Global                                     |
|                            | <b>Dynamic Variable</b>                      | Yes  |
| <b>Permitted Values</b>    | <b>Type</b>                                  | boolean                                    |
|                            | <b>Default</b>                               | OFF  |

Enables or disables the [InnoDB](#) Lock Monitor. When enabled, the [InnoDB](#) Lock Monitor prints additional information about locks in [SHOW ENGINE INNODB STATUS](#) output and in periodic output printed to the MySQL error log. Periodic output for the [InnoDB](#) Lock Monitor is printed as part of the standard [InnoDB](#) Monitor output. The standard [InnoDB](#) Monitor must therefore be enabled for the [InnoDB](#) Lock Monitor to print data to the MySQL error log periodically. See [Section 15.17, “InnoDB Monitors”](#) for more information.

- [innodb\\_strict\\_mode](#)

|                                       |  |                                    |
|---------------------------------------|--|------------------------------------|
| <b>Command-Line Format</b>            | <a href="#">--innodb_strict_mode=#</a> |                                    |
| <b>System Variable</b>                | <b>Name</b>                            | <a href="#">innodb_strict_mode</a> |
|                                       | <b>Variable Scope</b>                  | Global, Session                    |
|                                       | <b>Dynamic Variable</b>                | Yes                                |
| <b>Permitted Values (&lt;= 5.7.6)</b> | <b>Type</b>                            | boolean                            |
|                                       | <b>Default</b>                         | OFF                                |
| <b>Permitted Values (&gt;= 5.7.7)</b> | <b>Type</b>                            | boolean                            |
|                                       | <b>Default</b>                         | ON                                 |

When [innodb\\_strict\\_mode](#) is ON, [InnoDB](#) returns errors rather than warnings for certain conditions. As of MySQL 5.7.7, the default value is ON.

**Strict mode** helps guard against ignored typos and syntax errors in SQL, or other unintended consequences of various combinations of operational modes and SQL statements. When [innodb\\_strict\\_mode](#) is ON, [InnoDB](#) raises error conditions in certain cases, rather than issuing a warning and processing the specified statement (perhaps with unintended behavior). This is analogous to [sql\\_mode](#) in MySQL, which controls what SQL syntax MySQL accepts, and determines whether it silently ignores errors, or validates input syntax and data values.

The `innodb_strict_mode` setting affects the handling of syntax errors for `CREATE TABLE`, `ALTER TABLE`, `CREATE INDEX`, and `OPTIMIZE TABLE` statements. `innodb_strict_mode` also enables a record size check, so that an `INSERT` or `UPDATE` never fails due to the record being too large for the selected page size.

Oracle recommends enabling `innodb_strict_mode` when using `ROW_FORMAT` and `KEY_BLOCK_SIZE` clauses on `CREATE TABLE`, `ALTER TABLE`, and `CREATE INDEX` statements. When `innodb_strict_mode` is `OFF`, InnoDB ignores conflicting clauses and creates the table or index, with only a warning in the message log. The resulting table might have different behavior than you intended, such as having no compression when you tried to create a compressed table. When `innodb_strict_mode` is `ON`, such problems generate an immediate error and the table or index is not created, avoiding a troubleshooting session later.

You can turn `innodb_strict_mode` `ON` or `OFF` on the command line when you start `mysqld`, or in the configuration file `my.cnf` or `my.ini`. You can also enable or disable `innodb_strict_mode` at runtime with the statement `SET [GLOBAL|SESSION] innodb_strict_mode=mode`, where `mode` is either `ON` or `OFF`. Changing the `GLOBAL` setting requires the `SUPER` privilege and affects the operation of all clients that subsequently connect. Any client can change the `SESSION` setting for `innodb_strict_mode`, and the setting affects only that client.

`innodb_strict_mode` is not applicable to general tablespaces. Tablespace management rules for general tablespaces are strictly enforced independently of `innodb_strict_mode`. For more information, see [Section 14.1.19, “CREATE TABLESPACE Syntax”](#).

- `innodb_support_xa`

|                            |                                  |                                |
|----------------------------|----------------------------------|--------------------------------|
| <b>Deprecated</b>          | 5.7.10                           |                                |
| <b>Command-Line Format</b> | <code>--innodb_support_xa</code> |                                |
| <b>System Variable</b>     | <b>Name</b>                      | <code>innodb_support_xa</code> |
|                            | <b>Variable Scope</b>            | Global, Session                |
|                            | <b>Dynamic Variable</b>          | Yes                            |
| <b>Permitted Values</b>    | <b>Type</b>                      | boolean                        |
|                            | <b>Default</b>                   | <code>TRUE</code>              |

Enables InnoDB support for two-phase commit in `XA` transactions, causing an extra disk flush for transaction preparation. This setting is the default. The XA mechanism is used internally and is essential for any server that has its binary log turned on and is accepting changes to its data from more than one thread. If you turn it off, transactions can be written to the binary log in a different order from the one in which the live database is committing them. This can produce different data when the binary log is replayed in disaster recovery or on a replication slave. Do not turn it off on a replication master server unless you have an unusual setup where only one thread is able to change data.

`innodb_support_xa` is deprecated and will be removed in a future MySQL release. InnoDB support for two-phase commit in XA transactions is always enabled as of MySQL 5.7.10. Disabling `innodb_support_xa` is no longer permitted as it makes replication unsafe and prevents performance gains associated with binary log group commit.

- `innodb_sync_array_size`

|                            |   |                                     |
|----------------------------|---|-------------------------------------|
| <b>Command-Line Format</b> | <code>--innodb_sync_array_size=#</code> |                                     |
| <b>System Variable</b>     | <b>Name</b>                             | <code>innodb_sync_array_size</code> |

|                         |                         |         |
|-------------------------|-------------------------|---------|
| <b>Permitted Values</b> | <b>Variable Scope</b>   | Global  |
|                         | <b>Dynamic Variable</b> | No      |
|                         | <b>Type</b>             | integer |
|                         | <b>Default</b>          | 1       |
|                         | <b>Min Value</b>        | 1       |
|                         | <b>Max Value</b>        | 1024    |

Splits an internal data structure used to coordinate threads, for higher concurrency in workloads with large numbers of waiting threads. This setting must be configured when the MySQL instance is starting up, and cannot be changed afterward. Increasing this option value is recommended for workloads that frequently produce a large number of waiting threads, typically greater than 768.

- [innodb\\_sync\\_spin\\_loops](#)

|                            |   |  |
|----------------------------|---|--|
| <b>Command-Line Format</b> | <code>--innodb_sync_spin_loops=#</code> |  |
| <b>System Variable</b>     | <b>Name</b>                             | <a href="#">innodb_sync_spin_loops</a> |
|                            | <b>Variable Scope</b>                   | Global                                 |
|                            | <b>Dynamic Variable</b>                 | Yes                                    |
| <b>Permitted Values</b>    | <b>Type</b>                             | integer                                |
|                            | <b>Default</b>                          | 30                                     |
|                            | <b>Min Value</b>                        | 0                                      |
|                            | <b>Max Value</b>                        | 4294967295                             |

The number of times a thread waits for an [InnoDB](#) mutex to be freed before the thread is suspended. The default value is 30.

- [innodb\\_sync\\_debug](#)

|                            |                                    |                                   |
|----------------------------|------------------------------------|-----------------------------------|
| <b>Introduced</b>          | 5.7.8                              |                                   |
| <b>Command-Line Format</b> | <code>--innodb_sync_debug=#</code> |                                   |
| <b>System Variable</b>     | <b>Name</b>                        | <a href="#">innodb_sync_debug</a> |
|                            | <b>Variable Scope</b>              | Global                            |
|                            | <b>Dynamic Variable</b>            | No                                |
| <b>Permitted Values</b>    | <b>Type</b>                        | boolean                           |
|                            | <b>Default</b>                     | OFF                               |

Enables sync debug checking for the [InnoDB](#) storage engine. This option is only available if debugging support is compiled in using the `WITH_DEBUG CMake` option.

Prior to MySQL 5.7.8, enabling [InnoDB](#) sync debug checking required that the Debug Sync facility be enabled using the [ENABLE\\_DEBUG\\_SYNC](#) CMake option. This requirement was removed in MySQL 5.7.8 with the introduction of the [innodb\\_sync\\_debug](#) configuration option.

- [innodb\\_table\\_locks](#)

|                            |                                   |                                    |
|----------------------------|-----------------------------------|------------------------------------|
| <b>Command-Line Format</b> | <code>--innodb_table_locks</code> |                                    |
| <b>System Variable</b>     | <b>Name</b>                       | <a href="#">innodb_table_locks</a> |
|                            | <b>Variable Scope</b>             | Global, Session                    |
|                            | <b>Dynamic Variable</b>           | Yes                                |
| <b>Permitted Values</b>    | <b>Type</b>                       | boolean                            |
|                            | <b>Default</b>                    | <code>TRUE</code>                  |

If `autocommit = 0`, [InnoDB](#) honors `LOCK TABLES`; MySQL does not return from `LOCK TABLES ... WRITE` until all other threads have released all their locks to the table. The default value of [innodb\\_table\\_locks](#) is 1, which means that `LOCK TABLES` causes [InnoDB](#) to lock a table internally if `autocommit = 0`.

In MySQL 5.7, [innodb\\_table\\_locks = 0](#) has no effect for tables locked explicitly with `LOCK TABLES ... WRITE`. It does have an effect for tables locked for read or write by `LOCK TABLES ... WRITE` implicitly (for example, through triggers) or by `LOCK TABLES ... READ`.

- [innodb\\_temp\\_data\\_file\\_path](#)

|                            |  |  |
|----------------------------|--|--|
| <b>Introduced</b>          | 5.7.1  |  |
| <b>Command-Line Format</b> | <code>--innodb_temp_data_file_path=file</code> |  |
| <b>System Variable</b>     | <b>Name</b>                                    | <a href="#">innodb_temp_data_file_path</a> |
|                            | <b>Variable Scope</b>                          | Global                                     |
|                            | <b>Dynamic Variable</b>                        | No   |
| <b>Permitted Values</b>    | <b>Type</b>                                    | string                                     |
|                            | <b>Default</b>                                 | <code>ibtmp1:12M:autoextend</code>         |

Specifies the path, file name, and file size for [InnoDB](#) temporary tablespace data files. The full directory path for a file is formed by concatenating [innodb\\_data\\_home\\_dir](#) to the path specified by [innodb\\_temp\\_data\\_file\\_path](#). File size is specified in KB, MB, or GB (1024MB) by appending `K`, `M`, or `G` to the size value. The sum of the sizes of the files must be slightly larger than 12MB. If you do not specify [innodb\\_temp\\_data\\_file\\_path](#), the default behavior is to create a single auto-extending temporary tablespace data file, slightly larger than 12MB, named `ibtmp1`. The size limit of individual files is determined by your operating system. You can set the file size to more than 4GB on operating systems that support big files. Use of raw disk partitions for temporary tablespace data files is not supported.

The name of a [InnoDB](#) temporary table tablespace data file cannot be the same as the name of a [InnoDB](#) data file. Any inability or error creating a temporary tablespace data file is treated as fatal and server startup will be refused. The temporary table tablespace has a dynamically generated space ID, which can change on each server restart.

The [InnoDB](#) temporary tablespace is shared by all non-compressed [InnoDB](#) temporary tables. Compressed [InnoDB](#) temporary tables reside in per-table tablespace files, which are located in the temporary file directory defined by `tmpdir`.

Metadata about active [InnoDB](#) temporary tables is found in [INFORMATION\\_SCHEMA.INNODB\\_TEMP\\_TABLE\\_INFO](#).

- [innodb\\_tmpdir](#)

|                            |                                   |                               |
|----------------------------|-----------------------------------|-------------------------------|
| <b>Introduced</b>          | 5.7.11                            |                               |
| <b>Command-Line Format</b> | <code>--innodb_tmpdir=path</code> |                               |
| <b>System Variable</b>     | <b>Name</b>                       | <a href="#">innodb_tmpdir</a> |
|                            | <b>Variable Scope</b>             | Global, Session               |
|                            | <b>Dynamic Variable</b>           | Yes                           |
| <b>Permitted Values</b>    | <b>Type</b>                       | directory name                |
|                            | <b>Default</b>                    | <a href="#">NULL</a>          |

The [innodb\\_tmpdir](#) option is used to define an alternate directory for temporary sort files created during online [ALTER TABLE](#) operations that rebuild the table.

Online [ALTER TABLE](#) operations that rebuild a table also create an *intermediate* table file in the same directory as the original table. The [innodb\\_tmpdir](#) option is not applicable to intermediate table files.

A valid value is any directory path other than the MySQL data directory path. If the value is [NULL](#) (the default), temporary files are created MySQL temporary directory ([\\$TMPDIR](#) on Unix, [%TEMP%](#) on Windows, or the directory specified by the `--tmpdir` configuration option). If an [innodb\\_tmpdir](#) directory is specified, existence of the directory and permissions are only checked when [innodb\\_tmpdir](#) is configured using a [SET](#) statement. If a symlink is provided in a directory string, the symlink is resolved and stored as an absolute path. The path should not exceed 512 bytes. An online [ALTER TABLE](#) operation reports an error if [innodb\\_tmpdir](#) is set to an invalid directory. [innodb\\_tmpdir](#) overrides the MySQL [tmpdir](#) setting but only for online [ALTER TABLE](#) operations.

The [FILE](#) privilege is required to configure [innodb\\_tmpdir](#).

The [innodb\\_tmpdir](#) option was introduced to help avoid overflowing a temporary file directory located on a [tmpfs](#) file system. Such overflows could occur as a result of large temporary sort files created during online [ALTER TABLE](#) operations that rebuild the table.

In replication environments, only consider replicating an [innodb\\_tmpdir](#) setting if all servers have the same operating system environment. Otherwise, replicating an [innodb\\_tmpdir](#) setting could result in a replication failure when running online [ALTER TABLE](#) operations that rebuild the table. If server operating environments differ, it is recommended that you configure [innodb\\_tmpdir](#) on each server individually.

For related information, see [Where InnoDB Stores Temporary Files](#).

- [innodb\\_thread\\_concurrency](#)

|                            |  |   |
|----------------------------|--|---|
| <b>Command-Line Format</b> | <code>--innodb_thread_concurrency=#</code> |   |
| <b>System Variable</b>     | <b>Name</b>                                | <a href="#">innodb_thread_concurrency</a> |
|                            | <b>Variable Scope</b>                      | Global                                    |
|                            | <b>Dynamic Variable</b>                    | Yes                                       |

|                  |           |         |
|------------------|-----------|---------|
| Permitted Values | Type      | integer |
|                  | Default   | 0       |
|                  | Min Value | 0       |
|                  | Max Value | 1000    |

InnoDB tries to keep the number of operating system threads concurrently inside InnoDB less than or equal to the limit given by this variable (InnoDB uses operating system threads to process user transactions). Once the number of threads reaches this limit, additional threads are placed into a wait state within a “First In, First Out” (FIFO) queue for execution. Threads waiting for locks are not counted in the number of concurrently executing threads.

The range of this variable is 0 to 1000. A value of 0 (the default) is interpreted as infinite concurrency (no concurrency checking). Disabling thread concurrency checking enables InnoDB to create as many threads as it needs. A value of 0 also disables the `queries inside InnoDB` and `queries in queue counters` in the `ROW OPERATIONS` section of `SHOW ENGINE INNODB STATUS` output.

Consider setting this variable if your MySQL instance shares CPU resources with other applications, or if your workload or number of concurrent users is growing. The correct setting depends on workload, computing environment, and the version of MySQL that you are running. You will need to test a range of values to determine the setting that provides the best performance. `innodb_thread_concurrency` is a dynamic variable, which allows you to experiment with different settings on a live test system. If a particular setting performs poorly, you can quickly set `innodb_thread_concurrency` back to 0.

Use the following guidelines to help find and maintain an appropriate setting:

- If the number of concurrent user threads for a workload is less than 64, set `innodb_thread_concurrency=0`.
- If your workload is consistently heavy or occasionally spikes, start by setting `innodb_thread_concurrency=128`, and lowering the value to 96, 80, 64, and so on, until you find the number of threads that provides the best performance. For example, suppose your system typically has 40 to 50 users, but periodically the number increases to 60, 70, or even 200. You find that performance is stable at 80 concurrent users but starts to show a regression above this number. In this case, you would set `innodb_thread_concurrency=80` to avoid impacting performance.
- If you do not want InnoDB to use more than a certain number of vCPUs for user threads (20 vCPUs for example), set `innodb_thread_concurrency` to this number (or possibly lower, depending on performance results). If your goal is to isolate MySQL from other applications, you may consider binding the `mysqld` process exclusively to the vCPUs. Be aware, however, that exclusive binding could result in non-optimal hardware usage if the `mysqld` process is not consistently busy. In this case, you might bind the `mysqld` process to the vCPUs but also allow other applications to use some or all of the vCPUs.

#### Note

From an operating system perspective, using a resource management solution (if available) to manage how CPU time is shared among applications may be preferable to binding the `mysqld` process. For example, you could assign 90% of vCPU time to a given application while other critical process *are not* running, and scale that value back to 40% when other critical processes *are* running.

- `innodb_thread_concurrency` values that are too high can cause performance regression due to increased contention on system internals and resources.
- In some cases, the optimal `innodb_thread_concurrency` setting can be smaller than the number of vCPUs.
- Monitor and analyze your system regularly. Changes to workload, number of users, or computing environment may require that you adjust the `innodb_thread_concurrency` setting.

For related information, see [Section 15.6.6, “Configuring Thread Concurrency for InnoDB”](#).

- `innodb_trx_purge_view_update_only_debug`

|                            |  |  |
|----------------------------|--|--|
| <b>Command-Line Format</b> | <code>--innodb_trx_purge_view_update_only_debug=#</code> |  |
| <b>System Variable</b>     | <b>Name</b>  | <code>innodb_trx_purge_view_update_only_debug</code> |
|                            | <b>Variable Scope</b>                                    | Global   |
|                            | <b>Dynamic Variable</b>                                  | Yes  |
| <b>Permitted Values</b>    | <b>Type</b>  | boolean  |
|                            | <b>Default</b>   | <code>OFF</code>                                     |

Pauses purging of delete-marked records while allowing the purge view to be updated. This option artificially creates a situation in which the purge view is updated but purges have not yet been performed. This option is only available if debugging support is compiled in using the `WITH_DEBUG CMake` option.

- `innodb_trx_rseg_n_slots_debug`

|                            |  |  |
|----------------------------|--|--|
| <b>Command-Line Format</b> | <code>--innodb_trx_rseg_n_slots_debug=#</code> |  |
| <b>System Variable</b>     | <b>Name</b>                                    | <code>innodb_trx_rseg_n_slots_debug</code> |
|                            | <b>Variable Scope</b>                          | Global                                     |
|                            | <b>Dynamic Variable</b>                        | Yes  |
| <b>Permitted Values</b>    | <b>Type</b>                                    | integer                                    |
|                            | <b>Default</b>                                 | <code>0</code>                             |
|                            | <b>Max Value</b>                               | <code>1024</code>                          |

Sets a debug flag that limits `TRX_RSEG_N_SLOTS` to a given value for the `trx_rsegf_undo_find_free` function which looks for a free slot for an undo log segment. This option is only available if debugging support is compiled in using the `WITH_DEBUG CMake` option.

- `innodb_thread_sleep_delay`

|                            |  |  |
|----------------------------|--|--|
| <b>Command-Line Format</b> | <code>--innodb_thread_sleep_delay=#</code> |  |
| <b>System Variable</b>     | <b>Name</b>                                | <code>innodb_thread_sleep_delay</code> |
|                            | <b>Variable Scope</b>                      | Global                                 |
|                            | <b>Dynamic Variable</b>                    | Yes                                    |

|  |                  |                      |
|--|------------------|----------------------|
| <b>Permitted Values</b> ( $\geq$ 5.7.4)                  | <b>Type</b>      | integer              |
|  | <b>Default</b>   | 10000                |
|  | <b>Min Value</b> | 0                    |
|  | <b>Max Value</b> | 10000000             |
| <b>Permitted Values</b> (32-bit platforms, $\leq$ 5.7.3) | <b>Type</b>      | integer              |
|  | <b>Default</b>   | 10000                |
|  | <b>Min Value</b> | 0                    |
|  | <b>Max Value</b> | 4294967295           |
| <b>Permitted Values</b> (64-bit platforms, $\leq$ 5.7.3) | <b>Type</b>      | integer              |
|  | <b>Default</b>   | 10000                |
|  | <b>Min Value</b> | 0                    |
|  | <b>Max Value</b> | 18446744073709551615 |

How long [InnoDB](#) threads sleep before joining the [InnoDB](#) queue, in microseconds. The default value is 10000. A value of 0 disables sleep. In MySQL 5.6.3 and higher, you can set the configuration option [innodb\\_adaptive\\_max\\_sleep\\_delay](#) to the highest value you would allow for [innodb\\_thread\\_sleep\\_delay](#), and InnoDB automatically adjusts [innodb\\_thread\\_sleep\\_delay](#) up or down depending on the current thread-scheduling activity. This dynamic adjustment helps the thread scheduling mechanism to work smoothly during times when the system is lightly loaded and when it is operating near full capacity.

For more information, see [Section 15.6.6, “Configuring Thread Concurrency for InnoDB”](#).

- [innodb\\_undo\\_directory](#)

|   |   |                                       |
|---|---|---------------------------------------|
| <b>Command-Line Format</b>              | <code>--innodb_undo_directory=dir_name</code> |                                       |
| <b>System Variable</b>                  | <b>Name</b>                                   | <a href="#">innodb_undo_directory</a> |
|   | <b>Variable Scope</b>                         | Global                                |
|   | <b>Dynamic Variable</b>                       | No                                    |
| <b>Permitted Values</b> ( $\leq$ 5.7.7) | <b>Type</b>                                   | directory name                        |
|   | <b>Default</b>                                | .                                     |
| <b>Permitted Values</b> ( $\geq$ 5.7.8) | <b>Type</b>                                   | directory name                        |

The path where [InnoDB](#) creates separate tablespaces for the undo logs. Typically used to place undo logs on a different storage device. Used in conjunction with [innodb\\_undo\\_logs](#) and [innodb\\_undo\\_tablespaces](#), which determine the disk layout of the undo logs outside the [system tablespace](#).

Prior to MySQL 5.7.8, the [innodb\\_undo\\_directory](#) default value is “.”, which represents the same directory where [InnoDB](#) creates its other log files by default. As of MySQL 5.7.8, there is no default value (it is NULL). If a path is not specified, undo tablespaces are created in the MySQL data directory, as defined by [datadir](#).

For more information about configuring separate tablespaces for undo logs, see [Section 15.7.7, “Storing InnoDB Undo Logs in Separate Tablespaces”](#).

- `innodb_undo_log_truncate`

|                            |   |                                       |
|----------------------------|---|---------------------------------------|
| <b>Introduced</b>          | 5.7.5                                     |                                       |
| <b>Command-Line Format</b> | <code>--innodb_undo_log_truncate=#</code> |                                       |
| <b>System Variable</b>     | <b>Name</b>                               | <code>innodb_undo_log_truncate</code> |
|                            | <b>Variable Scope</b>                     | Global                                |
|                            | <b>Dynamic Variable</b>                   | Yes                                   |
| <b>Permitted Values</b>    | <b>Type</b>                               | boolean                               |
|                            | <b>Default</b>                            | <code>OFF</code>                      |

When you enable `innodb_undo_log_truncate`, undo tablespaces that exceed the threshold value defined by `innodb_max_undo_log_size` are marked for truncation. Only undo logs that reside in undo tablespaces can be truncated. Truncation of undo logs that reside in the system tablespace is not supported. For truncation to occur, there must be at least two undo tablespaces and two redo-enabled undo logs configured to use the undo tablespaces. This means that `innodb_undo_tablespaces` must be set to a value equal to or greater than 2, and `innodb_undo_logs` must set to a value equal to or greater than 35.

The `innodb_purge_rseg_truncate_frequency` configuration option can be used to expedite truncation of undo tablespaces.

For more information, see [Section 15.7.8, “Truncating Undo Logs That Reside in Undo Tablespaces”](#).

- `innodb_undo_logs`

|                            |                                   |                               |
|----------------------------|-----------------------------------|-------------------------------|
| <b>Command-Line Format</b> | <code>--innodb_undo_logs=#</code> |                               |
| <b>System Variable</b>     | <b>Name</b>                       | <code>innodb_undo_logs</code> |
|                            | <b>Variable Scope</b>             | Global                        |
|                            | <b>Dynamic Variable</b>           | Yes                           |
| <b>Permitted Values</b>    | <b>Type</b>                       | integer                       |
|                            | <b>Default</b>                    | <code>128</code>              |
|                            | <b>Min Value</b>                  | <code>0</code>                |
|                            | <b>Max Value</b>                  | <code>128</code>              |

Defines the number of [rollback segments](#) used by InnoDB. The `innodb_undo_logs` option replaces `innodb_rollback_segments`.

One rollback segment is always assigned to the system tablespace, and as of MySQL 5.7.2, 32 rollback segments are reserved for use by temporary tables and are hosted in the temporary tablespace (`ibtmp1`). To allocate additional rollback segments for data-modifying transactions that generate undo records, `innodb_undo_logs` must be set to a value greater than 33. If you configure separate undo tablespaces, the rollback segment in the system tablespace is rendered inactive. Each rollback segment can support a maximum of 1024 data-modifying transactions.

When `innodb_undo_logs` is set to 32 or less, InnoDB assigns one rollback segment to the system tablespace and 32 to the temporary tablespace (`ibtmp1`).

When `innodb_undo_logs` is set to a value greater than 32, InnoDB assigns one rollback segment to the system tablespace, 32 to the temporary tablespace (`ibtmp1`), and additional rollback segments to undo tablespaces, if present. If undo tablespaces are not present, additional rollback segments are assigned to the system tablespace.

Although you can increase or decrease the number of rollback segments used by InnoDB, the number of rollback segments physically present in the system never decreases. Thus you might start with a low value for this parameter and gradually increase it, to avoid allocating rollback segments that are not required. If `innodb_undo_logs` is not set, it defaults to the maximum value of 128. For the total number of available rollback segments, rather than the number of active ones, see the `InnoDB_available_undo_logs` status variable.

For information about rollback segments, see [Section 15.3, “InnoDB Multi-Versioning”](#). For information about configuring separate undo tablespaces, see [Section 15.7.7, “Storing InnoDB Undo Logs in Separate Tablespaces”](#).

- `innodb_undo_tablespaces`

|                                       |  |                                      |
|---------------------------------------|--|--------------------------------------|
| <b>Command-Line Format</b>            | <code>--innodb_undo_tablespaces=#</code> |                                      |

|                                       | <b>Max Value</b>                         | 126                                  |
| <b>Permitted Values (&gt;= 5.7.8)</b> | <b>Type</b>                              | integer                              |
|                                       | <b>Default</b>                           | 0                                    |
|                                       | <b>Min Value</b>                         | 0                                    |
|                                       | <b>Max Value</b>                         | 95                                   |

The number of `tablespace` files that `rollback segments` are divided between. By default, rollback segments are assigned to the `system tablespace`, and the system tablespace is always assigned at least one rollback segment.

Because undo logs can become large during long-running transactions, having undo logs in multiple tablespaces reduces the maximum size of any one tablespace. The undo tablespace files are created in the location defined by `innodb_undo_directory`, with names in the form of `undoN`, where `N` is a sequential series of integers (including leading zeros). The default size of an undo tablespace file is 10M.

#### Important

`innodb_undo_tablespaces` can only be configured prior to initializing the MySQL instance and cannot be changed afterward. If no value is specified,

the instance is initialized using the default setting (0). Attempting to restart InnoDB with a greater number of undo tablespaces than specified when the MySQL instance was initialized results in a startup failure and an error stating that InnoDB did not find the expected number of undo tablespaces.

As MySQL 5.7.2, 32 of 128 rollback segments are reserved for temporary tables, as described in [Section 15.4.12.1, “InnoDB Temporary Table Undo Logs”](#). One rollback segment is always assigned to the system tablespace, which leaves 95 rollback segments available for undo tablespaces. This change effectively reduces the `innodb_undo_tablespaces` maximum limit from 126 to 95, and in MySQL 5.7.8, the `innodb_undo_tablespaces` maximum value is reduced to 95.

For information about configuring separate undo tablespaces, see [Section 15.7.7, “Storing InnoDB Undo Logs in Separate Tablespaces”](#).

- `innodb_use_native_aio`

|                            |  |                                    |
|----------------------------|--|------------------------------------|
| <b>Command-Line Format</b> | <code>--innodb_use_native_aio=#</code> |                                    |
| <b>System Variable</b>     | <b>Name</b>                            | <code>innodb_use_native_aio</code> |
|                            | <b>Variable Scope</b>                  | Global                             |
|                            | <b>Dynamic Variable</b>                | No                                 |
| <b>Permitted Values</b>    | <b>Type</b>                            | boolean                            |
|                            | <b>Default</b>                         | ON                                 |

Specifies whether to use the Linux asynchronous I/O subsystem. This variable applies to Linux systems only, and cannot be changed while the server is running. Normally, you do not need to touch this option, because it is enabled by default.

As of MySQL 5.5, the [asynchronous I/O](#) capability that InnoDB has on Windows systems is available on Linux systems. (Other Unix-like systems continue to use synchronous I/O calls.) This feature improves the scalability of heavily I/O-bound systems, which typically show many pending reads/writes in the output of the command `SHOW ENGINE INNODB STATUS\G`.

Running with a large number of InnoDB I/O threads, and especially running multiple such instances on the same server machine, can exceed capacity limits on Linux systems. In this case, you may receive the following error:

```
EAGAIN: The specified maxevents exceeds the user's limit of available events.
```

You can typically address this error by writing a higher limit to `/proc/sys/fs/aio-max-nr`.

However, if a problem with the asynchronous I/O subsystem in the OS prevents InnoDB from starting, you can start the server with `innodb_use_native_aio=0` disabled (use `innodb_use_native_aio=0` in the option file). This option may also be turned off automatically during startup if InnoDB detects a potential problem such as a combination of `tmpdir` location, `tmpfs` filesystem, and Linux kernel that does not support AIO on `tmpfs`.

- `innodb_use_sys_malloc`

|                            |  |                                    |
|----------------------------|--|------------------------------------|
| <b>Deprecated</b>          | 5.6.3                                  |                                    |
| <b>Removed</b>             | 5.7.4                                  |                                    |
| <b>Command-Line Format</b> | <code>--innodb_use_sys_malloc=#</code> |                                    |
| <b>System Variable</b>     | <b>Name</b>                            | <code>innodb_use_sys_malloc</code> |

|                         |                         |         |
|-------------------------|-------------------------|---------|
|                         | <b>Variable Scope</b>   | Global  |
|                         | <b>Dynamic Variable</b> | No      |
| <b>Permitted Values</b> | <b>Type</b>             | boolean |
|                         | <b>Default</b>          | ON      |

Whether [InnoDB](#) uses the operating system memory allocator (ON) or its own (OFF). The default value is ON. See [Section 15.6.4, “Configuring the Memory Allocator for InnoDB”](#) for more information.

`innodb_use_sys_malloc` was deprecated in MySQL 5.6.3 and removed in MySQL 5.7.4.

- `innodb_version`

The [InnoDB](#) version number. In 5.7, the separate numbering for [InnoDB](#) does not apply and this value is the same as for the `version` variable.

- `innodb_write_io_threads`

|                            |  |                                      |
|----------------------------|--|--------------------------------------|
| <b>Command-Line Format</b> | <code>--innodb_write_io_threads=#</code> |                                      |
| <b>System Variable</b>     | <b>Name</b>                              | <code>innodb_write_io_threads</code> |
|                            | <b>Variable Scope</b>                    | Global                               |
|                            | <b>Dynamic Variable</b>                  | No                                   |
| <b>Permitted Values</b>    | <b>Type</b>                              | integer                              |
|                            | <b>Default</b>                           | 4                                    |
|                            | <b>Min Value</b>                         | 1                                    |
|                            | <b>Max Value</b>                         | 64                                   |

The number of I/O threads for write operations in [InnoDB](#). The default value is 4. Its counterpart for read threads is `innodb_read_io_threads`. See [Section 15.6.7, “Configuring the Number of Background InnoDB I/O Threads”](#) for more information. For general I/O tuning advice, see [Section 9.5.8, “Optimizing InnoDB Disk I/O”](#).

#### Note

On Linux systems, running multiple MySQL servers (typically more than 12) with default settings for `innodb_read_io_threads`, `innodb_write_io_threads`, and the Linux `aio-max-nr` setting can exceed system limits. Ideally, increase the `aio-max-nr` setting; as a workaround, you might reduce the settings for one or both of the MySQL configuration options.

You should also take into consideration the value of `sync_binlog`, which controls synchronization of the binary log to disk.

For general I/O tuning advice, see [Section 9.5.8, “Optimizing InnoDB Disk I/O”](#).

## 15.15 InnoDB INFORMATION\_SCHEMA Tables

This section provides information and usage examples for [InnoDB INFORMATION\\_SCHEMA](#) tables.

[InnoDB INFORMATION\\_SCHEMA](#) tables provide metadata, status information, and statistics about various aspects of the [InnoDB](#) storage engine. You can view a list of [InnoDB INFORMATION\\_SCHEMA](#) tables by issuing a [SHOW TABLES](#) statement on the [INFORMATION\\_SCHEMA](#) database:

```
mysql> SHOW TABLES FROM INFORMATION_SCHEMA LIKE 'INNODB%';
```

For table definitions, see [Section 23.31, “InnoDB INFORMATION\\_SCHEMA Tables”](#). For general information regarding the [MySQL INFORMATION\\_SCHEMA](#) database, see [Chapter 23, INFORMATION\\_SCHEMA Tables](#).

## 15.15.1 InnoDB INFORMATION\_SCHEMA Tables about Compression

There are two pairs of [InnoDB INFORMATION\\_SCHEMA](#) tables about compression that can provide insight into how well compression is working overall:

- [INNODB\\_CMP](#) and [INNODB\\_CMP\\_RESET](#) contain information about the number of compression operations and the amount of time spent performing compression.
- [INNODB\\_CMPMEM](#) and [INNODB\\_CMP\\_RESET](#) contain information about the way memory is allocated for compression.

### 15.15.1.1 INNODB\_CMP and INNODB\_CMP\_RESET

The [INNODB\\_CMP](#) and [INNODB\\_CMP\\_RESET](#) tables contain status information about operations related to compressed tables, which are described in [Section 15.9, “InnoDB Table and Page Compression”](#). The [PAGE\\_SIZE](#) column reports the compressed [page size](#).

These two tables have identical contents, but reading from [INNODB\\_CMP\\_RESET](#) resets the statistics on compression and uncompression operations. For example, if you archive the output of [INNODB\\_CMP\\_RESET](#) every 60 minutes, you see the statistics for each hourly period. If you monitor the output of [INNODB\\_CMP](#) (making sure never to read [INNODB\\_CMP\\_RESET](#)), you see the cumulated statistics since InnoDB was started.

For the table definition, see [Section 23.31.4, “The INFORMATION\\_SCHEMA INNODB\\_CMP and INNODB\\_CMP\\_RESET Tables”](#).

### 15.15.1.2 INNODB\_CMPMEM and INNODB\_CMPMEM\_RESET

The [INNODB\\_CMPMEM](#) and [INNODB\\_CMPMEM\\_RESET](#) tables contain status information about compressed pages that reside in the buffer pool. Please consult [Section 15.9, “InnoDB Table and Page Compression”](#) for further information on compressed tables and the use of the buffer pool. The [INNODB\\_CMP](#) and [INNODB\\_CMP\\_RESET](#) tables should provide more useful statistics on compression.

## Internal Details

[InnoDB](#) uses a [buddy allocator](#) system to manage memory allocated to [pages of various sizes](#), from 1KB to 16KB. Each row of the two tables described here corresponds to a single page size.

The [INNODB\\_CMPMEM](#) and [INNODB\\_CMPMEM\\_RESET](#) tables have identical contents, but reading from [INNODB\\_CMPMEM\\_RESET](#) resets the statistics on relocation operations. For example, if every 60 minutes you archived the output of [INNODB\\_CMPMEM\\_RESET](#), it would show the hourly statistics. If you never read [INNODB\\_CMPMEM\\_RESET](#) and monitored the output of [INNODB\\_CMPMEM](#) instead, it would show the cumulated statistics since [InnoDB](#) was started.

For the table definition, see [Section 23.31.5, “The INFORMATION\\_SCHEMA INNODB\\_CMPMEM and INNODB\\_CMPMEM\\_RESET Tables”](#).

### 15.15.1.3 Using the Compression Information Schema Tables

#### Example 15.10 Using the Compression Information Schema Tables

The following is sample output from a database that contains compressed tables (see [Section 15.9, “InnoDB Table and Page Compression”](#), `INNODB_CMP`, `INNODB_CMP_PER_INDEX`, and `INNODB_CMPMEM`).

The following table shows the contents of `INFORMATION_SCHEMA.INNODB_CMP` under a light [workload](#). The only compressed page size that the buffer pool contains is 8K. Compressing or uncompressing pages has consumed less than a second since the time the statistics were reset, because the columns `COMPRESS_TIME` and `UNCOMPRESS_TIME` are zero.

| page size | compress ops | compress ops ok | compress time | uncompress ops | uncompress time |
|-----------|--------------|-----------------|---------------|----------------|-----------------|
| 1024      | 0            | 0               | 0             | 0              | 0               |
| 2048      | 0            | 0               | 0             | 0              | 0               |
| 4096      | 0            | 0               | 0             | 0              | 0               |
| 8192      | 1048         | 921             | 0             | 61             | 0               |
| 16384     | 0            | 0               | 0             | 0              | 0               |

According to `INNODB_CMPMEM`, there are 6169 compressed 8KB pages in the [buffer pool](#). The only other allocated block size is 64 bytes. The smallest `PAGE_SIZE` in `INNODB_CMPMEM` is used for block descriptors of those compressed pages for which no uncompressed page exists in the buffer pool. We see that there are 5910 such pages. Indirectly, we see that 259 (6169-5910) compressed pages also exist in the buffer pool in uncompressed form.

The following table shows the contents of `INFORMATION_SCHEMA.INNODB_CMPMEM` under a light [workload](#). Some memory is unusable due to fragmentation of the memory allocator for compressed pages: `SUM(PAGE_SIZE*PAGES_FREE)=6784`. This is because small memory allocation requests are fulfilled by splitting bigger blocks, starting from the 16K blocks that are allocated from the main buffer pool, using the buddy allocation system. The fragmentation is this low because some allocated blocks have been relocated (copied) to form bigger adjacent free blocks. This copying of `SUM(PAGE_SIZE*RELOCATION_OPS)` bytes has consumed less than a second (`SUM(RELOCATION_TIME)=0`).

| page size | pages used | pages free | relocation ops | relocation time |
|-----------|------------|------------|----------------|-----------------|
| 64        | 5910       | 0          | 2436           | 0               |
| 128       | 0          | 1          | 0              | 0               |
| 256       | 0          | 0          | 0              | 0               |
| 512       | 0          | 1          | 0              | 0               |
| 1024      | 0          | 0          | 0              | 0               |
| 2048      | 0          | 1          | 0              | 0               |
| 4096      | 0          | 1          | 0              | 0               |
| 8192      | 6169       | 0          | 5              | 0               |
| 16384     | 0          | 0          | 0              | 0               |

### 15.15.2 InnoDB INFORMATION\_SCHEMA Transaction and Locking Information

Three `InnoDB INFORMATION_SCHEMA` tables enable you to monitor transactions and diagnose potential locking problems:

- [INNODB\\_TRX](#): Contains information about every transaction currently executing inside [InnoDB](#), including the transaction state (for example, whether it is running or waiting for a lock), when the transaction started, and the particular SQL statement the transaction is executing.
- [INNODB\\_LOCKS](#): Each transaction in InnoDB that is waiting for another transaction to release a lock ([INNODB\\_TRX.TRX\\_STATE](#) is [LOCK\\_WAIT](#)) is blocked by exactly one blocking lock request. That blocking lock request is for a row or table lock held by another transaction in an incompatible mode. A lock that blocks a transaction is always held in a mode incompatible with the mode of requested lock (read vs. write, shared vs. exclusive). The blocked transaction cannot proceed until the other transaction commits or rolls back, thereby releasing the requested lock. For every blocked transaction, [INNODB\\_LOCKS](#) contains one row that describes each lock the transaction has requested, and for which it is waiting. [INNODB\\_LOCKS](#) also contains one row for each lock that is blocking another transaction, whatever the state of the transaction that holds the lock ([INNODB\\_TRX.TRX\\_STATE](#) is [RUNNING](#), [LOCK\\_WAIT](#), [ROLLING\\_BACK](#) or [COMMITTING](#)).
- [INNODB\\_LOCK\\_WAITS](#): This table indicates which transactions are waiting for a given lock, or for which lock a given transaction is waiting. This table contains one or more rows for each blocked transaction, indicating the lock it has requested and any locks that are blocking that request. The [REQUESTED\\_LOCK\\_ID](#) value refers to the lock requested by a transaction, and the [BLOCKING\\_LOCK\\_ID](#) value refers to the lock (held by another transaction) that prevents the first transaction from proceeding. For any given blocked transaction, all rows in [INNODB\\_LOCK\\_WAITS](#) have the same value for [REQUESTED\\_LOCK\\_ID](#) and different values for [BLOCKING\\_LOCK\\_ID](#).

For more information about the preceding tables, see [Section 23.31.27](#), “The [INFORMATION\\_SCHEMA INNODB\\_TRX](#) Table”, [Section 23.31.13](#), “The [INFORMATION\\_SCHEMA INNODB\\_LOCKS](#) Table”, and [Section 23.31.14](#), “The [INFORMATION\\_SCHEMA INNODB\\_LOCK\\_WAITS](#) Table”.

### 15.15.2.1 Using InnoDB Transaction and Locking Information

#### Identifying Blocking Transactions

It is sometimes helpful to identify which transaction blocks another. The tables that contain information about [InnoDB](#) transactions and data locks enable you to determine which transaction is waiting for another, and which resource is being requested. (For descriptions of these tables, see [Section 15.15.2](#), “[InnoDB INFORMATION\\_SCHEMA Transaction and Locking Information](#)”.)

Suppose that three sessions are running concurrently. Each session corresponds to a MySQL thread, and executes one transaction after another. Consider the state of the system when these sessions have issued the following statements, but none has yet committed its transaction:

- Session A:

```
BEGIN;
SELECT a FROM t FOR UPDATE;
SELECT SLEEP(100);
```

- Session B:

```
SELECT b FROM t FOR UPDATE;
```

- Session C:

```
SELECT c FROM t FOR UPDATE;
```

In this scenario, use the following query to see which transactions are waiting and which transactions are blocking them:

```
SELECT
  r.trx_id waiting_trx_id,
```

```

r.trx_mysql_thread_id waiting_thread,
r.trx_query waiting_query,
b.trx_id blocking_trx_id,
b.trx_mysql_thread_id blocking_thread,
b.trx_query blocking_query
FROM      information_schema.innodb_lock_waits w
INNER JOIN information_schema.innodb_trx b
  ON b.trx_id = w.blocking_trx_id
INNER JOIN information_schema.innodb_trx r
  ON r.trx_id = w.requesting_trx_id;

```

Or, more simply, use the `sys` schema `innodb_lock_waits` view:

```

SELECT
  waiting_trx_id,
  waiting_pid,
  waiting_query,
  blocking_trx_id,
  blocking_pid,
  blocking_query
FROM sys.innodb_lock_waits;

```

| waiting<br>trx id | waiting<br>thread | waiting query                 | blocking<br>trx id | blocking<br>thread | blocking query                |
|-------------------|-------------------|-------------------------------|--------------------|--------------------|-------------------------------|
| A4                | 6                 | SELECT b FROM t FOR<br>UPDATE | A3                 | 5                  | SELECT SLEEP(100)             |
| A5                | 7                 | SELECT c FROM t FOR<br>UPDATE | A3                 | 5                  | SELECT SLEEP(100)             |
| A5                | 7                 | SELECT c FROM t FOR<br>UPDATE | A4                 | 6                  | SELECT b FROM t FOR<br>UPDATE |

In the preceding table, you can identify sessions by the “waiting query” or “blocking query” columns. As you can see:

- Session B (trx id [A4](#), thread [6](#)) and Session C (trx id [A5](#), thread [7](#)) are both waiting for Session A (trx id [A3](#), thread [5](#)).
- Session C is waiting for Session B as well as Session A.

You can see the underlying data in the tables `INNODB_TRX`, `INNODB_LOCKS`, and `INNODB_LOCK_WAITS`.

The following table shows some sample contents of `INFORMATION_SCHEMA.INNODB_TRX`.

| trx<br>id | trx<br>state | trx started            | trx<br>requested<br>lock id | trx wait started       | trx<br>weight | trx mysql<br>thread id | trx query                     |
|-----------|--------------|------------------------|-----------------------------|------------------------|---------------|------------------------|-------------------------------|
| A3        | RUN-<br>NING | 2008-01-15<br>16:44:54 | NULL                        | NULL                   | 2             | 5                      | SELECT<br>SLEEP(100)          |

## Correlating InnoDB Transactions with MySQL Sessions

Sometimes it is useful to correlate internal `InnoDB` locking information with the session-level information maintained by MySQL. For example, you might like to know, for a given `InnoDB` transaction ID, the corresponding MySQL session ID and name of the session that may be holding a lock, and thus blocking other transactions.

The following output from the `INFORMATION_SCHEMA` tables is taken from a somewhat loaded system. As can be seen, there are several transactions running.

The following `INNODB_LOCKS` and `INNODB_LOCK_WAITS` tables show that:

- Transaction `77F` (executing an `INSERT`) is waiting for transactions `77E`, `77D`, and `77B` to commit.
- Transaction `77E` (executing an `INSERT`) is waiting for transactions `77D` and `77B` to commit.
- Transaction `77D` (executing an `INSERT`) is waiting for transaction `77B` to commit.
- Transaction `77B` (executing an `INSERT`) is waiting for transaction `77A` to commit.
- Transaction `77A` is running, currently executing `SELECT`.
- Transaction `E56` (executing an `INSERT`) is waiting for transaction `E55` to commit.
- Transaction `E55` (executing an `INSERT`) is waiting for transaction `19C` to commit.
- Transaction `19C` is running, currently executing an `INSERT`.

### Note

There may be inconsistencies between queries shown in the `INFORMATION_SCHEMA.PROCESSLIST` and `INNODB_TRX` tables. For an explanation, see [Section 15.15.2.3, “Persistence and Consistency of InnoDB Transaction and Locking Information”](#).

The following table shows the contents of `INFORMATION_SCHEMA.PROCESSLIST` for a system running a heavy [workload](#).

| ID  | USER | HOST      | DB   | COMMAND | TIME | STATE  | INFO                      |
|-----|------|-----------|------|---------|------|--------|---------------------------|
| 384 | root | localhost | test | Query   | 10   | update | INSERT INTO t2 VALUES ... |
| 257 | root | localhost | test | Query   | 3    | update | INSERT INTO t2 VALUES ... |
| 130 | root | localhost | test | Query   | 0    | update | INSERT INTO t2 VALUES ... |
| 61  | root | localhost | test | Query   | 1    | update | INSERT INTO t2 VALUES ... |

| ID | USER | HOST      | DB   | COMMAND | TIME | STATE     | INFO                      |
|----|------|-----------|------|---------|------|-----------|---------------------------|
| 8  | root | localhost | test | Query   | 1    | update    | INSERT INTO t2 VALUES ... |
| 4  | root | localhost | test | Query   | 0    | preparing | SELECT * FROM PROCESSLIST |
| 2  | root | localhost | test | Sleep   | 566  |           | NULL                      |

The following table shows the contents of `INFORMATION_SCHEMA.INNODB_TRX` for a system running a heavy [workload](#).

| trx id | trx state | trx started         | trx requested lock id | trx wait started    | trx weight | trx mysql thread id | trx query                            |

### 15.15.2.2 InnoDB Lock and Lock-Wait Information

When a transaction updates a row in a table, or locks it with `SELECT FOR UPDATE`, InnoDB establishes a list or queue of locks on that row. Similarly, InnoDB maintains a list of locks on a table for table-level locks. If a second transaction wants to update a row or lock a table already locked by a prior transaction in an incompatible mode, InnoDB adds a lock request for the row to the corresponding queue. For a lock to be acquired by a transaction, all incompatible lock requests previously entered into the lock queue for that row or table must be removed (which occurs when the transactions holding or requesting those locks either commit or roll back).

A transaction may have any number of lock requests for different rows or tables. At any given time, a transaction may request a lock that is held by another transaction, in which case it is blocked by that other transaction. The requesting transaction must wait for the transaction that holds the blocking lock to commit or roll back. If a transaction is not waiting for a lock, it is in a `RUNNING` state. If a transaction is waiting for a lock, it is in a `LOCK WAIT` state. (The `INFORMATION_SCHEMA.INNODB_TRX` table indicates transaction state values.)

The `INNODB_LOCKS` table holds one or more rows for each `LOCK WAIT` transaction, indicating any lock requests that prevent its progress. This table also contains one row describing each lock in a queue of locks pending for a given row or table. The `INNODB_LOCK_WAITS` table shows which locks already held by a transaction are blocking locks requested by other transactions.

### 15.15.2.3 Persistence and Consistency of InnoDB Transaction and Locking Information

The data exposed by the transaction and locking tables (`INNODB_TRX`, `INNODB_LOCKS`, and `INNODB_LOCK_WAITS`) represents a glimpse into fast-changing data. This is not like user tables, where the data changes only when application-initiated updates occur. The underlying data is internal system-managed data, and can change very quickly.

For performance reasons, and to minimize the chance of misleading joins between the transaction and locking tables, InnoDB collects the required transaction and locking information into an intermediate buffer whenever a `SELECT` on any of the tables is issued. This buffer is refreshed only if more than 0.1 seconds has elapsed since the last time the buffer was read. The data needed to fill the three tables is fetched atomically and consistently and is saved in this global internal buffer, forming a point-in-time “snapshot”. If multiple table accesses occur within 0.1 seconds (as they almost certainly do when MySQL processes a join among these tables), then the same snapshot is used to satisfy the query.

A correct result is returned when you join any of these tables together in a single query, because the data for the three tables comes from the same snapshot. Because the buffer is not refreshed with every query of any of these tables, if you issue separate queries against these tables within a tenth of a second, the results are the same from query to query. On the other hand, two separate queries of the same or different tables issued more than a tenth of a second apart may see different results, since the data come from different snapshots.

Because InnoDB must temporarily stall while the transaction and locking data is collected, too frequent queries of these tables can negatively impact performance as seen by other users.

As these tables contain sensitive information (at least `INNODB_LOCKS.LOCK_DATA` and `INNODB_TRX.TRX_QUERY`), for security reasons, only the users with the `PROCESS` privilege are allowed to `SELECT` from them.

As described previously, the data that fills the transaction and locking tables (`INNODB_TRX`, `INNODB_LOCKS` and `INNODB_LOCK_WAITS`) is fetched automatically and saved to an intermediate buffer that provides a “point-in-time” snapshot. The data across all three tables is consistent when queried from the same snapshot. However, the underlying data changes so fast that similar glimpses at other, similarly fast-changing data, may not be in synchrony. Thus, you should be careful when comparing data in the InnoDB transaction and locking tables with data in the `PROCESSLIST` table. The data from the `PROCESSLIST` table does not come from the same snapshot as the data about locking and transactions. Even if you issue a single `SELECT` (joining `INNODB_TRX` and `PROCESSLIST`, for example), the content of those tables is generally not consistent. `INNODB_TRX` may reference rows that are not present in `PROCESSLIST` or the currently executing SQL query of a transaction shown in `INNODB_TRX.TRX_QUERY` may differ from the one in `PROCESSLIST.INFO`.

### 15.15.3 InnoDB INFORMATION\_SCHEMA System Tables

You can extract metadata about schema objects managed by InnoDB using InnoDB `INFORMATION_SCHEMA` system tables. This information comes from the InnoDB internal system tables (also referred to as the InnoDB data dictionary), which cannot be queried directly like regular InnoDB tables. Traditionally, you would get this type of information using the techniques from [Section 15.17, “InnoDB Monitors”](#), setting up InnoDB monitors and parsing the output from the `SHOW ENGINE INNODB STATUS` statement. The InnoDB `INFORMATION_SCHEMA` table interface allows you to query this data using SQL.

With the exception of `INNODB_SYS_TABLESTATS`, for which there is no corresponding internal system table, InnoDB `INFORMATION_SCHEMA` system tables are populated with data read directly from internal InnoDB system tables rather than from metadata that is cached in memory.

InnoDB `INFORMATION_SCHEMA` system tables include the tables listed below. `INNODB_SYS_DATAFILES` and `INNODB_SYS_TABLESPACES` were added in MySQL 5.6.6 with the introduction of support for the `DATA DIRECTORY='directory'` clause of the `CREATE TABLE` statement, which allows InnoDB file-per-table tablespaces (`.ibd` files) to be created in a location outside the MySQL data directory.

```
mysql> SHOW TABLES FROM INFORMATION_SCHEMA LIKE 'INNODB_SYS%';
+-----+
| Tables_in_information_schema (INNODB_SYS%) |
+-----+
| INNODB_SYS_DATAFILES                       |
| INNODB_SYS_TABLESTATS                     |
| INNODB_SYS_FOREIGN                         |
| INNODB_SYS_COLUMNS                         |
+-----+
```

|                         |
|-------------------------|
| INNODB_SYS_INDEXES      |
| INNODB_SYS_FIELDS       |
| INNODB_SYS_TABLESPACES  |
| INNODB_SYS_FOREIGN_COLS |
| INNODB_SYS_TABLES       |

The table names are indicative of the type of data provided:

- [INNODB\\_SYS\\_TABLES](#) provides metadata about [InnoDB](#) tables, equivalent to the information in the [SYS\\_TABLES](#) table in the [InnoDB](#) data dictionary.
- [INNODB\\_SYS\\_COLUMNS](#) provides metadata about [InnoDB](#) table columns, equivalent to the information in the [SYS\\_COLUMNS](#) table in the [InnoDB](#) data dictionary.
- [INNODB\\_SYS\\_INDEXES](#) provides metadata about [InnoDB](#) indexes, equivalent to the information in the [SYS\\_INDEXES](#) table in the [InnoDB](#) data dictionary.
- [INNODB\\_SYS\\_FIELDS](#) provides metadata about the key columns (fields) of [InnoDB](#) indexes, equivalent to the information in the [SYS\\_FIELDS](#) table in the [InnoDB](#) data dictionary.
- [INNODB\\_SYS\\_TABLESTATS](#) provides a view of low-level status information about [InnoDB](#) tables that is derived from in-memory data structures. There is no corresponding internal [InnoDB](#) system table.
- [INNODB\\_SYS\\_DATAFILES](#) provides data file path information for [InnoDB](#) file-per-table and general tablespaces, equivalent to information in the [SYS\\_DATAFILES](#) table in the [InnoDB](#) data dictionary.
- [INNODB\\_SYS\\_TABLESPACES](#) provides metadata about [InnoDB](#) file-per-table and general tablespaces, equivalent to the information in the [SYS\\_TABLESPACES](#) table in the [InnoDB](#) data dictionary.
- [INNODB\\_SYS\\_FOREIGN](#) provides metadata about foreign keys defined on [InnoDB](#) tables, equivalent to the information in the [SYS\\_FOREIGN](#) table in the [InnoDB](#) data dictionary.
- [INNODB\\_SYS\\_FOREIGN\\_COLS](#) provides metadata about the columns of foreign keys that are defined on [InnoDB](#) tables, equivalent to the information in the [SYS\\_FOREIGN\\_COLS](#) table in the [InnoDB](#) data dictionary.

[InnoDB INFORMATION\\_SCHEMA](#) system tables can be joined together through fields such as [TABLE\\_ID](#), [INDEX\\_ID](#), and [SPACE](#), allowing you to easily retrieve all available data for an object you want to study or monitor.

Refer to the [InnoDB INFORMATION\\_SCHEMA](#) documentation for information about the columns of each table.

### Example 15.11 InnoDB INFORMATION\_SCHEMA System Tables

This example uses a simple table ([t1](#)) with a single index ([i1](#)) to demonstrate the type of metadata found in the [InnoDB INFORMATION\\_SCHEMA](#) system tables.

1. Create a test database and table [t1](#):

```
mysql> CREATE DATABASE test;

mysql> USE test;

mysql> CREATE TABLE t1 (
  col1 INT,
  col2 CHAR(10),
  col3 VARCHAR(10))
ENGINE = InnoDB;

mysql> CREATE INDEX i1 ON t1(col1);
```

2. After creating the table [t1](#), query [INNODB\\_SYS\\_TABLES](#) to locate the metadata for [test/t1](#):

```
mysql> SELECT * FROM INFORMATION_SCHEMA.INNODB_SYS_TABLES WHERE NAME='test/t1' \G
***** 1. row *****
      TABLE_ID: 71
        NAME: test/t1
        FLAG: 1
        N_COLS: 6
        SPACE: 57
    FILE_FORMAT: Antelope
    ROW_FORMAT: Compact
    ZIP_PAGE_SIZE: 0
    ...
```

Table `t1` has a `TABLE_ID` of 71. The `FLAG` field provides bit level information about table format and storage characteristics. There are six columns, three of which are hidden columns created by InnoDB (`DB_ROW_ID`, `DB_TRX_ID`, and `DB_ROLL_PTR`). The ID of the table's `SPACE` is 57 (a value of 0 would indicate that the table resides in the system tablespace). The `FILE_FORMAT` is Antelope, and the `ROW_FORMAT` is Compact. `ZIP_PAGE_SIZE` only applies to tables with a `Compressed` row format.

- Using the `TABLE_ID` information from `INNODB_SYS_TABLES`, query the `INNODB_SYS_COLUMNS` table for information about the table's columns.

```
mysql> SELECT * FROM INFORMATION_SCHEMA.INNODB_SYS_COLUMNS where TABLE_ID = 71 \G
***** 1. row *****
      TABLE_ID: 71
        NAME: col1
        POS: 0
        MTYPE: 6
        PRTYPE: 1027
        LEN: 4
***** 2. row *****
      TABLE_ID: 71
        NAME: col2
        POS: 1
        MTYPE: 2
        PRTYPE: 524542
        LEN: 10
***** 3. row *****
      TABLE_ID: 71
        NAME: col3
        POS: 2
        MTYPE: 1
        PRTYPE: 524303
        LEN: 10
```

In addition to the `TABLE_ID` and column `NAME`, `INNODB_SYS_COLUMNS` provides the ordinal position (`POS`) of each column (starting from 0 and incrementing sequentially), the column `MTYPE` or “main type” (6 = INT, 2 = CHAR, 1 = VARCHAR), the `PRTYPE` or “precise type” (a binary value with bits that represent the MySQL data type, character set code, and nullability), and the column length (`LEN`).

- Using the `TABLE_ID` information from `INNODB_SYS_TABLES` once again, query `INNODB_SYS_INDEXES` for information about the indexes associated with table `t1`.

```
mysql> SELECT * FROM INFORMATION_SCHEMA.INNODB_SYS_INDEXES WHERE TABLE_ID = 71 \G
***** 1. row *****
      INDEX_ID: 111
        NAME: GEN_CLUST_INDEX
      TABLE_ID: 71
        TYPE: 1
        N_FIELDS: 0
        PAGE_NO: 3
        SPACE: 57
    MERGE_THRESHOLD: 50
***** 2. row *****
      INDEX_ID: 112
        NAME: i1
```

```

TABLE_ID: 71
TYPE: 0
N_FIELDS: 1
PAGE_NO: 4
SPACE: 57
MERGE_THRESHOLD: 50

```

`INNODB_SYS_INDEXES` returns data for two indexes. The first index is `GEN_CLUST_INDEX`, which is a clustered index created by `InnoDB` if the table does not have a user-defined clustered index. The second index (`i1`) is the user-defined secondary index.

The `INDEX_ID` is an identifier for the index that is unique across all databases in an instance. The `TABLE_ID` identifies the table that the index is associated with. The index `TYPE` value indicates the type of index (1 = Clustered Index, 0 = Secondary index). The `N_FIELDS` value is the number of fields that comprise the index. `PAGE_NO` is the root page number of the index B-tree, and `SPACE` is the ID of the tablespace where the index resides. A non-zero value indicates that the index does not reside in the system tablespace. `MERGE_THRESHOLD` defines a percentage threshold value for the amount of data in an index page. If the amount of data in an index page falls below the this value (the default is 50%) when a row is deleted or when a row is shortened by an update operation, `InnoDB` attempts to merge the index page with a neighboring index page.

- Using the `INDEX_ID` information from `INNODB_SYS_INDEXES`, query `INNODB_SYS_FIELDS` for information about the fields of index `i1`.

```

mysql> SELECT * FROM INFORMATION_SCHEMA.INNODB_SYS_FIELDS where INDEX_ID = 112 \G
***** 1. row *****
INDEX_ID: 112
NAME: coll
POS: 0

```

`INNODB_SYS_FIELDS` provides the `NAME` of the indexed field and its ordinal position within the index. If the index (`i1`) had been defined on multiple fields, `INNODB_SYS_FIELDS` would provide metadata for each of the indexed fields.

- Using the `SPACE` information from `INNODB_SYS_TABLES`, query `INNODB_SYS_TABLESPACES` table for information about the table's tablespace.

```

mysql> SELECT * FROM INFORMATION_SCHEMA.INNODB_SYS_TABLESPACES WHERE SPACE = 57 \G
***** 1. row *****
SPACE: 57
NAME: test/t1
FLAG: 0
FILE_FORMAT: Antelope
ROW_FORMAT: Compact or Redundant
PAGE_SIZE: 16384
ZIP_PAGE_SIZE: 0

```

In addition to the `SPACE` ID of the tablespace and the `NAME` of the associated table, `INNODB_SYS_TABLESPACES` provides tablespace `FLAG` data, which is bit level information about tablespace format and storage characteristics. Also provided are tablespace `FILE_FORMAT`, `ROW_FORMAT`, `PAGE_SIZE`, and `ZIP_PAGE_SIZE` data (`ZIP_PAGE_SIZE` is applicable to tablespaces with a `Compressed` row format).

- Using the `SPACE` information from `INNODB_SYS_TABLES` once again, query `INNODB_SYS_DATAFILES` for the location of the tablespace data file.

```

mysql> SELECT * FROM INFORMATION_SCHEMA.INNODB_SYS_DATAFILES WHERE SPACE = 57 \G
***** 1. row *****
SPACE: 57
PATH: ./test/t1.ibd

```

The datafile is located in the `test` directory under MySQL's `data` directory. If a `file-per-table` tablespace were created in a location outside the MySQL data directory using the `DATA DIRECTORY` clause of the `CREATE TABLE` statement, the tablespace `PATH` would be a fully qualified directory path.

- As a final step, insert a row into table `t1` (`TABLE_ID = 71`) and view the data in the `INNODB_SYS_TABLESTATS` table. The data in this table is used by the MySQL optimizer to calculate which index to use when querying an InnoDB table. This information is derived from in-memory data structures. There is no corresponding internal InnoDB system table.

```
mysql> INSERT INTO t1 VALUES(5, 'abc', 'def');
Query OK, 1 row affected (0.06 sec)

mysql> SELECT * FROM INFORMATION_SCHEMA.INNODB_SYS_TABLESTATS where TABLE_ID = 71 \G
***** 1. row *****
      TABLE_ID: 71
        NAME: test/t1
  STATS_INITIALIZED: Initialized
        NUM_ROWS: 1
    CLUST_INDEX_SIZE: 1
    OTHER_INDEX_SIZE: 0
    MODIFIED_COUNTER: 1
        AUTOINC: 0
        REF_COUNT: 1
```

The `STATS_INITIALIZED` field indicates whether or not statistics have been collected for the table. `NUM_ROWS` is the current estimated number of rows in the table. The `CLUST_INDEX_SIZE` and `OTHER_INDEX_SIZE` fields report the number of pages on disk that store clustered and secondary indexes for the table, respectively. The `MODIFIED_COUNTER` value shows the number of rows modified by DML operations and cascade operations from foreign keys. The `AUTOINC` value is the next number to be issued for any autoincrement-based operation. There are no autoincrement columns defined on table `t1`, so the value is 0. The `REF_COUNT` value is a counter. When the counter reaches 0, it signifies that the table metadata can be evicted from the table cache.

### Example 15.12 Foreign Key INFORMATION\_SCHEMA System Tables

The `INNODB_SYS_FOREIGN` and `INNODB_SYS_FOREIGN_COLS` tables provide data about foreign key relationships. This example uses a parent table and child table with a foreign key relationship to demonstrate the data found in the `INNODB_SYS_FOREIGN` and `INNODB_SYS_FOREIGN_COLS` tables.

- Create the test database with parent and child tables:

```
mysql> CREATE DATABASE test;

mysql> USE test;

mysql> CREATE TABLE parent (id INT NOT NULL,
-> PRIMARY KEY (id)) ENGINE=INNODB;

mysql> CREATE TABLE child (id INT, parent_id INT,
-> INDEX par_ind (parent_id),
-> CONSTRAINT fk1
-> FOREIGN KEY (parent_id) REFERENCES parent(id)
-> ON DELETE CASCADE) ENGINE=INNODB;
```

- After the parent and child tables are created, query `INNODB_SYS_FOREIGN` and locate the foreign key data for the `test/child` and `test/parent` foreign key relationship:

```
mysql> SELECT * FROM INFORMATION_SCHEMA.INNODB_SYS_FOREIGN \G
***** 1. row *****
      ID: test/fk1
  FOR_NAME: test/child
  REF_NAME: test/parent
    N_COLS: 1
    TYPE: 1
```

Metadata includes the foreign key `ID` (`fk1`), which is named for the `CONSTRAINT` that was defined on the child table. The `FOR_NAME` is the name of the child table where the foreign key is defined. `REF_NAME` is the name of the parent table (the “referenced” table). `N_COLS` is the number of columns in the foreign key index. `TYPE` is a numerical value representing bit flags that provide additional information about the foreign key column. In this case, the `TYPE` value is 1,

which indicates that the `ON DELETE CASCADE` option was specified for the foreign key. See the `INNODB_SYS_FOREIGN` table definition for more information about `TYPE` values.

- Using the foreign key `ID`, query `INNODB_SYS_FOREIGN_COLS` to view data about the columns of the foreign key.

```
mysql> SELECT * FROM INFORMATION_SCHEMA.INNODB_SYS_FOREIGN_COLS WHERE ID = 'test/fk1' \G
***** 1. row *****
      ID: test/fk1
FOR_COL_NAME: parent_id
REF_COL_NAME: id
      POS: 0
```

`FOR_COL_NAME` is the name of the foreign key column in the child table, and `REF_COL_NAME` is the name of the referenced column in the parent table. The `POS` value is the ordinal position of the key field within the foreign key index, starting at zero.

### Example 15.13 Joining InnoDB INFORMATION\_SCHEMA System Tables

This example demonstrates joining three InnoDB `INFORMATION_SCHEMA` system tables (`INNODB_SYS_TABLES`, `INNODB_SYS_TABLESPACES`, and `INNODB_SYS_TABLESTATS`) to gather file format, row format, page size, and index size information about tables in the employees sample database.

The following table name aliases are used to shorten the query string:

- `INFORMATION_SCHEMA.INNODB_SYS_TABLES: a`
- `INFORMATION_SCHEMA.INNODB_SYS_TABLESPACES: b`
- `INFORMATION_SCHEMA.INNODB_SYS_TABLESTATS: c`

An `IF()` control flow function is used to account for compressed tables. If a table is compressed, the index size is calculated using `ZIP_PAGE_SIZE` rather than `PAGE_SIZE`. `CLUST_INDEX_SIZE` and `OTHER_INDEX_SIZE`, which are reported in bytes, are divided by `1024*1024` to provide index sizes in megabytes (MBs). MB values are rounded to zero decimal spaces using the `ROUND()` function.

```
mysql> SELECT a.NAME, a.FILE_FORMAT, a.ROW_FORMAT,
@page_size :=
  IF(a.ROW_FORMAT='Compressed',
    b.ZIP_PAGE_SIZE, b.PAGE_SIZE)
  AS page_size,
ROUND((@page_size * c.CLUST_INDEX_SIZE)
/(1024*1024)) AS pk_mb,
ROUND((@page_size * c.OTHER_INDEX_SIZE)
/(1024*1024)) AS secidx_mb
FROM INFORMATION_SCHEMA.INNODB_SYS_TABLES a
INNER JOIN INFORMATION_SCHEMA.INNODB_SYS_TABLESPACES b on a.NAME = b.NAME
INNER JOIN INFORMATION_SCHEMA.INNODB_SYS_TABLESTATS c on b.NAME = c.NAME
WHERE a.NAME LIKE 'employees/%'
ORDER BY a.NAME DESC;
```

| NAME                   | FILE_FORMAT | ROW_FORMAT | page_size | pk_mb | secidx_mb |
|------------------------|-------------|------------|-----------|-------|-----------|
| employees/titles       | Antelope    | Compact    | 16384     | 20    | 11        |
| employees/salaries     | Antelope    | Compact    | 16384     | 91    | 33        |
| employees/employees    | Antelope    | Compact    | 16384     | 15    | 0         |
| employees/dept_manager | Antelope    | Compact    | 16384     | 0     | 0         |
| employees/dept_emp     | Antelope    | Compact    | 16384     | 12    | 10        |
| employees/departments  | Antelope    | Compact    | 16384     | 0     | 0         |

## 15.15.4 InnoDB INFORMATION\_SCHEMA FULLTEXT Index Tables

With the introduction of `FULLTEXT` index support for InnoDB tables in MySQL 5.6.4, the following tables were added to the `INFORMATION_SCHEMA` database:

```
mysql> SHOW TABLES FROM INFORMATION_SCHEMA LIKE 'INNODB_FT%';
```

|   |
|---|
| Tables_in_INFORMATION_SCHEMA (INNODB_FT%) |
| INNODB_FT_CONFIG                          |
| INNODB_FT_BEING_DELETED                   |
| INNODB_FT_DELETED                         |
| INNODB_FT_DEFAULT_STOPWORD                |
| INNODB_FT_INDEX_TABLE                     |
| INNODB_FT_INDEX_CACHE                     |

## Table Overview

- **INNODB\_FT\_CONFIG**: Displays metadata about the **FULLTEXT** index and associated processing for an **InnoDB** table.
- **INNODB\_FT\_BEING\_DELETED**: Provides a snapshot of the **INNODB\_FT\_DELETED** table that is only used during an **OPTIMIZE TABLE** maintenance operation. When **OPTIMIZE TABLE** is run, the **INNODB\_FT\_BEING\_DELETED** table is emptied, and DOC\_IDs are removed from the **INNODB\_FT\_DELETED** table. Because the contents of **INNODB\_FT\_BEING\_DELETED** typically have a short lifetime, this table has limited utility for monitoring or debugging. For information about running **OPTIMIZE TABLE** on tables with **FULLTEXT** indexes, see [Section 13.9.6, “Fine-Tuning MySQL Full-Text Search”](#).
- **INNODB\_FT\_DELETED**: Records rows that are deleted from the **FULLTEXT** index for an **InnoDB** table. To avoid expensive index reorganization during DML operations for an **InnoDB FULLTEXT** index, the information about newly deleted words is stored separately, filtered out of search results when you perform a text search, and removed from the main search index only when you run **OPTIMIZE TABLE**.

- **INNODB\_FT\_DEFAULT\_STOPWORD**: Holds a list of **stopwords** that are used by default when creating a **FULLTEXT** index.

For information about the **INNODB\_FT\_DEFAULT\_STOPWORD** table, see [Section 13.9.4, “Full-Text Stopwords”](#).

- **INNODB\_FT\_INDEX\_TABLE**: Contains data about the inverted index used to process text searches against the **FULLTEXT** index.
- **INNODB\_FT\_INDEX\_CACHE**: Contains token information about newly inserted rows in a **FULLTEXT** index. To avoid expensive index reorganization during DML operations, the information about newly indexed words is stored separately, and combined with the main search index only when **OPTIMIZE TABLE** is run, when the server is shut down, or when the cache size exceeds a limit defined by **innodb\_ft\_cache\_size** or **innodb\_ft\_total\_cache\_size**.

### Note

With the exception of the **INNODB\_FT\_DEFAULT\_STOPWORD** table, you must set the **innodb\_ft\_aux\_table** configuration variable to the name of the table (*database\_name/table\_name*) that contains the **FULLTEXT** index. Otherwise, the **InnoDB FULLTEXT** index **INFORMATION\_SCHEMA** tables appear empty.

## Example 15.14 InnoDB FULLTEXT Index INFORMATION\_SCHEMA Tables

This example uses a table with a **FULLTEXT** index to demonstrate the data contained in the **FULLTEXT** index **INFORMATION\_SCHEMA** tables.

1. Create a table with a **FULLTEXT** index and insert some data:

```
mysql> CREATE TABLE articles (
  id INT UNSIGNED AUTO_INCREMENT NOT NULL PRIMARY KEY,
  title VARCHAR(200),
  body TEXT,
  FULLTEXT (title,body)
) ENGINE=InnoDB;
```

```
INSERT INTO articles (title,body) VALUES
  ('MySQL Tutorial','DBMS stands for DataBase ...'),
  ('How To Use MySQL Well','After you went through a ...'),
  ('Optimizing MySQL','In this tutorial we will show ...'),
  ('1001 MySQL Tricks','1. Never run mysqld as root. 2. ...'),
  ('MySQL vs. YourSQL','In the following database comparison ...'),
  ('MySQL Security','When configured properly, MySQL ...');
```

2. Set the `innodb_ft_aux_table` variable to the name of the table with the `FULLTEXT` index. If this variable is not set, the `InnoDB FULLTEXT INFORMATION_SCHEMA` tables appear empty, with the exception of the `INNODB_FT_DEFAULT_STOPWORD` table.

```
SET GLOBAL innodb_ft_aux_table = 'test/articles';
```

3. Query the `INNODB_FT_INDEX_CACHE` table, which shows information about newly inserted rows in a `FULLTEXT` index. To avoid expensive index reorganization during DML operations, data for newly inserted rows remains in the `FULLTEXT` index cache until `OPTIMIZE TABLE` is run (or until the server is shutdown or cache limits are exceeded).

```
mysql> SELECT * FROM INFORMATION_SCHEMA.INNODB_FT_INDEX_CACHE LIMIT 5;
```

| WORD       | FIRST_DOC_ID | LAST_DOC_ID | DOC_COUNT | DOC_ID | POSITION |
|------------|--------------|-------------|-----------|--------|----------|
| 1001       | 5            | 5           | 1         | 5      | 0        |
| after      | 3            | 3           | 1         | 3      | 22       |
| comparison | 6            | 6           | 1         | 6      | 44       |
| configured | 7            | 7           | 1         | 7      | 20       |
| database   | 2            | 6           | 2         | 2      | 31       |

4. Enable `innodb_optimize_fulltext_only` and run `OPTIMIZE TABLE` on the table that contains the `FULLTEXT` index. This operation flushes the contents of the `FULLTEXT` index cache to the main `FULLTEXT` index. `innodb_optimize_fulltext_only` changes the way the `OPTIMIZE TABLE` statement operates on `InnoDB` tables, and is intended to be enabled temporarily, during maintenance operations on `InnoDB` tables with `FULLTEXT` indexes.

```
mysql> SET GLOBAL innodb_optimize_fulltext_only=ON;
Query OK, 0 rows affected (0.00 sec)
```

```
mysql> OPTIMIZE TABLE articles;
```

| Table         | Op       | Msg_type | Msg_text |
|---------------|----------|----------|----------|
| test.articles | optimize | status   | OK       |

5. Query the `INNODB_FT_INDEX_TABLE` table to view information about data in the main `FULLTEXT` index, including information about the data that was just flushed from the `FULLTEXT` index cache.

```
mysql> SELECT * FROM INFORMATION_SCHEMA.INNODB_FT_INDEX_TABLE LIMIT 5;
```

| WORD       | FIRST_DOC_ID | LAST_DOC_ID | DOC_COUNT | DOC_ID | POSITION |
|------------|--------------|-------------|-----------|--------|----------|
| 1001       | 5            | 5           | 1         | 5      | 0        |
| after      | 3            | 3           | 1         | 3      | 22       |
| comparison | 6            | 6           | 1         | 6      | 44       |
| configured | 7            | 7           | 1         | 7      | 20       |
| database   | 2            | 6           | 2         | 2      | 31       |

The `INNODB_FT_INDEX_CACHE` table is now empty since the `OPTIMIZE TABLE` operation flushed the `FULLTEXT` index cache.

```
mysql> SELECT * FROM INFORMATION_SCHEMA.INNODB_FT_INDEX_CACHE LIMIT 5;
Empty set (0.00 sec)
```

6. Delete some records from the `test/articles` table.

```
mysql> DELETE FROM test.articles WHERE id < 4;
Query OK, 3 rows affected (0.11 sec)
```

7. Query the `INNODB_FT_DELETED` table. This table records rows that are deleted from the `FULLTEXT` index. To avoid expensive index reorganization during DML operations, information about newly deleted records is stored separately, filtered out of search results when you do a text search, and removed from the main search index when you run `OPTIMIZE TABLE`.

```
mysql> SELECT * FROM INFORMATION_SCHEMA.INNODB_FT_DELETED;
+-----+
| DOC_ID |
+-----+
|      2 |
|      3 |
|      4 |
+-----+
```

8. Run `OPTIMIZE TABLE` to remove the deleted records.

```
mysql> OPTIMIZE TABLE articles;
+-----+-----+-----+-----+
| Table          | Op       | Msg_type | Msg_text |
+-----+-----+-----+-----+
| test.articles | optimize | status   | OK        |
+-----+-----+-----+-----+
```

The `INNODB_FT_DELETED` table should now appear empty.

```
mysql> SELECT * FROM INFORMATION_SCHEMA.INNODB_FT_DELETED;
Empty set (0.00 sec)
```

9. Query the `INNODB_FT_CONFIG` table. This table contains metadata about the `FULLTEXT` index and related processing:
  - `optimize_checkpoint_limit` is the number of seconds after which an `OPTIMIZE TABLE` run will stop.
  - `synced_doc_id` is the next `DOC_ID` to be issued.
  - `stopword_table_name` is the `database/table` name for a user-defined stopwords table. This field appears empty if there is no user-defined stopwords table.
  - `use_stopword` indicates whether or not a stopwords table is used, which is defined when the `FULLTEXT` index is created.

```
mysql> SELECT * FROM INFORMATION_SCHEMA.INNODB_FT_CONFIG;
+-----+-----+
| KEY                               | VALUE |
+-----+-----+
| optimize_checkpoint_limit         | 180   |
| synced_doc_id                     | 8     |
| stopwords_table_name               |       |
| use_stopword                      | 1     |
+-----+-----+
```

## 15.15.5 InnoDB INFORMATION\_SCHEMA Buffer Pool Tables

The `InnoDB INFORMATION_SCHEMA` buffer pool tables provide buffer pool status information and metadata about the pages within the `InnoDB` buffer pool. The tables were introduced in MySQL 5.6.2 and later backported to MySQL 5.5 (in MySQL 5.5.28) and MySQL 5.1 (in MySQL 5.1.66).

The `InnoDB INFORMATION_SCHEMA` buffer pool tables include those listed below:

```
mysql> SHOW TABLES FROM INFORMATION_SCHEMA LIKE 'INNODB_BUFFER%';
+-----+
| Tables_in_INFORMATION_SCHEMA (INNODB_BUFFER%) |
+-----+
```

|                          |  |
|--------------------------|--|
| INNODB_BUFFER_PAGE_LRU   |  |
| INNODB_BUFFER_PAGE       |  |
| INNODB_BUFFER_POOL_STATS |  |
| +-----+                  |  |

## Table Overview

- [INNODB\\_BUFFER\\_PAGE](#): Holds information about each page in the [InnoDB](#) buffer pool.
- [INNODB\\_BUFFER\\_PAGE\\_LRU](#): Holds information about the pages in the [InnoDB](#) buffer pool, in particular how they are ordered in the LRU list that determines which pages to evict from the buffer pool when it becomes full. The [INNODB\\_BUFFER\\_PAGE\\_LRU](#) table has the same columns as the [INNODB\\_BUFFER\\_PAGE](#) table, except that the [INNODB\\_BUFFER\\_PAGE\\_LRU](#) table has an [LRU\\_POSITION](#) column instead of a [BLOCK\\_ID](#) column.
- [INNODB\\_BUFFER\\_POOL\\_STATS](#): Provides buffer pool status information. Much of the same information is provided by [SHOW ENGINE INNODB STATUS](#) output, or may be obtained using [InnoDB](#) buffer pool server status variables.

### Warning

Querying the [INNODB\\_BUFFER\\_PAGE](#) table or [INNODB\\_BUFFER\\_PAGE\\_LRU](#) table can introduce significant performance overhead. Do not query these tables on a production system unless you are aware of the performance impact that your query may have, and have determined it to be acceptable. To avoid impacting performance, reproduce the issue you want to investigate on a test instance and run your queries on the test instance.

### Example 15.15 Querying System Data in the INNODB\_BUFFER\_PAGE Table

This query provides an approximate count of pages that contain system data by excluding pages where the [TABLE\\_NAME](#) value is either [NULL](#) or includes a slash / or period . in the table name, which indicates a user-defined table.

```
SELECT COUNT(*) FROM INFORMATION_SCHEMA.INNODB_BUFFER_PAGE
WHERE TABLE_NAME IS NULL OR (INSTR(TABLE_NAME, '/') = 0 AND INSTR(TABLE_NAME, '.') = 0);
+-----+
| COUNT(*) |
+-----+
|      1516 |
+-----+
```

This query returns the approximate number of pages that contain system data, the total number of buffer pool pages, and an approximate percentage of pages that contain system data.

```
SELECT
  (SELECT COUNT(*) FROM INFORMATION_SCHEMA.INNODB_BUFFER_PAGE
   WHERE TABLE_NAME IS NULL OR (INSTR(TABLE_NAME, '/') = 0 AND INSTR(TABLE_NAME, '.') = 0)
  ) AS system_pages,
  (
    SELECT COUNT(*)
    FROM INFORMATION_SCHEMA.INNODB_BUFFER_PAGE
  ) AS total_pages,
  (
    SELECT ROUND((system_pages/total_pages) * 100)
  ) AS system_page_percentage;
+-----+-----+-----+
| system_pages | total_pages | system_page_percentage |
+-----+-----+-----+
|          295 |          8192 |              4 |
+-----+-----+-----+
```

The type of system data in the buffer pool can be determined by querying the [PAGE\\_TYPE](#) value. For example, the following query returns eight distinct [PAGE\\_TYPE](#) values among the pages that contain system data:

```
mysql> SELECT DISTINCT PAGE_TYPE FROM INFORMATION_SCHEMA.INNODB_BUFFER_PAGE
```

```
WHERE TABLE_NAME IS NULL OR (INSTR(TABLE_NAME, '/') = 0 AND INSTR(TABLE_NAME, '.') = 0);
```

| PAGE_TYPE         |
|-------------------|
| SYSTEM            |
| IBUF_BITMAP       |
| UNKNOWN           |
| FILE_SPACE_HEADER |
| INODE             |
| UNDO_LOG          |
| ALLOCATED         |

### Example 15.16 Querying User Data in the INNODB\_BUFFER\_PAGE Table

This query provides an approximate count of pages containing user data by counting pages where the `TABLE_NAME` value is **NOT NULL** and **NOT LIKE** `'%INNODB_SYS_TABLES%'`.

```
mysql> SELECT COUNT(*) FROM INFORMATION_SCHEMA.INNODB_BUFFER_PAGE
WHERE TABLE_NAME IS NOT NULL AND TABLE_NAME NOT LIKE '%INNODB_SYS_TABLES%';
```

| COUNT(*) |
|----------|
| 7897     |

This query returns the approximate number of pages that contain user data, the total number of buffer pool pages, and an approximate percentage of pages that contain user data.

```
mysql> SELECT
(SELECT COUNT(*) FROM INFORMATION_SCHEMA.INNODB_BUFFER_PAGE
WHERE TABLE_NAME IS NOT NULL AND (INSTR(TABLE_NAME, '/') > 0 OR INSTR(TABLE_NAME, '.') > 0)
) AS user_pages,
(
SELECT COUNT(*)
FROM information_schema.INNODB_BUFFER_PAGE
) AS total_pages,
(
SELECT ROUND((user_pages/total_pages) * 100)
) AS user_page_percentage;
```

| user_pages | total_pages | user_page_percentage |
|------------|-------------|----------------------|
| 7897       | 8192        | 96                   |

This query identifies user-defined tables with pages in the buffer pool:

```
mysql> SELECT DISTINCT TABLE_NAME FROM INFORMATION_SCHEMA.INNODB_BUFFER_PAGE
WHERE TABLE_NAME IS NOT NULL AND (INSTR(TABLE_NAME, '/') > 0 OR INSTR(TABLE_NAME, '.') > 0)
AND TABLE_NAME NOT LIKE 'mysql`.`innodb_%';
```

| TABLE_NAME              |
|-------------------------|
| `employees`.`salaries`  |
| `employees`.`employees` |

### Example 15.17 Querying Index Data in the INNODB\_BUFFER\_PAGE Table

For information about index pages, query the `INDEX_NAME` column using the name of the index. For example, the following query returns the number of pages and total data size of pages for the `emp_no` index that is defined on the `employees.salaries` table:

```
mysql> SELECT INDEX_NAME, COUNT(*) AS Pages,
ROUND(SUM(IF(COMPRESSED_SIZE = 0, @@global.innodb_page_size, COMPRESSED_SIZE))/1024/1024)
AS 'Total Data (MB)'
FROM INFORMATION_SCHEMA.INNODB_BUFFER_PAGE
WHERE INDEX_NAME='emp_no' AND TABLE_NAME = 'employees`.`salaries`;
```

| INDEX_NAME | Pages | Total Data (MB) |
|------------|-------|-----------------|
|------------|-------|-----------------|

|        |      |    |
|--------|------|----|
| emp_no | 1609 | 25 |
|--------|------|----|

This query returns the number of pages and total data size of pages for all indexes defined on the `employees.salaries` table:

```
mysql> SELECT INDEX_NAME, COUNT(*) AS Pages,
ROUND(SUM(IF(COMPRESSED_SIZE = 0, @@global.innodb_page_size, COMPRESSED_SIZE))/1024/1024)
AS 'Total Data (MB)'
FROM INFORMATION_SCHEMA.INNODB_BUFFER_PAGE
WHERE TABLE_NAME = 'employees`.`salaries`'
GROUP BY INDEX_NAME;
```

| INDEX_NAME | Pages | Total Data (MB) |
|------------|-------|-----------------|
| emp_no     | 1608  | 25              |
| PRIMARY    | 6086  | 95              |

#### Example 15.18 Querying LRU\_POSITION Data in the INNODB\_BUFFER\_PAGE\_LRU Table

The `INNODB_BUFFER_PAGE_LRU` table holds information about the pages in the InnoDB buffer pool, in particular how they are ordered that determines which pages to evict from the buffer pool when it becomes full. The definition for this page is the same as for `INNODB_BUFFER_PAGE`, except this table has an `LRU_POSITION` column instead of a `BLOCK_ID` column.

This query counts the number of positions at a specific location in the LRU list occupied by pages of the `employees.employees` table.

```
mysql> SELECT COUNT(LRU_POSITION) FROM INFORMATION_SCHEMA.INNODB_BUFFER_PAGE_LRU
WHERE TABLE_NAME='employees`.`employees`' AND LRU_POSITION < 3072;
```

| COUNT(LRU_POSITION) |
|---------------------|
| 548                 |

#### Example 15.19 Querying the INNODB\_BUFFER\_POOL\_STATS Table

The `INNODB_BUFFER_POOL_STATS` table provides information similar to `SHOW ENGINE INNODB STATUS` and InnoDB buffer pool status variables.

```
mysql> SELECT * FROM information_schema.INNODB_BUFFER_POOL_STATS \G
***** 1. row *****
      POOL_ID: 0
      POOL_SIZE: 8192
      FREE_BUFFERS: 1
      DATABASE_PAGES: 8173
      OLD_DATABASE_PAGES: 3014
      MODIFIED_DATABASE_PAGES: 0
      PENDING_DECOMPRESS: 0
      PENDING_READS: 0
      PENDING_FLUSH_LRU: 0
      PENDING_FLUSH_LIST: 0
      PAGES_MADE_YOUNG: 15907
      PAGES_NOT_MADE_YOUNG: 3803101
      PAGES_MADE_YOUNG_RATE: 0
      PAGES_MADE_NOT_YOUNG_RATE: 0
      NUMBER_PAGES_READ: 3270
      NUMBER_PAGES_CREATED: 13176
      NUMBER_PAGES_WRITTEN: 15109
      PAGES_READ_RATE: 0
      PAGES_CREATE_RATE: 0
      PAGES_WRITTEN_RATE: 0
      NUMBER_PAGES_GET: 33069332
      HIT_RATE: 0
      YOUNG_MAKE_PER_THOUSAND_GETS: 0
      NOT_YOUNG_MAKE_PER_THOUSAND_GETS: 0
      NUMBER_PAGES_READ_AHEAD: 2713
      NUMBER_READ_AHEAD_EVICTED: 0
      READ_AHEAD_RATE: 0
```

```

READ_AHEAD_EVICTED_RATE: 0
LRU_IO_TOTAL: 0
LRU_IO_CURRENT: 0
UNCOMPRESS_TOTAL: 0
UNCOMPRESS_CURRENT: 0

```

For comparison, `SHOW ENGINE INNODB STATUS` output and InnoDB buffer pool status variable output is shown below, based on the same data set.

For more information about `SHOW ENGINE INNODB STATUS` output, see [Section 15.17.3, “InnoDB Standard Monitor and Lock Monitor Output”](#).

```

mysql> SHOW ENGINE INNODB STATUS \G
...
-----
BUFFER POOL AND MEMORY
-----
Total large memory allocated 137428992
Dictionary memory allocated 579084
Buffer pool size      8192
Free buffers          1
Database pages        8173
Old database pages    3014
Modified db pages     0
Pending reads         0
Pending writes: LRU 0, flush list 0, single page 0
Pages made young 15907, not young 3803101
0.00 youngs/s, 0.00 non-youngs/s
Pages read 3270, created 13176, written 15109
0.00 reads/s, 0.00 creates/s, 0.00 writes/s
No buffer pool page gets since the last printout
Pages read ahead 0.00/s, evicted without access 0.00/s, Random read ahead 0.00/s
LRU len: 8173, unzip_LRU len: 0
I/O sum[0]:cur[0], unzip sum[0]:cur[0]
...

```

For status variable descriptions, see [Section 6.1.7, “Server Status Variables”](#).

```

mysql> SHOW STATUS LIKE 'Innodb_buffer%';
+-----+-----+
| Variable_name | Value |
+-----+-----+
| Innodb_buffer_pool_dump_status | not started |
| Innodb_buffer_pool_load_status | not started |
| Innodb_buffer_pool_resize_status | not started |
| Innodb_buffer_pool_pages_data | 8173 |
| Innodb_buffer_pool_bytes_data | 133906432 |
| Innodb_buffer_pool_pages_dirty | 0 |
| Innodb_buffer_pool_bytes_dirty | 0 |
| Innodb_buffer_pool_pages_flushed | 15109 |
| Innodb_buffer_pool_pages_free | 1 |
| Innodb_buffer_pool_pages_misc | 18 |
| Innodb_buffer_pool_pages_total | 8192 |
| Innodb_buffer_pool_read_ahead_rnd | 0 |
| Innodb_buffer_pool_read_ahead | 2713 |
| Innodb_buffer_pool_read_ahead_evicted | 0 |
| Innodb_buffer_pool_read_requests | 33069332 |
| Innodb_buffer_pool_reads | 558 |
| Innodb_buffer_pool_wait_free | 0 |
| Innodb_buffer_pool_write_requests | 11985961 |
+-----+-----+

```

## 15.15.6 InnoDB INFORMATION\_SCHEMA Metrics Table

The `INNODB_METRICS` table, introduced in MySQL 5.6.2, consolidates all InnoDB performance and resource-related counters into a single `INFORMATION_SCHEMA` table.

The columns of the `INNODB_METRICS` table are shown in the following example. For a description of each column, see [Section 23.31.15, “The INFORMATION\\_SCHEMA INNODB\\_METRICS Table”](#).

```

mysql> SELECT * FROM INFORMATION_SCHEMA.INNODB_METRICS WHERE NAME="dml_inserts" \G

```

```

***** 1. row *****
      NAME: dml_inserts
      SUBSYSTEM: dml
      COUNT: 46273
      MAX_COUNT: 46273
      MIN_COUNT: NULL
      AVG_COUNT: 492.2659574468085
      COUNT_RESET: 46273
      MAX_COUNT_RESET: 46273
      MIN_COUNT_RESET: NULL
      AVG_COUNT_RESET: NULL
      TIME_ENABLED: 2014-11-28 16:07:53
      TIME_DISABLED: NULL
      TIME_ELAPSED: 94
      TIME_RESET: NULL
      STATUS: enabled
      TYPE: status_counter
      COMMENT: Number of rows inserted

```

## Enabling, Disabling, and Resetting Counters

You can enable, disable, and reset counters using the following configuration options:

- `innodb_monitor_enable`: Enables one or more counters.

```
SET GLOBAL innodb_monitor_enable = [counter-name|module_name|pattern|all];
```

- `innodb_monitor_disable`: Disables one or more counters.

```
SET GLOBAL innodb_monitor_disable = [counter-name|module_name|pattern|all];
```

- `innodb_monitor_reset`: Resets the count value for one or more counters to zero.

```
SET GLOBAL innodb_monitor_reset = [counter-name|module_name|pattern|all];
```

- `innodb_monitor_reset_all`: Resets all values for one or more counters. A counter must be disabled before using `innodb_monitor_reset_all`.

```
SET GLOBAL innodb_monitor_reset_all = [counter-name|module_name|pattern|all];
```

You can also enable counters and counter modules at startup using the MySQL server configuration file. For example, to enable the `log` module, `metadata_table_handles_opened` and `metadata_table_handles_closed` counters, enter the following line in the `[mysqld]` section of your `my.cnf` configuration file.

```

[mysqld]
innodb_monitor_enable = module_recovery,metadata_table_handles_opened,metadata_table_handles_closed

```

When enabling multiple counters or modules in your configuration file, you must specify the `innodb_monitor_enable` configuration option followed by counter and module names separated by a comma, as shown in the example above. Only the `innodb_monitor_enable` option can be used in your configuration file. The disable and reset configuration options are only supported on the command line.

### Note

Because each counter imposes some degree of runtime overhead on the server, typically you enable more counters on test and development servers during experimentation and benchmarking, and only enable counters on production servers to diagnose known issues or monitor aspects that are likely to be bottlenecks for a particular server and workload.

## Counters

The counters represented in the `INNODB_METRICS` table are subject to change, so for the most up-to-date list, query a running MySQL server. The list below shows counters that are available as of MySQL 5.7.6.

Counters that are enabled by default correspond to those used by `SHOW ENGINE INNODB STATUS`. Counters used by `SHOW ENGINE INNODB STATUS` are always “on” at a system level but you can disable these counters for the `INNODB_METRICS` table, as required. Also, counter status is not persistent. Unless specified otherwise, counters revert to their default enabled or disabled status when the server is restarted.

If you run programs that would be affected by additions or changes to the `INNODB_METRICS` table, it is recommended that you review releases notes and query the `INNODB_METRICS` table for the new release prior to upgrading.

```
mysql> SELECT name, subsystem, status FROM INFORMATION_SCHEMA.INNODB_METRICS ORDER BY NAME;
```

| name                                     | subsystem           | status   |
|--|---------------------|----------|
| adaptive_hash_pages_added                | adaptive_hash_index | disabled |
| adaptive_hash_pages_removed              | adaptive_hash_index | disabled |
| adaptive_hash_rows_added                 | adaptive_hash_index | disabled |
| adaptive_hash_rows_deleted_no_hash_entry | adaptive_hash_index | disabled |
| adaptive_hash_rows_removed               | adaptive_hash_index | disabled |
| adaptive_hash_rows_updated               | adaptive_hash_index | disabled |
| adaptive_hash_searches                   | adaptive_hash_index | enabled  |
| adaptive_hash_searches_btree             | adaptive_hash_index | enabled  |
| buffer_data_reads                        | buffer              | enabled  |
| buffer_data_written                      | buffer              | enabled  |
| buffer_flush_adaptive                    | buffer              | disabled |
| buffer_flush_adaptive_avg_pass           | buffer              | disabled |
| buffer_flush_adaptive_avg_time_est       | buffer              | disabled |
| buffer_flush_adaptive_avg_time_slot      | buffer              | disabled |
| buffer_flush_adaptive_avg_time_thread    | buffer              | disabled |
| buffer_flush_adaptive_pages              | buffer              | disabled |
| buffer_flush_adaptive_total_pages        | buffer              | disabled |
| buffer_flush_avg_page_rate               | buffer              | disabled |
| buffer_flush_avg_pass                    | buffer              | disabled |
| buffer_flush_avg_time                    | buffer              | disabled |

## Counter Modules

The module names correspond to, but are not identical to, the values from the [SUBSYSTEM](#) column of the [INNODB\\_METRICS](#) table. Rather enabling, disabling, or resetting counters individually, you can use module names to quickly enable, disable, or reset all counters for a particular subsystem. For example, use [module\\_dml](#) to enable all counters associated with the [dml](#) subsystem.

```
mysql> SET GLOBAL innodb_monitor_enable = module_dml;

mysql> SELECT name, subsystem, status FROM INFORMATION_SCHEMA.INNODB_METRICS
WHERE subsystem = 'dml';
```

| name        | subsystem | status  |
|-------------|-----------|---------|
| dml_reads   | dml       | enabled |
| dml_inserts | dml       | enabled |
| dml_deletes | dml       | enabled |
| dml_updates | dml       | enabled |

Here are the values you can use for [module\\_name](#) with the [innodb\\_monitor\\_enable](#) and related configuration options, along with the corresponding [SUBSYSTEM](#) names:

- [module\\_adaptive\\_hash](#) (subsystem = [adaptive\\_hash\\_index](#))
- [module\\_buffer](#) (subsystem = [buffer](#))
- [module\\_buffer\\_page](#) (subsystem = [buffer\\_page\\_io](#))
- [module\\_compress](#) (subsystem = [compression](#))
- [module\\_ddl](#) (subsystem = [ddl](#))

- `module_dml` (subsystem = `dml`)
- `module_file` (subsystem = `file_system`)
- `module_ibuf_system` (subsystem = `change_buffer`)
- `module_icp` (subsystem = `icp`)
- `module_index` (subsystem = `index`)
- `module_innodb` (subsystem = `innodb`)
- `module_lock` (subsystem = `lock`)
- `module_log` (subsystem = `recovery`)
- `module_metadata` (subsystem = `metadata`)
- `module_os` (subsystem = `os`)
- `module_purge` (subsystem = `purge`)
- `module_trx` (subsystem = `transaction`)

### Example 15.20 Working with INNODB\_METRICS Table Counters

This example demonstrates enabling, disabling, and resetting a counter, and querying counter data in the `INNODB_METRICS` table.

1. Create a simple `InnoDB` table:

```
mysql> USE test;
Database changed

mysql> CREATE TABLE t1 (c1 INT) ENGINE=INNODB;
Query OK, 0 rows affected (0.02 sec)
```

2. Enable the `dml_inserts` counter.

```
mysql> SET GLOBAL innodb_monitor_enable = dml_inserts;
Query OK, 0 rows affected (0.01 sec)
```

A description of the `dml_inserts` counter can be found in the `COMMENT` column of the `INNODB_METRICS` table:

```
mysql> SELECT NAME, COMMENT FROM INFORMATION_SCHEMA.INNODB_METRICS WHERE NAME="dml_inserts";
+-----+-----+
| NAME          | COMMENT                                |
+-----+-----+
| dml_inserts   | Number of rows inserted              |
+-----+-----+
```

3. Query the `INNODB_METRICS` table for the `dml_inserts` counter data. Because no DML operations have been performed, the counter values are zero or NULL. The `TIME_ENABLED` and `TIME_ELAPSED` values indicate when the counter was last enabled and how many seconds have elapsed since this time.

```
mysql> SELECT * FROM INFORMATION_SCHEMA.INNODB_METRICS WHERE NAME="dml_inserts" \G
***** 1. row *****
      NAME: dml_inserts
    SUBSYSTEM: dml
      COUNT: 0
    MAX_COUNT: 0
    MIN_COUNT: NULL
    AVG_COUNT: 0
    COUNT_RESET: 0
MAX_COUNT_RESET: 0
MIN_COUNT_RESET: NULL
AVG_COUNT_RESET: NULL
```

```

TIME_ENABLED: 2014-12-04 14:18:28
TIME_DISABLED: NULL
TIME_ELAPSED: 28
TIME_RESET: NULL
STATUS: enabled
TYPE: status_counter
COMMENT: Number of rows inserted

```

4. Insert three rows of data into the table.

```

mysql> INSERT INTO t1 values(1);
Query OK, 1 row affected (0.00 sec)

mysql> INSERT INTO t1 values(2);
Query OK, 1 row affected (0.00 sec)

mysql> INSERT INTO t1 values(3);
Query OK, 1 row affected (0.00 sec)

```

5. Query the `INNODB_METRICS` table again for the `dml_inserts` counter data. A number of counter values have now incremented including `COUNT`, `MAX_COUNT`, `AVG_COUNT`, and `COUNT_RESET`. Refer to the `INNODB_METRICS` table definition for descriptions of these values.

```

mysql> SELECT * FROM INFORMATION_SCHEMA.INNODB_METRICS WHERE NAME="dml_inserts"\G
***** 1. row *****
      NAME: dml_inserts
    SUBSYSTEM: dml
      COUNT: 3
    MAX_COUNT: 3
    MIN_COUNT: NULL
    AVG_COUNT: 0.046153846153846156
    COUNT_RESET: 3
MAX_COUNT_RESET: 3
MIN_COUNT_RESET: NULL
AVG_COUNT_RESET: NULL
    TIME_ENABLED: 2014-12-04 14:18:28
    TIME_DISABLED: NULL
    TIME_ELAPSED: 65
    TIME_RESET: NULL
      STATUS: enabled
      TYPE: status_counter
    COMMENT: Number of rows inserted

```

6. Reset the `dml_inserts` counter, and query the `INNODB_METRICS` table again for the `dml_inserts` counter data. The `%_RESET` values that were reported previously, such as `COUNT_RESET` and `MAX_RESET`, are set back to zero. Values such as `COUNT`, `MAX_COUNT`, and `AVG_COUNT`, which cumulatively collect data from the time the counter is enabled, are unaffected by the reset.

```

mysql> SET GLOBAL innodb_monitor_reset = dml_inserts;
Query OK, 0 rows affected (0.00 sec)

mysql> SELECT * FROM INFORMATION_SCHEMA.INNODB_METRICS WHERE NAME="dml_inserts"\G
***** 1. row *****
      NAME: dml_inserts
    SUBSYSTEM: dml
      COUNT: 3
    MAX_COUNT: 3
    MIN_COUNT: NULL
    AVG_COUNT: 0.03529411764705882
    COUNT_RESET: 0
MAX_COUNT_RESET: 0
MIN_COUNT_RESET: NULL
AVG_COUNT_RESET: 0
    TIME_ENABLED: 2014-12-04 14:18:28
    TIME_DISABLED: NULL
    TIME_ELAPSED: 85
    TIME_RESET: 2014-12-04 14:19:44
      STATUS: enabled
      TYPE: status_counter

```

COMMENT: Number of rows inserted

- To reset all counter values, you must first disable the counter. Disabling the counter sets the `STATUS` value to `disbaled`.

```
mysql> SET GLOBAL innodb_monitor_disable = dml_inserts;
Query OK, 0 rows affected (0.00 sec)

mysql> SELECT * FROM INFORMATION_SCHEMA.INNODB_METRICS WHERE NAME="dml_inserts"\G
***** 1. row *****
      NAME: dml_inserts
    SUBSYSTEM: dml
      COUNT: 3
    MAX_COUNT: 3
    MIN_COUNT: NULL
    AVG_COUNT: 0.030612244897959183
  COUNT_RESET: 0
MAX_COUNT_RESET: 0
MIN_COUNT_RESET: NULL
AVG_COUNT_RESET: 0
    TIME_ENABLED: 2014-12-04 14:18:28
    TIME_DISABLED: 2014-12-04 14:20:06
    TIME_ELAPSED: 98
      TIME_RESET: NULL
      STATUS: disabled
      TYPE: status_counter
    COMMENT: Number of rows inserted
```

#### Note

Wildcard match is supported for counter and module names. For example, instead of specifying the full `dml_inserts` counter name, you can specify `dml_i%`. You can also enable, disable, or reset multiple counters or modules at once using a wildcard match. For example, specify `dml_%` to enable, disable, or reset all counters that begin with `dml_`.

- After the counter is disabled, you can reset all counter values using the `innodb_monitor_reset_all` option. All values are set to zero or NULL.

```
mysql> SET GLOBAL innodb_monitor_reset_all = dml_inserts;
Query OK, 0 rows affected (0.00 sec)

mysql> SELECT * FROM INFORMATION_SCHEMA.INNODB_METRICS WHERE NAME="dml_inserts"\G
***** 1. row *****
      NAME: dml_inserts
    SUBSYSTEM: dml
      COUNT: 0
    MAX_COUNT: NULL
    MIN_COUNT: NULL
    AVG_COUNT: NULL
  COUNT_RESET: 0
MAX_COUNT_RESET: NULL
MIN_COUNT_RESET: NULL
AVG_COUNT_RESET: NULL
    TIME_ENABLED: NULL
    TIME_DISABLED: NULL
    TIME_ELAPSED: NULL
      TIME_RESET: NULL
      STATUS: disabled
      TYPE: status_counter
    COMMENT: Number of rows inserted
```

## 15.15.7 InnoDB INFORMATION\_SCHEMA Temporary Table Information Table

The `INNODB_TEMP_TABLE_INFO` table, introduced in MySQL 5.7.1, provides users with a snapshot of active InnoDB temporary tables. The table contains metadata about all user and system-created

temporary tables that are active within a given [InnoDB](#) instance with the exception of optimized temporary tables that are used internally by [InnoDB](#).

```
mysql> SHOW TABLES FROM INFORMATION_SCHEMA LIKE 'INNODB_TEMP%';
+-----+
| Tables_in_INFORMATION_SCHEMA (INNODB_TEMP%) |
+-----+
| INNODB_TEMP_TABLE_INFO                      |
+-----+
```

For the table definition, see [Section 23.31.26](#), “The INFORMATION\_SCHEMA INNODB\_TEMP\_TABLE\_INFO Table”.

### Example 15.21 INNODB\_TEMP\_TABLE\_INFO

This example demonstrates characteristics of the [INNODB\\_TEMP\\_TABLE\\_INFO](#) table.

1. Create a simple [InnoDB](#) temporary table with a single column:

```
mysql> CREATE TEMPORARY TABLE t1 (c1 INT PRIMARY KEY) ENGINE=INNODB;
Query OK, 0 rows affected (0.00 sec)
```

2. Query the [INNODB\\_TEMP\\_TABLE\\_INFO](#) table to view the temporary table's metadata.

```
mysql> SELECT * FROM INFORMATION_SCHEMA.INNODB_TEMP_TABLE_INFO\G
***** 1. row *****
      TABLE_ID: 194
        NAME: #sql7a79_1_0
       N_COLS: 4
        SPACE: 182
PER_TABLE_TABLESPACE: FALSE
      IS_COMPRESSED: FALSE
```

The [TABLE\\_ID](#) is a unique identifier for the temporary table. The [NAME](#) column displays the system-generated name for the temporary table, which is prefixed with “#sql”. The number of columns ([N\\_COLS](#)) is 4 rather than 1 because [InnoDB](#) always creates three hidden table columns ([DB\\_ROW\\_ID](#), [DB\\_TRX\\_ID](#), and [DB\\_ROLL\\_PTR](#)). [PER\\_TABLE\\_TABLESPACE](#) and [IS\\_COMPRESSED](#) only report [TRUE](#) for compressed temporary tables.

3. Create a compressed temporary table. Before you do so, ensure that [innodb\\_file\\_format](#) is set to [Barracuda](#), which is required to create tables with a compressed row format.

```
mysql> SET GLOBAL innodb_file_format="Barracuda";
Query OK, 0 rows affected (0.00 sec)

mysql> CREATE TEMPORARY TABLE t2 (c1 INT) ROW_FORMAT=COMPRESSED ENGINE=INNODB;
Query OK, 0 rows affected (0.01 sec)
```

4. Query the [INNODB\\_TEMP\\_TABLE\\_INFO](#) table again.

```
mysql> CREATE TEMPORARY TABLE t2 (c1 INT) ROW_FORMAT=COMPRESSED ENGINE=INNODB;
Query OK, 0 rows affected (0.01 sec)

mysql> SELECT * FROM INFORMATION_SCHEMA.INNODB_TEMP_TABLE_INFO\G
***** 1. row *****
      TABLE_ID: 195
        NAME: #sql7a79_1_1
       N_COLS: 4
        SPACE: 183
PER_TABLE_TABLESPACE: TRUE
      IS_COMPRESSED: TRUE
***** 2. row *****
      TABLE_ID: 194
        NAME: #sql7a79_1_0
       N_COLS: 4
        SPACE: 182
PER_TABLE_TABLESPACE: FALSE
```

```
IS_COMPRESSED: FALSE
```

`PER_TABLE_TABLESPACE` and `IS_COMPRESSED` report `TRUE` for the compressed temporary table. The `SPACE` ID for the compressed temporary table is different because compressed temporary tables are created in separate per-table tablespaces. Non-compressed temporary tables share a single tablespace (`ibtmp1`, by default) and report the same `SPACE` ID.

- Restart MySQL and query the `INNODB_TEMP_TABLE_INFO` table.

```
mysql> SELECT * FROM INFORMATION_SCHEMA.INNODB_TEMP_TABLE_INFO\G
Empty set (0.00 sec)
```

An empty set is returned because the `INNODB_TEMP_TABLE_INFO` table and the data within it are not persisted to disk on server shutdown.

- Create a new temporary table.

```
mysql> CREATE TEMPORARY TABLE t1 (c1 INT PRIMARY KEY) ENGINE=INNODB;
Query OK, 0 rows affected (0.00 sec)
```

- Query the `INNODB_TEMP_TABLE_INFO` table to view the temporary table's metadata.

```
mysql> SELECT * FROM INFORMATION_SCHEMA.INNODB_TEMP_TABLE_INFO\G
***** 1. row *****
      TABLE_ID: 196
        NAME: #sql7b0e_1_0
       N_COLS: 4
        SPACE: 184
PER_TABLE_TABLESPACE: FALSE
      IS_COMPRESSED: FALSE
```

The `SPACE` ID is new because it is dynamically generated on server restart.

## 15.15.8 Retrieving InnoDB Tablespace Metadata from INFORMATION\_SCHEMA.FILES

As of MySQL 5.7.8, the `INFORMATION_SCHEMA.FILES` table provides metadata about all InnoDB tablespace types including [file-per-table tablespaces](#), [general tablespaces](#), the [system tablespace](#), [temporary table tablespaces](#), and [undo tablespaces](#) (if present).

This section provides InnoDB-specific usage examples. For more information about data provided by the `INFORMATION_SCHEMA.FILES` table, see [Section 23.8, “The INFORMATION\\_SCHEMA FILES Table”](#).

### Note

The `INNODB_SYS_TABLESPACES` and `INNODB_SYS_DATAFILES` tables also provide metadata about InnoDB tablespaces, but data is limited to file-per-table and general tablespaces.

This query retrieves metadata about the InnoDB system tablespace from fields of the `INFORMATION_SCHEMA.FILES` table that are pertinent to InnoDB tablespaces. `INFORMATION_SCHEMA.FILES` fields that are not relevant to InnoDB always return NULL, and are excluded from the query.

```
mysql> SELECT FILE_ID, FILE_NAME, FILE_TYPE, TABLESPACE_NAME, FREE_EXTENTS,
TOTAL_EXTENTS, EXTENT_SIZE, INITIAL_SIZE, MAXIMUM_SIZE, AUTOEXTEND_SIZE, DATA_FREE, STATUS ENGINE
FROM INFORMATION_SCHEMA.FILES WHERE TABLESPACE_NAME LIKE 'innodb_system' \G
***** 1. row *****
      FILE_ID: 0
     FILE_NAME: ./ibdata1
    FILE_TYPE: TABLESPACE
TABLESPACE_NAME: innodb_system
    FREE_EXTENTS: 0
```

```

TOTAL_EXTENTS: 12
EXTENT_SIZE: 1048576
INITIAL_SIZE: 12582912
MAXIMUM_SIZE: NULL
AUTOEXTEND_SIZE: 67108864
DATA_FREE: 4194304
ENGINE: NORMAL

```

This query retrieves the `FILE_ID` (equivalent to the space ID) and the `FILE_NAME` (which includes path information) for InnoDB file-per-table and general tablespaces. File-per-table and general tablespaces have a `.ibd` file extension.

```

mysql> SELECT FILE_ID, FILE_NAME FROM INFORMATION_SCHEMA.FILES
WHERE FILE_NAME LIKE '%.ibd%' ORDER BY FILE_ID;

```

| FILE_ID | FILE_NAME                             |
|---------|---------------------------------------|
| 2       | ./mysql/plugin.ibd                    |
| 3       | ./mysql/servers.ibd                   |
| 4       | ./mysql/help_topic.ibd                |
| 5       | ./mysql/help_category.ibd             |
| 6       | ./mysql/help_relation.ibd             |
| 7       | ./mysql/help_keyword.ibd              |
| 8       | ./mysql/time_zone_name.ibd            |
| 9       | ./mysql/time_zone.ibd                 |
| 10      | ./mysql/time_zone_transition.ibd      |
| 11      | ./mysql/time_zone_transition_type.ibd |
| 12      | ./mysql/time_zone_leap_second.ibd     |
| 13      | ./mysql/innodb_table_stats.ibd        |
| 14      | ./mysql/innodb_index_stats.ibd        |
| 15      | ./mysql/slave_relay_log_info.ibd      |
| 16      | ./mysql/slave_master_info.ibd         |
| 17      | ./mysql/slave_worker_info.ibd         |
| 18      | ./mysql/gtid_executed.ibd             |
| 19      | ./mysql/server_cost.ibd               |
| 20      | ./mysql/engine_cost.ibd               |
| 21      | ./sys/sys_config.ibd                  |
| 23      | ./test/t1.ibd                         |
| 26      | /home/user/test/test/t2.ibd           |

This query retrieves the `FILE_ID` and `FILE_NAME` for InnoDB temporary tablespaces. Temporary tablespace file names are prefixed by `ibtmp`.

```

mysql> SELECT FILE_ID, FILE_NAME FROM INFORMATION_SCHEMA.FILES
WHERE FILE_NAME LIKE '%ibtmp%';

```

| FILE_ID | FILE_NAME |
|---------|-----------|
| 22      | ./ibtmp1  |

Similarly, InnoDB undo tablespace file names are prefixed by `undo`. The following query returns the `FILE_ID` and `FILE_NAME` for InnoDB undo tablespaces, if separate undo tablespaces are configured.

```

mysql> SELECT FILE_ID, FILE_NAME FROM INFORMATION_SCHEMA.FILES
WHERE FILE_NAME LIKE '%undo%';

```

## 15.16 InnoDB Integration with MySQL Performance Schema

This section provides a brief introduction to InnoDB integration with Performance Schema. For comprehensive Performance Schema documentation, see [Chapter 24, MySQL Performance Schema](#).

You can profile certain internal InnoDB operations using the MySQL [Performance Schema feature](#). This type of tuning is primarily for expert users who evaluate optimization strategies to overcome performance bottlenecks. DBAs can also use this feature for capacity planning, to see whether their typical workload encounters any performance bottlenecks with a particular combination of CPU, RAM,

and disk storage; and if so, to judge whether performance can be improved by increasing the capacity of some part of the system.

To use this feature to examine [InnoDB](#) performance:

- You must be generally familiar with how to use the [Performance Schema feature](#). For example, you should know how enable instruments and consumers, and how to query [performance\\_schema](#) tables to retrieve data. For an introductory overview, see [Section 24.1, “Performance Schema Quick Start”](#).
- You should be familiar with Performance Schema instruments that are available for [InnoDB](#). To view [InnoDB](#)-related instruments, you can query the [setup\\_instruments](#) table for instrument names that contain 'innodb'.

```
mysql> SELECT * FROM setup_instruments WHERE NAME LIKE '%innodb%';
```

| NAME   | ENABLED | TIMED |
|--|---------|-------|
| wait/synch/mutex/innodb/commit_cond_mutex            | NO      | NO    |
| wait/synch/mutex/innodb/innobase_share_mutex         | NO      | NO    |
| wait/synch/mutex/innodb/autoinc_mutex                | NO      | NO    |
| wait/synch/mutex/innodb/buf_pool_mutex               | NO      | NO    |
| wait/synch/mutex/innodb/buf_pool_zip_mutex           | NO      | NO    |
| wait/synch/mutex/innodb/cache_last_read_mutex        | NO      | NO    |
| wait/synch/mutex/innodb/dict_foreign_err_mutex       | NO      | NO    |
| wait/synch/mutex/innodb/dict_sys_mutex               | NO      | NO    |
| wait/synch/mutex/innodb/recalc_pool_mutex            | NO      | NO    |
| wait/synch/mutex/innodb/file_format_max_mutex        | NO      | NO    |
| ...  |         |       |
| wait/io/file/innodb/innodb_data_file                 | YES     | YES   |
| wait/io/file/innodb/innodb_log_file                  | YES     | YES   |
| wait/io/file/innodb/innodb_temp_file                 | YES     | YES   |
| stage/innodb/alter table (end)                       | YES     | YES   |
| stage/innodb/alter table (flush)                     | YES     | YES   |
| stage/innodb/alter table (insert)                    | YES     | YES   |
| stage/innodb/alter table (log apply index)           | YES     | YES   |
| stage/innodb/alter table (log apply table)           | YES     | YES   |
| stage/innodb/alter table (merge sort)                | YES     | YES   |
| stage/innodb/alter table (read PK and internal sort) | YES     | YES   |
| stage/innodb/buffer pool load                        | YES     | YES   |
| memory/innodb/buf_buf_pool                           | NO      | NO    |
| memory/innodb/dict_stats_bg_recalc_pool_t            | NO      | NO    |
| memory/innodb/dict_stats_index_map_t                 | NO      | NO    |
| memory/innodb/dict_stats_n_diff_on_level             | NO      | NO    |
| memory/innodb/other                                  | NO      | NO    |
| memory/innodb/row_log_buf                            | NO      | NO    |
| memory/innodb/row_merge_sort                         | NO      | NO    |
| memory/innodb/std                                    | NO      | NO    |
| memory/innodb/sync_debug_latches                     | NO      | NO    |
| memory/innodb/trx_sys_t::rw_trx_ids                  | NO      | NO    |
| ...  |         |       |

```
155 rows in set (0.00 sec)
```

For additional information about the instrumented [InnoDB](#) objects, you can query Performance Schema [instances tables](#), which provide additional information about instrumented objects. Instance tables relevant to [InnoDB](#) include:

- The [mutex\\_instances](#) table
- The [rwlock\\_instances](#) table
- The [cond\\_instances](#) table
- The [file\\_instances](#) table

**Note**

Mutexes and RW-locks related to the [InnoDB](#) buffer pool are not included in this coverage; the same applies to the output of the `SHOW ENGINE INNODB MUTEX` command.

For example, to view information about instrumented [InnoDB](#) file objects seen by the Performance Schema when executing file I/O instrumentation, you might issue the following query:

```
mysql> SELECT * FROM file_instances WHERE EVENT_NAME LIKE '%innodb%\G
***** 1. row *****
FILE_NAME: /path/to/mysql-5.7/data/ibdata1
EVENT_NAME: wait/io/file/innodb/innodb_data_file
OPEN_COUNT: 3
***** 2. row *****
FILE_NAME: /path/to/mysql-5.7/data/ib_logfile0
EVENT_NAME: wait/io/file/innodb/innodb_log_file
OPEN_COUNT: 2
***** 3. row *****
FILE_NAME: /path/to/mysql-5.7/data/ib_logfile1
EVENT_NAME: wait/io/file/innodb/innodb_log_file
OPEN_COUNT: 2
***** 4. row *****
FILE_NAME: /path/to/mysql-5.7/data/mysql/engine_cost.ibd
EVENT_NAME: wait/io/file/innodb/innodb_data_file
OPEN_COUNT: 3
...
```

- You should be familiar with [performance\\_schema](#) tables that store [InnoDB](#) event data. Tables relevant to [InnoDB](#)-related events include:
  - The [Wait Event](#) tables, which store wait events.
  - The [Summary](#) tables, which provide aggregated information for terminated events over time. Summary tables include [file I/O summary tables](#), which aggregate information about I/O operations.
  - [Stage Event](#) tables, which store event data for [InnoDB ALTER TABLE](#) and buffer pool load operations. For more information, see [Section 15.16.1, “Monitoring ALTER TABLE Progress for InnoDB Tables Using Performance Schema”](#), and [Monitoring Buffer Pool Load Progress Using Performance Schema](#).

If you are only interested in [InnoDB](#)-related objects, use the clause `WHERE EVENT_NAME LIKE '%innodb%'` or `WHERE NAME LIKE '%innodb%'` (as required) when querying these tables.

## 15.16.1 Monitoring ALTER TABLE Progress for InnoDB Tables Using Performance Schema

As of MySQL 5.7.6, you can monitor [ALTER TABLE](#) progress for [InnoDB](#) tables using [Performance Schema](#).

There are seven stage events that represent different phases of [ALTER TABLE](#). Each stage event reports a running total of [WORK\\_COMPLETED](#) and [WORK\\_ESTIMATED](#) for the overall [ALTER TABLE](#) operation as it progresses through its different phases. [WORK\\_ESTIMATED](#) is calculated using a formula that takes into account all of the work that [ALTER TABLE](#) performs, and may be revised during [ALTER TABLE](#) processing. [WORK\\_COMPLETED](#) and [WORK\\_ESTIMATED](#) values are an abstract representation of all of the work performed by [ALTER TABLE](#).

In order of occurrence, [ALTER TABLE](#) stage events include:

- `stage/innodb/alter table (read PK and internal sort)`: This stage is active when [ALTER TABLE](#) is in the reading-primary-key phase. It starts with [WORK\\_COMPLETED=0](#) and

`WORK_ESTIMATED` set to the estimated number of pages in the primary key. When the stage is completed, `WORK_ESTIMATED` is updated to the actual number of pages in the primary key.

- `stage/innodb/alter table (merge sort)`: This stage is repeated for each index added by the `ALTER TABLE` operation.
- `stage/innodb/alter table (insert)`: This stage is repeated for each index added by the `ALTER TABLE` operation.
- `stage/innodb/alter table (log apply index)`: This stage includes the application of DML log generated while `ALTER TABLE` was running.
- `stage/innodb/alter table (flush)`: Before this stage begins, `WORK_ESTIMATED` is updated with a more accurate estimate, based on the length of the flush list.
- `stage/innodb/alter table (log apply table)`: This stage includes the application of concurrent DML log generated while `ALTER TABLE` was running. The duration of this phase depends on the extent of table changes. This phase is instant if no concurrent DML was run on the table.
- `stage/innodb/alter table (end)`: Includes any remaining work that appeared after the flush phase, such as reapplying DML that was executed on the table while `ALTER TABLE` was running.

#### Note

InnoDB `ALTER TABLE` stage events do not currently account for the addition of spatial indexes.

## ALTER TABLE Monitoring Example Using Performance Schema

The following example demonstrates how to enable the `stage/innodb/alter table%` stage event instruments and related consumer tables to monitor `ALTER TABLE` progress. For information about Performance Schema stage event instruments and related consumers, see [Section 24.10.5, “Performance Schema Stage Event Tables”](#).

1. Enable the `stage/innodb/alter%` instruments:

```
mysql> UPDATE setup_instruments SET ENABLED = 'YES' WHERE NAME LIKE 'stage/innodb/alter%';
Query OK, 7 rows affected (0.00 sec)
Rows matched: 7  Changed: 7  Warnings: 0
```

2. Enable the stage event consumer tables, which include `events_stages_current`, `events_stages_history`, and `events_stages_history_long`.

```
mysql> UPDATE setup_consumers SET ENABLED = 'YES' WHERE NAME LIKE '%stages%';
Query OK, 3 rows affected (0.00 sec)
Rows matched: 3  Changed: 3  Warnings: 0
```

3. Run an `ALTER TABLE` operation. In this example, a `middle_name` column is added to the `employees` table of the `employees` sample database.

```
mysql> ALTER TABLE employees.employees ADD COLUMN middle_name varchar(14) AFTER first_name;
Query OK, 0 rows affected (9.27 sec)
Records: 0  Duplicates: 0  Warnings: 0
```

4. Check the progress of the `ALTER TABLE` operation by querying the Performance Schema `events_stages_current` table. The stage event shown differs depending on which `ALTER TABLE` phase is currently in progress. The `WORK_COMPLETED` column shows the work completed. The `WORK_ESTIMATED` column provides an estimate of the remaining work.

```
mysql> SELECT EVENT_NAME, WORK_COMPLETED, WORK_ESTIMATED FROM events_stages_current;
+-----+-----+-----+
| EVENT_NAME                                     | WORK_COMPLETED | WORK_ESTIMATED |
+-----+-----+-----+
| stage/innodb/alter table (read PK and internal sort) |             280 |             1245 |
+-----+-----+-----+
```

```
1 row in set (0.01 sec)
```

The `events_stages_current` table returns an empty set if the `ALTER TABLE` operation has completed. In this case, you can check the `events_stages_history` table to view event data for the completed operation. For example:

```
mysql> SELECT EVENT_NAME, WORK_COMPLETED, WORK_ESTIMATED FROM events_stages_history;
```

| EVENT_NAME   | WORK_COMPLETED | WORK_ESTIMATED |
|--|----------------|----------------|
| stage/innodb/alter table (read PK and internal sort) | 886            | 1213           |
| stage/innodb/alter table (flush)                     | 1213           | 1213           |
| stage/innodb/alter table (log apply table)           | 1597           | 1597           |
| stage/innodb/alter table (end)                       | 1597           | 1597           |
| stage/innodb/alter table (log apply table)           | 1981           | 1981           |

```
5 rows in set (0.00 sec)
```

As shown above, the `WORK_ESTIMATED` value was revised during `ALTER TABLE` processing. The estimated work after completion of the initial stage is 1213. When `ALTER TABLE` processing completed, `WORK_ESTIMATED` was set to the actual value, which is 1981.

## 15.16.2 Monitoring InnoDB Mutex Waits Using Performance Schema

A mutex is a synchronization mechanism used in the code to enforce that only one thread at a given time can have access to a common resource. When two or more threads executing in the server need to access the same resource, the threads compete against each other. The first thread to obtain a lock on the mutex causes the other threads to wait until the lock is released.

For InnoDB mutexes that are instrumented, mutex waits can be monitored using [Performance Schema](#). Wait event data collected in Performance Schema tables can help identify mutexes with the most waits or the greatest total wait time, for example.

The following example demonstrates how to enable InnoDB mutex wait instruments, how to enable associated consumers, and how to query wait event data.

1. To view available InnoDB mutex wait instruments, query the Performance Schema `setup_instruments` table, as shown below. All InnoDB mutex wait instruments are disabled by default.

```
mysql> SELECT * FROM performance_schema.setup_instruments
-> WHERE NAME LIKE '%wait/synch/mutex/innodb%';
```

| NAME  | ENABLED | TIMED |
|---|---------|-------|
| wait/synch/mutex/innodb/commit_cond_mutex             | NO      | NO    |
| wait/synch/mutex/innodb/innobase_share_mutex          | NO      | NO    |
| wait/synch/mutex/innodb/autoinc_mutex                 | NO      | NO    |
| wait/synch/mutex/innodb/buf_pool_mutex                | NO      | NO    |
| wait/synch/mutex/innodb/buf_pool_zip_mutex            | NO      | NO    |
| wait/synch/mutex/innodb/cache_last_read_mutex         | NO      | NO    |
| wait/synch/mutex/innodb/dict_foreign_err_mutex        | NO      | NO    |
| wait/synch/mutex/innodb/dict_sys_mutex                | NO      | NO    |
| wait/synch/mutex/innodb/recalc_pool_mutex             | NO      | NO    |
| wait/synch/mutex/innodb/file_format_max_mutex         | NO      | NO    |
| wait/synch/mutex/innodb/file_system_mutex             | NO      | NO    |
| wait/synch/mutex/innodb/flush_list_mutex              | NO      | NO    |
| wait/synch/mutex/innodb/fts_bg_threads_mutex          | NO      | NO    |
| wait/synch/mutex/innodb/fts_delete_mutex              | NO      | NO    |
| wait/synch/mutex/innodb/fts_optimize_mutex            | NO      | NO    |
| wait/synch/mutex/innodb/fts_doc_id_mutex              | NO      | NO    |
| wait/synch/mutex/innodb/log_flush_order_mutex         | NO      | NO    |
| wait/synch/mutex/innodb/hash_table_mutex              | NO      | NO    |
| wait/synch/mutex/innodb/ibuf_bitmap_mutex             | NO      | NO    |
| wait/synch/mutex/innodb/ibuf_mutex                    | NO      | NO    |
| wait/synch/mutex/innodb/ibuf_pessimistic_insert_mutex | NO      | NO    |
| wait/synch/mutex/innodb/log_sys_mutex                 | NO      | NO    |

|   |    |    |
|---|----|----|
| wait/synch/mutex/innodb/page_zip_stat_per_index_mutex | NO | NO |
| wait/synch/mutex/innodb/purge_sys_pq_mutex            | NO | NO |
| wait/synch/mutex/innodb/recv_sys_mutex                | NO | NO |
| wait/synch/mutex/innodb/recv_writer_mutex             | NO | NO |
| wait/synch/mutex/innodb/redo_rseg_mutex               | NO | NO |
| wait/synch/mutex/innodb/noredoreg_mutex               | NO | NO |
| wait/synch/mutex/innodb/rw_lock_list_mutex            | NO | NO |
| wait/synch/mutex/innodb/rw_lock_mutex                 | NO | NO |
| wait/synch/mutex/innodb/srv_dict_tmpfile_mutex        | NO | NO |
| wait/synch/mutex/innodb/srv_innodb_monitor_mutex      | NO | NO |
| wait/synch/mutex/innodb/srv_misc_tmpfile_mutex        | NO | NO |
| wait/synch/mutex/innodb/srv_monitor_file_mutex        | NO | NO |
| wait/synch/mutex/innodb/buf_dblwr_mutex               | NO | NO |
| wait/synch/mutex/innodb/trx_undo_mutex                | NO | NO |
| wait/synch/mutex/innodb/trx_pool_mutex                | NO | NO |
| wait/synch/mutex/innodb/trx_pool_manager_mutex        | NO | NO |
| wait/synch/mutex/innodb/srv_sys_mutex                 | NO | NO |
| wait/synch/mutex/innodb/lock_mutex                    | NO | NO |
| wait/synch/mutex/innodb/lock_wait_mutex               | NO | NO |
| wait/synch/mutex/innodb/trx_mutex                     | NO | NO |
| wait/synch/mutex/innodb/srv_threads_mutex             | NO | NO |

49 rows in set (0.02 sec)

- Some [InnoDB](#) mutex instances are created at server startup and are only instrumented if the associated instrument is also enabled at server startup. To ensure that all [InnoDB](#) mutex instances are instrumented and enabled, add the following [performance-schema-instrument](#) rule to your MySQL configuration file:

```
performance-schema-instrument='wait/synch/mutex/innodb/%=ON'
```

If you do not require wait event data for all [InnoDB](#) mutexes, you can disable specific instruments by adding additional [performance-schema-instrument](#) rules to your MySQL configuration file. For example, to disable [InnoDB](#) mutex wait event instruments related to full-text search, add the following rule:

```
performance-schema-instrument='wait/synch/mutex/innodb/fts%=OFF'
```

#### Note

Rules with a longer prefix such as [wait/synch/mutex/innodb/fts%](#) take precedence over rules with shorter prefixes such as [wait/synch/mutex/innodb/%](#).

After adding the [performance-schema-instrument](#) rules to your configuration file, restart the server. All the [InnoDB](#) mutexes except for those related to full text search are enabled. To verify, query the [setup\\_instruments](#) table. The [ENABLED](#) and [TIMED](#) columns should be set to [YES](#) for the instruments that you enabled.

```
mysql> SELECT * FROM performance_schema.setup_instruments
-> WHERE NAME LIKE '%wait/synch/mutex/innodb%';
```

| NAME   | ENABLED | TIMED |
|--|---------|-------|
| wait/synch/mutex/innodb/commit_cond_mutex    | YES     | YES   |
| wait/synch/mutex/innodb/innobase_share_mutex | YES     | YES   |
| wait/synch/mutex/innodb/autoinc_mutex        | YES     | YES   |
| ...  |         |       |
| wait/synch/mutex/innodb/zip_pad_mutex        | YES     | YES   |

49 rows in set (0.00 sec)

3. Enable wait event consumers by updating the `setup_consumers` table. Wait event consumers are disabled by default.

```
mysql> UPDATE performance_schema.setup_consumers SET enabled = 'YES'
      -> WHERE name like 'events_waits%';
Query OK, 3 rows affected (0.00 sec)
Rows matched: 3  Changed: 3  Warnings: 0
```

You can verify that wait event consumers are enabled by querying the `setup_consumers` table. The `events_waits_current`, `events_waits_history`, and `events_waits_history_long` consumers should be enabled.

```
mysql> SELECT * FROM performance_schema.setup_consumers;
+-----+-----+
| NAME                                | ENABLED |
+-----+-----+
| events_stages_current               | NO      |
| events_stages_history               | NO      |
| events_stages_history_long          | NO      |
| events_statements_current           | YES     |
| events_statements_history           | YES     |
| events_statements_history_long      | NO      |
| events_transactions_current         | YES     |
| events_transactions_history         | YES     |
| events_transactions_history_long    | NO      |
| events_waits_current                | YES     |
| events_waits_history                | YES     |
| events_waits_history_long           | YES     |
| global_instrumentation              | YES     |
| thread_instrumentation              | YES     |
| statements_digest                   | YES     |
+-----+-----+
15 rows in set (0.00 sec)
```

4. Once instruments and consumers are enabled, run the workload that you want to monitor. In this example, the `mysqlslap` load emulation client is used to simulate a workload.

```
shell> ./mysqlslap --auto-generate-sql --concurrency=100 --iterations=10
      -> --number-of-queries=1000 --number-char-cols=6 --number-int-cols=6;
```

5. Query the wait event data. In this example, wait event data is queried from the `events_waits_summary_global_by_event_name` table which aggregates data found in the `events_waits_current`, `events_waits_history`, and `events_waits_history_long` tables. Data is summarized by event name (`EVENT_NAME`), which is the name of the instrument that produced the event. Summarized data includes:

- `COUNT_STAR`

The number of summarized wait events.

- `SUM_TIMER_WAIT`

The total wait time of the summarized timed wait events.

- `MIN_TIMER_WAIT`

The minimum wait time of the summarized timed wait events.

- `AVG_TIMER_WAIT`

The average wait time of the summarized timed wait events.

- `MAX_TIMER_WAIT`

The maximum wait time of the summarized timed wait events.

The following query returns the instrument name (`EVENT_NAME`), the number of wait events (`COUNT_STAR`), and the total wait time for the events for that instrument (`SUM_TIMER_WAIT`). Because waits are timed in picoseconds (trillionths of a second) by default, wait times are divided by 1000000000 to show wait times in milliseconds. Data is presented in descending order, by the number of summarized wait events (`COUNT_STAR`). You can adjust the `ORDER BY` clause to order the data by total wait time.

```
mysql> SELECT EVENT_NAME, COUNT_STAR, SUM_TIMER_WAIT/1000000000 SUM_TIMER_WAIT_MS
-> FROM performance_schema.events_waits_summary_global_by_event_name
-> WHERE SUM_TIMER_WAIT > 0 AND EVENT_NAME LIKE 'wait/synch/mutex/innodb/%'
-> ORDER BY COUNT_STAR DESC;
```

| EVENT_NAME                                       | COUNT_STAR | SUM_TIMER_WAIT_MS |
|--|------------|-------------------|
| wait/synch/mutex/innodb/os_mutex                 | 78831      | 10.3283           |
| wait/synch/mutex/innodb/log_sys_mutex            | 41488      | 6510.3233         |
| wait/synch/mutex/innodb/trx_sys_mutex            | 29770      | 1107.9687         |
| wait/synch/mutex/innodb/lock_mutex               | 24212      | 104.0724          |
| wait/synch/mutex/innodb/trx_mutex                | 22756      | 1.9421            |
| wait/synch/mutex/innodb/rseg_mutex               | 20333      | 3.6220            |
| wait/synch/mutex/innodb/dict_sys_mutex           | 13422      | 2.2284            |
| wait/synch/mutex/innodb/mutex_list_mutex         | 12694      | 344.1164          |
| wait/synch/mutex/innodb/fil_system_mutex         | 9208       | 0.9542            |
| wait/synch/mutex/innodb/rw_lock_list_mutex       | 8304       | 0.1794            |
| wait/synch/mutex/innodb/trx_undo_mutex           | 6190       | 0.6801            |
| wait/synch/mutex/innodb/buf_pool_mutex           | 2869       | 29.4623           |
| wait/synch/mutex/innodb/innobase_share_mutex     | 2005       | 0.1349            |
| wait/synch/mutex/innodb/flush_list_mutex         | 1274       | 0.1300            |
| wait/synch/mutex/innodb/file_format_max_mutex    | 1016       | 0.0469            |
| wait/synch/mutex/innodb/purge_sys_bh_mutex       | 1004       | 0.0326            |
| wait/synch/mutex/innodb/buf_dblwr_mutex          | 640        | 0.0437            |
| wait/synch/mutex/innodb/log_flush_order_mutex    | 437        | 0.0510            |
| wait/synch/mutex/innodb/recv_sys_mutex           | 394        | 0.0202            |
| wait/synch/mutex/innodb/srv_sys_mutex            | 169        | 0.5259            |
| wait/synch/mutex/innodb/lock_wait_mutex          | 154        | 0.1172            |
| wait/synch/mutex/innodb/ibuf_mutex               | 9          | 0.0027            |
| wait/synch/mutex/innodb/srv_innodb_monitor_mutex | 2          | 0.0009            |
| wait/synch/mutex/innodb/ut_list_mutex            | 1          | 0.0001            |
| wait/synch/mutex/innodb/recv_writer_mutex        | 1          | 0.0005            |

25 rows in set (0.01 sec)

#### Note

The preceding result set includes wait event data produced during the startup process. To exclude this data, you can truncate the `events_waits_summary_global_by_event_name` table immediately after startup and before running your workload. However, the truncate operation itself may produce a negligible amount wait event data.

```
mysql> TRUNCATE performance_schema.events_waits_summary_global_by_event_name;
```

## 15.17 InnoDB Monitors

InnoDB monitors provide information about the InnoDB internal state. This information is useful for performance tuning.

### 15.17.1 InnoDB Monitor Types

There are four types of InnoDB monitors:

- The standard InnoDB Monitor displays the following types of information:

- Table and record locks held by each active transaction.
- Lock waits of a transaction.
- Semaphore waits of threads.
- Pending file I/O requests.
- Buffer pool statistics.
- Purge and change buffer merge activity of the main [InnoDB](#) thread.
- The [InnoDB](#) Lock Monitor prints additional lock information as part of the standard [InnoDB](#) Monitor output.
- The [InnoDB](#) Tablespace Monitor prints a list of file segments in the shared tablespace and validates the tablespace allocation data structures.
- The [InnoDB](#) Table Monitor prints the contents of the [InnoDB](#) internal data dictionary.

**Note**

The Tablespace Monitor and Table Monitor were deprecated in MySQL 5.6.3 and have been removed in MySQL 5.7.4. For the Tablespace Monitor, equivalent functionality will be introduced before the GA release of MySQL 5.7. For the Table Monitor, equivalent information can be obtained from [InnoDB INFORMATION\\_SCHEMA](#) tables.

For additional information about [InnoDB](#) monitors, see:

- Mark Leith: [InnoDB Table and Tablespace Monitors](#)

## 15.17.2 Enabling InnoDB Monitors

When you enable [InnoDB](#) monitors for periodic output, [InnoDB](#) writes their output to the `mysqld` server standard error output (`stderr`). In this case, no output is sent to clients. When switched on, [InnoDB](#) monitors print data about every 15 seconds. Server output usually is directed to the error log (see [Section 6.4.2, “The Error Log”](#)). This data is useful in performance tuning. On Windows, start the server from a command prompt in a console window with the `--console` option if you want to direct the output to the window rather than to the error log.

[InnoDB](#) sends diagnostic output to `stderr` or to files rather than to `stdout` or fixed-size memory buffers, to avoid potential buffer overflows. As a side effect, the output of `SHOW ENGINE INNODB STATUS` is written to a status file in the MySQL data directory every fifteen seconds. The name of the file is `innodb_status.pid`, where `pid` is the server process ID. [InnoDB](#) removes the file for a normal shutdown. If abnormal shutdowns have occurred, instances of these status files may be present and must be removed manually. Before removing them, you might want to examine them to see whether they contain useful information about the cause of abnormal shutdowns. The `innodb_status.pid` file is created only if the configuration option `innodb-status-file=1` is set.

[InnoDB](#) monitors should be enabled only when you actually want to see monitor information because output generation does result in some performance decrement. Also, if you enable monitor output, your error log may become quite large if you forget to disable it later.

**Note**

To assist with troubleshooting, [InnoDB](#) temporarily enables standard [InnoDB](#) Monitor output under certain conditions. For more information, see [Section 15.21, “InnoDB Troubleshooting”](#).

Each monitor begins with a header containing a timestamp and the monitor name. For example:

```
=====
2014-10-16 18:37:29 0x7fc2a95c1700 INNODB MONITOR OUTPUT
=====
```

The header for the standard `InnoDB Monitor` (`INNODB MONITOR OUTPUT`) is also used for the Lock Monitor because the latter produces the same output with the addition of extra lock information.

Enabling an `InnoDB` monitor for periodic output involves using a `CREATE TABLE` statement to create a specially named `InnoDB` table that is associated with the monitor. For example, to enable the standard `InnoDB` Monitor, you would create an `InnoDB` table named `innodb_monitor`.

Using `CREATE TABLE` syntax is just a way to pass a command to the `InnoDB` engine through MySQL's SQL parser. The only things that matter are the table name and that it be an `InnoDB` table. The structure of the table is not relevant. If you shut down the server, the monitor does not restart automatically when you restart the server. Drop the monitor table and issue a new `CREATE TABLE` statement to start the monitor.

#### Note

The `CREATE TABLE` method of enabling `InnoDB` monitors was removed in MySQL 5.7.4. Use the `innodb_status_output` and `innodb_status_output_locks` system variables to enable the standard `InnoDB` Monitor and `InnoDB` Lock Monitor.

The `PROCESS` privilege is required to enable and disable `InnoDB` Monitors.

## Enabling the Standard InnoDB Monitor

Prior to MySQL 5.7.4, enable the standard `InnoDB` Monitor for periodic output by creating the `innodb_monitor` table:

```
CREATE TABLE innodb_monitor (a INT) ENGINE=INNODB;
```

To disable the standard `InnoDB` Monitor, drop the table:

```
DROP TABLE innodb_monitor;
```

As of MySQL 5.7.4, enable the standard `InnoDB` Monitor by setting the `innodb_status_output` system variable to `ON`.

```
set GLOBAL innodb_status_output=ON;
```

To disable the standard `InnoDB` Monitor, set `innodb_status_output` to `OFF`.

When you shut down the server, the `innodb_status_output` variable is set to the default `OFF` value.

## Obtaining Standard InnoDB Monitor Output On Demand

As an alternative to enabling the standard `InnoDB` Monitor for periodic output, you can obtain standard `InnoDB` Monitor output on demand using the `SHOW ENGINE INNODB STATUS` SQL statement, which fetches the output to your client program. If you are using the `mysql` interactive client, the output is more readable if you replace the usual semicolon statement terminator with `\G`:

```
mysql> SHOW ENGINE INNODB STATUS\G
```

`SHOW ENGINE INNODB STATUS` output also includes `InnoDB` Lock Monitor data if the `InnoDB` Lock Monitor is enabled.

## Enabling the InnoDB Lock Monitor

Prior to MySQL 5.7.4, enable the [InnoDB](#) Lock Monitor for periodic output by creating the `innodb_lock_monitor` table:

```
CREATE TABLE innodb_lock_monitor (a INT) ENGINE=INNODB;
```

To disable the [InnoDB](#) Lock Monitor, drop the table:

```
DROP TABLE innodb_lock_monitor;
```

[InnoDB](#) Lock Monitor data is printed with the standard [InnoDB](#) Monitor output. Both the [InnoDB](#) standard Monitor and [InnoDB](#) Lock Monitor must be enabled to have [InnoDB](#) Lock Monitor data printed periodically.

As of MySQL 5.7.4, you can also enable the [InnoDB](#) Lock Monitor by setting the `innodb_status_output_locks` system variable to `ON`. As with the `CREATE TABLE` method for enabling [InnoDB](#) Monitors, both the [InnoDB](#) standard Monitor and [InnoDB](#) Lock Monitor must be enabled to have [InnoDB](#) Lock Monitor data printed periodically:

```
set GLOBAL innodb_status_output=ON;
set GLOBAL innodb_status_output_locks=ON;
```

When you shut down the server, the `innodb_status_output` and `innodb_status_output_locks` variables are set to the default `OFF` value.

To disable the [InnoDB](#) Lock Monitor, set `innodb_status_output_locks` to `OFF`. Set `innodb_status_output` to `OFF` to also disable the standard [InnoDB](#) Monitor.

### Note

To enable the [InnoDB](#) Lock Monitor for `SHOW ENGINE INNODB STATUS` output, you are only required to enable `innodb_status_output_locks`.

## Enabling the InnoDB Tablespace Monitor

To enable the [InnoDB](#) Tablespace Monitor for periodic output, create the `innodb_tablespace_monitor` table:

```
CREATE TABLE innodb_tablespace_monitor (a INT) ENGINE=INNODB;
```

To disable the standard [InnoDB](#) Tablespace Monitor, drop the table:

```
DROP TABLE innodb_tablespace_monitor;
```

### Note

The Tablespace Monitor was removed in MySQL 5.7.4. InnoDB tablespace metadata can be obtained from [INFORMATION\\_SCHEMA](#) tables.

## Enabling the InnoDB Table Monitor

To enable the [InnoDB](#) Table Monitor for periodic output, create the `innodb_table_monitor` table:

```
CREATE TABLE innodb_table_monitor (a INT) ENGINE=INNODB;
```

To disable the [InnoDB](#) Table Monitor, drop the table:

```
DROP TABLE innodb_table_monitor;
```

**Note**

The Tablespace Monitor was removed in MySQL 5.7.4. InnoDB tablespace metadata can be obtained from [INFORMATION\\_SCHEMA](#) tables.

### 15.17.3 InnoDB Standard Monitor and Lock Monitor Output

The Lock Monitor is the same as the Standard Monitor except that it includes additional lock information. Enabling either monitor for periodic output turns on the same output stream, but the stream includes extra information if the Lock Monitor is enabled. For example, if you enable the Standard Monitor and Lock Monitor, that turns on a single output stream. The stream includes extra lock information until you disable the Lock Monitor.

Standard Monitor output is limited to 1MB when produced using the [SHOW ENGINE INNODB STATUS](#) statement. This limit does not apply to output written to the server's error output.

Example Standard Monitor output:

```
mysql> SHOW ENGINE INNODB STATUS\G
***** 1. row *****
  Type: InnoDB
  Name:
  Status:
=====
2014-10-16 18:37:29 0x7fc2a95c1700 INNODB MONITOR OUTPUT

END OF INNODB MONITOR OUTPUT
=====

```

## Standard Monitor Output Sections

For a description of each metric reported by the Standard Monitor, refer to the [Metrics](#) chapter in the [Oracle Enterprise Manager for MySQL Database User's Guide](#).

### Status

This section shows the timestamp, the monitor name, and the number of seconds that per-second averages are based on. The number of seconds is the elapsed time between the current time and the last time [InnoDB](#) Monitor output was printed.

### BACKGROUND THREAD

The [srv\\_master\\_thread](#) lines shows work done by the main background thread.

### SEMAPHORES

This section reports threads waiting for a semaphore and statistics on how many times threads have needed a spin or a wait on a mutex or a rw-lock semaphore. A large number of threads waiting for semaphores may be a result of disk I/O, or contention problems inside [InnoDB](#). Contention can be due to heavy parallelism of queries or problems in operating system thread scheduling. Setting the [innodb\\_thread\\_concurrency](#) system variable smaller than the default value might help in such

situations. The `Spin rounds per wait` line shows the number of spinlock rounds per OS wait for a mutex.

The line that reports mutex spin waits, rounds, and OS waits information was removed from `SHOW ENGINE INNODB STATUS` output in MySQL 5.7.8. Mutex metrics are reported by `SHOW ENGINE INNODB MUTEX`.

#### **LATEST FOREIGN KEY ERROR**

This section provides information about the most recent foreign key constraint error. It is not present if no such error has occurred. The contents include the statement that failed as well as information about the constraint that failed and the referenced and referencing tables.

#### **LATEST DETECTED DEADLOCK**

This section provides information about the most recent deadlock. It is not present if no deadlock has occurred. The contents show which transactions are involved, the statement each was attempting to execute, the locks they have and need, and which transaction `InnoDB` decided to roll back to break the deadlock. The lock modes reported in this section are explained in [Section 15.5.1, “InnoDB Locking”](#).

#### **TRANSACTIONS**

If this section reports lock waits, your applications might have lock contention. The output can also help to trace the reasons for transaction deadlocks.

#### **FILE I/O**

This section provides information about threads that `InnoDB` uses to perform various types of I/O. The first few of these are dedicated to general `InnoDB` processing. The contents also display information for pending I/O operations and statistics for I/O performance.

The number of these threads are controlled by the `innodb_read_io_threads` and `innodb_write_io_threads` parameters. See [Section 15.14, “InnoDB Startup Options and System Variables”](#).

#### **INSERT BUFFER AND ADAPTIVE HASH INDEX**

This section shows the status of the `InnoDB` insert buffer (also referred to as the `change buffer`) and the adaptive hash index.

For related information, see [Section 15.4.2, “Change Buffer”](#), and [Section 15.4.3, “Adaptive Hash Index”](#).

#### **LOG**

This section displays information about the `InnoDB` log. The contents include the current log sequence number, how far the log has been flushed to disk, and the position at which `InnoDB` last took a checkpoint. (See [Section 15.12.3, “InnoDB Checkpoints”](#).) The section also displays information about pending writes and write performance statistics.

#### **BUFFER POOL AND MEMORY**

This section gives you statistics on pages read and written. You can calculate from these numbers how many data file I/O operations your queries currently are doing.

For buffer pool statistics descriptions, see [Section 15.6.3.9, “Monitoring the Buffer Pool Using the InnoDB Standard Monitor”](#). For additional information about the operation of the buffer pool, see [Section 15.6.3.1, “The InnoDB Buffer Pool”](#).

#### **ROW OPERATIONS**

This section shows what the main thread is doing, including the number and performance rate for each type of row operation.

## 15.17.4 InnoDB Tablespace Monitor Output

### Note

The Tablespace Monitor was removed in MySQL 5.7.4. InnoDB tablespace metadata can be obtained from [INFORMATION\\_SCHEMA](#) tables.

The [InnoDB](#) Tablespace Monitor prints information about the file segments in the shared tablespace and validates the tablespace allocation data structures. The Tablespace Monitor does not describe file-per-table tablespaces created with the [innodb\\_file\\_per\\_table](#) option.

Example [InnoDB](#) Tablespace Monitor output:

```
=====
090408 21:28:09 INNODB TABLESPACE MONITOR OUTPUT

fragm pages 1; free extents 0; not full extents 0: pages 0
NUMBER of file segments: 73
Validating tablespace
Validation ok
-----
END OF INNODB TABLESPACE MONITOR OUTPUT
=====
```

The Tablespace Monitor output includes information about the shared tablespace as a whole, followed by a list containing a breakdown for each segment within the tablespace.

In this example using the default [page size](#), the tablespace consists of database pages that are 16KB each. The pages are grouped into [extents](#) of size 1MB (64 consecutive pages).

The initial part of the output that displays overall tablespace information has this format:

```
FILE SPACE INFO: id 0
size 13440, free limit 3136, free extents 28
not full frag extents 2: used pages 78, full frag extents 3
first seg id not used 0 23845
```

Overall tablespace information includes these values:

- [id](#): The tablespace ID. A value of 0 refers to the shared tablespace.

- **size**: The current tablespace size in pages.
- **free limit**: The minimum page number for which the free list has not been initialized. Pages at or above this limit are free.
- **free extents**: The number of free extents.
- **not full frag extents, used pages**: The number of fragment extents that are not completely filled, and the number of pages in those extents that have been allocated.
- **full frag extents**: The number of completely full fragment extents.
- **first seg id not used**: The first unused segment ID.

Individual segment information has this format:

```
SEGMENT id 0 15 space 0; page 2; res 160 used 160; full ext 2
fragm pages 32; free extents 0; not full extents 0; pages 0
```

Segment information includes these values:

**id**: The segment ID.

**space, page**: The tablespace number and page within the tablespace where the segment “inode” is located. A tablespace number of 0 indicates the shared tablespace. **InnoDB** uses inodes to keep track of segments in the tablespace. The other fields displayed for a segment (**id**, **res**, and so forth) are derived from information in the inode.

**res**: The number of pages allocated (reserved) for the segment.

**used**: The number of allocated pages in use by the segment.

**full ext**: The number of extents allocated for the segment that are completely used.

**fragm pages**: The number of initial pages that have been allocated to the segment.

**free extents**: The number of extents allocated for the segment that are completely unused.

**not full extents**: The number of extents allocated for the segment that are partially used.

**pages**: The number of pages used within the not-full extents.

When a segment grows, it starts as a single page, and **InnoDB** allocates the first pages for it one at a time, up to 32 pages (this is the **fragm pages** value). After that, **InnoDB** allocates complete extents. **InnoDB** can add up to 4 extents at a time to a large segment to ensure good sequentiality of data.

For the example segment shown earlier, it has 32 fragment pages, plus 2 full extents (64 pages each), for a total of 160 pages used out of 160 pages allocated. The following segment has 32 fragment pages and one partially full extent using 14 pages for a total of 46 pages used out of 96 pages allocated:

```
SEGMENT id 0 1 space 0; page 2; res 96 used 46; full ext 0
fragm pages 32; free extents 0; not full extents 1; pages 14
```

It is possible for a segment that has extents allocated to it to have a **fragm pages** value less than 32 if some of the individual pages have been deallocated subsequent to extent allocation.

## 15.17.5 InnoDB Table Monitor Output

### Note

The **InnoDB** Table Monitor was removed in MySQL 5.7.4. Equivalent information can be obtained from **InnoDB INFORMATION\_SCHEMA** tables. See [Section 23.31, “InnoDB INFORMATION\\_SCHEMA Tables”](#).

The [InnoDB](#) Table Monitor prints the contents of the [InnoDB](#) internal data dictionary.

The output contains one section per table. The [SYS\\_FOREIGN](#) and [SYS\\_FOREIGN\\_COLS](#) sections are for internal data dictionary tables that maintain information about foreign keys. There are also sections for the Table Monitor table and each user-created [InnoDB](#) table. Suppose that the following two tables have been created in the `test` database:

```
CREATE TABLE parent
(
  par_id      INT NOT NULL,
  fname       CHAR(20),
  lname       CHAR(20),
  PRIMARY KEY (par_id),
  UNIQUE INDEX (lname, fname)
) ENGINE = INNODB;

CREATE TABLE child
(
  par_id      INT NOT NULL,
  child_id    INT NOT NULL,
  name        VARCHAR(40),
  birth       DATE,
  weight      DECIMAL(10,2),
  misc_info   VARCHAR(255),
  last_update TIMESTAMP,
  PRIMARY KEY (par_id, child_id),
  INDEX (name),
  FOREIGN KEY (par_id) REFERENCES parent (par_id)
    ON DELETE CASCADE
    ON UPDATE CASCADE
) ENGINE = INNODB;
```

Then the Table Monitor output will look something like this (reformatted slightly):

```
=====
090420 12:09:32 INNODB TABLE MONITOR OUTPUT
=====
-----
TABLE: name SYS_FOREIGN, id 0 11, columns 7, indexes 3, appr.rows 1

-----
END OF INNODB TABLE MONITOR OUTPUT
=====

```

For each table, Table Monitor output contains a section that displays general information about the table and specific information about its columns, indexes, and foreign keys.

The general information for each table includes the table name (in *db\_name/tbl\_name* format except for internal tables), its ID, the number of columns and indexes, and an approximate row count.

The **COLUMNS** part of a table section lists each column in the table. Information for each column indicates its name and data type characteristics. Some internal columns are added by InnoDB, such as **DB\_ROW\_ID** (row ID), **DB\_TRX\_ID** (transaction ID), and **DB\_ROLL\_PTR** (a pointer to the rollback/undo data).

- **DATA\_xxx**: These symbols indicate the data type. There may be multiple **DATA\_xxx** symbols for a given column.
- **prtype**: The column's "precise" type. This field includes information such as the column data type, character set code, nullability, signedness, and whether it is a binary string. This field is described in the `innobase/include/data0type.h` source file.
- **len**: The column length in bytes.

Each **INDEX** part of the table section provides the name and characteristics of one table index:

- **name**: The index name. If the name is **PRIMARY**, the index is a primary key. If the name is **GEN\_CLUST\_INDEX**, the index is the clustered index that is created automatically if the table definition doesn't include a primary key or non-**NULL** unique index. See [Section 15.8.9, "Clustered and Secondary Indexes"](#).

- `id`: The index ID.
- `fields`: The number of fields in the index, as a value in `m/n` format:
  - `m` is the number of user-defined columns; that is, the number of columns you would see in the index definition in a `CREATE TABLE` statement.
  - `n` is the total number of index columns, including those added internally. For the clustered index, the total includes the other columns in the table definition, plus any columns added internally. For a secondary index, the total includes the columns from the primary key that are not part of the secondary index.
- `uniq`: The number of leading fields that are enough to determine index values uniquely.
- `type`: The index type. This is a bit field. For example, 1 indicates a clustered index and 2 indicates a unique index, so a clustered index (which always contains unique values), will have a `type` value of 3. An index with a `type` value of 0 is neither clustered nor unique. The flag values are defined in the `innobase/include/dict0mem.h` source file.
- `root page`: The index root page number.
- `appr. key vals`: The approximate index cardinality.
- `leaf pages`: The approximate number of leaf pages in the index.
- `size pages`: The approximate total number of pages in the index.
- `FIELDS`: The names of the fields in the index. For a clustered index that was generated automatically, the field list begins with the internal `DB_ROW_ID` (row ID) field. `DB_TRX_ID` and `DB_ROLL_PTR` are always added internally to the clustered index, following the fields that comprise the primary key. For a secondary index, the final fields are those from the primary key that are not part of the secondary index.

The end of the table section lists the `FOREIGN KEY` definitions that apply to the table. This information appears whether the table is a referencing or referenced table.

## 15.18 InnoDB Backup and Recovery

The key to safe database management is making regular backups. Depending on your data volume, number of MySQL servers, and database workload, you can use these techniques, alone or in combination: **hot backup** with MySQL Enterprise Backup; **cold backup** by copying files while the MySQL server is shut down; **physical backup** for fast operation (especially for restore); **logical backup** with `mysqldump` for smaller data volumes or to record the structure of schema objects.

### Hot Backups

The `mysqlbackup` command, part of the MySQL Enterprise Backup component, lets you back up a running MySQL instance, including `InnoDB` and `MyISAM` tables, with minimal disruption to operations while producing a consistent snapshot of the database. When `mysqlbackup` is copying `InnoDB` tables, reads and writes to both `InnoDB` and `MyISAM` tables can continue. During the copying of `MyISAM` tables, reads (but not writes) to those tables are permitted. MySQL Enterprise Backup can also create compressed backup files, and back up subsets of tables and databases. In conjunction with MySQL's binary log, users can perform point-in-time recovery. MySQL Enterprise Backup is part of the MySQL Enterprise subscription. For more details, see [Section 28.2, "MySQL Enterprise Backup Overview"](#).

### Cold Backups

If you can shut down your MySQL server, you can make a binary backup that consists of all files used by `InnoDB` to manage its tables. Use the following procedure:

1. Do a **slow shutdown** of the MySQL server and make sure that it stops without errors.

2. Copy all [InnoDB](#) data files (`ibdata` files and `.ibd` files) into a safe place.
3. Copy all the `.frm` files for [InnoDB](#) tables to a safe place.
4. Copy all [InnoDB](#) log files (`ib_logfile` files) to a safe place.
5. Copy your `my.cnf` configuration file or files to a safe place.

## Alternative Backup Types

In addition to making binary backups as just described, regularly make dumps of your tables with `mysqldump`. A binary file might be corrupted without you noticing it. Dumped tables are stored into text files that are human-readable, so spotting table corruption becomes easier. Also, because the format is simpler, the chance for serious data corruption is smaller. `mysqldump` also has a `--single-transaction` option for making a consistent snapshot without locking out other clients. See [Section 8.3.1, “Establishing a Backup Policy”](#).

Replication works with [InnoDB](#) tables, so you can use MySQL replication capabilities to keep a copy of your database at database sites requiring high availability.

## Performing Recovery

To recover your [InnoDB](#) database to the present from the time at which the binary backup was made, you must run your MySQL server with binary logging turned on, even before taking the backup. To achieve point-in-time recovery after restoring a backup, you can apply changes from the binary log that occurred after the backup was made. See [Section 8.5, “Point-in-Time \(Incremental\) Recovery Using the Binary Log”](#).

To recover from a crash of your MySQL server, the only requirement is to restart it. [InnoDB](#) automatically checks the logs and performs a roll-forward of the database to the present. [InnoDB](#) automatically rolls back uncommitted transactions that were present at the time of the crash. During recovery, `mysqld` displays output something like this:

```
InnoDB: Database was not shut down normally.
InnoDB: Starting recovery from log files...
InnoDB: Starting log scan based on checkpoint at
InnoDB: log sequence number 0 13674004
InnoDB: Doing recovery: scanned up to log sequence number 0 13739520
InnoDB: Doing recovery: scanned up to log sequence number 0 13805056
InnoDB: Doing recovery: scanned up to log sequence number 0 13870592
InnoDB: Doing recovery: scanned up to log sequence number 0 13936128
...
InnoDB: Doing recovery: scanned up to log sequence number 0 20555264
InnoDB: Doing recovery: scanned up to log sequence number 0 20620800
InnoDB: Doing recovery: scanned up to log sequence number 0 20664692
InnoDB: 1 uncommitted transaction(s) which must be rolled back
InnoDB: Starting rollback of uncommitted transactions
InnoDB: Rolling back trx no 16745
InnoDB: Rolling back of trx no 16745 completed
InnoDB: Rollback of uncommitted transactions completed
InnoDB: Starting an apply batch of log records to the database...
InnoDB: Apply batch completed
InnoDB: Started
mysqld: ready for connections
```

If your database becomes corrupted or disk failure occurs, you must perform the recovery using a backup. In the case of corruption, first find a backup that is not corrupted. After restoring the base backup, do a point-in-time recovery from the binary log files using `mysqlbinlog` and `mysql` to restore the changes that occurred after the backup was made.

In some cases of database corruption, it is enough just to dump, drop, and re-create one or a few corrupt tables. You can use the `CHECK TABLE` SQL statement to check whether a table is corrupt, although `CHECK TABLE` naturally cannot detect every possible kind of corruption.

In some cases, apparent database page corruption is actually due to the operating system corrupting its own file cache, and the data on disk may be okay. It is best first to try restarting your computer. Doing so may eliminate errors that appeared to be database page corruption. If MySQL still has trouble starting because of [InnoDB](#) consistency problems, see [Section 15.21.2, “Forcing InnoDB Recovery”](#) for steps to start the instance in a diagnostic mode where you can dump the data.

## 15.18.1 The InnoDB Recovery Process

[InnoDB crash recovery](#) consists of several steps:

- Applying the [redo log](#): Redo log application is the first step and is performed during initialization, before accepting any connections. If all changes were flushed from the [buffer pool](#) to the [tablespaces](#) (`ibdata*` and `*.ibd` files) at the time of the shutdown or crash, the redo log application can be skipped. If the redo log files are missing at startup, [InnoDB](#) skips the redo log application.

Removing redo logs to speed up the recovery process is not recommended, even if some data loss is acceptable. Removing redo logs should only be considered an option after a clean shutdown is performed, with `innodb_fast_shutdown` set to 0 or 1.

- [Rolling back incomplete transactions](#): Any transactions that were active at the time of crash or [fast shutdown](#). The time it takes to roll back an incomplete transaction can be three or four times the amount of time a transaction is active before it is interrupted, depending on server load.

You cannot cancel transactions that are in the process of being rolled back. In extreme cases, when rolling back transactions is expected to take an exceptionally long time, it may be faster to start [InnoDB](#) with an `innodb_force_recovery` setting of 3 or greater. See [Section 15.21.2, “Forcing InnoDB Recovery”](#) for more information.

- [Change buffer merge](#): Applying changes from the change buffer (part of the [system tablespace](#)) to leaf pages of secondary indexes, as the index pages are read to the buffer pool.
- [Purge](#): Deleting delete-marked records that are no longer visible for any active transaction.

The steps that follow redo log application do not depend on the redo log (other than for logging the writes) and are performed in parallel with normal processing. Of these, only rollback of incomplete transactions is special to crash recovery. The insert buffer merge and the purge are performed during normal processing.

After redo log application, [InnoDB](#) attempts to accept connections as early as possible, to reduce downtime. As part of crash recovery, [InnoDB](#) rolls back any transactions that were not committed or in `XA PREPARE` state when the server crashed. The rollback is performed by a background thread, executed in parallel with transactions from new connections. Until the rollback operation is completed, new connections may encounter locking conflicts with recovered transactions.

In most situations, even if the MySQL server was killed unexpectedly in the middle of heavy activity, the recovery process happens automatically and no action is needed from the DBA. If a hardware failure or severe system error corrupted [InnoDB](#) data, MySQL might refuse to start. In that case, see [Section 15.21.2, “Forcing InnoDB Recovery”](#) for the steps to troubleshoot such an issue.

For information about the binary log and [InnoDB](#) crash recovery, see [Section 6.4.4, “The Binary Log”](#).

## 15.18.2 Tablespace Discovery During Crash Recovery

If, during crash recovery, [InnoDB](#) encounters redo logs written since the last checkpoint, the redo logs must be applied to the affected tablespaces. The process that identifies affected tablespaces is referred to as *tablespace discovery*.

Prior to MySQL 5.7.5, tablespace files were referenced in redo logs by a `space_id`, which is a numeric identifier. In the file system, however, [file-per-table](#) tablespaces are known by a `*.ibd` file name, which required that [InnoDB](#) construct a “space\_id-file name” map in order to apply redo logs. To

construct the map, InnoDB traversed the data directory, reading the first page of each \*.ibd file. This process could result in unnecessary downtime for MySQL instances with numerous \*.ibd files.

In MySQL 5.6.6, the introduction of support for the CREATE TABLE DATA DIRECTORY clause for file-per-table tablespaces further complicated tablespace discovery. The DATA DIRECTORY enhancement introduced .isl files as placeholders that point to the location of \*.ibd files stored outside of the MySQL data directory.

In MySQL 5.7.5, instead of reading the first page of all \$datadir/\*/\*.ibd files and checking the contents of \$datadir/\*/\*.isl files before applying redo logs, InnoDB uses a new redo log record type to identify the file-per-table tablespaces that have been modified since the last checkpoint. An MLOG\_FILE\_NAME record, which contains the tablespace space\_id and file name, is written to the redo log when a tablespace page is modified. The benefits of MLOG\_FILE\_NAME redo log records include:

- Elimination of file system scans prior to redo log application. The MLOG\_FILE\_NAME redo log record provides the information necessary to identify and locate tablespaces that have changed since the last checkpoint.
- Only \*.ibd files modified since the last checkpoint are accessed.
- \*.ibd files that are not attached to the InnoDB instance are ignored when redo logs are applied.
- InnoDB no longer silently discards redo log records for missing \*.ibd files unless there is an MLOG\_FILE\_DELETE record in the redo log. For example, if a file rename fails, resulting in a “missing” \*.ibd file, you can manually rename the file and restart crash recovery. Missing \*.ibd files are ignored in innodb\_force\_recovery mode.
- During recovery, the redo log is read from the last checkpoint to the detected logical end of the log. If tablespace files that are referenced in the scanned portion of the redo log are missing, startup is refused.
- Failure scenarios related to inconsistent \*.isl files are eliminated. \*.isl files are now only used after redo log apply, when opening tables.

In MySQL 5.7.6, two tablespace discovery searches were added with the introduction of InnoDB general tablespaces.

- The first search traverses SYS\_TABLESPACES and related entries in SYS\_DATAFILES, in the internal data dictionary. All previously created general tablespaces are opened, including general tablespaces that are empty.
- The second search traverses SYS\_TABLES, in the internal data dictionary. For tables with a SPACE ID greater than 0, the SPACE ID is looked up in SYS\_DATAFILES to ensure that the tablespace is opened.

## 15.19 InnoDB and MySQL Replication

MySQL replication works for InnoDB tables as it does for MyISAM tables. It is also possible to use replication in a way where the storage engine on the slave is not the same as the original storage engine on the master. For example, you can replicate modifications to an InnoDB table on the master to a MyISAM table on the slave.

To set up a new slave for a master, make a copy of the InnoDB tablespace and the log files, as well as the .frm files of the InnoDB tables, and move the copies to the slave. If the innodb\_file\_per\_table option is enabled, copy the .ibd files as well. For the proper procedure to do this, see [Section 15.18, “InnoDB Backup and Recovery”](#).

To make a new slave without taking down the master or an existing slave, use the [MySQL Enterprise Backup](#) product. If you can shut down the master or an existing slave, take a [cold backup](#) of the InnoDB tablespaces and log files and use that to set up a slave.

Transactions that fail on the master do not affect replication at all. MySQL replication is based on the binary log where MySQL writes SQL statements that modify data. A transaction that fails (for example, because of a foreign key violation, or because it is rolled back) is not written to the binary log, so it is not sent to slaves. See [Section 14.3.1, “START TRANSACTION, COMMIT, and ROLLBACK Syntax”](#).

**Replication and CASCADE.** Cascading actions for InnoDB tables on the master are replicated on the slave *only* if the tables sharing the foreign key relation use InnoDB on both the master and slave. This is true whether you are using statement-based or row-based replication. Suppose that you have started replication, and then create two tables on the master using the following `CREATE TABLE` statements:

```
CREATE TABLE fc1 (
  i INT PRIMARY KEY,
  j INT
) ENGINE = InnoDB;

CREATE TABLE fc2 (
  m INT PRIMARY KEY,
  n INT,
  FOREIGN KEY ni (n) REFERENCES fc1 (i)
    ON DELETE CASCADE
) ENGINE = InnoDB;
```

Suppose that the slave does not have InnoDB support enabled. If this is the case, then the tables on the slave are created, but they use the MyISAM storage engine, and the `FOREIGN KEY` option is ignored. Now we insert some rows into the tables on the master:

```
master> INSERT INTO fc1 VALUES (1, 1), (2, 2);
Query OK, 2 rows affected (0.09 sec)
Records: 2 Duplicates: 0 Warnings: 0

master> INSERT INTO fc2 VALUES (1, 1), (2, 2), (3, 1);
Query OK, 3 rows affected (0.19 sec)
Records: 3 Duplicates: 0 Warnings: 0
```

At this point, on both the master and the slave, table `fc1` contains 2 rows, and table `fc2` contains 3 rows, as shown here:

```
master> SELECT * FROM fc1;
+-----+
| i | j |
+-----+
| 1 | 1 |
| 2 | 2 |
+-----+
2 rows in set (0.00 sec)

master> SELECT * FROM fc2;
+-----+
| m | n |
+-----+
| 1 | 1 |
| 2 | 2 |
| 3 | 1 |
+-----+
3 rows in set (0.00 sec)

slave> SELECT * FROM fc1;
+-----+
| i | j |
+-----+
| 1 | 1 |
| 2 | 2 |
+-----+
2 rows in set (0.00 sec)

slave> SELECT * FROM fc2;
```

```

+---+-----+
| m | n |
+---+-----+
| 1 | 1 |
| 2 | 2 |
| 3 | 1 |
+---+-----+
3 rows in set (0.00 sec)

```

Now suppose that you perform the following `DELETE` statement on the master:

```

master> DELETE FROM fc1 WHERE i=1;
Query OK, 1 row affected (0.09 sec)

```

Due to the cascade, table `fc2` on the master now contains only 1 row:

```

master> SELECT * FROM fc2;
+---+-----+
| m | n |
+---+-----+
| 2 | 2 |
+---+-----+
1 row in set (0.00 sec)

```

However, the cascade does not propagate on the slave because on the slave the `DELETE` for `fc1` deletes no rows from `fc2`. The slave's copy of `fc2` still contains all of the rows that were originally inserted:

```

slave> SELECT * FROM fc2;
+---+-----+
| m | n |
+---+-----+
| 1 | 1 |
| 3 | 1 |
| 2 | 2 |
+---+-----+
3 rows in set (0.00 sec)

```

This difference is due to the fact that the cascading deletes are handled internally by the `InnoDB` storage engine, which means that none of the changes are logged.

## 15.20 InnoDB memcached Plugin

The `InnoDB memcached` plugin (`daemon_memcached`) provides an integrated `memcached` daemon that automatically stores and retrieves data from `InnoDB` tables, turning the MySQL server into a fast “key-value store”. Instead of formulating queries in SQL, you can use simple `get`, `set`, and `incr` operations that avoid the performance overhead associated with SQL parsing and constructing a query optimization plan. You can also access the same `InnoDB` tables through SQL for convenience, complex queries, bulk operations, and other strengths of traditional database software.

This “NoSQL-style” interface uses the `memcached` API to speed up database operations, letting `InnoDB` handle memory caching using its `buffer pool` mechanism. Data modified through `memcached` operations such as `add`, `set`, and `incr` are stored to disk, in `InnoDB` tables. The combination of `memcached` simplicity and `InnoDB` reliability and consistency provides users with the best of both worlds, as explained in [Section 15.20.1, “Benefits of the InnoDB memcached Plugin”](#). For an architectural overview, see [Section 15.20.2, “InnoDB memcached Architecture”](#).

### 15.20.1 Benefits of the InnoDB memcached Plugin

This section outlines advantages the `daemon_memcached` plugin. The combination of `InnoDB` tables and `memcached` offers advantages over using either by themselves.

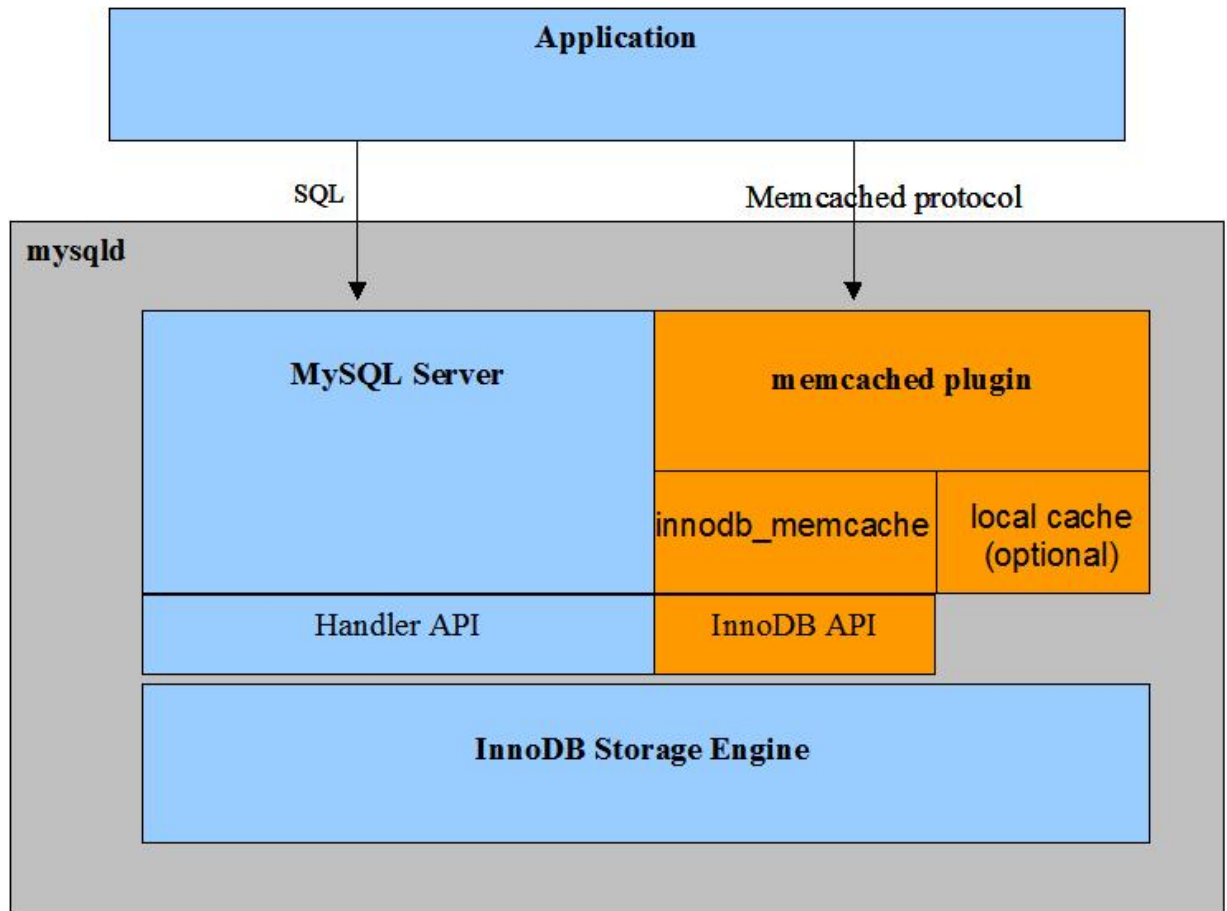

- Direct access to the `InnoDB` storage engine avoids the parsing and planning overhead of SQL.

- Running [memcached](#) in the same process space as the MySQL server avoids the network overhead of passing requests back and forth.
- Data written using the [memcached](#) protocol is transparently written to an [InnoDB](#) table, without going through the MySQL SQL layer. You can control frequency of writes to achieve higher raw performance when updating non-critical data.
- Data requested through the [memcached](#) protocol is transparently queried from an [InnoDB](#) table, without going through the MySQL SQL layer.
- Subsequent requests for the same data is served from the [InnoDB](#) buffer pool. The buffer pool handles the in-memory caching. You can tune performance of data-intensive operations using [InnoDB](#) configuration options.
- Data can be unstructured or structured, depending on the type of application. You can create a new table for data, or use existing tables.
- [InnoDB](#) can handle composing and decomposing multiple column values into a single [memcached](#) item value, reducing the amount of string parsing and concatenation required in your application. For example, you can store the string value `2|4|6|8` in the [memcached](#) cache, and have [InnoDB](#) split the value based on a separator character, then store the result in four numeric columns.
- The transfer between memory and disk is handled automatically, simplifying application logic.
- Data is stored in a MySQL database to protect against crashes, outages, and corruption.
- You can access the underlying [InnoDB](#) table through SQL for reporting, analysis, ad hoc queries, bulk loading, multi-step transactional computations, set operations such as union and intersection, and other operations suited to the expressiveness and flexibility of SQL.
- You can ensure high availability by using the [daemon\\_memcached](#) plugin on a [master server](#) in combination with MySQL replication.
- The integration of [memcached](#) with MySQL provides a way to make in-memory data persistent, so you can use it for more significant kinds of data. You can use more [add](#), [incr](#), and similar write operations in your application without concern that data could be lost. You can stop and start the [memcached](#) server without losing updates made to cached data. To guard against unexpected outages, you can take advantage of [InnoDB](#) crash recovery, replication, and backup capabilities.
- The way [InnoDB](#) does fast [primary key](#) lookups is a natural fit for [memcached](#) single-item queries. The direct, low-level database access path used by the [daemon\\_memcached](#) plugin is much more efficient for key-value lookups than equivalent SQL queries.
- The serialization features of [memcached](#), which can turn complex data structures, binary files, or even code blocks into storeable strings, offer a simple way to get such objects into a database.
- Because you can access the underlying data through SQL, you can produce reports, search or update across multiple keys, and call functions such as [AVG\( \)](#) and [MAX\( \)](#) on [memcached](#) data. All of these operations are expensive or complicated using [memcached](#) by itself.
- You do not need to manually load data into [memcached](#) at startup. As particular keys are requested by an application, values are retrieved from the database automatically, and cached in memory using the [InnoDB](#) [buffer pool](#).
- Because [memcached](#) consumes relatively little CPU, and its memory footprint is easy to control, it can run comfortably alongside a MySQL instance on the same system.
- Because data consistency is enforced by mechanisms used for regular [InnoDB](#) tables, you do not have to worry about stale [memcached](#) data or fallback logic to query the database in the case of a missing key.

## 15.20.2 InnoDB memcached Architecture

The [InnoDB memcached](#) plugin implements [memcached](#) as a MySQL plugin daemon that accesses the [InnoDB](#) storage engine directly, bypassing the MySQL SQL layer.

The following diagram illustrates how an application accesses data through the [daemon\\_memcached](#) plugin, compared with SQL.

Features of the [daemon\\_memcached](#) plugin:

- [memcached](#) as a daemon plugin of [mysqld](#). Both [mysqld](#) and [memcached](#) run in the same process space, with very low latency access to data.
- Direct access to [InnoDB](#) tables, bypassing the SQL parser, the optimizer, and even the Handler API layer.
- Standard [memcached](#) protocols, including the text-based protocol and the binary protocol. The [daemon\\_memcached](#) plugin passes all 55 compatibility tests of the [memcapable](#) command.
- Multi-column support. You can map multiple columns into the “value” part of the key/value store, with column values delimited by a user-specified separator character.
- By default, the [memcached](#) protocol is used to read and write data directly to [InnoDB](#), letting MySQL manage in-memory caching using the [InnoDB buffer pool](#). The default settings represent a combination of high reliability and the fewest surprises for database applications. For example, default settings avoid uncommitted data on the database side, or stale data returned for [memcached get](#) requests.
- Advanced users can configure the system as a traditional [memcached](#) server, with all data cached only in the [memcached](#) engine (memory caching), or use a combination of the “[memcached](#) engine” (memory caching) and the [InnoDB memcached](#) engine ([InnoDB](#) as backend persistent storage).
- Control over how often data is passed back and forth between [InnoDB](#) and [memcached](#) operations through the [innodb\\_api\\_bk\\_commit\\_interval](#), [daemon\\_memcached\\_r\\_batch\\_size](#), and

`daemon_memcached_w_batch_size` configuration options. Batch size options default to a value of 1 for maximum reliability.

- The ability to specify `memcached` options through the `daemon_memcached_option` configuration parameter. For example, you can change the port that `memcached` listens on, reduce the maximum number of simultaneous connections, change the maximum memory size for a key/value pair, or enable debugging messages for the error log.
- The `innodb_api_trx_level` configuration option controls the transaction `isolation level` on queries processed by `memcached`. Although `memcached` has no concept of `transactions`, you can use this option to control how soon `memcached` sees changes caused by SQL statements issued on the table used by the `daemon_memcached` plugin. By default, `innodb_api_trx_level` is set to `READ UNCOMMITTED`.
- The `innodb_api_enable_md1` option can be used to lock the table at the MySQL level, so that the mapped table cannot be dropped or altered by `DDL` through the SQL interface. Without the lock, the table can be dropped from the MySQL layer, but kept in `InnoDB` storage until `memcached` or some other user stops using it. “MDL” stands for “metadata locking”.

## Differences Between InnoDB memcached and Traditional memcached

You may already be familiar with using `memcached` with MySQL, as described in [Section 17.2, “Using MySQL with memcached”](#). This section describes how features of the integrated `InnoDB memcached` plugin differ from traditional `memcached`.

- Installation: The `memcached` library comes with the MySQL server, making installation and setup relatively easy. Installation involves running the `innodb_memcached_config.sql` script to create a `demo_test` table for `memcached` to use, issuing an `INSTALL PLUGIN` statement to enable the `daemon_memcached` plugin, and adding desired `memcached` options to a MySQL configuration file or startup script. You might still install the traditional `memcached` distribution for additional utilities such as `memcp`, `memcat`, and `memcapable`.

For comparison with traditional `memcached`, see [Section 17.2.1, “Installing memcached”](#).

- Deployment: With traditional `memcached`, it is typical to run large numbers of low-capacity `memcached` servers. A typical deployment of the `daemon_memcached` plugin, however, involves a smaller number of moderate or high-powered servers that are already running MySQL. The benefit of this configuration is in improving efficiency of individual database servers rather than exploiting unused memory or distributing lookups across large numbers of servers. In the default configuration, very little memory is used for `memcached`, and in-memory lookups are served from the `InnoDB buffer pool`, which automatically caches the most recently and frequently used data. As with a traditional MySQL server instance, keep the value of the `innodb_buffer_pool_size` configuration option as high as practical (without causing paging at the OS level), so that as much work as possible is performed in memory.

For comparison with traditional `memcached`, see [Section 17.2.2.2, “memcached Deployment”](#).

- Expiry: By default (that is, using the `innodb_only` caching policy), the latest data from the `InnoDB` table is always returned, so the expiry options have no practical effect. If you change the caching policy to `caching` or `cache-only`, the expiry options work as usual, but requested data might be stale if it is updated in the underlying table before it expires from the memory cache.

For comparison with traditional `memcached`, see [Section 17.2.2.4, “Data Expiry”](#).

- Namespaces: `memcached` is like a large directory where you give files elaborate names with prefixes and suffixes to keep the files from conflicting. The `daemon_memcached` plugin lets you use similar naming conventions for keys, with one addition. Key names in the format `@@table_id.key.table_id` are decoded to reference a specific a table, using mapping data from the `innodb_memcache.containers` table. The `key` is looked up in or written to the specified table.

The @@ notation only works for individual calls to `get`, `add`, and `set` functions, but not others such as `incr` or `delete`. To designate a default table for subsequent `memcached` operations within a session, perform a `get` request using the @@ notation with a `table_id`, but without the key portion. For example:

```
get @@table_id
```

Subsequent `get`, `set`, `incr`, `delete`, and other operations use the table designated by `table_id` in the `innodb_memcached.containers.name` column.

For comparison with traditional `memcached`, see [Section 17.2.2.3, “Using Namespaces”](#).

- Hashing and distribution: The default configuration, which uses the `innodb_only` caching policy, is suitable for a traditional deployment configuration where all data is available on all servers, such as a set of replication slave servers.

If you physically divide data, as in a sharded configuration, you can split data across several machines running the `daemon_memcached` plugin, and use the traditional `memcached` hashing mechanism to route requests to a particular machine. On the MySQL side, you would typically let all data be inserted by `add` requests to `memcached` so that appropriate values are stored in the database on the appropriate server.

For comparison with traditional `memcached`, see [Section 17.2.2.5, “memcached Hashing/Distribution Types”](#).

- Memory usage: By default (with the `innodb_only` caching policy), the `memcached` protocol passes information back and forth with InnoDB tables, and the InnoDB buffer pool handles in-memory lookups instead of `memcached` memory usage growing and shrinking. Relatively little memory is used on the `memcached` side.

If you switch the caching policy to `caching` or `cache-only`, the normal rules of `memcached` memory usage apply. Memory for `memcached` data values is allocated in terms of “slabs”. You can control slab size and maximum memory used for `memcached`.

Either way, you can monitor and troubleshoot the `daemon_memcached` plugin using the familiar `statistics` system, accessed through the standard protocol, over a `telnet` session, for example. Extra utilities are not included with the `daemon_memcached` plugin. You can use the `memcached-tool script` to install a full `memcached` distribution.

For comparison with traditional `memcached`, see [Section 17.2.2.7, “Memory Allocation within memcached”](#).

- Thread usage: MySQL threads and `memcached` threads co-exist on the same server. Limits imposed on threads by the operating system apply to the total number of threads.

For comparison with traditional `memcached`, see [Section 17.2.2.8, “memcached Thread Support”](#).

- Log usage: Because the `memcached` daemon is run alongside the MySQL server and writes to `stderr`, the `-v`, `-vv`, and `-vvv` options for logging write output to the MySQL `error log`.

For comparison with traditional `memcached`, see [Section 17.2.2.9, “memcached Logs”](#).

- `memcached` operations: Familiar `memcached` operations such as `get`, `set`, `add`, and `delete` are available. Serialization (that is, the exact string format representing complex data structures) depends on the language interface.

For comparison with traditional `memcached`, see [Section 17.2.3.1, “Basic memcached Operations”](#).

- Using `memcached` as a MySQL front end: This is the primary purpose of the InnoDB `memcached` plugin. An integrated `memcached` daemon improves application performance, and having InnoDB handle data transfers between memory and disk simplifies application logic.

For comparison with traditional `memcached`, see [Section 17.2.3.2, “Using `memcached` as a MySQL Caching Layer”](#).

- Utilities: The MySQL server includes the `libmemcached` library but not additional command-line utilities. To use commands such as `memcp`, `memcat`, and `memcapable` commands, install a full `memcached` distribution. When `memrm` and `memflush` remove items from the cache, the items are also removed from the underlying InnoDB table.

For comparison with traditional `memcached`, see [libmemcached Command-Line Utilities](#).

- Programming interfaces: You can access the MySQL server through the `daemon_memcached` plugin using all supported languages: [C and C++](#), [Java](#), [Perl](#), [Python](#), [PHP](#), and [Ruby](#). Specify the server hostname and port as with a traditional `memcached` server. By default, the `daemon_memcached` plugin listens on port `11211`. You can use both the [text and binary protocols](#). You can customize the [behavior](#) of `memcached` functions at runtime. Serialization (that is, the exact string format representing complex data structures) depends on the language interface.

For comparison with traditional `memcached`, see [Section 17.2.3, “Developing a `memcached` Application”](#).

- Frequently asked questions: MySQL has an extensive FAQ for traditional `memcached`. The FAQ is mostly applicable, except that using InnoDB tables as a storage medium for `memcached` data means that you can use `memcached` for more write-intensive applications than before, rather than as a read-only cache.

See [Section 17.2.5, “`memcached` FAQ”](#).

## 15.20.3 Setting Up the InnoDB memcached Plugin

This section describes how to set up the `daemon_memcached` plugin on a MySQL server. Because the `memcached` daemon is tightly integrated with the MySQL server to avoid network traffic and minimize latency, you perform this process on each MySQL instance that uses this feature.

### Note

Before setting up the `daemon_memcached` plugin, consult [Section 15.20.4, “Security Considerations for the InnoDB memcached Plugin”](#) to understand the security procedures required to prevent unauthorized access.

## Prerequisites

- The `daemon_memcached` plugin is only supported on Linux, Solaris, and OS X platforms. Other operating systems are not supported.
- When building MySQL from source, you must build with `-DWITH_INNO_DB_MEMCACHED=ON`. This build option generates two shared libraries in the MySQL plugin directory (`plugin_dir`) that are required to run the `daemon_memcached` plugin:
  - `libmemcached.so`: the `memcached` daemon plugin to MySQL.
  - `innodb_engine.so`: an InnoDB API plugin to `memcached`.
- `libevent` must be installed.
- If you did not build MySQL from source, the `libevent` library is not included in your installation. Use the installation method for your operating system to install `libevent` 1.4.12 or later. For example, depending on the operating system, you might use `apt-get`, `yum`, or `port install`. For example, on Ubuntu Linux, use:

```
sudo apt-get install libevent-dev
```

- If you installed MySQL from a source code release, `libevent` 1.4.12 is bundled with the package and is located at the top level of the MySQL source code directory. If you use the bundled version of `libevent`, no action is required. If you want to use a local system version of `libevent`, you must build MySQL with the `-DWITH_LIBEVENT` build option set to `system` or `yes`.

## Installing and Configuring the InnoDB memcached Plugin

1. Configure the `daemon_memcached` plugin so it can interact with InnoDB tables by running the `innodb_memcached_config.sql` configuration script, which is located in `MYSQL_HOME/share`. This script installs the `innodb_memcache` database with three required tables (`cache_policies`, `config_options`, and `containers`). It also installs the `demo_test` sample table in the `test` database.

```
mysql> source MYSQL_HOME/share/innodb_memcached_config.sql
```

Running the `innodb_memcached_config.sql` script is a one-time operation. The tables remain in place if you later uninstall and re-install the `daemon_memcached` plugin.

```
mysql> USE innodb_memcache;
mysql> SHOW TABLES;
+-----+
| Tables_in_innodb_memcache |
+-----+
| cache_policies            |
| config_options            |
| containers                 |
+-----+

mysql> USE test;
mysql> SHOW TABLES;
+-----+
| Tables_in_test |
+-----+
| demo_test       |
+-----+
```

Of these tables, the `innodb_memcache.containers` table is the most important. Entries in the `containers` table provide a mapping to InnoDB table columns. Each InnoDB table used with the `daemon_memcached` plugin requires an entry in the `containers` table.

The `innodb_memcached_config.sql` script inserts a single entry in the `containers` table that provides a mapping for the `demo_test` table. It also inserts a single row of data into the `demo_test` table. This data allows you to immediately verify the installation after the setup is completed.

```
mysql> SELECT * FROM innodb_memcache.containers\G
***** 1. row *****
      name: aaa
    db_schema: test
    db_table: demo_test
  key_columns: c1
value_columns: c2
      flags: c3
    cas_column: c4
expire_time_column: c5
unique_idx_name_on_key: PRIMARY

mysql> SELECT * FROM test.demo_test;
+-----+-----+-----+-----+-----+
| c1 | c2 | c3 | c4 | c5 |
+-----+-----+-----+-----+-----+
| AA | HELLO, HELLO | 8 | 0 | 0 |
+-----+-----+-----+-----+-----+
```

For more information about `innodb_memcache` tables and the `demo_test` sample table, see [Section 15.20.7, “InnoDB memcached Plugin Internals”](#).

2. Activate the `daemon_memcached` plugin by running the `INSTALL PLUGIN` statement:

```
mysql> INSTALL PLUGIN daemon_memcached soname "libmemcached.so";
```

Once the plugin is installed, it is automatically activated each time the MySQL server is restarted.

## Verifying the InnoDB and memcached Setup

To verify the `daemon_memcached` plugin setup, use a `telnet` session to issue `memcached` commands. By default, the `memcached` daemon listens on port 11211.

1. Retrieve data from the `test.demo_test` table. The single row of data in the `demo_test` table has a key value of `AA`.

```
telnet localhost 11211
Trying 127.0.0.1...
Connected to localhost.
Escape character is '^['.
get AA
VALUE AA 8 12
HELLO, HELLO
END
```

2. Insert data using a `set` command.

```
set BB 10 0 16
GOODBYE, GOODBYE
STORED
```

where:

- `set` is the command to store a value
  - `BB` is the key
  - `10` is a flag for the operation; ignored by `memcached` but may be used by the client to indicate any type of information; specify `0` if unused
  - `0` is the expiration time (TTL); specify `0` if unused
  - `16` is the length of the supplied value block in bytes
  - `GOODBYE, GOODBYE` is the value that is stored
3. Verify that the data inserted is stored in MySQL by connecting to the MySQL server and querying the `test.demo_test` table.

```
mysql> SELECT * FROM test.demo_test;
+-----+-----+-----+-----+-----+
| c1 | c2 | c3 | c4 | c5 |
+-----+-----+-----+-----+
| AA | HELLO, HELLO | 8 | 0 | 0 |
| BB | GOODBYE, GOODBYE | 10 | 1 | 0 |
+-----+-----+-----+-----+
```

4. Return to the `telnet` session and retrieve the data that you inserted earlier using key `BB`.

```
get BB
VALUE BB 10 16
GOODBYE, GOODBYE
```

```
END
quit
```

If you shut down the MySQL server, which also shuts off the integrated `memcached` server, further attempts to access the `memcached` data will fail with a connection error. Normally, the `memcached` data also disappears at this point, and you would require application logic to load the data back into memory when `memcached` is restarted. However, the `InnoDB memcached` plugin automates this process for you.

When you restart MySQL, `get` operations once again return the key/value pairs you stored in the earlier `memcached` session. When a key is requested and the associated value is not already in the memory cache, the value is automatically queried from the MySQL `test.demo_test` table.

## Creating a New Table and Column Mapping

This example shows how to setup your own `InnoDB` table with the `daemon_memcached` plugin.

1. Create an `InnoDB` table. The table must have a key column with a unique index. The key column of the city table is `city_id`, which is defined as the primary key. The table must also include columns for `flags`, `cas`, and `expiry` values. There may be one or more value columns. The `city` table has three value columns (`name`, `state`, `country`).

### Note

There is no special requirement with respect to column names as long as a valid mapping is added to the `innodb_memcache.containers` table.

```
mysql> CREATE TABLE city (
-> city_id VARCHAR(32),
-> name VARCHAR(1024),
-> state VARCHAR(1024),
-> country VARCHAR(1024),
-> flags INT,
-> cas BIGINT UNSIGNED,
-> expiry INT,
-> primary key(city_id)
-> ) ENGINE=InnoDB;
```

2. Add an entry to the `innodb_memcache.containers` table so that the `daemon_memcached` plugin knows how to access the `InnoDB` table. The entry must satisfy the `innodb_memcache.containers` table definition. For a description of each field, see [Section 15.20.7, “InnoDB memcached Plugin Internals”](#).

```
mysql> DESCRIBE innodb_memcache.containers;
```

| Field                  | Type         | Null | Key | Default | Extra |
|------------------------|--------------|------|-----|---------|-------|
| name                   | varchar(50)  | NO   | PRI | NULL    |       |
| db_schema              | varchar(250) | NO   |     | NULL    |       |
| db_table               | varchar(250) | NO   |     | NULL    |       |
| key_columns            | varchar(250) | NO   |     | NULL    |       |
| value_columns          | varchar(250) | YES  |     | NULL    |       |
| flags                  | varchar(250) | NO   |     | 0       |       |
| cas_column             | varchar(250) | YES  |     | NULL    |       |
| expire_time_column     | varchar(250) | YES  |     | NULL    |       |
| unique_idx_name_on_key | varchar(250) | NO   |     | NULL    |       |

The `innodb_memcache.containers` table entry for the city table is defined as:

```
mysql> INSERT INTO `innodb_memcache`.`containers` (
-> `name`, `db_schema`, `db_table`, `key_columns`, `value_columns`,
-> `flags`, `cas_column`, `expire_time_column`, `unique_idx_name_on_key`
-> VALUES ('default', 'test', 'city', 'city_id', 'name|state|country',
-> 'flags','cas','expiry','PRIMARY');
```

- `default` is specified for the `containers.name` column to configure the `city` table as the default InnoDB table to be used with the `daemon_memcached` plugin.
  - Multiple InnoDB table columns (`name`, `state`, `country`) are mapped to `containers.value_columns` using a “|” delimiter.
  - The `flags`, `cas_column`, and `expire_time_column` fields of the `innodb_memcache.containers` table are typically not significant in applications using the `daemon_memcached` plugin. However, a designated InnoDB table column is required for each. When inserting data, specify `0` for these columns if they are unused.
3. After updating the `innodb_memcache.containers` table, restart the `daemon_memcache` plugin to apply the changes.

```
mysql> UNINSTALL PLUGIN daemon_memcached;

mysql> INSTALL PLUGIN daemon_memcached soname "libmemcached.so";
```

4. Using telnet, insert data into the `city` table using a `memcached set` command.

```
telnet localhost 11211
Trying 127.0.0.1...
Connected to localhost.
Escape character is '^]'.
set B 0 0 22
BANGALORE|BANGALORE|IN
STORED
```

5. Using MySQL, query the `test.city` table to verify that the data you inserted was stored.

```
mysql> SELECT * FROM test.city;
+-----+-----+-----+-----+-----+-----+-----+
| city_id | name      | state      | country | flags | cas | expiry |
+-----+-----+-----+-----+-----+-----+-----+
| B       | BANGALORE | BANGALORE | IN      | 0     | 3   | 0       |
+-----+-----+-----+-----+-----+-----+-----+
```

6. Using MySQL, insert additional data into the `test.city` table.

```
mysql> INSERT INTO city VALUES ('C','CHENNAI','TAMIL NADU','IN', 0, 0 ,0);
mysql> INSERT INTO city VALUES ('D','DELHI','DELHI','IN', 0, 0, 0);
mysql> INSERT INTO city VALUES ('H','HYDERABAD','TELANGANA','IN', 0, 0, 0);
mysql> INSERT INTO city VALUES ('M','MUMBAI','MAHARASHTRA','IN', 0, 0, 0);
```

#### Note

It is recommended that you specify a value of `0` for the `flags`, `cas_column`, and `expire_time_column` fields if they are unused.

7. Using telnet, issue a `memcached get` command to retrieve data you inserted using MySQL.

```
get H
VALUE H 0 22
HYDERABAD|TELANGANA|IN
END
```

## Configuring the InnoDB memcached Plugin

Traditional `memcached` configuration options may be specified in a MySQL configuration file or a `mysqld` startup string, encoded in the argument of the `daemon_memcached_option` configuration parameter. `memcached` configuration options take effect when the plugin is loaded, which occurs each time the MySQL server is started.

For example, to make `memcached` listen on port 11222 instead of the default port 11211, specify `-p11222` as an argument of the `daemon_memcached_option` configuration option:

```
mysqld .... --daemon_memcached_option="-p11222"
```

Other `memcached` options can be encoded in the `daemon_memcached_option` string. For example, you can specify options to reduce the maximum number of simultaneous connections, change the maximum memory size for a key/value pair, or enable debugging messages for the error log, and so on.

There are also configuration options specific to the `daemon_memcached` plugin. These include:

- `daemon_memcached_engine_lib_name`: Specifies the shared library that implements the InnoDB `memcached` plugin. The default setting is `innodb_engine.so`.
- `daemon_memcached_engine_lib_path`: The path of the directory containing the shared library that implements the InnoDB `memcached` plugin. The default is NULL, representing the plugin directory.
- `daemon_memcached_r_batch_size`: Defines the batch commit size for read operations (`get`). It specifies the number of `memcached` read operations after which a `commit` occurs. `daemon_memcached_r_batch_size` is set to 1 by default so that every `get` request accesses the most recently committed data in the InnoDB table, whether the data was updated through `memcached` or by SQL. When the value is greater than 1, the counter for read operations is incremented with each `get` call. A `flush_all` call resets both read and write counters.
- `daemon_memcached_w_batch_size`: Defines the batch commit size for write operations (`set`, `replace`, `append`, `prepend`, `incr`, `decr`, and so on). `daemon_memcached_w_batch_size` is set to 1 by default so that no uncommitted data is lost in case of an outage, and so that SQL queries on the underlying table access the most recent data. When the value is greater than 1, the counter for write operations is incremented for each `add`, `set`, `incr`, `decr`, and `delete` call. A `flush_all` call resets both read and write counters.

By default, you do not need to modify `daemon_memcached_engine_lib_name` or `daemon_memcached_engine_lib_path`. You might configure these options if, for example, you want to use a different storage engine for `memcached` (such as the NDB `memcached` engine).

`daemon_memcached` plugin configuration parameters may be specified in the MySQL configuration file or in a `mysqld` startup string. They take effect when you load the `daemon_memcached` plugin.

When making changes to `daemon_memcached` plugin configuration, reload the plugin to apply the changes. To do so, issue the following statements:

```
mysql> UNINSTALL PLUGIN daemon_memcached;

mysql> INSTALL PLUGIN daemon_memcached soname "libmemcached.so";
```

Configuration settings, required tables, and data are preserved when the plugin is restarted.

For additional information about enabling and disabling plugins, see [Section 6.5.2, “Installing and Uninstalling Plugins”](#).

## 15.20.4 Security Considerations for the InnoDB memcached Plugin

### Caution

Consult this section before deploying the `daemon_memcached` plugin on a production server, or even on a test server if the MySQL instance contains sensitive data.

Because `memcached` does not use an authentication mechanism by default, and the optional SASL authentication is not as strong as traditional DBMS security measures, only keep non-sensitive data

in the MySQL instance that uses the `daemon_memcached` plugin, and wall off any servers that use this configuration from potential intruders. Do not allow `memcached` access to these servers from the Internet; only allow access from within a firewalled intranet, ideally from a subnet whose membership you can restrict.

## Password-Protecting memcached Using SASL

SASL support provides the capability to protect your MySQL database from unauthenticated access through `memcached` clients. This section explains how to enable SASL with the `daemon_memcached` plugin. The steps are almost identical to those performed to enable SASL for a traditional `memcached` server.

SASL stands for “Simple Authentication and Security Layer”, a standard for adding authentication support to connection-based protocols. `memcached` added SASL support in version 1.4.3.

SASL authentication is only supported with the binary protocol.

`memcached` clients are only able to access InnoDB tables that are registered in the `innodb_memcache.containers` table. Even though a DBA can place access restrictions on such tables, access through `memcached` applications cannot be controlled. For this reason, SASL support is provided to control access to InnoDB tables associated with the `daemon_memcached` plugin.

The following section shows how to build, enable, and test an SASL-enabled `daemon_memcached` plugin.

## Building and Enabling SASL with the InnoDB memcached Plugin

By default, an SASL-enabled `daemon_memcached` plugin is not included in MySQL release packages, since an SASL-enabled `daemon_memcached` plugin requires building `memcached` with SASL libraries. To enable SASL support, download the MySQL source and rebuild the `daemon_memcached` plugin after downloading the SASL libraries:

1. Install the SASL development and utility libraries. For example, on Ubuntu, use `apt-get` to obtain the libraries:

```
sudo apt-get -f install libsasl2-2 sasl2-bin libsasl2-2 libsasl2-dev libsasl2-modules
```

2. Build the `daemon_memcached` plugin shared libraries with SASL capability by adding `ENABLE_MEMCACHED_SASL=1` to your `cmake` options. `memcached` also provides *simple cleartext password support*, which facilitates testing. To enable simple cleartext password support, specify the `ENABLE_MEMCACHED_SASL_PWDB=1` `cmake` option.

In summary, add following three `cmake` options:

```
cmake ... -DWITH_INNODB_MEMCACHED=1 -DENABLE_MEMCACHED_SASL=1 -DENABLE_MEMCACHED_SASL_PWDB=1
```

3. Install the `daemon_memcached` plugin, as described in [Section 15.20.3, “Setting Up the InnoDB memcached Plugin”](#).
4. Configure a user name and password file. (This example uses `memcached` simple cleartext password support.)
  - a. In a file, create a user named `testname` and define the password as `testpasswd`:

```
echo "testname:testpasswd:::::::::" >/home/jy/memcached-sasl-db
```

- b. Configure the `MEMCACHED_SASL_PWDB` environment variable to inform `memcached` of the user name and password file:

```
export MEMCACHED_SASL_PWDB=/home/jy/memcached-sasl-db
```

- c. Inform `memcached` that a cleartext password is used:

```
echo "mech_list: plain" > /home/jy/work2/msasl/clients/memcached.conf
export SASL_CONF_PATH=/home/jy/work2/msasl/clients
```

5. Enable SASL by restarting the MySQL server with the `memcached -S` option encoded in the `daemon_memcached_option` configuration parameter:

```
mysqld ... --daemon_memcached_option="-S"
```

6. To test the setup, use an SASL-enabled client such as [SASL-enabled libmemcached](#).

```
memcp --servers=localhost:11211 --binary --username=testname
--password=testpasswd myfile.txt

memcat --servers=localhost:11211 --binary --username=testname
--password=testpasswd myfile.txt
```

If you specify an incorrect user name or password, the operation is rejected with a `memcache error AUTHENTICATION FAILURE` message. In this case, examine the cleartext password set in the `memcached-sasl-db` file to verify that the credentials you supplied are correct.

There are other methods to test SASL authentication with `memcached`, but the method described above is the most straightforward.

## 15.20.5 Writing Applications for the InnoDB memcached Plugin

Typically, writing an application for the `InnoDB memcached` plugin involves some degree of rewriting or adapting existing code that uses MySQL or the `memcached` API.

- With the `daemon_memcached` plugin, instead of many traditional `memcached` servers running on low-powered machines, you will have the same number of `memcached` servers as MySQL servers, running on relatively high-powered machines with substantial disk storage and memory. You might reuse some existing code that works with the `memcached` API, but adaptation is likely required due to the different server configuration.
- The data stored through the `daemon_memcached` plugin goes into `VARCHAR`, `TEXT`, or `BLOB` columns, and must be converted to do numeric operations. You can perform the conversion on the application side, or by using the `CAST( )` function in queries.
- Coming from a database background, you might be used to general-purpose SQL tables with many columns. The tables accessed by `memcached` code likely have only a few or even a single column holding data values.
- You might adapt parts of your application that perform single-row queries, inserts, updates, or deletes, to improve performance in critical sections of code. Both [queries](#) (read) and [DML](#) (write) operations can be substantially faster when performed through the `InnoDB memcached` interface. The performance improvement for writes is typically greater than the performance improvement for reads, so you might focus on adapting code that performs logging or records interactive choices on a web site.

The following sections explore these points in more detail.

### 15.20.5.1 Adapting an Existing MySQL Schema for the InnoDB memcached Plugin

Consider these aspects of `memcached` applications when adapting an existing MySQL schema or application to use the `daemon_memcached` plugin:

- `memcached` keys cannot contain spaces or newlines, because these characters are used as separators in the ASCII protocol. If you are using lookup values that contain spaces, transform or

hash them into values without spaces before using them as keys in calls to `add()`, `set()`, `get()`, and so on. Although theoretically these characters are allowed in keys in programs that use the binary protocol, you should restrict the characters used in keys to ensure compatibility with a broad range of clients.

- If there is a short numeric **primary key** column in an **InnoDB** table, use it as the unique lookup key for **memcached** by converting the integer to a string value. If the **memcached** server is used for multiple applications, or with more than one **InnoDB** table, consider modifying the name to ensure that it is unique. For example, prepend the table name, or the database name and the table name, before the numeric value.

#### Note

The **daemon\_memcached** plugin supports inserts and reads on mapped **InnoDB** tables that have an **INTEGER** defined as the primary key.

- You cannot use a partitioned table for data queried or stored using **memcached**.
- The **memcached** protocol passes numeric values around as strings. To store numeric values in the underlying **InnoDB** table, to implement counters that can be used in SQL functions such as **SUM()** or **AVG()**, for example:
  - Use **VARCHAR** columns with enough characters to hold all the digits of the largest expected number (and additional characters if appropriate for the negative sign, decimal point, or both).
  - In any query that performs arithmetic using column values, use the **CAST()** function to convert the values from string to integer, or to some other numeric type. For example:

```
-- Alphabetic entries are returned as zero.
select cast(c2 as unsigned integer) from demo_test;
-- Since there could be numeric values of 0, can't disqualify them.
-- Test the string values to find the ones that are integers, and average only those.
select avg(cast(c2 as unsigned integer)) from demo_test
  where c2 between '0' and '9999999999';
-- Views let you hide the complexity of queries. The results are already converted;
-- no need to repeat conversion functions and WHERE clauses each time.
create view numbers as select c1 key, cast(c2 as unsigned integer) val
  from demo_test where c2 between '0' and '9999999999';
select sum(val) from numbers;
```

#### Note

Any alphabetic values in the result set are converted into 0 by the call to **CAST()**. When using functions such as **AVG()**, which depend on the number of rows in the result set, include **WHERE** clauses to filter out non-numeric values.

- If the **InnoDB** column used as a key could have values longer than 250 bytes, hash the value to less than 250 bytes.
- To use an existing table with the **daemon\_memcached** plugin, define an entry for it in the **innodb\_memcache.containers** table. To make that table the default for all **memcached** requests, specify a value of **default** in the **name** column, then restart the MySQL server to make the change take effect. If you use multiple tables for different classes of **memcached** data, set up multiple entries in the **innodb\_memcache.containers** table with **name** values of your choice, then issue a **memcached** request in the form of `get @@name` or `set @@name` within the application to specify the table to be used for subsequent **memcached** requests.

For an example of using a table other than the predefined **test.demo\_test** table, see [Example 15.22, “Using Your Own Table with an InnoDB memcached Application”](#). For the required table layout, see [Section 15.20.7, “InnoDB memcached Plugin Internals”](#).

- To use multiple InnoDB table column values with memcached key/value pairs, specify column names separated by comma, semicolon, space, or pipe characters in the `value_columns` field of the `innodb_memcache.containers` entry for the InnoDB table. For example, specify `col1,col2,col3` or `col1|col2|col3` in the `value_columns` field.

Concatenate the column values into a single string using the pipe character as a separator before passing the string to `memcached add` or `set` calls. The string is unpacked automatically into the correct column. Each `get` call returns a single string containing the column values that is also delimited by the pipe character. You can unpack the values using the appropriate application language syntax.

### Example 15.22 Using Your Own Table with an InnoDB memcached Application

This example shows how to use your own table with a sample Python application that uses `memcached` for data manipulation.

The example assumes that the `daemon_memcached` plugin is installed as described in [Section 15.20.3, “Setting Up the InnoDB memcached Plugin”](#). It also assumes that your system is configured to run a Python script that uses the `python-memcache` module.

1. Create the `multicol` table which stores country information including population, area, and driver side data ('R' for right and 'L' for left).

```
mysql> USE test;

mysql> CREATE TABLE `multicol` (
  -> `country` varchar(128) NOT NULL DEFAULT '',
  -> `population` varchar(10) DEFAULT NULL,
  -> `area_sq_km` varchar(9) DEFAULT NULL,
  -> `drive_side` varchar(1) DEFAULT NULL,
  -> `c3` int(11) DEFAULT NULL,
  -> `c4` bigint(20) unsigned DEFAULT NULL,
  -> `c5` int(11) DEFAULT NULL,
  -> PRIMARY KEY (`country`)
  -> ) ENGINE=InnoDB DEFAULT CHARSET=latin1;
```

2. Insert a record into the `innodb_memcache.containers` table so that the `daemon_memcached` plugin can access the `multicol` table.

```
mysql> INSERT INTO innodb_memcache.containers
  -> (name,db_schema,db_table,key_columns,value_columns,flags,cas_column,
  -> expire_time_column,unique_idx_name_on_key)
  -> VALUES
  -> ('bbb','test','multicol','country','population,area_sq_km,drive_side',
  -> 'c3','c4','c5','PRIMARY');

mysql> COMMIT;
```

- The `innodb_memcache.containers` record for the `multicol` table specifies a `name` value of 'bbb', which is the table identifier.

#### Note

If a single InnoDB table is used for all `memcached` applications, the `name` value can be set to `default` to avoid using @@ notation to switch tables.

- The `db_schema` column is set to `test`, which is the name of the database where the `multicol` table resides.
- The `db_table` column is set to `multicol`, which is the name of the InnoDB table.
- `key_columns` is set to the unique `country` column. The `country` column is defined as the primary key in the `multicol` table definition.

- Rather than a single InnoDB table column to hold a composite data value, data is divided among three table columns (`population`, `area_sq_km`, and `drive_side`). To accommodate multiple value columns, a comma-separated list of columns is specified in the `value_columns` field. The columns defined in the `value_columns` field are the columns used when storing or retrieving values.
  - Values for the `flags`, `expire_time`, and `cas_column` fields are based on values used in the `demo.test` sample table. These fields are typically not significant in applications that use the `daemon_memcached` plugin because MySQL keeps data synchronized, and there is no need to worry about data expiring or becoming stale.
  - The `unique_idx_name_on_key` field is set to `PRIMARY`, which refers to the primary index defined on the unique `country` column in the `multicol` table.
3. Copy the sample Python application into a file. In this example, the sample script is copied to a file named `multicol.py`.

The sample Python application inserts data into the `multicol` table and retrieves data for all keys, demonstrating how to access an InnoDB table through the `daemon_memcached` plugin.

```
import sys, os
import memcache

def connect_to_memcached():
    memc = memcache.Client(['127.0.0.1:11211'], debug=0);
    print "Connected to memcached."
    return memc

def banner(message):
    print
    print "=" * len(message)
    print message
    print "=" * len(message)

country_data = [
    ("Canada", "34820000", "9984670", "R"),
    ("USA", "314242000", "9826675", "R"),
    ("Ireland", "6399152", "84421", "L"),
    ("UK", "62262000", "243610", "L"),
    ("Mexico", "113910608", "1972550", "R"),
    ("Denmark", "5543453", "43094", "R"),
    ("Norway", "5002942", "385252", "R"),
    ("UAE", "8264070", "83600", "R"),
    ("India", "1210193422", "3287263", "L"),
    ("China", "1347350000", "9640821", "R"),
]

def switch_table(memc, table):
    key = "@@" + table
    print "Switching default table to '" + table + "' by issuing GET for '" + key + "'."
    result = memc.get(key)

def insert_country_data(memc):
    banner("Inserting initial data via memcached interface")
    for item in country_data:
        country = item[0]
        population = item[1]
        area = item[2]
        drive_side = item[3]

        key = country
        value = "|".join([population, area, drive_side])
        print "Key = " + key
        print "Value = " + value

        if memc.add(key, value):
            print "Added new key, value pair."
```

```

    else:
        print "Updating value for existing key."
        memc.set(key,value)

def query_country_data(memc):
    banner("Retrieving data for all keys (country names)")
    for item in country_data:
        key = item[0]
        result = memc.get(key)
        print "Here is the result retrieved from the database for key " + key + ":"
        print result
        (m_population, m_area, m_drive_side) = result.split("|")
        print "Unpacked population value: " + m_population
        print "Unpacked area value      : " + m_area
        print "Unpacked drive side value: " + m_drive_side

if __name__ == '__main__':

    memc = connect_to_memcached()
    switch_table(memc,"bbb")
    insert_country_data(memc)
    query_country_data(memc)

    sys.exit(0)

```

Sample Python application notes:

- No database authorization is required to run the application, since data manipulation is performed through the `memcached` interface. The only required information is the port number on the local system where the `memcached` daemon listens.
- To make sure the application uses the `multicol` table, the `switch_table()` function is called, which performs a dummy `get` or `set` request using `@@` notation. The `name` value in the request is `bbb`, which is the `multicol` table identifier defined in the `innodb_memcache.containers.name` field.

A more descriptive `name` value might be used in a real-world application. This example simply illustrates that a table identifier is specified rather than the table name in `get @@...` requests.

- The utility functions used to insert and query data demonstrate how to turn a Python data structure into pipe-separated values for sending data to MySQL with `add` or `set` requests, and how to unpack the pipe-separated values returned by `get` requests. This extra processing is only required when mapping a single `memcached` value to multiple MySQL table columns.

#### 4. Run the sample Python application.

```
shell> python multicol.py
```

If successful, the sample application returns this output:

```

Connected to memcached.
Switching default table to 'bbb' by issuing GET for '@@bbb'.

```

```
dtprice@ubuntu:~$
```

- Query the `innodb_memcache.containers` table to view the record you inserted earlier for the `multicol` table. The first record is the sample entry for the `demo_test` table that is created during the initial `daemon_memcached` plugin setup. The second record is the entry you inserted for the `multicol` table.

```
mysql> SELECT * FROM innodb_memcache.containers\G
***** 1. row *****
      name: aaa
    db_schema: test
    db_table: demo_test
  key_columns: c1
value_columns: c2
      flags: c3
    cas_column: c4
expire_time_column: c5
unique_idx_name_on_key: PRIMARY
***** 2. row *****
      name: bbb
    db_schema: test
    db_table: multicol
  key_columns: country
value_columns: population,area_sq_km,drive_side
      flags: c3
    cas_column: c4
expire_time_column: c5
unique_idx_name_on_key: PRIMARY
```

- Query the `multicol` table to view data inserted by the sample Python application. The data is available for MySQL queries, which demonstrates how the same data can be accessed using SQL or through applications (using the appropriate [MySQL Connector or API](#)).

```
mysql> SELECT * FROM test.multicol;
+-----+-----+-----+-----+-----+-----+-----+
| country | population | area_sq_km | drive_side | c3 | c4 | c5 |
+-----+-----+-----+-----+-----+-----+
| Canada | 34820000 | 9984670 | R | 0 | 11 | 0 |
| China | 1347350000 | 9640821 | R | 0 | 20 | 0 |
| Denmark | 5543453 | 43094 | R | 0 | 16 | 0 |
| India | 1210193422 | 3287263 | L | 0 | 19 | 0 |

| Mexico | 113910608 | 1972550 | R | 0 | 15 | 0 |
| Norway | 5002942 | 385252 | R | 0 | 17 | 0 |
| UAE | 8264070 | 83600 | R | 0 | 18 | 0 |
| UK | 62262000 | 243610 | L | 0 | 14 | 0 |
| USA | 314242000 | 9826675 | R | 0 | 12 | 0 |
+-----+-----+-----+-----+-----+-----+
```

#### Note

Always allow sufficient size to hold necessary digits, decimal points, sign characters, leading zeros, and so on when defining the length for columns that are treated as numbers. Too-long values in a string column such as a `VARCHAR` are truncated by removing some characters, which could produce nonsensical numeric values.

- Optionally, run report-type queries on the `InnoDB` table that stores the `memcached` data.

You can produce reports through SQL queries, performing calculations and tests across any columns, not just the `country` key column. (Because the following examples use data from only a few countries, the numbers are for illustration purposes only.) The following queries return the average population of countries where people drive on the right, and the average size of countries whose names start with “U”:

```
mysql> SELECT AVG(population) FROM multicol WHERE drive_side = 'R';
+-----+
```

```

| avg(population) |
+-----+
| 261304724.7142857 |
+-----+

mysql> SELECT SUM(area_sq_km) FROM multicol WHERE country LIKE 'U%';
+-----+
| sum(area_sq_km) |
+-----+
| 10153885 |
+-----+

```

Because the `population` and `area_sq_km` columns store character data rather than strongly typed numeric data, functions such as `AVG()` and `SUM()` work by converting each value to a number first. This approach *does not work* for operators such as `<` or `>`, for example, when comparing character-based values, `9 > 1000`, which is not expected from a clause such as `ORDER BY population DESC`. For the most accurate type treatment, perform queries against views that cast numeric columns to the appropriate types. This technique lets you issue simple `SELECT *` queries from database applications, while ensuring that casting, filtering, and ordering is correct. The following example shows a view that can be queried to find the top three countries in descending order of population, with the results reflecting the latest data in the `multicol` table, and with population and area figures treated as numbers:

```

mysql> CREATE VIEW populous_countries AS
-> SELECT
->   country,
->   cast(population as unsigned integer) population,
->   cast(area_sq_km as unsigned integer) area_sq_km,
->   drive_side FROM multicol
-> ORDER BY CAST(population as unsigned integer) DESC
-> LIMIT 3;

mysql> SELECT * FROM populous_countries;
+-----+-----+-----+-----+
| country | population | area_sq_km | drive_side |
+-----+-----+-----+-----+
| China   | 1347350000 | 9640821    | R          |
| India   | 1210193422 | 3287263    | L          |
| USA     | 314242000  | 9826675    | R          |
+-----+-----+-----+-----+

mysql> DESC populous_countries;
+-----+-----+-----+-----+-----+-----+
| Field      | Type                | Null | Key | Default | Extra |
+-----+-----+-----+-----+-----+-----+
| country    | varchar(128)        | NO   |     |         |       |
| population | bigint(10) unsigned | YES  |     | NULL    |       |
| area_sq_km | int(9) unsigned     | YES  |     | NULL    |       |
| drive_side | varchar(1)          | YES  |     | NULL    |       |
+-----+-----+-----+-----+-----+-----+

```

### 15.20.5.2 Adapting a memcached Application for the InnoDB memcached Plugin

Consider these aspects of MySQL and InnoDB tables when adapting existing memcached applications to use the `daemon_memcached` plugin:

- If there are key values longer than a few bytes, it may be more efficient to use a numeric auto-increment column as the **primary key** of the InnoDB table, and to create a unique **secondary index** on the column that contains the memcached key values. This is because InnoDB performs best for large-scale insertions if primary key values are added in sorted order (as they are with auto-increment values). Primary key values are included in secondary indexes, which takes up unnecessary space if the primary key is a long string value.
- If you store several different classes of information using memcached, consider setting up a separate InnoDB table for each type of data. Define additional table identifiers in the `innodb_memcache.containers` table, and use the `@@table_id.key` notation to store and

retrieve items from different tables. Physically dividing different types of information allows you tune the characteristics of each table for optimum space utilization, performance, and reliability. For example, you might enable [compression](#) for a table that holds blog posts, but not for a table that holds thumbnail images. You might back up one table more frequently than another because it holds critical data. You might create additional [secondary indexes](#) on tables that are frequently used to generate reports using SQL.

- Preferably, configure a stable set of table definitions for use with the [daemon\\_memcached](#) plugin, and leave the tables in place permanently. Changes to the [innodb\\_memcache.containers](#) table take effect the next time the [innodb\\_memcache.containers](#) table is queried. Entries in the containers table are processed at startup, and are consulted whenever an unrecognized table identifier (as defined by [containers.name](#)) is requested using @@ notation. Thus, new entries are visible as soon as you use the associated table identifier, but changes to existing entries require a server restart before they take effect.
- When you use the default [innodb\\_only](#) caching policy, calls to [add\(\)](#), [set\(\)](#), [incr\(\)](#), and so on can succeed but still trigger debugging messages such as [while expecting 'STORED', got unexpected response 'NOT\\_STORED'](#). Debug messages occur because new and updated values are sent directly to the [InnoDB](#) table without being saved in the memory cache, due to the [innodb\\_only](#) caching policy.

### 15.20.5.3 Tuning InnoDB memcached Plugin Performance

Because using [InnoDB](#) in combination with [memcached](#) involves writing all data to disk, whether immediately or sometime later, raw performance is expected to be somewhat slower than using [memcached](#) by itself. When using the [InnoDB memcached](#) plugin, focus tuning goals for [memcached](#) operations on achieving better performance than equivalent SQL operations.

Benchmarks suggest that queries and [DML](#) operations (inserts, updates, and deletes) that use the [memcached](#) interface are faster than traditional SQL. DML operations typically see a larger improvements. Therefore, consider adapting write-intensive applications to use the [memcached](#) interface first. Also consider prioritizing adaptation of write-intensive applications that use fast, lightweight mechanisms that lack reliability.

### Adapting SQL Queries

The types of queries that are most suited to simple [GET](#) requests are those with a single clause or a set of [AND](#) conditions in the [WHERE](#) clause:

```
SQL:
SELECT col FROM tbl WHERE key = 'key_value';

memcached:
GET key_value

SQL:
SELECT col FROM tbl WHERE col1 = val1 and col2 = val2 and col3 = val3;

memcached:
# Since you must always know these 3 values to look up the key,
# combine them into a unique string and use that as the key
# for all ADD, SET, and GET operations.
key_value = val1 + ":" + val2 + ":" + val3
GET key_value

SQL:
SELECT 'key exists!' FROM tbl
  WHERE EXISTS (SELECT col1 FROM tbl WHERE KEY = 'key_value') LIMIT 1;

memcached:
# Test for existence of key by asking for its value and checking if the call succeeds,
# ignoring the value itself. For existence checking, you typically only store a very
# short value such as "1".
GET key_value
```

## Using System Memory

For best performance, deploy the `daemon_memcached` plugin on machines that are configured as typical database servers, where the majority of system RAM is devoted to the `InnoDB buffer pool`, through the `innodb_buffer_pool_size` configuration option. For systems with multi-gigabyte buffer pools, consider raising the value of `innodb_buffer_pool_instances` for maximum throughput when most operations involve data that is already cached in memory.

## Reducing Redundant I/O

`InnoDB` has a number of settings that let you choose the balance between high reliability, in case of a crash, and the amount of I/O overhead during high write workloads. For example, consider setting the `innodb_doublewrite` to 0 and `innodb_flush_log_at_trx_commit` to 2. Measure performance with different `innodb_flush_method` settings.

### Note

`innodb_support_xa` is deprecated and will be removed in a future release. As of MySQL 5.7.10, `InnoDB` support for two-phase commit in XA transactions is always enabled and disabling `innodb_support_xa` is no longer permitted.

For other ways to reduce or tune I/O for table operations, see [Section 9.5.8, “Optimizing InnoDB Disk I/O”](#).

## Reducing Transactional Overhead

A default value of 1 for `daemon_memcached_r_batch_size` and `daemon_memcached_w_batch_size` is intended for maximum reliability of results and safety of stored or updated data.

Depending on the type of application, you might increase one or both of these settings to reduce the overhead of frequent `commit` operations. On a busy system, you might increase `daemon_memcached_r_batch_size`, knowing that changes to data made through SQL may not become visible to `memcached` immediately (that is, until *N* more `get` operations are processed). When processing data where every write operation must be reliably stored, leave `daemon_memcached_w_batch_size` set to 1. Increase the setting when processing large numbers of updates intended only for statistical analysis, where losing the last *N* updates in a crash is an acceptable risk.

For example, imagine a system that monitors traffic crossing a busy bridge, recording data for approximately 100,000 vehicles each day. If the application counts different types of vehicles to analyze traffic patterns, changing `daemon_memcached_w_batch_size` from 1 to 100 reduces I/O overhead for commit operations by 99%. In case of an outage, a maximum of 100 records are lost, which may be an acceptable margin of error. If instead the application performed automated toll collection for each car, you would set `daemon_memcached_w_batch_size` to 1 to ensure that each toll record is immediately saved to disk.

Because of the way `InnoDB` organizes `memcached` key values on disk, if you have a large number of keys to create, it may be faster to sort the data items by key value in the application and `add` them in sorted order, rather than create keys in arbitrary order.

The `memslap` command, which is part of the regular `memcached` distribution but not included with the `daemon_memcached` plugin, can be useful for benchmarking different configurations. It can also be used to generate sample key/value pairs to use in your own benchmarks. See [libmemcached Command-Line Utilities](#) for details.

### 15.20.5.4 Controlling Transactional Behavior of the InnoDB memcached Plugin

Unlike traditional `memcached`, the `daemon_memcached` plugin allows you to control durability of data values produced through calls to `add`, `set`, `incr`, and so on. By default, data written through

the `memcached` interface is stored to disk, and calls to `get` return the most recent value from disk. Although the default behavior does not offer the best possible raw performance, it is still fast compared to the SQL interface for `InnoDB` tables.

As you gain experience using the `daemon_memcached` plugin, you can consider relaxing durability settings for non-critical classes of data, at the risk of losing some updated values in the event of an outage, or returning data that is slightly out-of-date.

## Frequency of Commits

One tradeoff between durability and raw performance is how frequently new and changed data is `committed`. If data is critical, it should be committed immediately so that it is safe in case of a crash or outage. If data is less critical, such as counters that are reset after a crash or logging data that you can afford to lose, you might prefer higher raw throughput that is available with less frequent commits.

When a `memcached` operation inserts, updates, or deletes data in the underlying `InnoDB` table, the change might be committed to the `InnoDB` table instantly (if `daemon_memcached_w_batch_size=1`) or some time later (if the `daemon_memcached_w_batch_size` value is greater than 1). In either case, the change cannot be rolled back. If you increase the value of `daemon_memcached_w_batch_size` to avoid high I/O overhead during busy times, commits could become infrequent when the workload decreases. As a safety measure, a background thread automatically commits changes made through the `memcached` API at regular intervals. The interval is controlled by the `innodb_api_bk_commit_interval` configuration option, which has a default setting of 5 seconds.

When a `memcached` operation inserts or updates data in the underlying `InnoDB` table, the changed data is immediately visible to other `memcached` requests because the new value remains in the memory cache, even if it is not yet committed on the MySQL side.

## Transaction Isolation

When a `memcached` operation such as `get` or `incr` causes a query or DML operation on the underlying `InnoDB` table, you can control whether the operation sees the very latest data written to the table, only data that has been committed, or other variations of transaction `isolation level`. Use the `innodb_api_trx_level` configuration option to control this feature. The numeric values specified for this option correspond to isolation levels such as `REPEATABLE READ`. See the description of the `innodb_api_trx_level` option for information about other settings.

A strict isolation level ensures that data you retrieve is not rolled back or changed suddenly causing subsequent queries to return different values. However, strict isolation levels require greater `locking` overhead, which can cause waits. For a NoSQL-style application that does not use long-running transactions, you can typically use the default isolation level or switch to a less strict isolation level.

## Disabling Row Locks for memcached DML Operations

The `innodb_api_disable_rowlock` option can be used to disable row locks when `memcached` requests through the `daemon_memcached` plugin cause DML operations. By default, `innodb_api_disable_rowlock` is set to `OFF` which means that `memcached` requests row locks for `get` and `set` operations. When `innodb_api_disable_rowlock` is set to `ON`, `memcached` requests a table lock instead of row locks.

The `innodb_api_disable_rowlock` option is not dynamic. It must be specified at startup on the `mysqld` command line or entered in a MySQL configuration file.

## Allowing or Disallowing DDL

By default, you can perform `DDL` operations such as `ALTER TABLE` on tables used by the `daemon_memcached` plugin. To avoid potential slowdowns when these tables are used for high-throughput applications, disable DDL operations on these tables by enabling

`innodb_api_enable_md1` at startup. This option is less appropriate when accessing the same tables through both `memcached` and SQL, because it blocks `CREATE INDEX` statements on the tables, which could be important for running reporting queries.

## Storing Data on Disk, in Memory, or Both

The `innodb_memcache.cache_policies` table specifies whether to store data written through the `memcached` interface to disk (`innodb_only`, the default); in memory only, as with traditional `memcached` (`cache-only`); or both (`caching`).

With the `caching` setting, if `memcached` cannot find a key in memory, it searches for the value in an InnoDB table. Values returned from `get` calls under the `caching` setting could be out-of-date if the values were updated on disk in the InnoDB table but are not yet expired from the memory cache.

The caching policy can be set independently for `get`, `set` (including `incr` and `decr`), `delete`, and `flush` operations.

For example, you might allow `get` and `set` operations to query or update a table and the `memcached` memory cache at the same time (using the `caching` setting), while making `delete`, `flush`, or both operate only on the in-memory copy (using the `cache-only` setting). That way, deleting or flushing an item only expires the item from the cache, and the latest value is returned from the InnoDB table the next time the item is requested.

```
mysql> SELECT * FROM innodb_memcache.cache_policies;
+-----+-----+-----+-----+-----+
| policy_name | get_policy | set_policy | delete_policy | flush_policy |
+-----+-----+-----+-----+-----+
| cache_policy | innodb_only | innodb_only | innodb_only | innodb_only |
+-----+-----+-----+-----+-----+

mysql> UPDATE innodb_memcache.cache_policies SET set_policy = 'caching'
-> WHERE policy_name = 'cache_policy';
```

`innodb_memcache.cache_policies` values are only read at startup. After changing values in this table, uninstall and reinstall the `daemon_memcached` plugin to ensure that changes take effect.

```
mysql> UNINSTALL PLUGIN daemon_memcached;

mysql> INSTALL PLUGIN daemon_memcached soname "libmemcached.so";
```

### 15.20.5.5 Adapting DML Statements to memcached Operations

Benchmarks suggest that the `daemon_memcached` plugin speeds up DML operations (inserts, updates, and deletes) more than it speeds up queries. Therefore, consider focussing initial development efforts on write-intensive applications that are I/O-bound, and look for opportunities to use MySQL with the `daemon_memcached` plugin for new write-intensive applications.

Single-row DML statements are the easiest types of statements to turn into `memcached` operations. `INSERT` becomes `add`, `UPDATE` becomes `set`, `incr` or `decr`, and `DELETE` becomes `delete`. These operations are guaranteed to only affect one row when issued through the `memcached` interface, because the `key` is unique within the table.

In the following SQL examples, `t1` refers to the table used for `memcached` operations, based on the configuration in the `innodb_memcache.containers` table. `key` refers to the column listed under `key_columns`, and `val` refers to the column listed under `value_columns`.

```
INSERT INTO t1 (key,val) VALUES (some_key,some_value);
SELECT val FROM t1 WHERE key = some_key;
UPDATE t1 SET val = new_value WHERE key = some_key;
UPDATE t1 SET val = val + x WHERE key = some_key;
DELETE FROM t1 WHERE key = some_key;
```

The following `TRUNCATE TABLE` and `DELETE` statements, which remove all rows from the table, correspond to the `flush_all` operation, where `t1` is configured as the table for `memcached` operations, as in the previous example.

```
TRUNCATE TABLE t1;
DELETE FROM t1;
```

### 15.20.5.6 Performing DML and DDL Statements on the Underlying InnoDB Table

You can access the underlying `InnoDB` table (which is `test.demo_test` by default) through standard SQL interfaces. However, there are some restrictions:

- When querying a table that is also accessed through the `memcached` interface, remember that `memcached` operations can be configured to be committed periodically rather than after every write operation. This behavior is controlled by the `daemon_memcached_w_batch_size` option. If this option is set to a value greater than `1`, use `READ UNCOMMITTED` queries to find rows that were just inserted.

```
mysql> SET SESSION TRANSACTION ISOLATION LEVEL READ UNCOMMITTED;

mysql> SELECT * FROM demo_test;
```

|      |      |     |      |           |      |      |    |      |    |      |
|------|------|-----|------|-----------|------|------|----|------|----|------|
| cx   | cy   | c1  | cz   | c2        | ca   | CB   | c3 | cu   | c4 | C5   |
| NULL | NULL | all | NULL | 123456789 | NULL | NULL | 10 | NULL | 3  | NULL |

- When modifying a table using SQL that is also accessed through the `memcached` interface, you can configure `memcached` operations to start a new transaction periodically rather than for every read operation. This behavior is controlled by the `daemon_memcached_r_batch_size` option. If this option is set to a value greater than `1`, changes made to the table using SQL are not immediately visible to `memcached` operations.
- The `InnoDB` table is either IS (intention shared) or IX (intention exclusive) locked for all operations in a transaction. If you increase `daemon_memcached_r_batch_size` and `daemon_memcached_w_batch_size` substantially from their default value of `1`, the table is most likely locked between each operation, preventing `DDL` statements on the table.

## 15.20.6 The InnoDB memcached Plugin and Replication

Because the `daemon_memcached` plugin supports the MySQL `binary log`, updates made on a `master server` through the `memcached` interface can be replicated for backup, balancing intensive read workloads, and high availability. All `memcached` commands are supported with binary logging.

You do not need to set up the `daemon_memcached` plugin on `slave servers`. The primary advantage of this configuration is increased write throughput on the master. The speed of the replication mechanism is not affected.

The following sections show how to use the binary log capability when using the `daemon_memcached` plugin with MySQL replication. It is assumed that you have completed the setup described in [Section 15.20.3, “Setting Up the InnoDB memcached Plugin”](#).

### Enabling the InnoDB memcached Binary Log

- To use the `daemon_memcached` plugin with the MySQL `binary log`, enable the `innodb_api_enable_binlog` configuration option on the `master server`. This option can only be set at server startup. You must also enable the MySQL binary log on the master server using the `--log-bin` option. You can add these options to the MySQL configuration file, or on the `mysqld` command line.

```
mysqld ... --log-bin --innodb_api_enable_binlog=1
```

2. Configure the master and slave server, as described in [Section 18.1.2, “Setting Up Binary Log File Position Based Replication”](#).
3. Use `mysqldump` to create a master data snapshot, and sync the snapshot to the slave server.

```
master shell> mysqldump --all-databases --lock-all-tables > dbdump.db
slave shell> mysql < dbdump.db
```

4. On the master server, issue `SHOW MASTER STATUS` to obtain the master binary log coordinates.

```
mysql> SHOW MASTER STATUS;
```

5. On the slave server, use a `CHANGE MASTER TO` statement to set up a slave server using the master binary log coordinates.

```
mysql> CHANGE MASTER TO
      MASTER_HOST='localhost',
      MASTER_USER='root',
      MASTER_PASSWORD='',
      MASTER_PORT = 13000,
      MASTER_LOG_FILE='0.000001',
      MASTER_LOG_POS=114;
```

6. Start the slave.

```
mysql> START SLAVE;
```

If the error log prints output similar to the following, the slave is ready for replication.

```
2013-09-24T13:04:38.639684Z 49 [Note] Slave I/O thread: connected to
master 'root@localhost:13000', replication started in log '0.000001'
at position 114
```

## Testing the InnoDB memcached Replication Configuration

This example demonstrates how to test the [InnoDB memcached](#) replication configuration using the [memcached](#) and `telnet` to insert, update, and delete data. A MySQL client is used to verify results on the master and slave servers.

The example uses the `demo_test` table, which was created by the [innodb\\_memcached\\_config.sql](#) configuration script during the initial setup of the `daemon_memcached` plugin. The `demo_test` table contains a single example record.

1. Use the `set` command to insert a record with a key of `test1`, a flag value of `10`, an expiration value of `0`, a cas value of `1`, and a value of `t1`.

```
telnet 127.0.0.1 11211
Trying 127.0.0.1...
Connected to 127.0.0.1.
Escape character is '^]'.
set test1 10 0 1
t1
STORED
```

2. On the master server, check that the record was inserted into the `demo_test` table. Assuming the `demo_test` table was not previously modified, there should be two records. The example record with a key of `AA`, and the record you just inserted, with a key of `test1`. The `c1` column maps to the key, the `c2` column to the value, the `c3` column to the flag value, the `c4` column to the cas value, and the `c5` column to the expiration time. The expiration time was set to `0`, since it is unused.

```
mysql> SELECT * FROM test.demo_test;
```

| c1    | c2           | c3 | c4 | c5 |
|-------|--------------|----|----|----|
| AA    | HELLO, HELLO | 8  | 0  | 0  |
| test1 | t1           | 10 | 1  | 0  |

3. Check to verify that the same record was replicated to the slave server.

```
mysql> SELECT * FROM test.demo_test;
```

| c1    | c2           | c3 | c4 | c5 |
|-------|--------------|----|----|----|
| AA    | HELLO, HELLO | 8  | 0  | 0  |
| test1 | t1           | 10 | 1  | 0  |

4. Use the `set` command to update the key to a value of `new`.

```
telnet 127.0.0.1 11211
Trying 127.0.0.1...
Connected to 127.0.0.1.
Escape character is '^]'.
set test1 10 0 2
new
STORED
```

The update is replicated to the slave server (notice that the `cas` value is also updated).

```
mysql> SELECT * FROM test.demo_test;
```

| c1    | c2           | c3 | c4 | c5 |
|-------|--------------|----|----|----|
| AA    | HELLO, HELLO | 8  | 0  | 0  |
| test1 | new          | 10 | 2  | 0  |

5. Delete the `test1` record using a `delete` command.

```
telnet 127.0.0.1 11211
Trying 127.0.0.1...
Connected to 127.0.0.1.
Escape character is '^]'.
delete test1
DELETED
```

When the `delete` operation is replicated to the slave, the `test1` record on the slave is also deleted.

```
mysql> SELECT * FROM test.demo_test;
```

| c1 | c2           | c3 | c4 | c5 |
|----|--------------|----|----|----|
| AA | HELLO, HELLO | 8  | 0  | 0  |

6. Remove all rows from the table using the `flush_all` command.

```
telnet 127.0.0.1 11211
Trying 127.0.0.1...
Connected to 127.0.0.1.
Escape character is '^]'.
flush_all
OK
```

```
mysql> SELECT * FROM test.demo_test;
```

```
Empty set (0.00 sec)
```

7. Telnet to the master server and enter two new records.

```
telnet 127.0.0.1 11211
Trying 127.0.0.1...
Connected to 127.0.0.1.
Escape character is '^]'
set test2 10 0 4
again
STORED
set test3 10 0 5
again1
STORED
```

8. Confirm that the two records were replicated to the slave server.

```
mysql> SELECT * FROM test.demo_test;
+-----+-----+-----+-----+-----+
| c1    | c2    | c3    | c4    | c5    |
+-----+-----+-----+-----+-----+
| test2 | again | 10    | 4     | 0     |
| test3 | again1| 10    | 5     | 0     |
+-----+-----+-----+-----+-----+
```

9. Remove all rows from the table using the `flush_all` command.

```
telnet 127.0.0.1 11211
Trying 127.0.0.1...
Connected to 127.0.0.1.
Escape character is '^]'.
flush_all
OK
```

10. Check to ensure that the `flush_all` operation was replicated on the slave server.

```
mysql> SELECT * FROM test.demo_test;
Empty set (0.00 sec)
```

## InnoDB memcached Binary Log Notes

### Binary Log Format:

- Most `memcached` operations are mapped to **DML** statements (analogous to insert, delete, update). Since there is no actual SQL statement being processed by the MySQL server, all `memcached` commands (except for `flush_all`) use Row-Based Replication (RBR) logging, which is independent of any server `binlog_format` setting.
- The `memcached flush_all` command is mapped to the **TRUNCATE TABLE** command. Since **DDL** commands can only use statement-based logging, the `flush_all` command is replicated by sending a **TRUNCATE TABLE** statement.

### Transactions:

- The concept of **transactions** has not typically been part of `memcached` applications. For performance considerations, `daemon_memcached_r_batch_size` and `daemon_memcached_w_batch_size` are used to control the batch size for read and write transactions. These settings do not affect replication. Each SQL operation on the underlying **InnoDB** table is replicated after successful completion.
- The default value of `daemon_memcached_w_batch_size` is `1`, which means that each `memcached` write operation is committed immediately. This default setting incurs a certain amount of performance overhead to avoid inconsistencies in the data that is visible on the master and slave servers. The replicated records are always available immediately on the slave server. If you set `daemon_memcached_w_batch_size` to a value greater than `1`, records inserted or updated

through `memcached` are not immediately visible on the master server; to view the records on the master server before they are committed, issue `SET TRANSACTION ISOLATION LEVEL READ UNCOMMITTED`.

## 15.20.7 InnoDB memcached Plugin Internals

### InnoDB API for the InnoDB memcached Plugin

The `InnoDB memcached` engine accesses `InnoDB` through `InnoDB` APIs, most of which are directly adopted from embedded `InnoDB`. `InnoDB` API functions are passed to the `InnoDB memcached` engine as callback functions. `InnoDB` API functions access the `InnoDB` tables directly, and are mostly DML operations with the exception of `TRUNCATE TABLE`.

`memcached` commands are implemented through the `InnoDB memcached` API. The following table outlines how `memcached` commands are mapped to DML or DDL operations.

**Table 15.15 memcached Commands and Associated DML or DDL Operations**

| memcached Command      | DML or DDL Operations   |
|------------------------|---|
| <code>get</code>       | a read/fetch command  |
| <code>set</code>       | a search followed by an <code>INSERT</code> or <code>UPDATE</code> (depending on whether or not a key exists) |
| <code>add</code>       | a search followed by an <code>INSERT</code> or <code>UPDATE</code>  |
| <code>replace</code>   | a search followed by an <code>UPDATE</code>   |
| <code>append</code>    | a search followed by an <code>UPDATE</code> (appends data to the result before <code>UPDATE</code> )          |
| <code>prepend</code>   | a search followed by an <code>UPDATE</code> (prepends data to the result before <code>UPDATE</code> )         |
| <code>incr</code>      | a search followed by an <code>UPDATE</code>   |
| <code>decr</code>      | a search followed by an <code>UPDATE</code>   |
| <code>delete</code>    | a search followed by a <code>DELETE</code>  |
| <code>flush_all</code> | <code>TRUNCATE TABLE</code> (DDL)   |

### InnoDB memcached Plugin Configuration Tables

This section describes configuration tables used by the `daemon_memcached` plugin. The `cache_policies` table, `config_options` table, and `containers` table are created by the `innodb_memcached_config.sql` configuration script in the `innodb_memcache` database.

```
mysql> USE innodb_memcache;
Database changed
mysql> SHOW TABLES;
+-----+
| Tables_in_innodb_memcache |
+-----+
| cache_policies            |
| config_options            |
| containers                |
+-----+
```

#### cache\_policies Table

The `cache_policies` table defines a cache policy for the `InnoDB memcached` installation. You can specify individual policies for `get`, `set`, `delete`, and `flush` operations, within a single cache policy. The default setting for all operations is `innodb_only`.

- `innodb_only`: Use `InnoDB` as the data store.
- `cache-only`: Use the `memcached` engine as the data store.

- **cacheing**: Use both InnoDB and the memcached engine as data stores. In this case, if memcached cannot find a key in memory, it searches for the value in an InnoDB table.
- **disable**: Disable caching.

**Table 15.16 cache\_policies Columns**

| Column                     | Description  |
|----------------------------|--|
| <code>policy_name</code>   | Name of the cache policy. The default cache policy name is <code>cache_policy</code> .   |
| <code>get_policy</code>    | The cache policy for get operations. Valid values are <code>innodb_only</code> , <code>cache-only</code> , <code>cacheing</code> , or <code>disabled</code> . The default setting is <code>innodb_only</code> .    |
| <code>set_policy</code>    | The cache policy for set operations. Valid values are <code>innodb_only</code> , <code>cache-only</code> , <code>cacheing</code> , or <code>disabled</code> . The default setting is <code>innodb_only</code> .    |
| <code>delete_policy</code> | The cache policy for delete operations. Valid values are <code>innodb_only</code> , <code>cache-only</code> , <code>cacheing</code> , or <code>disabled</code> . The default setting is <code>innodb_only</code> . |
| <code>flush_policy</code>  | The cache policy for flush operations. Valid values are <code>innodb_only</code> , <code>cache-only</code> , <code>cacheing</code> , or <code>disabled</code> . The default setting is <code>innodb_only</code> .  |

## config\_options Table

The `config_options` table stores memcached-related settings that can be changed at runtime using SQL. Supported configuration options are `separator` and `table_map_delimiter`.

**Table 15.17 config\_options Columns**

| Column            | Description   |
|-------------------|---|
| <code>Name</code> | <p>Name of the memcached-related configuration option. The following configuration options are supported by the <code>config_options</code> table:</p> <ul style="list-style-type: none"> <li>• <b>separator</b>: Used to separate values of a long string into separate values when there are multiple <code>value_columns</code> defined. By default, the <code>separator</code> is a <code> </code> character. For example, if you define <code>col1</code>, <code>col2</code> as value columns, and you define <code> </code> as the separator, you can issue the following memcached command to insert values into <code>col1</code> and <code>col2</code>, respectively: <pre>set keyx 10 0 19 valuecolx valuecoly</pre> <code>valuecol1x</code> is stored in <code>col1</code> and <code>valuecoly</code> is stored in <code>col2</code>.</li> <li>• <b>table_map_delimiter</b>: The character separating the schema name and the table name when you use the <code>@@</code> notation in a key name to access a key in a specific table. For example, <code>@@t1.some_key</code> and <code>@@t2.some_key</code> have the same key value, but are stored in different tables.</li> </ul> |

| Column | Description   |
|--------|---|
| Value  | The value assigned to the <code>memcached</code> -related configuration option. |

## containers Table

The `containers` table is the most important of the three configuration tables. Each `InnoDB` table that is used to store `memcached` values must have an entry in the `containers` table. The entry provides a mapping between `InnoDB` table columns and container table columns, which is required for `memcached` to work with `InnoDB` tables.

The `containers` table contains a default entry for the `test.demo_test` table, which is created by the `innodb_memcached_config.sql` configuration script. To use the `daemon_memcached` plugin with your own `InnoDB` table, you must create an entry in the `containers` table.

**Table 15.18 containers Columns**

| Column                     | Description  |
|----------------------------|--|
| <code>name</code>          | The name given to the container. If an <code>InnoDB</code> table is not requested by name using <code>@@</code> notation, the <code>daemon_memcached</code> plugin uses the <code>InnoDB</code> table with a <code>containers.name</code> value of <code>default</code> . If there is no such entry, the first entry in the <code>containers</code> table, ordered alphabetically by <code>name</code> (ascending), determines the default <code>InnoDB</code> table.  |
| <code>db_schema</code>     | The name of the database where the <code>InnoDB</code> table resides. This is a required value.  |
| <code>db_table</code>      | The name of the <code>InnoDB</code> table that stores <code>memcached</code> values. This is a required value.   |
| <code>key_columns</code>   | The column in the <code>InnoDB</code> table that contains lookup key values for <code>memcached</code> operations. This is a required value.   |
| <code>value_columns</code> | The <code>InnoDB</code> table columns (one or more) that store <code>memcached</code> data. Multiple columns can be specified using the separator character specified in the <code>innodb_memcached.config_options</code> table. By default, the separator is a pipe character ( <code> </code> ). To specify multiple columns, separate them with the defined separator character. For example: <code>col1 col2 col3</code> . This is a required value.   |
| <code>flags</code>         | The <code>InnoDB</code> table columns that are used as flags (a user-defined numeric value that is stored and retrieved along with the main value) for <code>memcached</code> . A flag value can be used as a column specifier for some operations (such as <code>incr</code> , <code>prepend</code> ) if a <code>memcached</code> value is mapped to multiple columns, so that an operation is performed on a specified column. For example, if you have mapped a <code>value_columns</code> to three <code>InnoDB</code> table columns, and only want the increment operation performed on one columns, use the <code>flags</code> column to specify the column. If you do not use the <code>flags</code> column, set a value of <code>0</code> to indicate that it is unused. |

| Column                              | Description  |
|-------------------------------------|--|
| <code>cas_column</code>             | The InnoDB table column that stores compare-and-swap (cas) values. The <code>cas_column</code> value is related to the way <code>memcached</code> hashes requests to different servers and caches data in memory. Because the InnoDB <code>memcached</code> plugin is tightly integrated with a single <code>memcached</code> daemon, and the in-memory caching mechanism is handled by MySQL and the InnoDB buffer pool, this column is rarely needed. If you do not use this column, set a value of 0 to indicate that it is unused.   |
| <code>expire_time_column</code>     | The InnoDB table column that stores expiration values. The <code>expire_time_column</code> value is related to the way <code>memcached</code> hashes requests to different servers and caches data in memory. Because the InnoDB <code>memcached</code> plugin is tightly integrated with a single <code>memcached</code> daemon, and the in-memory caching mechanism is handled by MySQL and the InnoDB buffer pool, this column is rarely needed. If you do not use this column, set a value of 0 to indicate that the column is unused. As of MySQL 5.7.8, maximum expire time is defined as <code>INT_MAX32</code> or 2147483647 seconds (approximately 68 years). |
| <code>unique_idx_name_on_key</code> | The name of the index on the key column. It must be a unique index. It can be the <code>primary key</code> or a <code>secondary index</code> . Preferably, use the primary key of the InnoDB table. Using the primary key avoids a lookup that is performed when using a secondary index. You cannot make a <code>covering index</code> for <code>memcached</code> lookups; InnoDB returns an error if you try to define a composite secondary index over both the key and value columns.  |

### containers Table Column Constraints

- You must supply a value for `db_schema`, `db_name`, `key_columns`, `value_columns` and `unique_idx_name_on_key`. Specify 0 for `flags`, `cas_column`, and `expire_time_column` if they are unused. Failing to do so could cause your setup to fail.
- `key_columns`: The maximum limit for a `memcached` key is 250 characters, which is enforced by `memcached`. The mapped key must be a non-Null `CHAR` or `VARCHAR` type.
- `value_columns`: Must be mapped to a `CHAR`, `VARCHAR`, or `BLOB` column. There is no length restriction and the value can be NULL.
- `cas_column`: The `cas` value is a 64 bit integer. It must be mapped to a `BIGINT` of at least 8 bytes. If you do not use this column, set a value of 0 to indicate that it is unused.
- `expiration_time_column`: Must mapped to an `INTEGER` of at least 4 bytes. Expiration time is defined as a 32-bit integer for Unix time (the number of seconds since January 1, 1970, as a 32-bit value), or the number of seconds starting from the current time. For the latter, the number of seconds may not exceed 60\*60\*24\*30 (the number of seconds in 30 days). If the number sent by a client is larger, the server considers it to be a real Unix time value rather than an offset from the current time. If you do not use this column, set a value of 0 to indicate that it is unused.
- `flags`: Must be mapped to an `INTEGER` of at least 32-bits and can be NULL. If you do not use this column, set a value of 0 to indicate that it is unused.

A pre-check is performed at plugin load time to enforce column constraints. If mismatches are found, the plugin will not load.

## Multiple Value Column Mapping

- During plugin initialization, when `InnoDB memcached` is configured with information defined in the `containers` table, each mapped column defined in `containers.value_columns` is verified against the mapped `InnoDB` table. If multiple `InnoDB` table columns are mapped, there is a check to ensure that each column exists and is the right type.
- At run-time, for `memcached` insert operations, if there are more delimited values than the number of mapped columns, only the number of mapped values are taken. For example, if there are six mapped columns, and seven delimited values are provided, only the first six delimited values are taken. The seventh delimited value is ignored.
- If there are fewer delimited values than mapped columns, unfilled columns are set to NULL. If an unfilled column cannot be set to NULL, insert operations will fail.
- If a table has more columns than mapped values, the extra columns do not affect results.

## The demo\_test Example Table

The `innodb_memcached_config.sql` configuration script creates a `demo_test` table in the `test` database, which can be used to verify `InnoDB memcached` plugin installation immediately after setup.

The `innodb_memcached_config.sql` configuration script also creates an entry for the `demo_test` table in the `innodb_memcache.containers` table.

```
mysql> SELECT * FROM innodb_memcache.containers\G
***** 1. row *****
      name: aaa
    db_schema: test
      db_table: demo_test
    key_columns: c1
  value_columns: c2
         flags: c3
      cas_column: c4
  expire_time_column: c5
unique_idx_name_on_key: PRIMARY

mysql> SELECT * FROM test.demo_test;
+-----+-----+-----+-----+
| c1 | c2 | c3 | c4 | c5 |
+-----+-----+-----+-----+
| AA | HELLO, HELLO | 8 | 0 | 0 |
+-----+-----+-----+-----+
```

## 15.20.8 Troubleshooting the InnoDB memcached Plugin

This section describes issues that you may encounter when using the `InnoDB memcached` plugin.

- If you encounter the following error in the MySQL error log, the server might fail to start:

```
failed to set rlimit for open files. Try running as root or requesting
smaller maxconns value.
```

The error message is from the `memcached` daemon. One solution is to raise the OS limit for the number of open files. The commands for checking and increasing the open file limit varies by operating system. This example shows commands for Linux and OS X:

```
# Linux
shell> ulimit -n
1024
shell> ulimit -n 4096
```

```
shell> ulimit -n
4096

# OS X
shell> ulimit -n
256
shell> ulimit -n 4096
shell> ulimit -n
4096
```

The other solution is to reduce the number of concurrent connections permitted for the `memcached` daemon. To do so, encode the `-c memcached` option in the `daemon_memcached_option` configuration parameter in the MySQL configuration file. The `-c` option has a default value of 1024.

```
[mysqld]
...
loose-daemon_memcached_option='-c 64'
```

- To troubleshoot problems where the `memcached` daemon is unable to store or retrieve `InnoDB` table data, encode the `-vvv memcached` option in the `daemon_memcached_option` configuration parameter in the MySQL configuration file. Examine the MySQL error log for debug output related to `memcached` operations.

```
[mysqld]
...
loose-daemon_memcached_option='-vvv'
```

- If columns specified to hold `memcached` values are the wrong data type, such as a numeric type instead of a string type, attempts to store key/value pairs will fail with no specific error code or message.
- If the `daemon_memcached` plugin causes MySQL server startup issues, you can temporarily disable the `daemon_memcached` plugin while troubleshooting by adding this line under the `[mysqld]` group in the MySQL configuration file:

```
daemon_memcached=OFF
```

For example, if you run the `INSTALL PLUGIN` statement before running the `innodb_memcached_config.sql` configuration script to set up the necessary database and tables, the server might crash and fail to start. The server could also fail to start if you incorrectly configure an entry in the `innodb_memcache.containers` table.

To uninstall the `memcached` plugin for a MySQL instance, issue the following statement:

```
mysql> UNINSTALL PLUGIN daemon_memcached;
```

- If you run more than one instance of MySQL on the same machine with the `daemon_memcached` plugin enabled in each instance, use the `daemon_memcached_option` configuration parameter to specify a unique `memcached` port for each `daemon_memcached` plugin.
- If an SQL statement cannot find the `InnoDB` table or finds no data in the table, but `memcached` API calls retrieve the expected data, you may be missing an entry for the `InnoDB` table in the `innodb_memcache.containers` table, or you may have not switched to the correct `InnoDB` table by issuing a `get` or `set` request using `@@table_id` notation. This problem could also occur if you change an existing entry in the `innodb_memcache.containers` table without restarting the MySQL server afterward. The free-form storage mechanism is flexible enough that your requests to store or retrieve a multi-column value such as `col1|col2|col3` may still work, even if the daemon is using the `test.demo_test` table which stores values in a single column.
- When defining your own `InnoDB` table for use with the `daemon_memcached` plugin, and columns in the table are defined as `NOT NULL`, ensure that values are supplied for the `NOT NULL` columns

when inserting a record for the table into the `innodb_memcache.containers` table. If the `INSERT` statement for the `innodb_memcache.containers` record contains fewer delimited values than there are mapped columns, unfilled columns are set to `NULL`. Attempting to insert a `NULL` value into a `NOT NULL` column causes the `INSERT` to fail, which may only become evident after you reinitialize the `daemon_memcached` plugin to apply changes to the `innodb_memcache.containers` table.

- If `cas_column` and `expire_time_column` fields of the `innodb_memcached.containers` table are set to `NULL`, the following error will be returned when attempting to load the `memcached` plugin:

```
InnoDB_Memcached: column 6 in the entry for config table 'containers' in
database 'innodb_memcache' has an invalid NULL value.
```

The `memcached` plugin rejects usage of `NULL` in the `cas_column` and `expire_time_column` columns. Set the value of these columns to `0` when the columns are unused.

- As the length of the `memcached` key and values increase, you might encounter size and length limits.
  - When the key exceeds 250 bytes, `memcached` operations return an error. This is currently a fixed limit within `memcached`.
  - `InnoDB` table limits may be encountered if values exceed 768 bytes in size, 3072 bytes in size, or half of the `innodb_page_size` value. These limits primarily apply if you intend to create an index on a value column to run report-generating queries on that column using SQL. See [Section 15.8.8, “Limits on InnoDB Tables”](#) for details.
  - The maximum size for the key-value combination is 1 MB.
- If you share configuration files across MySQL servers of different versions, using the latest configuration options for the `daemon_memcached` plugin could cause startup errors on older MySQL versions. To avoid compatibility problems, use the `loose` prefix with option names. For example, use `loose-daemon_memcached_option='-c 64'` instead of `daemon_memcached_option='-c 64'`.
- There is no restriction or check in place to validate character set settings. `memcached` stores and retrieves keys and values in bytes and is therefore not character set sensitive. However, you must ensure that the `memcached` client and the MySQL table use the same character set.
- `memcached` connections are blocked from accessing tables that contain an indexed virtual column. Accessing an indexed virtual column requires a callback to the server, but a `memcached` connection does not have access to the server code.

## 15.21 InnoDB Troubleshooting

The following general guidelines apply to troubleshooting `InnoDB` problems:

- When an operation fails or you suspect a bug, look at the MySQL server error log (see [Section 6.4.2, “The Error Log”](#)). [Section B.3, “Server Error Codes and Messages”](#) provides troubleshooting information for some of the common `InnoDB`-specific errors that you may encounter.
- If the failure is related to a `deadlock`, run with the `innodb_print_all_deadlocks` option enabled so that details about each deadlock are printed to the MySQL server error log. For information about deadlocks, see [Section 15.5.5, “Deadlocks in InnoDB”](#).
- Issues relating to the `InnoDB` data dictionary include failed `CREATE TABLE` statements (orphan table files), inability to open `InnoDB` files, and `system cannot find the path specified` errors. For information about these sorts of problems and errors, see [Section 15.21.3, “Troubleshooting InnoDB Data Dictionary Operations”](#).
- When troubleshooting, it is usually best to run the MySQL server from the command prompt, rather than through `mysqld_safe` or as a Windows service. You can then see what `mysqld` prints to the

console, and so have a better grasp of what is going on. On Windows, start `mysqld` with the `--console` option to direct the output to the console window.

- Enable the [InnoDB Monitors](#) to obtain information about a problem (see [Section 15.17, “InnoDB Monitors”](#)). If the problem is performance-related, or your server appears to be hung, you should enable the standard Monitor to print information about the internal state of [InnoDB](#). If the problem is with locks, enable the Lock Monitor. If the problem is with table creation, tablespaces, or data dictionary operations, refer to the [InnoDB Information Schema system tables](#) to examine contents of the [InnoDB](#) internal data dictionary.

[InnoDB](#) temporarily enables standard [InnoDB](#) Monitor output under the following conditions:

- A long semaphore wait
- [InnoDB](#) cannot find free blocks in the buffer pool
- Over 67% of the buffer pool is occupied by lock heaps or the adaptive hash index
- If you suspect that a table is corrupt, run `CHECK TABLE` on that table.

### 15.21.1 Troubleshooting InnoDB I/O Problems

The troubleshooting steps for [InnoDB](#) I/O problems depend on when the problem occurs: during startup of the MySQL server, or during normal operations when a DML or DDL statement fails due to problems at the file system level.

#### Initialization Problems

If something goes wrong when [InnoDB](#) attempts to initialize its tablespace or its log files, delete all files created by [InnoDB](#): all `ibdata` files and all `ib_logfile` files. If you already created some [InnoDB](#) tables, also delete the corresponding `.frm` files for these tables, and any `.ibd` files if you are using multiple tablespaces, from the MySQL database directories. Then try the [InnoDB](#) database creation again. For easiest troubleshooting, start the MySQL server from a command prompt so that you see what is happening.

#### Runtime Problems

If [InnoDB](#) prints an operating system error during a file operation, usually the problem has one of the following solutions:

- Make sure the [InnoDB](#) data file directory and the [InnoDB](#) log directory exist.
- Make sure `mysqld` has access rights to create files in those directories.
- Make sure `mysqld` can read the proper `my.cnf` or `my.ini` option file, so that it starts with the options that you specified.
- Make sure the disk is not full and you are not exceeding any disk quota.
- Make sure that the names you specify for subdirectories and data files do not clash.
- Doublecheck the syntax of the `innodb_data_home_dir` and `innodb_data_file_path` values. In particular, any `MAX` value in the `innodb_data_file_path` option is a hard limit, and exceeding that limit causes a fatal error.

### 15.21.2 Forcing InnoDB Recovery

To investigate database page corruption, you might dump your tables from the database with `SELECT ... INTO OUTFILE`. Usually, most of the data obtained in this way is intact. Serious corruption might cause `SELECT * FROM tbl_name` statements or [InnoDB](#) background operations

to crash or assert, or even cause InnoDB roll-forward recovery to crash. In such cases, you can use the `innodb_force_recovery` option to force the InnoDB storage engine to start up while preventing background operations from running, so that you can dump your tables. For example, you can add the following line to the `[mysqld]` section of your option file before restarting the server:

```
[mysqld]
innodb_force_recovery = 1
```

### Warning

Only set `innodb_force_recovery` to a value greater than 0 in an emergency situation, so that you can start InnoDB and dump your tables. Before doing so, ensure that you have a backup copy of your database in case you need to recreate it. Values of 4 or greater can permanently corrupt data files. Only use an `innodb_force_recovery` setting of 4 or greater on a production server instance after you have successfully tested the setting on separate physical copy of your database. When forcing InnoDB recovery, you should always start with `innodb_force_recovery=1` and only increase the value incrementally, as necessary.

`innodb_force_recovery` is 0 by default (normal startup without forced recovery). The permissible nonzero values for `innodb_force_recovery` are 1 to 6. A larger value includes the functionality of lesser values. For example, a value of 3 includes all of the functionality of values 1 and 2.

If you are able to dump your tables with an `innodb_force_recovery` value of 3 or less, then you are relatively safe that only some data on corrupt individual pages is lost. A value of 4 or greater is considered dangerous because data files can be permanently corrupted. A value of 6 is considered drastic because database pages are left in an obsolete state, which in turn may introduce more corruption into B-trees and other database structures.

As a safety measure, InnoDB prevents `INSERT`, `UPDATE`, or `DELETE` operations when `innodb_force_recovery` is greater than 0. As of MySQL 5.7.3, an `innodb_force_recovery` setting of 4 or greater places InnoDB in read-only mode.

- 1 (`SRV_FORCE_IGNORE_CORRUPT`)

Lets the server run even if it detects a corrupt page. Tries to make `SELECT * FROM tbl_name` jump over corrupt index records and pages, which helps in dumping tables.

- 2 (`SRV_FORCE_NO_BACKGROUND`)

Prevents the master thread and any purge threads from running. If a crash would occur during the purge operation, this recovery value prevents it.

- 3 (`SRV_FORCE_NO_TRX_UNDO`)

Does not run transaction rollbacks after crash recovery.

- 4 (`SRV_FORCE_NO_IBUF_MERGE`)

Prevents insert buffer merge operations. If they would cause a crash, does not do them. Does not calculate table statistics. This value can permanently corrupt data files. After using this value, be prepared to drop and recreate all secondary indexes. As of MySQL 5.7.3, sets InnoDB to read-only.

- 5 (`SRV_FORCE_NO_UNDO_LOG_SCAN`)

Does not look at undo logs when starting the database: InnoDB treats even incomplete transactions as committed. This value can permanently corrupt data files. As of MySQL 5.7.3, sets InnoDB to read-only.

- 6 (`SRV_FORCE_NO_LOG_REDO`)

Does not do the [redo log](#) roll-forward in connection with recovery. This value can permanently corrupt data files. Leaves database pages in an obsolete state, which in turn may introduce more corruption into B-trees and other database structures. As of MySQL 5.7.3, sets [InnoDB](#) to read-only.

You can [SELECT](#) from tables to dump them. With an [innodb\\_force\\_recovery](#) value of 3 or less you can [DROP](#) or [CREATE](#) tables. As of MySQL 5.7.9, [DROP TABLE](#) is also supported with an [innodb\\_force\\_recovery](#) value greater than 3.

If you know that a given table is causing a crash on rollback, you can drop it. If you encounter a runaway rollback caused by a failing mass import or [ALTER TABLE](#), you can kill the [mysqld](#) process and set [innodb\\_force\\_recovery](#) to 3 to bring the database up without the rollback, and then [DROP](#) the table that is causing the runaway rollback.

If corruption within the table data prevents you from dumping the entire table contents, a query with an [ORDER BY primary\\_key DESC](#) clause might be able to dump the portion of the table after the corrupted part.

If a high [innodb\\_force\\_recovery](#) value is required to start [InnoDB](#), there may be corrupted data structures that could cause complex queries (queries containing [WHERE](#), [ORDER BY](#), or other clauses) to fail. In this case, you may only be able to run basic [SELECT \\* FROM t](#) queries.

### 15.21.3 Troubleshooting InnoDB Data Dictionary Operations

Information about table definitions is stored both in the [.frm](#) files, and in the InnoDB [data dictionary](#). If you move [.frm](#) files around, or if the server crashes in the middle of a data dictionary operation, these sources of information can become inconsistent.

If a data dictionary corruption or consistency issue prevents you from starting [InnoDB](#), see [Section 15.21.2, “Forcing InnoDB Recovery”](#) for information about manual recovery.

#### CREATE TABLE Failure Due to Orphan Table

A symptom of an out-of-sync data dictionary is that a [CREATE TABLE](#) statement fails. If this occurs, look in the server's error log. If the log says that the table already exists inside the [InnoDB](#) internal data dictionary, you have an orphan table inside the [InnoDB](#) tablespace files that has no corresponding [.frm](#) file. The error message looks like this:

```
InnoDB: Error: table test/parent already exists in InnoDB internal
InnoDB: data dictionary. Have you deleted the .frm file
InnoDB: and not used DROP TABLE? Have you used DROP DATABASE
InnoDB: for InnoDB tables in MySQL version <= 3.23.43?
InnoDB: See the Restrictions section of the InnoDB manual.
InnoDB: You can drop the orphaned table inside InnoDB by
InnoDB: creating an InnoDB table with the same name in another
InnoDB: database and moving the .frm file to the current database.
InnoDB: Then MySQL thinks the table exists, and DROP TABLE will
InnoDB: succeed.
```

You can drop the orphan table by following the instructions given in the error message. If you are still unable to use [DROP TABLE](#) successfully, the problem may be due to name completion in the [mysql](#) client. To work around this problem, start the [mysql](#) client with the [--skip-auto-rehash](#) option and try [DROP TABLE](#) again. (With name completion on, [mysql](#) tries to construct a list of table names, which fails when a problem such as just described exists.)

#### Cannot Open File Error

Another symptom of an out-of-sync data dictionary is that MySQL prints an error that it cannot open an [InnoDB](#) file:

```
ERROR 1016: Can't open file: 'child2.ibd'. (errno: 1)
```

In the error log you can find a message like this:

```
InnoDB: Cannot find table test/child2 from the internal data dictionary
InnoDB: of InnoDB though the .frm file for the table exists. Maybe you
InnoDB: have deleted and recreated InnoDB data files but have forgotten
InnoDB: to delete the corresponding .frm files of InnoDB tables?
```

This means that there is an orphan `.frm` file without a corresponding table inside `InnoDB`. You can drop the orphan `.frm` file by deleting it manually.

## Orphan Intermediate Tables

If MySQL exits in the middle of an in-place `ALTER TABLE` operation (`ALGORITHM=INPLACE`), you may be left with an orphan intermediate table that takes up space on your system. Also, an orphan intermediate table in an otherwise empty `general tablespace` will prevent you from dropping the general tablespace. This section describes how to identify and remove orphan intermediate tables.

Intermediate table names begin with an `#sql-ib` prefix (e.g., `#sql-ib87-856498050`). The accompanying `.frm` file has an `#sql-*` prefix and is named differently (e.g., `#sql-36ab_2.frm`).

To identify orphan intermediate tables on your system, you can query `INFORMATION_SCHEMA.INNODB_SYS_TABLES`. Look for table names that begin with `#sql`. If the original table resides in a `file-per-table` tablespace, the tablespace file (the `#sql-*.ibd` file) for the orphan intermediate table should be visible in the database directory.

```
SELECT * FROM INFORMATION_SCHEMA.INNODB_SYS_TABLES WHERE NAME LIKE '%#sql%';
```

To remove an orphan intermediate table, perform the following steps:

1. In the database directory, rename the `#sql-*.frm` file to match the base name of the orphan intermediate table:

```
shell> mv #sql-36ab_2.frm #sql-ib87-856498050.frm
```

### Note

If there is no `.frm` file, you can recreate it. The `.frm` file must have the same table schema as the orphan intermediate table (it must have the same columns and indexes) and must be placed in the database directory of the orphan intermediate table.

2. Drop the orphan intermediate table by issuing a `DROP TABLE` statement, prefixing the name of the table with `#mysql50#` and enclosing the table name in backticks. For example:

```
mysql> DROP TABLE `#mysql50##sql-ib87-856498050`;
```

The `#mysql50#` prefix tells MySQL to ignore `file name safe encoding` introduced in MySQL 5.1. Enclosing the table name in backticks is required to perform SQL statements on table names with special characters such as `"#"`.

### Note

If a crash occurs during an in-place `ALTER TABLE` operation that was moving a table to a different tablespace, the recovery process restores the table to its original location but leaves an orphan intermediate table in the destination tablespace.

## Orphan Temporary Tables

If MySQL exits in the middle of a table-copying `ALTER TABLE` operation (`ALGORITHM=COPY`), you may be left with an orphan temporary table that takes up space on your system. Also, an orphan temporary

table in an otherwise empty [general tablespace](#) will prevent you from dropping the general tablespace. This section describes how to identify and remove orphan temporary tables.

Orphan temporary table names begin with an `#sql-` prefix (e.g., `#sql-540_3`). The accompanying `.frm` file has the same base name as the orphan temporary table.

#### Note

If there is no `.frm` file, you can recreate it. The `.frm` file must have the same table schema as the orphan temporary table (it must have the same columns and indexes) and must be placed in the database directory of the orphan temporary table.

To identify orphan temporary tables on your system, you can query `INFORMATION_SCHEMA.INNODB_SYS_TABLES`. Look for table names that begin with `#sql`. If the original table resides in a [file-per-table](#) tablespace, the tablespace file (the `#sql-*.ibd` file) for the orphan temporary table should be visible in the database directory.

```
SELECT * FROM INFORMATION_SCHEMA.INNODB_SYS_TABLES WHERE NAME LIKE '%#sql%';
```

To remove an orphan temporary table, drop the table by issuing a `DROP TABLE` statement, prefixing the name of the table with `#mysql50#` and enclosing the table name in backticks. For example:

```
mysql> DROP TABLE `#mysql50##sql-540_3`;
```

The `#mysql50#` prefix tells MySQL to ignore [file name safe encoding](#) introduced in MySQL 5.1. Enclosing the table name in backticks is required to perform SQL statements on table names with special characters such as `"#"`.

## Tablespace Does Not Exist

With `innodb_file_per_table` enabled, the following message might occur if the `.frm` or `.ibd` files (or both) are missing:

```
InnoDB: in InnoDB data dictionary has tablespace id N,
InnoDB: but tablespace with that id or name does not exist. Have
InnoDB: you deleted or moved .ibd files?
InnoDB: This may also be a table created with CREATE TEMPORARY TABLE
InnoDB: whose .ibd and .frm files MySQL automatically removed, but the
InnoDB: table still exists in the InnoDB internal data dictionary.
```

If this occurs, try the following procedure to resolve the problem:

1. Create a matching `.frm` file in some other database directory and copy it to the database directory where the orphan table is located.
2. Issue `DROP TABLE` for the original table. That should successfully drop the table and InnoDB should print a warning to the error log that the `.ibd` file was missing.

## Restoring Orphan File-Per-Table ibd Files

This procedure describes how to restore orphan [file-per-table](#) `.ibd` files to another MySQL instance. You might use this procedure if the system tablespace is lost or unrecoverable and you want to restore `.ibd` file backups on a new MySQL instance.

The procedure is not supported for [general tablespace](#) `.ibd` files.

The procedure assumes that you only have `.ibd` file backups, you are recovering to the same version of MySQL that initially created the orphan `.ibd` files, and that `.ibd` file backups are clean. See [Section 15.8.4, "Moving or Copying InnoDB Tables to Another Machine"](#) for information about creating clean backups.

Tablespace copying limitations outlined in [Section 15.7.6, “Copying File-Per-Table Tablespaces to Another Server”](#) are applicable to this procedure.

1. On the new MySQL instance, recreate the table in a database of the same name.

```
mysql> CREATE DATABASE sakila;

mysql> USE sakila;

mysql> CREATE TABLE actor (
->   actor_id SMALLINT UNSIGNED NOT NULL AUTO_INCREMENT,
->   first_name VARCHAR(45) NOT NULL,
->   last_name VARCHAR(45) NOT NULL,
->   last_update TIMESTAMP NOT NULL DEFAULT CURRENT_TIMESTAMP ON UPDATE CURRENT_TIMESTAMP,
->   PRIMARY KEY (actor_id),
->   KEY idx_actor_last_name (last_name)
-> )ENGINE=InnoDB DEFAULT CHARSET=utf8;
```

2. Discard the tablespace of the newly created table.

```
mysql> ALTER TABLE sakila.actor DISCARD TABLESPACE;
```

3. Copy the orphan `.ibd` file from your backup directory to the new database directory.

```
shell> cp /backup_directory/actor.ibd path/to/mysql-5.7/data/sakila/
```

4. Ensure that the `.ibd` file has the necessary file permissions.
5. Import the orphan `.ibd` file. A warning is issued indicating that `InnoDB` will attempt to import the file without schema verification.

```
mysql> ALTER TABLE sakila.actor IMPORT TABLESPACE; SHOW WARNINGS;
Query OK, 0 rows affected, 1 warning (0.15 sec)

Warning | 1810 | InnoDB: IO Read error: (2, No such file or directory)
Error opening './sakila/actor.cfg', will attempt to import
without schema verification
```

6. Query the table to verify that the `.ibd` file was successfully restored.

```
mysql> SELECT COUNT(*) FROM sakila.actor;
+-----+
| count(*) |
+-----+
|      200 |
+-----+
```

## 15.21.4 InnoDB Error Handling

The following items describe how `InnoDB` performs error handling. `InnoDB` sometimes rolls back only the statement that failed, other times it rolls back the entire transaction.

- If you run out of file space in a `tablespace`, a MySQL `Table is full` error occurs and `InnoDB` rolls back the SQL statement.
- A transaction `deadlock` causes `InnoDB` to `roll back` the entire `transaction`. Retry the whole transaction when this happens.

A lock wait timeout causes `InnoDB` to roll back only the single statement that was waiting for the lock and encountered the timeout. (To have the entire transaction roll back, start the server with the `--innodb_rollback_on_timeout` option.) Retry the statement if using the current behavior, or the entire transaction if using `--innodb_rollback_on_timeout`.

Both deadlocks and lock wait timeouts are normal on busy servers and it is necessary for applications to be aware that they may happen and handle them by retrying. You can make them less likely by doing as little work as possible between the first change to data during a transaction

and the commit, so the locks are held for the shortest possible time and for the smallest possible number of rows. Sometimes splitting work between different transactions may be practical and helpful.

When a transaction rollback occurs due to a deadlock or lock wait timeout, it cancels the effect of the statements within the transaction. But if the start-transaction statement was `START TRANSACTION` or `BEGIN` statement, rollback does not cancel that statement. Further SQL statements become part of the transaction until the occurrence of `COMMIT`, `ROLLBACK`, or some SQL statement that causes an implicit commit.

- A duplicate-key error rolls back the SQL statement, if you have not specified the `IGNORE` option in your statement.
- A `row too long error` rolls back the SQL statement.
- Other errors are mostly detected by the MySQL layer of code (above the `InnoDB` storage engine level), and they roll back the corresponding SQL statement. Locks are not released in a rollback of a single SQL statement.

During implicit rollbacks, as well as during the execution of an explicit `ROLLBACK` SQL statement, `SHOW PROCESSLIST` displays `Rolling back` in the `State` column for the relevant connection.

---

| 16.11.2 | The Common Database Server Layer .....              | 2554 |

Storage engines are MySQL components that handle the SQL operations for different table types. [InnoDB](#) is the default and most general-purpose storage engine, and Oracle recommends using it for tables except for specialized use cases. (The [CREATE TABLE](#) statement in MySQL 5.7 creates [InnoDB](#) tables by default.)

MySQL Server uses a pluggable storage engine architecture that enables storage engines to be loaded into and unloaded from a running MySQL server.

To determine which storage engines your server supports, use the [SHOW ENGINES](#) statement. The value in the [Support](#) column indicates whether an engine can be used. A value of [YES](#), [NO](#), or [DEFAULT](#) indicates that an engine is available, not available, or available and currently set as the default storage engine.

```
mysql> SHOW ENGINES\G
***** 1. row *****
      Engine: PERFORMANCE_SCHEMA
      Support: YES
      Comment: Performance Schema

...
```

This chapter covers use cases for special-purpose MySQL storage engines. It does not cover the default [InnoDB](#) storage engine or the [NDB](#) storage engine which are covered in [Chapter 15, The InnoDB Storage Engine](#), and [Chapter 20, MySQL NDB Cluster 7.5](#). For advanced users, this chapter also contains a description of the pluggable storage engine architecture (see [Section 16.11, “Overview of MySQL Storage Engine Architecture”](#)).

For information about storage engine support offered in commercial MySQL Server binaries, see [MySQL Enterprise Server 5.7](#), on the MySQL Web site. The storage engines available might depend on which edition of Enterprise Server you are using.

For answers to commonly asked questions about MySQL storage engines, see [Section A.2, “MySQL 5.7 FAQ: Storage Engines”](#).

## MySQL 5.7 Supported Storage Engines

- [InnoDB](#): The default storage engine in MySQL 5.7. [InnoDB](#) is a transaction-safe (ACID compliant) storage engine for MySQL that has commit, rollback, and crash-recovery capabilities to protect user data. [InnoDB](#) row-level locking (without escalation to coarser granularity locks) and Oracle-style consistent nonlocking reads increase multi-user concurrency and performance. [InnoDB](#) stores user data in clustered indexes to reduce I/O for common queries based on primary keys. To maintain data integrity, [InnoDB](#) also supports [FOREIGN KEY](#) referential-integrity constraints. For more information about [InnoDB](#), see [Chapter 15, The InnoDB Storage Engine](#).
- [MyISAM](#): These tables have a small footprint. [Table-level locking](#) limits the performance in read/write workloads, so it is often used in read-only or read-mostly workloads in Web and data warehousing configurations.
- [Memory](#): Stores all data in RAM, for fast access in environments that require quick lookups of non-critical data. This engine was formerly known as the [HEAP](#) engine. Its use cases are decreasing; [InnoDB](#) with its buffer pool memory area provides a general-purpose and durable way to keep most or all data in memory, and [NDBCLUSTER](#) provides fast key-value lookups for huge distributed data sets.
- [CSV](#): Its tables are really text files with comma-separated values. CSV tables let you import or dump data in CSV format, to exchange data with scripts and applications that read and write that same format. Because CSV tables are not indexed, you typically keep the data in [InnoDB](#) tables during normal operation, and only use CSV tables during the import or export stage.
- [Archive](#): These compact, unindexed tables are intended for storing and retrieving large amounts of seldom-referenced historical, archived, or security audit information.
- [Blackhole](#): The Blackhole storage engine accepts but does not store data, similar to the Unix `/dev/null` device. Queries always return an empty set. These tables can be used in replication

configurations where DML statements are sent to slave servers, but the master server does not keep its own copy of the data.

- **NDB** (also known as **NDBCLUSTER**): This clustered database engine is particularly suited for applications that require the highest possible degree of uptime and availability.
- **Merge**: Enables a MySQL DBA or developer to logically group a series of identical **MyISAM** tables and reference them as one object. Good for VLDB environments such as data warehousing.
- **Federated**: Offers the ability to link separate MySQL servers to create one logical database from many physical servers. Very good for distributed or data mart environments.
- **Example**: This engine serves as an example in the MySQL source code that illustrates how to begin writing new storage engines. It is primarily of interest to developers. The storage engine is a “stub” that does nothing. You can create tables with this engine, but no data can be stored in them or retrieved from them.

You are not restricted to using the same storage engine for an entire server or schema. You can specify the storage engine for any table. For example, an application might use mostly **InnoDB** tables, with one **CSV** table for exporting data to a spreadsheet and a few **MEMORY** tables for temporary workspaces.

### Choosing a Storage Engine

The various storage engines provided with MySQL are designed with different use cases in mind. The following table provides an overview of some storage engines provided with MySQL:

**Table 16.1 Storage Engines Feature Summary**

| Feature                      | MyISAM | Memory | InnoDB           | Archive | NDB   |
|------------------------------|--------|--------|------------------|---------|-------|
| Storage limits               | 256TB  | RAM    | 64TB             | None    | 384EB |
| Transactions                 | No     | No     | Yes              | No      | Yes   |
| Locking granularity          | Table  | Table  | Row              | Row     | Row   |
| MVCC                         | No     | No     | Yes              | No      | No    |
| Geospatial data type support | Yes    | No     | Yes              | Yes     | Yes   |
| Geospatial indexing support  | Yes    | No     | Yes <sup>a</sup> | No      | No    |
| B-tree indexes               | Yes    | Yes    | Yes              | No      | No    |
| T-tree indexes               | No     | No     | No               | No      | Yes   |
| Hash indexes                 | No     | Yes    | No <sup>b</sup>  | No      | Yes   |
| Full-text search indexes     | Yes    | No     | Yes <sup>c</sup> | No      | No    |
| Clustered indexes            | No     | No     | Yes              | No      | No    |
| Data caches                  | No     | N/A    | Yes              | No      | Yes   |

| Feature                                      | MyISAM           | Memory | InnoDB           | Archive | NDB |
|--|------------------|--------|------------------|---------|-----|
| Index caches                                 | Yes              | N/A    | Yes              | No      | Yes |
| Compressed data                              | Yes <sup>d</sup> | No     | Yes <sup>e</sup> | Yes     | No  |
| Encrypted data <sup>f</sup>                  | Yes              | Yes    | Yes              | Yes     | Yes |
| Cluster database support                     | No               | No     | No               | No      | Yes |
| Replication support <sup>g</sup>             | Yes              | Yes    | Yes              | Yes     | Yes |
| Foreign key support                          | No               | No     | Yes              | No      | No  |
| Backup / point-in-time recovery <sup>h</sup> | Yes              | Yes    | Yes              | Yes     | Yes |
| Query cache support                          | Yes              | Yes    | Yes              | Yes     | Yes |
| Update statistics for data dictionary        | Yes              | Yes    | Yes              | Yes     | Yes |

<sup>a</sup>InnoDB support for geospatial indexing is available in MySQL 5.7.5 and higher.

<sup>b</sup>InnoDB utilizes hash indexes internally for its Adaptive Hash Index feature.

<sup>c</sup>InnoDB support for FULLTEXT indexes is available in MySQL 5.6.4 and higher.

<sup>d</sup>Compressed MyISAM tables are supported only when using the compressed row format. Tables using the compressed row format with MyISAM are read only.

<sup>e</sup>Compressed InnoDB tables require the InnoDB Barracuda file format.

<sup>f</sup>Implemented in the server (via encryption functions). Data-at-rest tablespace encryption is available in MySQL 5.7 and higher.

<sup>g</sup>Implemented in the server, rather than in the storage engine.

<sup>h</sup>Implemented in the server, rather than in the storage engine.

## 16.1 Setting the Storage Engine

When you create a new table, you can specify which storage engine to use by adding an `ENGINE` table option to the `CREATE TABLE` statement:

```
-- ENGINE=INNODB not needed unless you have set a different
-- default storage engine.
CREATE TABLE t1 (i INT) ENGINE = INNODB;
-- Simple table definitions can be switched from one to another.
CREATE TABLE t2 (i INT) ENGINE = CSV;
CREATE TABLE t3 (i INT) ENGINE = MEMORY;
```

When you omit the `ENGINE` option, the default storage engine is used. The default engine is `InnoDB` in MySQL 5.7. You can specify the default engine by using the `--default-storage-engine` server startup option, or by setting the `default-storage-engine` option in the `my.cnf` configuration file.

You can set the default storage engine for the current session by setting the `default_storage_engine` variable:

```
SET default_storage_engine=NDBCLUSTER;
```

The storage engine for [TEMPORARY](#) tables created with [CREATE TEMPORARY TABLE](#) can be set separately from the engine for permanent tables by setting the `default_tmp_storage_engine`, either at startup or at runtime.

To convert a table from one storage engine to another, use an [ALTER TABLE](#) statement that indicates the new engine:

```
ALTER TABLE t ENGINE = InnoDB;
```

See [Section 14.1.18, “CREATE TABLE Syntax”](#), and [Section 14.1.8, “ALTER TABLE Syntax”](#).

If you try to use a storage engine that is not compiled in or that is compiled in but deactivated, MySQL instead creates a table using the default storage engine. For example, in a replication setup, perhaps your master server uses [InnoDB](#) tables for maximum safety, but the slave servers use other storage engines for speed at the expense of durability or concurrency.

By default, a warning is generated whenever [CREATE TABLE](#) or [ALTER TABLE](#) cannot use the default storage engine. To prevent confusing, unintended behavior if the desired engine is unavailable, enable the [NO\\_ENGINE\\_SUBSTITUTION](#) SQL mode. If the desired engine is unavailable, this setting produces an error instead of a warning, and the table is not created or altered. See [Section 6.1.8, “Server SQL Modes”](#).

For new tables, MySQL always creates an `.frm` file to hold the table and column definitions. The table's index and data may be stored in one or more other files, depending on the storage engine. The server creates the `.frm` file above the storage engine level. Individual storage engines create any additional files required for the tables that they manage. If a table name contains special characters, the names for the table files contain encoded versions of those characters as described in [Section 10.2.3, “Mapping of Identifiers to File Names”](#).

## 16.2 The MyISAM Storage Engine

[MyISAM](#) is based on the older (and no longer available) [ISAM](#) storage engine but has many useful extensions.

**Table 16.2 [MyISAM](#) Storage Engine Features**

|  |       |  |                  |  |       |
|--|-------|--|------------------|--|-------|
| <b>Storage limits</b>                              | 256TB | <b>Transactions</b>                    | No               | <b>Locking granularity</b>                   | Table |
| <b>MVCC</b>  | No    | <b>Geospatial data type support</b>    | Yes              | <b>Geospatial indexing support</b>           | Yes   |
| <b>B-tree indexes</b>                              | Yes   | <b>T-tree indexes</b>                  | No               | <b>Hash indexes</b>                          | No    |
| <b>Full-text search indexes</b>                    | Yes   | <b>Clustered indexes</b>               | No               | <b>Data caches</b>                           | No    |
| <b>Index caches</b>                                | Yes   | <b>Compressed data</b>                 | Yes <sup>a</sup> | <b>Encrypted data<sup>b</sup></b>            | Yes   |
| <b>Cluster database support</b>                    | No    | <b>Replication support<sup>c</sup></b> | Yes              | <b>Foreign key support</b>                   | No    |
| <b>Backup / point-in-time recovery<sup>d</sup></b> | Yes   | <b>Query cache support</b>             | Yes              | <b>Update statistics for data dictionary</b> | Yes   |

<sup>a</sup>Compressed MyISAM tables are supported only when using the compressed row format. Tables using the compressed row format with MyISAM are read only.

<sup>b</sup>Implemented in the server (via encryption functions). Data-at-rest tablespace encryption is available in MySQL 5.7 and higher.

<sup>c</sup>Implemented in the server, rather than in the storage engine.

<sup>d</sup>Implemented in the server, rather than in the storage engine.

Each [MyISAM](#) table is stored on disk in three files. The files have names that begin with the table name and have an extension to indicate the file type. An `.frm` file stores the table format. The data file has an `.MYD` ([MYData](#)) extension. The index file has an `.MYI` ([MYIndex](#)) extension.

To specify explicitly that you want a [MyISAM](#) table, indicate that with an [ENGINE](#) table option:

```
CREATE TABLE t (i INT) ENGINE = MYISAM;
```

In MySQL 5.7, it is normally necessary to use [ENGINE](#) to specify the [MyISAM](#) storage engine because [InnoDB](#) is the default engine.

You can check or repair [MyISAM](#) tables with the [mysqlcheck](#) client or [myisamchk](#) utility. You can also compress [MyISAM](#) tables with [myisampack](#) to take up much less space. See [Section 5.5.3, “mysqlcheck — A Table Maintenance Program”](#), [Section 5.6.3, “myisamchk — MyISAM Table-Maintenance Utility”](#), and [Section 5.6.5, “myisampack — Generate Compressed, Read-Only MyISAM Tables”](#).

[MyISAM](#) tables have the following characteristics:

- All data values are stored with the low byte first. This makes the data machine and operating system independent. The only requirements for binary portability are that the machine uses two's-complement signed integers and IEEE floating-point format. These requirements are widely used among mainstream machines. Binary compatibility might not be applicable to embedded systems, which sometimes have peculiar processors.

There is no significant speed penalty for storing data low byte first; the bytes in a table row normally are unaligned and it takes little more processing to read an unaligned byte in order than in reverse order. Also, the code in the server that fetches column values is not time critical compared to other code.

- All numeric key values are stored with the high byte first to permit better index compression.
- Large files (up to 63-bit file length) are supported on file systems and operating systems that support large files.
- There is a limit of  $(2^{32})^2$  (1.844E+19) rows in a [MyISAM](#) table.
- The maximum number of indexes per [MyISAM](#) table is 64.

The maximum number of columns per index is 16.

- The maximum key length is 1000 bytes. This can also be changed by changing the source and recompiling. For the case of a key longer than 250 bytes, a larger key block size than the default of 1024 bytes is used.
- When rows are inserted in sorted order (as when you are using an [AUTO\\_INCREMENT](#) column), the index tree is split so that the high node only contains one key. This improves space utilization in the index tree.
- Internal handling of one [AUTO\\_INCREMENT](#) column per table is supported. [MyISAM](#) automatically updates this column for [INSERT](#) and [UPDATE](#) operations. This makes [AUTO\\_INCREMENT](#) columns faster (at least 10%). Values at the top of the sequence are not reused after being deleted. (When an [AUTO\\_INCREMENT](#) column is defined as the last column of a multiple-column index, reuse of values deleted from the top of a sequence does occur.) The [AUTO\\_INCREMENT](#) value can be reset with [ALTER TABLE](#) or [myisamchk](#).
- Dynamic-sized rows are much less fragmented when mixing deletes with updates and inserts. This is done by automatically combining adjacent deleted blocks and by extending blocks if the next block is deleted.
- [MyISAM](#) supports concurrent inserts: If a table has no free blocks in the middle of the data file, you can [INSERT](#) new rows into it at the same time that other threads are reading from the table. A free block can occur as a result of deleting rows or an update of a dynamic length row with more data than its current contents. When all free blocks are used up (filled in), future inserts become concurrent again. See [Section 9.11.3, “Concurrent Inserts”](#).

- You can put the data file and index file in different directories on different physical devices to get more speed with the `DATA DIRECTORY` and `INDEX DIRECTORY` table options to `CREATE TABLE`. See [Section 14.1.18, “CREATE TABLE Syntax”](#).
- `BLOB` and `TEXT` columns can be indexed.
- `NULL` values are permitted in indexed columns. This takes 0 to 1 bytes per key.
- Each character column can have a different character set. See [Section 11.1, “Character Set Support”](#).
- There is a flag in the `MyISAM` index file that indicates whether the table was closed correctly. If `mysqld` is started with the `--myisam-recover-options` option, `MyISAM` tables are automatically checked when opened, and are repaired if the table wasn't closed properly.
- `myisamchk` marks tables as checked if you run it with the `--update-state` option. `myisamchk --fast` checks only those tables that don't have this mark.
- `myisamchk --analyze` stores statistics for portions of keys, as well as for entire keys.
- `myisampack` can pack `BLOB` and `VARCHAR` columns.

`MyISAM` also supports the following features:

- Support for a true `VARCHAR` type; a `VARCHAR` column starts with a length stored in one or two bytes.
- Tables with `VARCHAR` columns may have fixed or dynamic row length.
- The sum of the lengths of the `VARCHAR` and `CHAR` columns in a table may be up to 64KB.
- Arbitrary length `UNIQUE` constraints.

## Additional Resources

- A forum dedicated to the `MyISAM` storage engine is available at <http://forums.mysql.com/list.php?21>.

### 16.2.1 MyISAM Startup Options

The following options to `mysqld` can be used to change the behavior of `MyISAM` tables. For additional information, see [Section 6.1.4, “Server Command Options”](#).

**Table 16.3 `MyISAM` Option/Variable Reference**

| Name   | Cmd-Line | Option File | System Var | Status Var | Var Scope | Dynamic |
|--|----------|-------------|------------|------------|-----------|---------|
| <a href="#">bulk_insert_buffer_size</a>        | Yes      | Yes         | Yes        |            | Both      | Yes     |
| <a href="#">concurrent_insert</a>              | Yes      | Yes         | Yes        |            | Global    | Yes     |
| <a href="#">delay-key-write</a>                | Yes      | Yes         |            |            | Global    | Yes     |
| - Variable:<br><a href="#">delay_key_write</a> |          |             | Yes        |            | Global    | Yes     |
| <a href="#">have_rtree_keys</a>                |          |             | Yes        |            | Global    | No      |
| <a href="#">key_buffer_size</a>                | Yes      | Yes         | Yes        |            | Global    | Yes     |

| <a href="#">myisam_sort_buffer_size</a>               | Yes      | Yes         | Yes        |            | Both      | Yes     |
| <a href="#">myisam_stats_method</a>                   | Yes      | Yes         | Yes        |            | Both      | Yes     |
| <a href="#">myisam_use_mmap</a>                       | Yes      | Yes         | Yes        |            | Global    | Yes     |
| <a href="#">skip-concurrent-insert</a>                | Yes      | Yes         |            |            |           |         |
| - Variable:<br><a href="#">concurrent_insert</a>      |          |             |            |            |           |         |
| <a href="#">tmp_table_size</a>                        | Yes      | Yes         | Yes        |            | Both      | Yes     |

- `--myisam-recover-options=mode`

Set the mode for automatic recovery of crashed [MyISAM](#) tables.

- `--delay-key-write=ALL`

Don't flush key buffers between writes for any [MyISAM](#) table.

#### Note

If you do this, you should not access [MyISAM](#) tables from another program (such as from another MySQL server or with [myisamchk](#)) when the tables are in use. Doing so risks index corruption. Using `--external-locking` does not eliminate this risk.

The following system variables affect the behavior of [MyISAM](#) tables. For additional information, see [Section 6.1.5, “Server System Variables”](#).

- `bulk_insert_buffer_size`

The size of the tree cache used in bulk insert optimization.

#### Note

This is a limit *per thread*!

- `myisam_max_sort_file_size`

The maximum size of the temporary file that MySQL is permitted to use while re-creating a [MyISAM](#) index (during `REPAIR TABLE`, `ALTER TABLE`, or `LOAD DATA INFILE`). If the file size would be larger than this value, the index is created using the key cache instead, which is slower. The value is given in bytes.

- `myisam_sort_buffer_size`

Set the size of the buffer used when recovering tables.

Automatic recovery is activated if you start `mysqld` with the `--myisam-recover-options` option. In this case, when the server opens a [MyISAM](#) table, it checks whether the table is marked as crashed

or whether the open count variable for the table is not 0 and you are running the server with external locking disabled. If either of these conditions is true, the following happens:

- The server checks the table for errors.
- If the server finds an error, it tries to do a fast table repair (with sorting and without re-creating the data file).
- If the repair fails because of an error in the data file (for example, a duplicate-key error), the server tries again, this time re-creating the data file.
- If the repair still fails, the server tries once more with the old repair option method (write row by row without sorting). This method should be able to repair any type of error and has low disk space requirements.

If the recovery wouldn't be able to recover all rows from previously completed statements and you didn't specify `FORCE` in the value of the `--myisam-recover-options` option, automatic repair aborts with an error message in the error log:

```
Error: Couldn't repair table: test.g00pages
```

If you specify `FORCE`, a warning like this is written instead:

```
Warning: Found 344 of 354 rows when repairing ./test/g00pages
```

If the automatic recovery value includes `BACKUP`, the recovery process creates files with names of the form `tbl_name-datetime.BAK`. You should have a `cron` script that automatically moves these files from the database directories to backup media.

## 16.2.2 Space Needed for Keys

`MyISAM` tables use B-tree indexes. You can roughly calculate the size for the index file as  $(key\_length + 4) / 0.67$ , summed over all keys. This is for the worst case when all keys are inserted in sorted order and the table doesn't have any compressed keys.

String indexes are space compressed. If the first index part is a string, it is also prefix compressed. Space compression makes the index file smaller than the worst-case figure if a string column has a lot of trailing space or is a `VARCHAR` column that is not always used to the full length. Prefix compression is used on keys that start with a string. Prefix compression helps if there are many strings with an identical prefix.

In `MyISAM` tables, you can also prefix compress numbers by specifying the `PACK_KEYS=1` table option when you create the table. Numbers are stored with the high byte first, so this helps when you have many integer keys that have an identical prefix.

## 16.2.3 MyISAM Table Storage Formats

`MyISAM` supports three different storage formats. Two of them, fixed and dynamic format, are chosen automatically depending on the type of columns you are using. The third, compressed format, can be created only with the `myisampack` utility (see [Section 5.6.5, “myisampack — Generate Compressed, Read-Only MyISAM Tables”](#)).

When you use `CREATE TABLE` or `ALTER TABLE` for a table that has no `BLOB` or `TEXT` columns, you can force the table format to `FIXED` or `DYNAMIC` with the `ROW_FORMAT` table option.

See [Section 14.1.18, “CREATE TABLE Syntax”](#), for information about `ROW_FORMAT`.

You can decompress (unpack) compressed `MyISAM` tables using `myisamchk --unpack`; see [Section 5.6.3, “myisamchk — MyISAM Table-Maintenance Utility”](#), for more information.

### 16.2.3.1 Static (Fixed-Length) Table Characteristics

Static format is the default for [MyISAM](#) tables. It is used when the table contains no variable-length columns ([VARCHAR](#), [VARBINARY](#), [BLOB](#), or [TEXT](#)). Each row is stored using a fixed number of bytes.

Of the three [MyISAM](#) storage formats, static format is the simplest and most secure (least subject to corruption). It is also the fastest of the on-disk formats due to the ease with which rows in the data file can be found on disk: To look up a row based on a row number in the index, multiply the row number by the row length to calculate the row position. Also, when scanning a table, it is very easy to read a constant number of rows with each disk read operation.

The security is evidenced if your computer crashes while the MySQL server is writing to a fixed-format [MyISAM](#) file. In this case, [myisamchk](#) can easily determine where each row starts and ends, so it can usually reclaim all rows except the partially written one. [MyISAM](#) table indexes can always be reconstructed based on the data rows.

#### Note

Fixed-length row format is only available for tables without [BLOB](#) or [TEXT](#) columns. Creating a table with these columns with an explicit [ROW\\_FORMAT](#) clause will not raise an error or warning; the format specification will be ignored.

Static-format tables have these characteristics:

- [CHAR](#) and [VARCHAR](#) columns are space-padded to the specified column width, although the column type is not altered. [BINARY](#) and [VARBINARY](#) columns are padded with [0x00](#) bytes to the column width.
- [NULL](#) columns require additional space in the row to record whether their values are [NULL](#). Each [NULL](#) column takes one bit extra, rounded up to the nearest byte.
- Very quick.
- Easy to cache.
- Easy to reconstruct after a crash, because rows are located in fixed positions.
- Reorganization is unnecessary unless you delete a huge number of rows and want to return free disk space to the operating system. To do this, use [OPTIMIZE TABLE](#) or [myisamchk -r](#).
- Usually require more disk space than dynamic-format tables.
- The expected row length in bytes for static-sized rows is calculated using the following expression:

```
row length = 1
             + (sum of column lengths)
             + (number of NULL columns + delete_flag + 7)/8
             + (number of variable-length columns)
```

[delete\\_flag](#) is 1 for tables with static row format. Static tables use a bit in the row record for a flag that indicates whether the row has been deleted. [delete\\_flag](#) is 0 for dynamic tables because the flag is stored in the dynamic row header.

### 16.2.3.2 Dynamic Table Characteristics

Dynamic storage format is used if a [MyISAM](#) table contains any variable-length columns ([VARCHAR](#), [VARBINARY](#), [BLOB](#), or [TEXT](#)), or if the table was created with the [ROW\\_FORMAT=DYNAMIC](#) table option.

Dynamic format is a little more complex than static format because each row has a header that indicates how long it is. A row can become fragmented (stored in noncontiguous pieces) when it is made longer as a result of an update.

You can use `OPTIMIZE TABLE` or `myisamchk -r` to defragment a table. If you have fixed-length columns that you access or change frequently in a table that also contains some variable-length columns, it might be a good idea to move the variable-length columns to other tables just to avoid fragmentation.

Dynamic-format tables have these characteristics:

- All string columns are dynamic except those with a length less than four.
- Each row is preceded by a bitmap that indicates which columns contain the empty string (for string columns) or zero (for numeric columns). This does not include columns that contain `NULL` values. If a string column has a length of zero after trailing space removal, or a numeric column has a value of zero, it is marked in the bitmap and not saved to disk. Nonempty strings are saved as a length byte plus the string contents.
- `NULL` columns require additional space in the row to record whether their values are `NULL`. Each `NULL` column takes one bit extra, rounded up to the nearest byte.
- Much less disk space usually is required than for fixed-length tables.
- Each row uses only as much space as is required. However, if a row becomes larger, it is split into as many pieces as are required, resulting in row fragmentation. For example, if you update a row with information that extends the row length, the row becomes fragmented. In this case, you may have to run `OPTIMIZE TABLE` or `myisamchk -r` from time to time to improve performance. Use `myisamchk -ei` to obtain table statistics.
- More difficult than static-format tables to reconstruct after a crash, because rows may be fragmented into many pieces and links (fragments) may be missing.
- The expected row length for dynamic-sized rows is calculated using the following expression:

```
3
+ (number of columns + 7) / 8
+ (number of char columns)
+ (packed size of numeric columns)
+ (length of strings)
+ (number of NULL columns + 7) / 8
```

There is a penalty of 6 bytes for each link. A dynamic row is linked whenever an update causes an enlargement of the row. Each new link is at least 20 bytes, so the next enlargement probably goes in the same link. If not, another link is created. You can find the number of links using `myisamchk -ed`. All links may be removed with `OPTIMIZE TABLE` or `myisamchk -r`.

### 16.2.3.3 Compressed Table Characteristics

Compressed storage format is a read-only format that is generated with the `myisampack` tool. Compressed tables can be uncompressed with `myisamchk`.

Compressed tables have the following characteristics:

- Compressed tables take very little disk space. This minimizes disk usage, which is helpful when using slow disks (such as CD-ROMs).
- Each row is compressed separately, so there is very little access overhead. The header for a row takes up one to three bytes depending on the biggest row in the table. Each column is compressed differently. There is usually a different Huffman tree for each column. Some of the compression types are:
  - Suffix space compression.
  - Prefix space compression.

- Numbers with a value of zero are stored using one bit.
- If values in an integer column have a small range, the column is stored using the smallest possible type. For example, a `BIGINT` column (eight bytes) can be stored as a `TINYINT` column (one byte) if all its values are in the range from `-128` to `127`.
- If a column has only a small set of possible values, the data type is converted to `ENUM`.
- A column may use any combination of the preceding compression types.
- Can be used for fixed-length or dynamic-length rows.

#### Note

While a compressed table is read only, and you cannot therefore update or add rows in the table, DDL (Data Definition Language) operations are still valid. For example, you may still use `DROP` to drop the table, and `TRUNCATE TABLE` to empty the table.

## 16.2.4 MyISAM Table Problems

The file format that MySQL uses to store data has been extensively tested, but there are always circumstances that may cause database tables to become corrupted. The following discussion describes how this can happen and how to handle it.

### 16.2.4.1 Corrupted MyISAM Tables

Even though the `MyISAM` table format is very reliable (all changes to a table made by an SQL statement are written before the statement returns), you can still get corrupted tables if any of the following events occur:

- The `mysqld` process is killed in the middle of a write.
- An unexpected computer shutdown occurs (for example, the computer is turned off).
- Hardware failures.
- You are using an external program (such as `myisamchk`) to modify a table that is being modified by the server at the same time.
- A software bug in the MySQL or `MyISAM` code.

Typical symptoms of a corrupt table are:

- You get the following error while selecting data from the table:

```
Incorrect key file for table: '...'. Try to repair it
```

- Queries don't find rows in the table or return incomplete results.

You can check the health of a `MyISAM` table using the `CHECK TABLE` statement, and repair a corrupted `MyISAM` table with `REPAIR TABLE`. When `mysqld` is not running, you can also check or repair a table with the `myisamchk` command. See [Section 14.7.2.2, “CHECK TABLE Syntax”](#), [Section 14.7.2.5, “REPAIR TABLE Syntax”](#), and [Section 5.6.3, “myisamchk — MyISAM Table-Maintenance Utility”](#).

If your tables become corrupted frequently, you should try to determine why this is happening. The most important thing to know is whether the table became corrupted as a result of a server crash. You can verify this easily by looking for a recent `restarted mysqld` message in the error log. If there is such a message, it is likely that table corruption is a result of the server dying. Otherwise, corruption may have occurred during normal operation. This is a bug. You should try to create a reproducible test

case that demonstrates the problem. See [Section B.5.3.3, “What to Do If MySQL Keeps Crashing”](#), and [Section 27.5, “Debugging and Porting MySQL”](#).

#### 16.2.4.2 Problems from Tables Not Being Closed Properly

Each [MyISAM](#) index file ([.MYI](#) file) has a counter in the header that can be used to check whether a table has been closed properly. If you get the following warning from [CHECK TABLE](#) or [myisamchk](#), it means that this counter has gone out of sync:

```
clients are using or haven't closed the table properly
```

This warning doesn't necessarily mean that the table is corrupted, but you should at least check the table.

The counter works as follows:

- The first time a table is updated in MySQL, a counter in the header of the index files is incremented.
- The counter is not changed during further updates.
- When the last instance of a table is closed (because a [FLUSH TABLES](#) operation was performed or because there is no room in the table cache), the counter is decremented if the table has been updated at any point.
- When you repair the table or check the table and it is found to be okay, the counter is reset to zero.
- To avoid problems with interaction with other processes that might check the table, the counter is not decremented on close if it was zero.

In other words, the counter can become incorrect only under these conditions:

- A [MyISAM](#) table is copied without first issuing [LOCK TABLES](#) and [FLUSH TABLES](#).
- MySQL has crashed between an update and the final close. (The table may still be okay because MySQL always issues writes for everything between each statement.)
- A table was modified by [myisamchk --recover](#) or [myisamchk --update-state](#) at the same time that it was in use by [mysqld](#).
- Multiple [mysqld](#) servers are using the table and one server performed a [REPAIR TABLE](#) or [CHECK TABLE](#) on the table while it was in use by another server. In this setup, it is safe to use [CHECK TABLE](#), although you might get the warning from other servers. However, [REPAIR TABLE](#) should be avoided because when one server replaces the data file with a new one, this is not known to the other servers.

In general, it is a bad idea to share a data directory among multiple servers. See [Section 6.6, “Running Multiple MySQL Instances on One Machine”](#), for additional discussion.

## 16.3 The MEMORY Storage Engine

The [MEMORY](#) storage engine (formerly known as [HEAP](#)) creates special-purpose tables with contents that are stored in memory. Because the data is vulnerable to crashes, hardware issues, or power outages, only use these tables as temporary work areas or read-only caches for data pulled from other tables.

**Table 16.4** [MEMORY](#) Storage Engine Features

|                       |     |                                     |    |                                    |       |
|-----------------------|-----|-------------------------------------|----|------------------------------------|-------|
| <b>Storage limits</b> | RAM | <b>Transactions</b>                 | No | <b>Locking granularity</b>         | Table |
| <b>MVCC</b>           | No  | <b>Geospatial data type support</b> | No | <b>Geospatial indexing support</b> | No    |
| <b>B-tree indexes</b> | Yes | <b>T-tree indexes</b>               | No | <b>Hash indexes</b>                | Yes   |

|  |     |  |     |  |     |
|--|-----|--|-----|--|-----|
| <b>Full-text search indexes</b>                    | No  | <b>Clustered indexes</b>               | No  | <b>Data caches</b>                           | N/A |
| <b>Index caches</b>                                | N/A | <b>Compressed data</b>                 | No  | <b>Encrypted data<sup>a</sup></b>            | Yes |
| <b>Cluster database support</b>                    | No  | <b>Replication support<sup>b</sup></b> | Yes | <b>Foreign key support</b>                   | No  |
| <b>Backup / point-in-time recovery<sup>c</sup></b> | Yes | <b>Query cache support</b>             | Yes | <b>Update statistics for data dictionary</b> | Yes |

<sup>a</sup>Implemented in the server (via encryption functions). Data-at-rest tablespace encryption is available in MySQL 5.7 and higher.

<sup>b</sup>Implemented in the server, rather than in the storage engine.

<sup>c</sup>Implemented in the server, rather than in the storage engine.

**When to Use MEMORY or MySQL Cluster.** Developers looking to deploy applications that use the [MEMORY](#) storage engine for important, highly available, or frequently updated data should consider whether MySQL Cluster is a better choice. A typical use case for the [MEMORY](#) engine involves these characteristics:

- Operations involving transient, non-critical data such as session management or caching. When the MySQL server halts or restarts, the data in [MEMORY](#) tables is lost.
- In-memory storage for fast access and low latency. Data volume can fit entirely in memory without causing the operating system to swap out virtual memory pages.
- A read-only or read-mostly data access pattern (limited updates).

MySQL Cluster offers the same features as the [MEMORY](#) engine with higher performance levels, and provides additional features not available with [MEMORY](#):

- Row-level locking and multiple-thread operation for low contention between clients.
- Scalability even with statement mixes that include writes.
- Optional disk-backed operation for data durability.
- Shared-nothing architecture and multiple-host operation with no single point of failure, enabling 99.999% availability.
- Automatic data distribution across nodes; application developers need not craft custom sharding or partitioning solutions.
- Support for variable-length data types (including [BLOB](#) and [TEXT](#)) not supported by [MEMORY](#).

For a white paper with more detailed comparison of the [MEMORY](#) storage engine and MySQL Cluster, see [Scaling Web Services with MySQL Cluster: An Alternative to the MySQL Memory Storage Engine](#). This white paper includes a performance study of the two technologies and a step-by-step guide describing how existing [MEMORY](#) users can migrate to MySQL Cluster.

## Performance Characteristics

[MEMORY](#) performance is constrained by contention resulting from single-thread execution and table lock overhead when processing updates. This limits scalability when load increases, particularly for statement mixes that include writes.

Despite the in-memory processing for [MEMORY](#) tables, they are not necessarily faster than [InnoDB](#) tables on a busy server, for general-purpose queries, or under a read/write workload. In particular, the table locking involved with performing updates can slow down concurrent usage of [MEMORY](#) tables from multiple sessions.

Depending on the kinds of queries performed on a [MEMORY](#) table, you might create indexes as either the default hash data structure (for looking up single values based on a unique key), or a general-purpose B-tree data structure (for all kinds of queries involving equality, inequality, or range operators

such as less than or greater than). The following sections illustrate the syntax for creating both kinds of indexes. A common performance issue is using the default hash indexes in workloads where B-tree indexes are more efficient.

## Physical Characteristics of MEMORY Tables

The `MEMORY` storage engine associates each table with one disk file, which stores the table definition (not the data). The file name begins with the table name and has an extension of `.frm`.

`MEMORY` tables have the following characteristics:

- Space for `MEMORY` tables is allocated in small blocks. Tables use 100% dynamic hashing for inserts. No overflow area or extra key space is needed. No extra space is needed for free lists. Deleted rows are put in a linked list and are reused when you insert new data into the table. `MEMORY` tables also have none of the problems commonly associated with deletes plus inserts in hashed tables.
- `MEMORY` tables use a fixed-length row-storage format. Variable-length types such as `VARCHAR` are stored using a fixed length.
- `MEMORY` tables cannot contain `BLOB` or `TEXT` columns.
- `MEMORY` includes support for `AUTO_INCREMENT` columns.
- Non-`TEMPORARY MEMORY` tables are shared among all clients, just like any other non-`TEMPORARY` table.

## DDL Operations for MEMORY Tables

To create a `MEMORY` table, specify the clause `ENGINE=MEMORY` on the `CREATE TABLE` statement.

```
CREATE TABLE t (i INT) ENGINE = MEMORY;
```

As indicated by the engine name, `MEMORY` tables are stored in memory. They use hash indexes by default, which makes them very fast for single-value lookups, and very useful for creating temporary tables. However, when the server shuts down, all rows stored in `MEMORY` tables are lost. The tables themselves continue to exist because their definitions are stored in `.frm` files on disk, but they are empty when the server restarts.

This example shows how you might create, use, and remove a `MEMORY` table:

```
mysql> CREATE TABLE test ENGINE=MEMORY
->     SELECT ip,SUM(downloads) AS down
->     FROM log_table GROUP BY ip;
mysql> SELECT COUNT(ip),AVG(down) FROM test;
mysql> DROP TABLE test;
```

The maximum size of `MEMORY` tables is limited by the `max_heap_table_size` system variable, which has a default value of 16MB. To enforce different size limits for `MEMORY` tables, change the value of this variable. The value in effect for `CREATE TABLE`, or a subsequent `ALTER TABLE` or `TRUNCATE TABLE`, is the value used for the life of the table. A server restart also sets the maximum size of existing `MEMORY` tables to the global `max_heap_table_size` value. You can set the size for individual tables as described later in this section.

## Indexes

The `MEMORY` storage engine supports both `HASH` and `BTREE` indexes. You can specify one or the other for a given index by adding a `USING` clause as shown here:

```
CREATE TABLE lookup
(id INT, INDEX USING HASH (id))
```

```
ENGINE = MEMORY;  
CREATE TABLE lookup  
  (id INT, INDEX USING BTREE (id))  
ENGINE = MEMORY;
```

For general characteristics of B-tree and hash indexes, see [Section 9.3.1, “How MySQL Uses Indexes”](#).

**MEMORY** tables can have up to 64 indexes per table, 16 columns per index and a maximum key length of 3072 bytes.

If a **MEMORY** table hash index has a high degree of key duplication (many index entries containing the same value), updates to the table that affect key values and all deletes are significantly slower. The degree of this slowdown is proportional to the degree of duplication (or, inversely proportional to the index cardinality). You can use a **BTREE** index to avoid this problem.

**MEMORY** tables can have nonunique keys. (This is an uncommon feature for implementations of hash indexes.)

Columns that are indexed can contain **NULL** values.

## User-Created and Temporary Tables

**MEMORY** table contents are stored in memory, which is a property that **MEMORY** tables share with internal temporary tables that the server creates on the fly while processing queries. However, the two types of tables differ in that **MEMORY** tables are not subject to storage conversion, whereas internal temporary tables are:

- If an internal temporary table becomes too large, the server automatically converts it to on-disk storage, as described in [Section 9.4.4, “Internal Temporary Table Use in MySQL”](#).
- User-created **MEMORY** tables are never converted to disk tables.

## Loading Data

To populate a **MEMORY** table when the MySQL server starts, you can use the `--init-file` option. For example, you can put statements such as `INSERT INTO ... SELECT` or `LOAD DATA INFILE` into this file to load the table from a persistent data source. See [Section 6.1.4, “Server Command Options”](#), and [Section 14.2.6, “LOAD DATA INFILE Syntax”](#).

## MEMORY Tables and Replication

A server's **MEMORY** tables become empty when it is shut down and restarted. If the server is a replication master, its slaves are not aware that these tables have become empty, so you see out-of-date content if you select data from the tables on the slaves. To synchronize master and slave **MEMORY** tables, when a **MEMORY** table is used on a master for the first time since it was started, a **DELETE** statement is written to the master's binary log, to empty the table on the slaves also. The slave still has outdated data in the table during the interval between the master's restart and its first use of the table. To avoid this interval when a direct query to the slave could return stale data, use the `--init-file` option to populate the **MEMORY** table on the master at startup.

## Managing Memory Use

The server needs sufficient memory to maintain all **MEMORY** tables that are in use at the same time.

Memory is not reclaimed if you delete individual rows from a **MEMORY** table. Memory is reclaimed only when the entire table is deleted. Memory that was previously used for deleted rows is re-used for new rows within the same table. To free all the memory used by a **MEMORY** table when you no longer require its contents, execute **DELETE** or **TRUNCATE TABLE** to remove all rows, or remove the table altogether using **DROP TABLE**. To free up the memory used by deleted rows, use **ALTER TABLE ENGINE=MEMORY** to force a table rebuild.

The memory needed for one row in a `MEMORY` table is calculated using the following expression:

```
SUM_OVER_ALL_BTREE_KEYS(max_length_of_key + sizeof(char*) * 4)
+ SUM_OVER_ALL_HASH_KEYS(sizeof(char*) * 2)
+ ALIGN(length_of_row+1, sizeof(char*))
```

`ALIGN()` represents a round-up factor to cause the row length to be an exact multiple of the `char` pointer size. `sizeof(char*)` is 4 on 32-bit machines and 8 on 64-bit machines.

As mentioned earlier, the `max_heap_table_size` system variable sets the limit on the maximum size of `MEMORY` tables. To control the maximum size for individual tables, set the session value of this variable before creating each table. (Do not change the global `max_heap_table_size` value unless you intend the value to be used for `MEMORY` tables created by all clients.) The following example creates two `MEMORY` tables, with a maximum size of 1MB and 2MB, respectively:

```
mysql> SET max_heap_table_size = 1024*1024;
Query OK, 0 rows affected (0.00 sec)

mysql> CREATE TABLE t1 (id INT, UNIQUE(id)) ENGINE = MEMORY;
Query OK, 0 rows affected (0.01 sec)

mysql> SET max_heap_table_size = 1024*1024*2;
Query OK, 0 rows affected (0.00 sec)

mysql> CREATE TABLE t2 (id INT, UNIQUE(id)) ENGINE = MEMORY;
Query OK, 0 rows affected (0.00 sec)
```

Both tables revert to the server's global `max_heap_table_size` value if the server restarts.

You can also specify a `MAX_ROWS` table option in `CREATE TABLE` statements for `MEMORY` tables to provide a hint about the number of rows you plan to store in them. This does not enable the table to grow beyond the `max_heap_table_size` value, which still acts as a constraint on maximum table size. For maximum flexibility in being able to use `MAX_ROWS`, set `max_heap_table_size` at least as high as the value to which you want each `MEMORY` table to be able to grow.

## Additional Resources

A forum dedicated to the `MEMORY` storage engine is available at <http://forums.mysql.com/list.php?92>.

## 16.4 The CSV Storage Engine

The `CSV` storage engine stores data in text files using comma-separated values format.

The `CSV` storage engine is always compiled into the MySQL server.

To examine the source for the `CSV` engine, look in the `storage/csv` directory of a MySQL source distribution.

When you create a `CSV` table, the server creates a table format file in the database directory. The file begins with the table name and has an `.frm` extension. The storage engine also creates a data file. Its name begins with the table name and has a `.CSV` extension. The data file is a plain text file. When you store data into the table, the storage engine saves it into the data file in comma-separated values format.

```
mysql> CREATE TABLE test (i INT NOT NULL, c CHAR(10) NOT NULL)
-> ENGINE = CSV;
Query OK, 0 rows affected (0.12 sec)

mysql> INSERT INTO test VALUES(1,'record one'),(2,'record two');
Query OK, 2 rows affected (0.00 sec)
Records: 2 Duplicates: 0 Warnings: 0
```

```
mysql> SELECT * FROM test;
+-----+
| i      | c      |
+-----+
| 1      | record one |
| 2      | record two |
+-----+
2 rows in set (0.00 sec)
```

Creating a CSV table also creates a corresponding Metafile that stores the state of the table and the number of rows that exist in the table. The name of this file is the same as the name of the table with the extension `CSM`.

If you examine the `test.CSV` file in the database directory created by executing the preceding statements, its contents should look like this:

```
"1","record one"
"2","record two"
```

This format can be read, and even written, by spreadsheet applications such as Microsoft Excel or StarOffice Calc.

### 16.4.1 Repairing and Checking CSV Tables

The CSV storage engines supports the `CHECK` and `REPAIR` statements to verify and if possible repair a damaged CSV table.

When running the `CHECK` statement, the CSV file will be checked for validity by looking for the correct field separators, escaped fields (matching or missing quotation marks), the correct number of fields compared to the table definition and the existence of a corresponding CSV metafile. The first invalid row discovered will report an error. Checking a valid table produces output like that shown below:

```
mysql> check table csvtest;
+-----+
| Table      | Op      | Msg_type | Msg_text |
+-----+
| test.csvtest | check   | status   | OK       |
+-----+
1 row in set (0.00 sec)
```

A check on a corrupted table returns a fault:

```
mysql> check table csvtest;
+-----+
| Table      | Op      | Msg_type | Msg_text |
+-----+
| test.csvtest | check   | error    | Corrupt  |
+-----+
1 row in set (0.01 sec)
```

If the check fails, the table is marked as crashed (corrupt). Once a table has been marked as corrupt, it is automatically repaired when you next run `CHECK` or execute a `SELECT` statement. The corresponding corrupt status and new status will be displayed when running `CHECK`:

```
mysql> check table csvtest;
+-----+
| Table      | Op      | Msg_type | Msg_text |
+-----+
| test.csvtest | check   | warning  | Table is marked as crashed |
| test.csvtest | check   | status   | OK       |
+-----+
2 rows in set (0.08 sec)
```

To repair a table you can use `REPAIR`, this copies as many valid rows from the existing CSV data as possible, and then replaces the existing CSV file with the recovered rows. Any rows beyond the corrupted data are lost.

```
mysql> repair table csvtest;
+-----+-----+-----+-----+
| Table      | Op      | Msg_type | Msg_text |
+-----+-----+-----+-----+
| test.csvtest | repair  | status   | OK       |
+-----+-----+-----+-----+
1 row in set (0.02 sec)
```

### Warning

During repair, only the rows from the CSV file up to the first damaged row are copied to the new table. All other rows from the first damaged row to the end of the table are removed, even valid rows.

## 16.4.2 CSV Limitations

The `CSV` storage engine does not support indexing.

Partitioning is not supported for tables using the `CSV` storage engine.

All tables that you create using the `CSV` storage engine must have the `NOT NULL` attribute on all columns. However, for backward compatibility, you can continue to use tables with nullable columns that were created in previous MySQL releases. (Bug #32050)

## 16.5 The ARCHIVE Storage Engine

The `ARCHIVE` storage engine produces special-purpose tables that store large amounts of unindexed data in a very small footprint.

**Table 16.5** `ARCHIVE` Storage Engine Features

|  |      |  |     |  |     |
|--|------|--|-----|--|-----|
| <b>Storage limits</b>                              | None | <b>Transactions</b>                    | No  | <b>Locking granularity</b>                   | Row |
| <b>MVCC</b>  | No   | <b>Geospatial data type support</b>    | Yes | <b>Geospatial indexing support</b>           | No  |
| <b>B-tree indexes</b>                              | No   | <b>T-tree indexes</b>                  | No  | <b>Hash indexes</b>                          | No  |
| <b>Full-text search indexes</b>                    | No   | <b>Clustered indexes</b>               | No  | <b>Data caches</b>                           | No  |
| <b>Index caches</b>                                | No   | <b>Compressed data</b>                 | Yes | <b>Encrypted data<sup>a</sup></b>            | Yes |
| <b>Cluster database support</b>                    | No   | <b>Replication support<sup>b</sup></b> | Yes | <b>Foreign key support</b>                   | No  |
| <b>Backup / point-in-time recovery<sup>c</sup></b> | Yes  | <b>Query cache support</b>             | Yes | <b>Update statistics for data dictionary</b> | Yes |

<sup>a</sup>Implemented in the server (via encryption functions). Data-at-rest tablespace encryption is available in MySQL 5.7 and higher.

<sup>b</sup>Implemented in the server, rather than in the storage engine.

<sup>c</sup>Implemented in the server, rather than in the storage engine.

The `ARCHIVE` storage engine is included in MySQL binary distributions. To enable this storage engine if you build MySQL from source, invoke `CMake` with the `-DWITH_ARCHIVE_STORAGE_ENGINE` option.

To examine the source for the `ARCHIVE` engine, look in the `storage/archive` directory of a MySQL source distribution.

You can check whether the `ARCHIVE` storage engine is available with the `SHOW ENGINES` statement.

When you create an `ARCHIVE` table, the server creates a table format file in the database directory. The file begins with the table name and has an `.frm` extension. The storage engine creates other files, all having names beginning with the table name. The data file has an extension of `.ARZ`. An `.ARN` file may appear during optimization operations.

The `ARCHIVE` engine supports `INSERT`, `REPLACE`, and `SELECT`, but not `DELETE` or `UPDATE`. It does support `ORDER BY` operations, `BLOB` columns, and basically all but spatial data types (see [Section 12.5.1, “Spatial Data Types”](#)). The `ARCHIVE` engine uses row-level locking.

The `ARCHIVE` engine supports the `AUTO_INCREMENT` column attribute. The `AUTO_INCREMENT` column can have either a unique or nonunique index. Attempting to create an index on any other column results in an error. The `ARCHIVE` engine also supports the `AUTO_INCREMENT` table option in `CREATE TABLE` statements to specify the initial sequence value for a new table or reset the sequence value for an existing table, respectively.

`ARCHIVE` does not support inserting a value into an `AUTO_INCREMENT` column less than the current maximum column value. Attempts to do so result in an `ER_DUP_KEY` error.

The `ARCHIVE` engine ignores `BLOB` columns if they are not requested and scans past them while reading.

**Storage:** Rows are compressed as they are inserted. The `ARCHIVE` engine uses `zlib` lossless data compression (see <http://www.zlib.net/>). You can use `OPTIMIZE TABLE` to analyze the table and pack it into a smaller format (for a reason to use `OPTIMIZE TABLE`, see later in this section). The engine also supports `CHECK TABLE`. There are several types of insertions that are used:

- An `INSERT` statement just pushes rows into a compression buffer, and that buffer flushes as necessary. The insertion into the buffer is protected by a lock. A `SELECT` forces a flush to occur.
- A bulk insert is visible only after it completes, unless other inserts occur at the same time, in which case it can be seen partially. A `SELECT` never causes a flush of a bulk insert unless a normal insert occurs while it is loading.

**Retrieval:** On retrieval, rows are uncompressed on demand; there is no row cache. A `SELECT` operation performs a complete table scan: When a `SELECT` occurs, it finds out how many rows are currently available and reads that number of rows. `SELECT` is performed as a consistent read. Note that lots of `SELECT` statements during insertion can deteriorate the compression, unless only bulk or delayed inserts are used. To achieve better compression, you can use `OPTIMIZE TABLE` or `REPAIR TABLE`. The number of rows in `ARCHIVE` tables reported by `SHOW TABLE STATUS` is always accurate. See [Section 14.7.2.4, “OPTIMIZE TABLE Syntax”](#), [Section 14.7.2.5, “REPAIR TABLE Syntax”](#), and [Section 14.7.5.36, “SHOW TABLE STATUS Syntax”](#).

## Additional Resources

- A forum dedicated to the `ARCHIVE` storage engine is available at <http://forums.mysql.com/list.php?112>.

## 16.6 The BLACKHOLE Storage Engine

The `BLACKHOLE` storage engine acts as a “black hole” that accepts data but throws it away and does not store it. Retrievals always return an empty result:

```
mysql> CREATE TABLE test(i INT, c CHAR(10)) ENGINE = BLACKHOLE;
Query OK, 0 rows affected (0.03 sec)

mysql> INSERT INTO test VALUES(1,'record one'),(2,'record two');
Query OK, 2 rows affected (0.00 sec)
Records: 2  Duplicates: 0  Warnings: 0

mysql> SELECT * FROM test;
Empty set (0.00 sec)
```

To enable the `BLACKHOLE` storage engine if you build MySQL from source, invoke `CMake` with the `-DWITH_BLACKHOLE_STORAGE_ENGINE` option.

To examine the source for the `BLACKHOLE` engine, look in the `sql` directory of a MySQL source distribution.

When you create a [BLACKHOLE](#) table, the server creates a table format file in the database directory. The file begins with the table name and has an `.frm` extension. There are no other files associated with the table.

The [BLACKHOLE](#) storage engine supports all kinds of indexes. That is, you can include index declarations in the table definition.

You can check whether the [BLACKHOLE](#) storage engine is available with the `SHOW ENGINES` statement.

Inserts into a [BLACKHOLE](#) table do not store any data, but if statement based binary logging is enabled, the SQL statements are logged and replicated to slave servers. This can be useful as a repeater or filter mechanism.

#### Note

When using the row based format for the binary log, updates and deletes are skipped, and neither logged nor applied. For this reason, you should use `STATEMENT` for the binary logging format, and not `ROW` or `MIXED`.

Suppose that your application requires slave-side filtering rules, but transferring all binary log data to the slave first results in too much traffic. In such a case, it is possible to set up on the master host a “dummy” slave process whose default storage engine is [BLACKHOLE](#), depicted as follows:

The master writes to its binary log. The “dummy” `mysql` process acts as a slave, applying the desired combination of `replicate-do-*` and `replicate-ignore-*` rules, and writes a new, filtered binary log of its own. (See [Section 18.1.6, “Replication and Binary Logging Options and Variables”](#).) This filtered log is provided to the slave.

The dummy process does not actually store any data, so there is little processing overhead incurred by running the additional `mysql` process on the replication master host. This type of setup can be repeated with additional replication slaves.

`INSERT` triggers for [BLACKHOLE](#) tables work as expected. However, because the [BLACKHOLE](#) table does not actually store any data, `UPDATE` and `DELETE` triggers are not activated: The `FOR EACH ROW` clause in the trigger definition does not apply because there are no rows.

Other possible uses for the [BLACKHOLE](#) storage engine include:

- Verification of dump file syntax.
- Measurement of the overhead from binary logging, by comparing performance using [BLACKHOLE](#) with and without binary logging enabled.

- [BLACKHOLE](#) is essentially a “no-op” storage engine, so it could be used for finding performance bottlenecks not related to the storage engine itself.

The [BLACKHOLE](#) engine is transaction-aware, in the sense that committed transactions are written to the binary log and rolled-back transactions are not.

### Blackhole Engine and Auto Increment Columns

The Blackhole engine is a no-op engine. Any operations performed on a table using Blackhole will have no effect. This should be born in mind when considering the behavior of primary key columns that auto increment. The engine will not automatically increment field values, and does not retain auto increment field state. This has important implications in replication.

Consider the following replication scenario where all three of the following conditions apply:

1. On a master server there is a blackhole table with an auto increment field that is a primary key.
2. On a slave the same table exists but using the MyISAM engine.
3. Inserts are performed into the master's table without explicitly setting the auto increment value in the [INSERT](#) statement itself or through using a [SET INSERT\\_ID](#) statement.

In this scenario replication will fail with a duplicate entry error on the primary key column.

In statement based replication, the value of [INSERT\\_ID](#) in the context event will always be the same. Replication will therefore fail due to trying insert a row with a duplicate value for a primary key column.

In row based replication, the value that the engine returns for the row always be the same for each insert. This will result in the slave attempting to replay two insert log entries using the same value for the primary key column, and so replication will fail.

### Column Filtering

When using row-based replication, ([binlog\\_format=ROW](#)), a slave where the last columns are missing from a table is supported, as described in the section [Section 18.4.1.10, “Replication with Differing Table Definitions on Master and Slave”](#).

This filtering works on the slave side, that is, the columns are copied to the slave before they are filtered out. There are at least two cases where it is not desirable to copy the columns to the slave:

1. If the data is confidential, so the slave server should not have access to it.
2. If the master has many slaves, filtering before sending to the slaves may reduce network traffic.

Master column filtering can be achieved using the [BLACKHOLE](#) engine. This is carried out in a way similar to how master table filtering is achieved - by using the [BLACKHOLE](#) engine and the [--replicate-do-table](#) or [--replicate-ignore-table](#) option.

The setup for the master is:

```
CREATE TABLE t1 (public_col_1, ..., public_col_N,  
                 secret_col_1, ..., secret_col_M) ENGINE=MyISAM;
```

The setup for the trusted slave is:

```
CREATE TABLE t1 (public_col_1, ..., public_col_N) ENGINE=BLACKHOLE;
```

The setup for the untrusted slave is:

```
CREATE TABLE t1 (public_col_1, ..., public_col_N) ENGINE=MyISAM;
```

## 16.7 The MERGE Storage Engine

The **MERGE** storage engine, also known as the **MRG\_MyISAM** engine, is a collection of identical **MyISAM** tables that can be used as one. “Identical” means that all tables have identical column and index information. You cannot merge **MyISAM** tables in which the columns are listed in a different order, do not have exactly the same columns, or have the indexes in different order. However, any or all of the **MyISAM** tables can be compressed with **myisampack**. See [Section 5.6.5, “myisampack — Generate Compressed, Read-Only MyISAM Tables”](#). Differences in table options such as **AVG\_ROW\_LENGTH**, **MAX\_ROWS**, or **PACK\_KEYS** do not matter.

An alternative to a **MERGE** table is a partitioned table, which stores partitions of a single table in separate files. Partitioning enables some operations to be performed more efficiently and is not limited to the **MyISAM** storage engine. For more information, see [Chapter 21, Partitioning](#).

When you create a **MERGE** table, MySQL creates two files on disk. The files have names that begin with the table name and have an extension to indicate the file type. An **.frm** file stores the table format, and an **.MRG** file contains the names of the underlying **MyISAM** tables that should be used as one. The tables do not have to be in the same database as the **MERGE** table.

You can use **SELECT**, **DELETE**, **UPDATE**, and **INSERT** on **MERGE** tables. You must have **SELECT**, **DELETE**, and **UPDATE** privileges on the **MyISAM** tables that you map to a **MERGE** table.

#### Note

The use of **MERGE** tables entails the following security issue: If a user has access to **MyISAM** table *t*, that user can create a **MERGE** table *m* that accesses *t*. However, if the user's privileges on *t* are subsequently revoked, the user can continue to access *t* by doing so through *m*.

Use of **DROP TABLE** with a **MERGE** table drops only the **MERGE** specification. The underlying tables are not affected.

To create a **MERGE** table, you must specify a **UNION=(list-of-tables)** option that indicates which **MyISAM** tables to use. You can optionally specify an **INSERT\_METHOD** option to control how inserts into the **MERGE** table take place. Use a value of **FIRST** or **LAST** to cause inserts to be made in the first or last underlying table, respectively. If you specify no **INSERT\_METHOD** option or if you specify it with a value of **NO**, inserts into the **MERGE** table are not permitted and attempts to do so result in an error.

The following example shows how to create a **MERGE** table:

```
mysql> CREATE TABLE t1 (
->   a INT NOT NULL AUTO_INCREMENT PRIMARY KEY,
->   message CHAR(20)) ENGINE=MyISAM;
mysql> CREATE TABLE t2 (
->   a INT NOT NULL AUTO_INCREMENT PRIMARY KEY,
->   message CHAR(20)) ENGINE=MyISAM;
mysql> INSERT INTO t1 (message) VALUES ('Testing'),('table'),('t1');
mysql> INSERT INTO t2 (message) VALUES ('Testing'),('table'),('t2');
mysql> CREATE TABLE total (
->   a INT NOT NULL AUTO_INCREMENT,
->   message CHAR(20), INDEX(a))
->   ENGINE=MERGE UNION=(t1,t2) INSERT_METHOD=LAST;
```

Column **a** is indexed as a **PRIMARY KEY** in the underlying **MyISAM** tables, but not in the **MERGE** table. There it is indexed but not as a **PRIMARY KEY** because a **MERGE** table cannot enforce uniqueness over the set of underlying tables. (Similarly, a column with a **UNIQUE** index in the underlying tables should be indexed in the **MERGE** table but not as a **UNIQUE** index.)

After creating the **MERGE** table, you can use it to issue queries that operate on the group of tables as a whole:

```
mysql> SELECT * FROM total;
+---+-----+
```

| a | message |
|---|---------|
| 1 | Testing |
| 2 | table   |
| 3 | t1      |
| 1 | Testing |
| 2 | table   |
| 3 | t2      |

To remap a [MERGE](#) table to a different collection of [MyISAM](#) tables, you can use one of the following methods:

- [DROP](#) the [MERGE](#) table and re-create it.
- Use [ALTER TABLE \*tbl\\_name\* UNION=\(...\)](#) to change the list of underlying tables.

It is also possible to use [ALTER TABLE ... UNION=\(\)](#) (that is, with an empty [UNION](#) clause) to remove all of the underlying tables. However, in this case, the table is effectively empty and inserts fail because there is no underlying table to take new rows. Such a table might be useful as a template for creating new [MERGE](#) tables with [CREATE TABLE ... LIKE](#).

The underlying table definitions and indexes must conform closely to the definition of the [MERGE](#) table. Conformance is checked when a table that is part of a [MERGE](#) table is opened, not when the [MERGE](#) table is created. If any table fails the conformance checks, the operation that triggered the opening of the table fails. This means that changes to the definitions of tables within a [MERGE](#) may cause a failure when the [MERGE](#) table is accessed. The conformance checks applied to each table are:

- The underlying table and the [MERGE](#) table must have the same number of columns.
- The column order in the underlying table and the [MERGE](#) table must match.
- Additionally, the specification for each corresponding column in the parent [MERGE](#) table and the underlying tables are compared and must satisfy these checks:
  - The column type in the underlying table and the [MERGE](#) table must be equal.
  - The column length in the underlying table and the [MERGE](#) table must be equal.
  - The column of the underlying table and the [MERGE](#) table can be [NULL](#).
- The underlying table must have at least as many indexes as the [MERGE](#) table. The underlying table may have more indexes than the [MERGE](#) table, but cannot have fewer.

#### Note

A known issue exists where indexes on the same columns must be in identical order, in both the [MERGE](#) table and the underlying [MyISAM](#) table. See Bug #33653.

Each index must satisfy these checks:

- The index type of the underlying table and the [MERGE](#) table must be the same.
- The number of index parts (that is, multiple columns within a compound index) in the index definition for the underlying table and the [MERGE](#) table must be the same.
- For each index part:
  - Index part lengths must be equal.
  - Index part types must be equal.
  - Index part languages must be equal.

- Check whether index parts can be [NULL](#).

If a [MERGE](#) table cannot be opened or used because of a problem with an underlying table, [CHECK TABLE](#) displays information about which table caused the problem.

## Additional Resources

- A forum dedicated to the [MERGE](#) storage engine is available at <http://forums.mysql.com/list.php?93>.

### 16.7.1 MERGE Table Advantages and Disadvantages

[MERGE](#) tables can help you solve the following problems:

- Easily manage a set of log tables. For example, you can put data from different months into separate tables, compress some of them with [myisampack](#), and then create a [MERGE](#) table to use them as one.
- Obtain more speed. You can split a large read-only table based on some criteria, and then put individual tables on different disks. A [MERGE](#) table structured this way could be much faster than using a single large table.
- Perform more efficient searches. If you know exactly what you are looking for, you can search in just one of the underlying tables for some queries and use a [MERGE](#) table for others. You can even have many different [MERGE](#) tables that use overlapping sets of tables.
- Perform more efficient repairs. It is easier to repair individual smaller tables that are mapped to a [MERGE](#) table than to repair a single large table.
- Instantly map many tables as one. A [MERGE](#) table need not maintain an index of its own because it uses the indexes of the individual tables. As a result, [MERGE](#) table collections are very fast to create or remap. (You must still specify the index definitions when you create a [MERGE](#) table, even though no indexes are created.)
- If you have a set of tables from which you create a large table on demand, you can instead create a [MERGE](#) table from them on demand. This is much faster and saves a lot of disk space.
- Exceed the file size limit for the operating system. Each [MyISAM](#) table is bound by this limit, but a collection of [MyISAM](#) tables is not.
- You can create an alias or synonym for a [MyISAM](#) table by defining a [MERGE](#) table that maps to that single table. There should be no really notable performance impact from doing this (only a couple of indirect calls and `memcpy()` calls for each read).

The disadvantages of [MERGE](#) tables are:

- You can use only identical [MyISAM](#) tables for a [MERGE](#) table.
- Some [MyISAM](#) features are unavailable in [MERGE](#) tables. For example, you cannot create [FULLTEXT](#) indexes on [MERGE](#) tables. (You can create [FULLTEXT](#) indexes on the underlying [MyISAM](#) tables, but you cannot search the [MERGE](#) table with a full-text search.)
- If the [MERGE](#) table is nontemporary, all underlying [MyISAM](#) tables must be nontemporary. If the [MERGE](#) table is temporary, the [MyISAM](#) tables can be any mix of temporary and nontemporary.
- [MERGE](#) tables use more file descriptors than [MyISAM](#) tables. If 10 clients are using a [MERGE](#) table that maps to 10 tables, the server uses  $(10 \times 10) + 10$  file descriptors. (10 data file descriptors for each of the 10 clients, and 10 index file descriptors shared among the clients.)
- Index reads are slower. When you read an index, the [MERGE](#) storage engine needs to issue a read on all underlying tables to check which one most closely matches a given index value. To read

the next index value, the `MERGE` storage engine needs to search the read buffers to find the next value. Only when one index buffer is used up does the storage engine need to read the next index block. This makes `MERGE` indexes much slower on `eq_ref` searches, but not much slower on `ref` searches. For more information about `eq_ref` and `ref`, see [Section 14.8.2, “EXPLAIN Syntax”](#).

## 16.7.2 MERGE Table Problems

The following are known problems with `MERGE` tables:

- In versions of MySQL Server prior to 5.1.23, it was possible to create temporary merge tables with nontemporary child `MyISAM` tables.  
  
From versions 5.1.23, `MERGE` children were locked through the parent table. If the parent was temporary, it was not locked and so the children were not locked either. Parallel use of the `MyISAM` tables corrupted them.
- If you use `ALTER TABLE` to change a `MERGE` table to another storage engine, the mapping to the underlying tables is lost. Instead, the rows from the underlying `MyISAM` tables are copied into the altered table, which then uses the specified storage engine.
- The `INSERT_METHOD` table option for a `MERGE` table indicates which underlying `MyISAM` table to use for inserts into the `MERGE` table. However, use of the `AUTO_INCREMENT` table option for that `MyISAM` table has no effect for inserts into the `MERGE` table until at least one row has been inserted directly into the `MyISAM` table.
- A `MERGE` table cannot maintain uniqueness constraints over the entire table. When you perform an `INSERT`, the data goes into the first or last `MyISAM` table (as determined by the `INSERT_METHOD` option). MySQL ensures that unique key values remain unique within that `MyISAM` table, but not over all the underlying tables in the collection.
- Because the `MERGE` engine cannot enforce uniqueness over the set of underlying tables, `REPLACE` does not work as expected. The two key facts are:
  - `REPLACE` can detect unique key violations only in the underlying table to which it is going to write (which is determined by the `INSERT_METHOD` option). This differs from violations in the `MERGE` table itself.
  - If `REPLACE` detects a unique key violation, it will change only the corresponding row in the underlying table it is writing to; that is, the first or last table, as determined by the `INSERT_METHOD` option.

Similar considerations apply for `INSERT ... ON DUPLICATE KEY UPDATE`.

- `MERGE` tables do not support partitioning. That is, you cannot partition a `MERGE` table, nor can any of a `MERGE` table's underlying `MyISAM` tables be partitioned.
- You should not use `ANALYZE TABLE`, `REPAIR TABLE`, `OPTIMIZE TABLE`, `ALTER TABLE`, `DROP TABLE`, `DELETE` without a `WHERE` clause, or `TRUNCATE TABLE` on any of the tables that are mapped into an open `MERGE` table. If you do so, the `MERGE` table may still refer to the original table and yield unexpected results. To work around this problem, ensure that no `MERGE` tables remain open by issuing a `FLUSH TABLES` statement prior to performing any of the named operations.

The unexpected results include the possibility that the operation on the `MERGE` table will report table corruption. If this occurs after one of the named operations on the underlying `MyISAM` tables, the corruption message is spurious. To deal with this, issue a `FLUSH TABLES` statement after modifying the `MyISAM` tables.

- `DROP TABLE` on a table that is in use by a `MERGE` table does not work on Windows because the `MERGE` storage engine's table mapping is hidden from the upper layer of MySQL. Windows does not permit open files to be deleted, so you first must flush all `MERGE` tables (with `FLUSH TABLES`) or drop the `MERGE` table before dropping the table.

- The definition of the [MyISAM](#) tables and the [MERGE](#) table are checked when the tables are accessed (for example, as part of a [SELECT](#) or [INSERT](#) statement). The checks ensure that the definitions of the tables and the parent [MERGE](#) table definition match by comparing column order, types, sizes and associated indexes. If there is a difference between the tables, an error is returned and the statement fails. Because these checks take place when the tables are opened, any changes to the definition of a single table, including column changes, column ordering, and engine alterations will cause the statement to fail.
- The order of indexes in the [MERGE](#) table and its underlying tables should be the same. If you use [ALTER TABLE](#) to add a [UNIQUE](#) index to a table used in a [MERGE](#) table, and then use [ALTER TABLE](#) to add a nonunique index on the [MERGE](#) table, the index ordering is different for the tables if there was already a nonunique index in the underlying table. (This happens because [ALTER TABLE](#) puts [UNIQUE](#) indexes before nonunique indexes to facilitate rapid detection of duplicate keys.) Consequently, queries on tables with such indexes may return unexpected results.
- If you encounter an error message similar to `ERROR 1017 (HY000): Can't find file: 'tbl_name.MRG' (errno: 2)`, it generally indicates that some of the underlying tables do not use the [MyISAM](#) storage engine. Confirm that all of these tables are [MyISAM](#).
- The maximum number of rows in a [MERGE](#) table is  $2^{64}$  (~1.844E+19; the same as for a [MyISAM](#) table). It is not possible to merge multiple [MyISAM](#) tables into a single [MERGE](#) table that would have more than this number of rows.
- Use of underlying [MyISAM](#) tables of differing row formats with a parent [MERGE](#) table is currently known to fail. See Bug #32364.
- You cannot change the union list of a nontemporary [MERGE](#) table when [LOCK TABLES](#) is in effect. The following does *not* work:

```
CREATE TABLE m1 ... ENGINE=MRG_MYISAM ...;
LOCK TABLES t1 WRITE, t2 WRITE, m1 WRITE;
ALTER TABLE m1 ... UNION=(t1,t2) ...;
```

However, you can do this with a temporary [MERGE](#) table.

- You cannot create a [MERGE](#) table with [CREATE ... SELECT](#), neither as a temporary [MERGE](#) table, nor as a nontemporary [MERGE](#) table. For example:

```
CREATE TABLE m1 ... ENGINE=MRG_MYISAM ... SELECT ...;
```

Attempts to do this result in an error: `tbl_name` is not [BASE TABLE](#).

- In some cases, differing [PACK\\_KEYS](#) table option values among the [MERGE](#) and underlying tables cause unexpected results if the underlying tables contain [CHAR](#) or [BINARY](#) columns. As a workaround, use [ALTER TABLE](#) to ensure that all involved tables have the same [PACK\\_KEYS](#) value. (Bug #50646)

## 16.8 The FEDERATED Storage Engine

The [FEDERATED](#) storage engine lets you access data from a remote MySQL database without using replication or cluster technology. Querying a local [FEDERATED](#) table automatically pulls the data from the remote (federated) tables. No data is stored on the local tables.

To include the [FEDERATED](#) storage engine if you build MySQL from source, invoke [CMake](#) with the `-DWITH_FEDERATED_STORAGE_ENGINE` option.

The [FEDERATED](#) storage engine is not enabled by default in the running server; to enable [FEDERATED](#), you must start the MySQL server binary using the `--federated` option.

To examine the source for the [FEDERATED](#) engine, look in the `storage/federated` directory of a MySQL source distribution.

## 16.8.1 FEDERATED Storage Engine Overview

When you create a table using one of the standard storage engines (such as [MyISAM](#), [CSV](#) or [InnoDB](#)), the table consists of the table definition and the associated data. When you create a [FEDERATED](#) table, the table definition is the same, but the physical storage of the data is handled on a remote server.

A [FEDERATED](#) table consists of two elements:

- A *remote server* with a database table, which in turn consists of the table definition (stored in the `.frm` file) and the associated table. The table type of the remote table may be any type supported by the remote `mysqld` server, including [MyISAM](#) or [InnoDB](#).
- A *local server* with a database table, where the table definition matches that of the corresponding table on the remote server. The table definition is stored within the `.frm` file. However, there is no data file on the local server. Instead, the table definition includes a connection string that points to the remote table.

When executing queries and statements on a [FEDERATED](#) table on the local server, the operations that would normally insert, update or delete information from a local data file are instead sent to the remote server for execution, where they update the data file on the remote server or return matching rows from the remote server.

The basic structure of a [FEDERATED](#) table setup is shown in [Figure 16.1, “FEDERATED Table Structure”](#).

**Figure 16.1 FEDERATED Table Structure**

When a client issues an SQL statement that refers to a [FEDERATED](#) table, the flow of information between the local server (where the SQL statement is executed) and the remote server (where the data is physically stored) is as follows:

1. The storage engine looks through each column that the [FEDERATED](#) table has and constructs an appropriate SQL statement that refers to the remote table.
2. The statement is sent to the remote server using the MySQL client API.
3. The remote server processes the statement and the local server retrieves any result that the statement produces (an affected-rows count or a result set).
4. If the statement produces a result set, each column is converted to internal storage engine format that the [FEDERATED](#) engine expects and can use to display the result to the client that issued the original statement.

The local server communicates with the remote server using MySQL client C API functions. It invokes `mysql_real_query()` to send the statement. To read a result set, it uses `mysql_store_result()` and fetches rows one at a time using `mysql_fetch_row()`.

## 16.8.2 How to Create FEDERATED Tables

To create a [FEDERATED](#) table you should follow these steps:

1. Create the table on the remote server. Alternatively, make a note of the table definition of an existing table, perhaps using the [SHOW CREATE TABLE](#) statement.
2. Create the table on the local server with an identical table definition, but adding the connection information that links the local table to the remote table.

For example, you could create the following table on the remote server:

```
CREATE TABLE test_table (
  id      INT(20) NOT NULL AUTO_INCREMENT,
  name    VARCHAR(32) NOT NULL DEFAULT '',
  other   INT(20) NOT NULL DEFAULT '0',
  PRIMARY KEY (id),
  INDEX name (name),
  INDEX other_key (other)
)
ENGINE=MyISAM
DEFAULT CHARSET=latin1;
```

To create the local table that will be federated to the remote table, there are two options available. You can either create the local table and specify the connection string (containing the server name, login, password) to be used to connect to the remote table using the [CONNECTION](#), or you can use an existing connection that you have previously created using the [CREATE SERVER](#) statement.

### Important

When you create the local table it *must* have an identical field definition to the remote table.

### Note

You can improve the performance of a [FEDERATED](#) table by adding indexes to the table on the host. The optimization will occur because the query sent to the remote server will include the contents of the [WHERE](#) clause and will be sent to the remote server and subsequently executed locally. This reduces the network traffic that would otherwise request the entire table from the server for local processing.

### 16.8.2.1 Creating a FEDERATED Table Using CONNECTION

To use the first method, you must specify the [CONNECTION](#) string after the engine type in a [CREATE TABLE](#) statement. For example:

```
CREATE TABLE federated_table (
  id      INT(20) NOT NULL AUTO_INCREMENT,
  name    VARCHAR(32) NOT NULL DEFAULT '',
  other   INT(20) NOT NULL DEFAULT '0',
  PRIMARY KEY (id),
  INDEX name (name),
  INDEX other_key (other)
)
ENGINE=FEDERATED
DEFAULT CHARSET=latin1
CONNECTION='mysql://fed_user@remote_host:9306/federated/test_table';
```

### Note

[CONNECTION](#) replaces the [COMMENT](#) used in some previous versions of MySQL.

The `CONNECTION` string contains the information required to connect to the remote server containing the table that will be used to physically store the data. The connection string specifies the server name, login credentials, port number and database/table information. In the example, the remote table is on the server `remote_host`, using port 9306. The name and port number should match the host name (or IP address) and port number of the remote MySQL server instance you want to use as your remote table.

The format of the connection string is as follows:

```
scheme://user_name[:password]@host_name[:port_num]/db_name/tbl_name
```

Where:

- `scheme`: A recognized connection protocol. Only `mysql` is supported as the `scheme` value at this point.
- `user_name`: The user name for the connection. This user must have been created on the remote server, and must have suitable privileges to perform the required actions (`SELECT`, `INSERT`, `UPDATE`, and so forth) on the remote table.
- `password`: (Optional) The corresponding password for `user_name`.
- `host_name`: The host name or IP address of the remote server.
- `port_num`: (Optional) The port number for the remote server. The default is 3306.
- `db_name`: The name of the database holding the remote table.
- `tbl_name`: The name of the remote table. The name of the local and the remote table do not have to match.

Sample connection strings:

```
CONNECTION='mysql://username:password@hostname:port/database/tablename'
CONNECTION='mysql://username@hostname/database/tablename'
CONNECTION='mysql://username:password@hostname/database/tablename'
```

### 16.8.2.2 Creating a FEDERATED Table Using CREATE SERVER

If you are creating a number of `FEDERATED` tables on the same server, or if you want to simplify the process of creating `FEDERATED` tables, you can use the `CREATE SERVER` statement to define the server connection parameters, just as you would with the `CONNECTION` string.

The format of the `CREATE SERVER` statement is:

```
CREATE SERVER
server_name
FOREIGN DATA WRAPPER wrapper_name
OPTIONS (option [, option] ...)
```

The `server_name` is used in the connection string when creating a new `FEDERATED` table.

For example, to create a server connection identical to the `CONNECTION` string:

```
CONNECTION='mysql://fed_user@remote_host:9306/federated/test_table';
```

You would use the following statement:

```
CREATE SERVER fedlink
FOREIGN DATA WRAPPER mysql
OPTIONS (USER 'fed_user', HOST 'remote_host', PORT 9306, DATABASE 'federated');
```

To create a `FEDERATED` table that uses this connection, you still use the `CONNECTION` keyword, but specify the name you used in the `CREATE SERVER` statement.

```
CREATE TABLE test_table (
  id      INT(20) NOT NULL AUTO_INCREMENT,
  name    VARCHAR(32) NOT NULL DEFAULT '',
  other   INT(20) NOT NULL DEFAULT '0',
  PRIMARY KEY (id),
  INDEX name (name),
  INDEX other_key (other)
)
ENGINE=FEDERATED
DEFAULT CHARSET=latin1
CONNECTION='fedlink/test_table';
```

The connection name in this example contains the name of the connection ([fedlink](#)) and the name of the table ([test\\_table](#)) to link to, separated by a slash. If you specify only the connection name without a table name, the table name of the local table is used instead.

For more information on [CREATE SERVER](#), see [Section 14.1.17, “CREATE SERVER Syntax”](#).

The [CREATE SERVER](#) statement accepts the same arguments as the [CONNECTION](#) string. The [CREATE SERVER](#) statement updates the rows in the [mysql.servers](#) table. See the following table for information on the correspondence between parameters in a connection string, options in the [CREATE SERVER](#) statement, and the columns in the [mysql.servers](#) table. For reference, the format of the [CONNECTION](#) string is as follows:

```
scheme://user_name[:password]@host_name[:port_num]/db_name/tbl_name
```

| Description       | CONNECTION string | CREATE SERVER option | mysql.servers column |
|-------------------|-------------------|----------------------|----------------------|
| Connection scheme | <i>scheme</i>     | wrapper_name         | Wrapper              |
| Remote user       | <i>user_name</i>  | USER                 | Username             |
| Remote password   | <i>password</i>   | PASSWORD             | Password             |
| Remote host       | <i>host_name</i>  | HOST                 | Host                 |
| Remote port       | <i>port_num</i>   | PORT                 | Port                 |
| Remote database   | <i>db_name</i>    | DATABASE             | Db                   |

### 16.8.3 FEDERATED Storage Engine Notes and Tips

You should be aware of the following points when using the [FEDERATED](#) storage engine:

- [FEDERATED](#) tables may be replicated to other slaves, but you must ensure that the slave servers are able to use the user/password combination that is defined in the [CONNECTION](#) string (or the row in the [mysql.servers](#) table) to connect to the remote server.

The following items indicate features that the [FEDERATED](#) storage engine does and does not support:

- The remote server must be a MySQL server.
- The remote table that a [FEDERATED](#) table points to *must* exist before you try to access the table through the [FEDERATED](#) table.
- It is possible for one [FEDERATED](#) table to point to another, but you must be careful not to create a loop.
- A [FEDERATED](#) table does not support indexes in the usual sense; because access to the table data is handled remotely, it is actually the remote table that makes use of indexes. This means that, for a query that cannot use any indexes and so requires a full table scan, the server fetches all rows from the remote table and filters them locally. This occurs regardless of any [WHERE](#) or [LIMIT](#) used with this [SELECT](#) statement; these clauses are applied locally to the returned rows.

Queries that fail to use indexes can thus cause poor performance and network overload. In addition, since returned rows must be stored in memory, such a query can also lead to the local server swapping, or even hanging.

- Care should be taken when creating a [FEDERATED](#) table since the index definition from an equivalent [MyISAM](#) or other table may not be supported. For example, creating a [FEDERATED](#) table with an index prefix on [VARCHAR](#), [TEXT](#) or [BLOB](#) columns will fail. The following definition in [MyISAM](#) is valid:

```
CREATE TABLE `T1`(`A` VARCHAR(100),UNIQUE KEY(`A`(30))) ENGINE=MYISAM;
```

The key prefix in this example is incompatible with the [FEDERATED](#) engine, and the equivalent statement will fail:

```
CREATE TABLE `T1`(`A` VARCHAR(100),UNIQUE KEY(`A`(30))) ENGINE=FEDERATED
CONNECTION='MYSQL://127.0.0.1:3306/TEST/T1';
```

If possible, you should try to separate the column and index definition when creating tables on both the remote server and the local server to avoid these index issues.

- Internally, the implementation uses [SELECT](#), [INSERT](#), [UPDATE](#), and [DELETE](#), but not [HANDLER](#).
- The [FEDERATED](#) storage engine supports [SELECT](#), [INSERT](#), [UPDATE](#), [DELETE](#), [TRUNCATE TABLE](#), and indexes. It does not support [ALTER TABLE](#), or any Data Definition Language statements that directly affect the structure of the table, other than [DROP TABLE](#). The current implementation does not use prepared statements.
- [FEDERATED](#) accepts [INSERT ... ON DUPLICATE KEY UPDATE](#) statements, but if a duplicate-key violation occurs, the statement fails with an error.
- Performance on a [FEDERATED](#) table when performing bulk inserts (for example, on a [INSERT INTO ... SELECT ...](#) statement) is slower than with other table types because each selected row is treated as an individual [INSERT](#) statement on the [FEDERATED](#) table.
- Transactions are not supported.
- [FEDERATED](#) performs bulk-insert handling such that multiple rows are sent to the remote table in a batch. This provides a performance improvement and enables the remote table to perform improvement. Also, if the remote table is transactional, it enables the remote storage engine to perform statement rollback properly should an error occur. This capability has the following limitations:
  - The size of the insert cannot exceed the maximum packet size between servers. If the insert exceeds this size, it is broken into multiple packets and the rollback problem can occur.
  - Bulk-insert handling does not occur for [INSERT ... ON DUPLICATE KEY UPDATE](#).
- There is no way for the [FEDERATED](#) engine to know if the remote table has changed. The reason for this is that this table must work like a data file that would never be written to by anything other than the database system. The integrity of the data in the local table could be breached if there was any change to the remote database.
- When using a [CONNECTION](#) string, you cannot use an '@' character in the password. You can get round this limitation by using the [CREATE SERVER](#) statement to create a server connection.
- The [insert\\_id](#) and [timestamp](#) options are not propagated to the data provider.
- Any [DROP TABLE](#) statement issued against a [FEDERATED](#) table drops only the local table, not the remote table.
- [FEDERATED](#) tables do not work with the query cache.
- User-defined partitioning is not supported for [FEDERATED](#) tables.

## 16.8.4 FEDERATED Storage Engine Resources

The following additional resources are available for the `FEDERATED` storage engine:

- A forum dedicated to the `FEDERATED` storage engine is available at <http://forums.mysql.com/list.php?105>.

## 16.9 The EXAMPLE Storage Engine

The `EXAMPLE` storage engine is a stub engine that does nothing. Its purpose is to serve as an example in the MySQL source code that illustrates how to begin writing new storage engines. As such, it is primarily of interest to developers.

To enable the `EXAMPLE` storage engine if you build MySQL from source, invoke `CMake` with the `-DWITH_EXAMPLE_STORAGE_ENGINE` option.

To examine the source for the `EXAMPLE` engine, look in the `storage/example` directory of a MySQL source distribution.

When you create an `EXAMPLE` table, the server creates a table format file in the database directory. The file begins with the table name and has an `.frm` extension. No other files are created. No data can be stored into the table. Retrievals return an empty result.

```
mysql> CREATE TABLE test (i INT) ENGINE = EXAMPLE;
Query OK, 0 rows affected (0.78 sec)

mysql> INSERT INTO test VALUES(1),(2),(3);
ERROR 1031 (HY000): Table storage engine for 'test' doesn't »
      have this option

mysql> SELECT * FROM test;
Empty set (0.31 sec)
```

The `EXAMPLE` storage engine does not support indexing.

## 16.10 Other Storage Engines

Other storage engines may be available from third parties and community members that have used the Custom Storage Engine interface.

Third party engines are not supported by MySQL. For further information, documentation, installation guides, bug reporting or for any help or assistance with these engines, please contact the developer of the engine directly.

For more information on developing a customer storage engine that can be used with the Pluggable Storage Engine Architecture, see [MySQL Internals: Writing a Custom Storage Engine](#).

## 16.11 Overview of MySQL Storage Engine Architecture

The MySQL pluggable storage engine architecture enables a database professional to select a specialized storage engine for a particular application need while being completely shielded from the need to manage any specific application coding requirements. The MySQL server architecture isolates the application programmer and DBA from all of the low-level implementation details at the storage level, providing a consistent and easy application model and API. Thus, although there are different capabilities across different storage engines, the application is shielded from these differences.

The pluggable storage engine architecture provides a standard set of management and support services that are common among all underlying storage engines. The storage engines themselves are the components of the database server that actually perform actions on the underlying data that is maintained at the physical server level.

This efficient and modular architecture provides huge benefits for those wishing to specifically target a particular application need—such as data warehousing, transaction processing, or high availability situations—while enjoying the advantage of utilizing a set of interfaces and services that are independent of any one storage engine.

The application programmer and DBA interact with the MySQL database through Connector APIs and service layers that are above the storage engines. If application changes bring about requirements that demand the underlying storage engine change, or that one or more storage engines be added to support new needs, no significant coding or process changes are required to make things work. The MySQL server architecture shields the application from the underlying complexity of the storage engine by presenting a consistent and easy-to-use API that applies across storage engines.

### 16.11.1 Pluggable Storage Engine Architecture

MySQL Server uses a pluggable storage engine architecture that enables storage engines to be loaded into and unloaded from a running MySQL server.

#### Plugging in a Storage Engine

Before a storage engine can be used, the storage engine plugin shared library must be loaded into MySQL using the `INSTALL PLUGIN` statement. For example, if the `EXAMPLE` engine plugin is named `example` and the shared library is named `ha_example.so`, you load it with the following statement:

```
mysql> INSTALL PLUGIN example SONAME 'ha_example.so';
```

To install a pluggable storage engine, the plugin file must be located in the MySQL plugin directory, and the user issuing the `INSTALL PLUGIN` statement must have `INSERT` privilege for the `mysql.plugin` table.

The shared library must be located in the MySQL server plugin directory, the location of which is given by the `plugin_dir` system variable.

#### Unplugging a Storage Engine

To unplug a storage engine, use the `UNINSTALL PLUGIN` statement:

```
mysql> UNINSTALL PLUGIN example;
```

If you unplug a storage engine that is needed by existing tables, those tables become inaccessible, but will still be present on disk (where applicable). Ensure that there are no tables using a storage engine before you unplug the storage engine.

### 16.11.2 The Common Database Server Layer

A MySQL pluggable storage engine is the component in the MySQL database server that is responsible for performing the actual data I/O operations for a database as well as enabling and enforcing certain feature sets that target a specific application need. A major benefit of using specific storage engines is that you are only delivered the features needed for a particular application, and therefore you have less system overhead in the database, with the end result being more efficient and higher database performance. This is one of the reasons that MySQL has always been known to have such high performance, matching or beating proprietary monolithic databases in industry standard benchmarks.

From a technical perspective, what are some of the unique supporting infrastructure components that are in a storage engine? Some of the key feature differentiations include:

- *Concurrency*: Some applications have more granular lock requirements (such as row-level locks) than others. Choosing the right locking strategy can reduce overhead and therefore improve overall

performance. This area also includes support for capabilities such as multi-version concurrency control or “snapshot” read.

- *Transaction Support*: Not every application needs transactions, but for those that do, there are very well defined requirements such as ACID compliance and more.
- *Referential Integrity*: The need to have the server enforce relational database referential integrity through DDL defined foreign keys.
- *Physical Storage*: This involves everything from the overall page size for tables and indexes as well as the format used for storing data to physical disk.
- *Index Support*: Different application scenarios tend to benefit from different index strategies. Each storage engine generally has its own indexing methods, although some (such as B-tree indexes) are common to nearly all engines.
- *Memory Caches*: Different applications respond better to some memory caching strategies than others, so although some memory caches are common to all storage engines (such as those used for user connections or MySQL's high-speed Query Cache), others are uniquely defined only when a particular storage engine is put in play.
- *Performance Aids*: This includes multiple I/O threads for parallel operations, thread concurrency, database checkpointing, bulk insert handling, and more.
- *Miscellaneous Target Features*: This may include support for geospatial operations, security restrictions for certain data manipulation operations, and other similar features.

Each set of the pluggable storage engine infrastructure components are designed to offer a selective set of benefits for a particular application. Conversely, avoiding a set of component features helps reduce unnecessary overhead. It stands to reason that understanding a particular application's set of requirements and selecting the proper MySQL storage engine can have a dramatic impact on overall system efficiency and performance.

Data is the currency of today's web, mobile, social, enterprise and cloud applications. Ensuring data is always available is a top priority for any organization. Minutes of downtime can result in significant loss of revenue and reputation.

There is no “one size fits all” approach to delivering High Availability (HA). Unique application attributes, business requirements, operational capabilities and legacy infrastructure can all influence HA technology selection. And technology is only one element in delivering HA: people and processes are just as critical as the technology itself.

MySQL is deployed into many applications demanding availability and scalability. **Availability** refers to the ability to cope with, and if necessary recover from, failures on the host, including failures of MySQL, the operating system, or the hardware and maintenance activity that may otherwise cause downtime. [Scalability](#) refers to the ability to spread both the database and the load of your application queries across multiple MySQL servers.

Because each application has different operational and availability requirements, MySQL offers a range of certified and supported solutions, delivering the appropriate levels of High Availability (HA) and scalability to meet service level requirements. Such solutions extend from replication, through virtualization and geographically redundant, multi-data center solutions delivering 99.999% uptime.

Selecting the right high availability solution for an application largely depends on:

- The level of availability required.
- The type of application being deployed.
- Accepted best practices within your own environment.

The primary solutions supported by MySQL include:

- MySQL Replication. Learn more: [Chapter 18, Replication](#).
- MySQL Fabric. Learn more: [MySQL Fabric](#).
- MySQL Cluster. Learn more: [Chapter 20, MySQL NDB Cluster 7.5](#).
- Oracle MySQL Cloud Service. [Learn more about MySQL Cloud Service](#).
- Oracle Clusterware Agent for MySQL. [Learn more about Oracle Clusterware](#).
- MySQL with Solaris Cluster. [Learn more about Solaris Cluster](#).

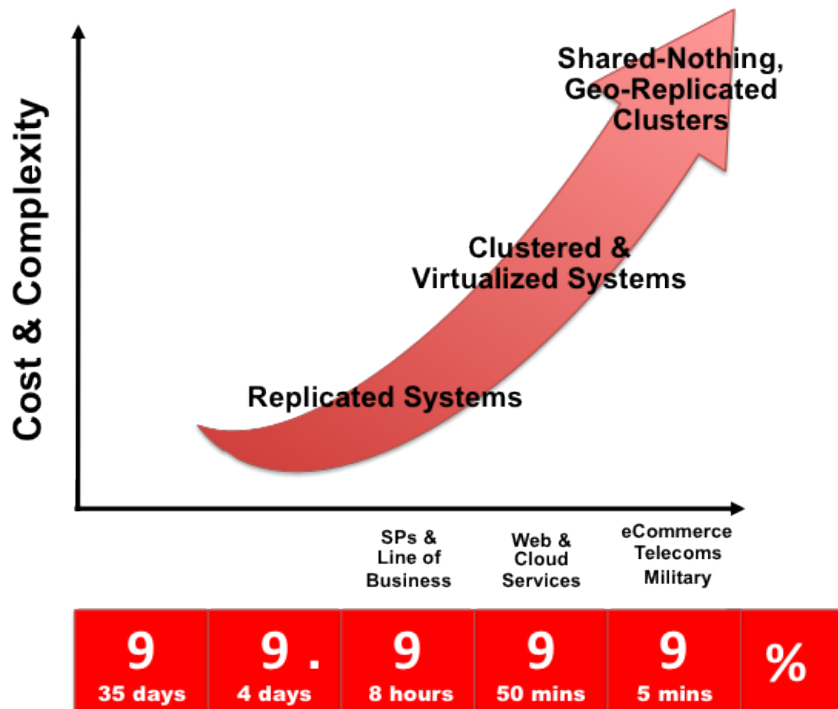

Further options are available using third-party solutions.

Each architecture used to achieve highly available database services is differentiated by the levels of uptime it offers. These architectures can be grouped into three main categories:

- Data Replication.
- Clustered & Virtualized Systems.
- Shared-Nothing, Geographically-Replicated Clusters.

As illustrated in the following figure, each of these architectures offers progressively higher levels of uptime, which must be balanced against potentially greater levels of cost and complexity that each can incur. Simply deploying a high availability architecture is not a guarantee of actually delivering HA. In fact, a poorly implemented and maintained shared-nothing cluster could easily deliver lower levels of availability than a simple data replication solution.

**Figure 17.1 Tradeoffs: Cost and Complexity versus Availability**

The following table compares the HA and Scalability capabilities of the various MySQL solutions:

**Table 17.1 Feature Comparison of MySQL HA Solutions**

| Requirement                      | MySQL Replication   | MySQL Cluster  |
|----------------------------------|---|--|
| <b>Availability</b>              |   |  |
| Platform Support                 | All Supported by MySQL Server ( <a href="http://www.mysql.com/support/supportedplatforms/database.html">http://www.mysql.com/support/supportedplatforms/database.html</a> ) | All Supported by MySQL Cluster ( <a href="http://www.mysql.com/support/supportedplatforms/cluster.html">http://www.mysql.com/support/supportedplatforms/cluster.html</a> ) |
| Automated IP Failover            | No  | Depends on Connector and Configuration   |
| Automated Database Failover      | No  | Yes  |
| Automatic Data Resynchronization | No  | Yes  |
| Typical Failover Time            | User / Script Dependent   | 1 Second and Less  |
| Synchronous Replication          | No, Asynchronous and Semisynchronous  | Yes  |
| Shared Storage                   | No, Distributed   | No, Distributed  |

| Requirement                                  | MySQL Replication                   | MySQL Cluster              |
|--|-------------------------------------|----------------------------|
| Geographic redundancy support                | Yes                                 | Yes, via MySQL Replication |
| Update Schema On-Line                        | No                                  | Yes                        |
| <b>Scalability</b>                           |                                     |                            |
| Number of Nodes                              | One Master, Multiple Slaves         | 255                        |
| Built-in Load Balancing                      | Reads, via MySQL Replication        | Yes, Reads and Writes      |
| Supports Read-Intensive Workloads            | Yes                                 | Yes                        |
| Supports Write-Intensive Workloads           | Yes, via Application-Level Sharding | Yes, via Auto-Sharding     |
| Scale On-Line (add nodes, repartition, etc.) | No                                  | Yes                        |

## 17.1 Using ZFS Replication

To support high availability environments, providing an instant copy of the information on both the currently active machine and the hot backup is a critical part of the HA solution. There are many solutions to this problem, such as [Chapter 18, Replication](#).

The ZFS file system provides functionality to create a snapshot of the file system contents, transfer the snapshot to another machine, and extract the snapshot to recreate the file system. You can create a snapshot at any time, and you can create as many snapshots as you like. By continually creating, transferring, and restoring snapshots, you can provide synchronization between one or more machines in a fashion similar to DRBD.

The following example shows a simple Solaris system running with a single ZFS pool, mounted at `/scratchpool`:

```

Filesystem              size   used   avail capacity  Mounted on
/dev/dsk/c0d0s0         4.6G   3.7G   886M    82%      /
/devices                0K     0K     0K     0%      /devices
ctfs                   0K     0K     0K     0%      /system/contract
proc                   0K     0K     0K     0%      /proc
mnttab                 0K     0K     0K     0%      /etc/mnttab
swap                  1.4G   892K   1.4G     1%      /etc/svc/volatile
objfs                  0K     0K     0K     0%      /system/object
/usr/lib/libc/libc_hwcapi.so.1
                        4.6G   3.7G   886M    82%      /lib/libc.so.1
fd                     0K     0K     0K     0%      /dev/fd
swap                  1.4G    40K   1.4G     1%      /tmp
swap                  1.4G    28K   1.4G     1%      /var/run
/dev/dsk/c0d0s7         26G   913M   25G     4%      /export/home
scratchpool            16G    24K   16G     1%      /scratchpool

```

The MySQL data is stored in a directory on `/scratchpool`. To help demonstrate some of the basic replication functionality, there are also other items stored in `/scratchpool` as well:

```

total 17
drwxr-xr-x  31 root    bin          50 Jul 21 07:32 DTT/
drwxr-xr-x   4 root    bin           5 Jul 21 07:32 SUNWmlib/
drwxr-xr-x  14 root    sys          16 Nov  5 09:56 SUNWspro/
drwxrwxrwx  19 1000   1000         40 Nov  6 19:16 emacs-22.1/

```

To create a snapshot of the file system, you use `zfs snapshot`, specifying the pool and the snapshot name:

```
root-shell> zfs snapshot scratchpool@snap1
```

To list the snapshots already taken:

```
root-shell> zfs list -t snapshot
NAME                USED  AVAIL  REFER  MOUNTPOINT
scratchpool@snap1    0      -    24.5K  -
scratchpool@snap2    0      -    24.5K  -
```

The snapshots themselves are stored within the file system metadata, and the space required to keep them varies as time goes on because of the way the snapshots are created. The initial creation of a snapshot is very quick, because instead of taking an entire copy of the data and metadata required to hold the entire snapshot, ZFS records only the point in time and metadata of when the snapshot was created.

As more changes to the original file system are made, the size of the snapshot increases because more space is required to keep the record of the old blocks. If you create lots of snapshots, say one per day, and then delete the snapshots from earlier in the week, the size of the newer snapshots might also increase, as the changes that make up the newer state have to be included in the more recent snapshots, rather than being spread over the seven snapshots that make up the week.

You cannot directly back up the snapshots because they exist within the file system metadata rather than as regular files. To get the snapshot into a format that you can copy to another file system, tape, and so on, you use the `zfs send` command to create a stream version of the snapshot.

For example, to write the snapshot out to a file:

```
root-shell> zfs send scratchpool@snap1 >/backup/scratchpool-snap1
```

Or tape:

```
root-shell> zfs send scratchpool@snap1 >/dev/rmt/0
```

You can also write out the incremental changes between two snapshots using `zfs send`:

```
root-shell> zfs send scratchpool@snap1 scratchpool@snap2 >/backup/scratchpool-changes
```

To recover a snapshot, you use `zfs recv`, which applies the snapshot information either to a new file system, or to an existing one.

### 17.1.1 Using ZFS for File System Replication

Because `zfs send` and `zfs recv` use streams to exchange data, you can use them to replicate information from one system to another by combining `zfs send`, `ssh`, and `zfs recv`.

For example, to copy a snapshot of the `scratchpool` file system to a new file system called `slavepool` on a new server, you would use the following command. This sequence combines the snapshot of `scratchpool`, the transmission to the slave machine (using `ssh` with login credentials), and the recovery of the snapshot on the slave using `zfs recv`:

```
root-shell> zfs send scratchpool@snap1 | ssh id@host pfexec zfs recv -F slavepool
```

The first part of the pipeline, `zfs send scratchpool@snap1`, streams the snapshot. The `ssh` command, and the command that it executes on the other server, `pfexec zfs recv -F slavepool`, receives the streamed snapshot data and writes it to `slavepool`. In this instance, I've specified the `-F` option which forces the snapshot data to be applied, and is therefore destructive. This is fine, as I'm creating the first version of my replicated file system.

On the slave machine, the replicated file system contains the exact same content:

```
root-shell> ls -al /slavepool/
total 23
drwxr-xr-x  6 root    root      7 Nov  8 09:13 ./
drwxr-xr-x 29 root    root      34 Nov  9 07:06 ../
drwxr-xr-x 31 root    bin       50 Jul 21 07:32 DTT/
drwxr-xr-x  4 root    bin       5 Jul 21 07:32 SUNWmlib/
drwxr-xr-x 14 root    sys       16 Nov  5 09:56 SUNWspro/
drwxrwxrwx 19 1000   1000      40 Nov  6 19:16 emacs-22.1/
```

Once a snapshot has been created, to synchronize the file system again, you create a new snapshot and then use the incremental snapshot feature of `zfs send` to send the changes between the two snapshots to the slave machine again:

```
root-shell> zfs send -i scratchpool@snapshot1 scratchpool@snapshot2 |ssh id@host pfexec zfs recv slavepool
```

This operation only succeeds if the file system on the slave machine has not been modified at all. You cannot apply the incremental changes to a destination file system that has changed. In the example above, the `ls` command would cause problems by changing the metadata, such as the last access time for files or directories.

To prevent changes on the slave file system, set the file system on the slave to be read-only:

```
root-shell> zfs set readonly=on slavepool
```

Setting `readonly` means that you cannot change the file system on the slave by normal means, including the file system metadata. Operations that would normally update metadata (like our `ls`) silently perform their function without attempting to update the file system state.

In essence, the slave file system is nothing but a static copy of the original file system. However, even when configured to be read-only, a file system can have snapshots applied to it. With the file system set to read only, re-run the initial copy:

```
root-shell> zfs send scratchpool@snap1 |ssh id@host pfexec zfs recv -F slavepool
```

Now you can make changes to the original file system and replicate them to the slave.

## 17.1.2 Configuring MySQL for ZFS Replication

Configuring MySQL on the source file system is a case of creating the data on the file system that you intend to replicate. The configuration file in the example below has been updated to use `/scratchpool/mysql-data` as the data directory, and now you can initialize the tables:

```
root-shell> mysql_install_db --defaults-file=/etc/mysql/5.5/my.cnf --user=mysql
```

To synchronize the initial information, perform a new snapshot and then send an incremental snapshot to the slave using `zfs send`:

```
root-shell> zfs snapshot scratchpool@snap2
root-shell> zfs send -i scratchpool@snap1 scratchpool@snap2|ssh id@host pfexec zfs recv slavepool
```

Doublecheck that the slave has the data by looking at the MySQL data directory on the `slavepool`:

```
root-shell> ls -al /slavepool/mysql-data/
```

Now you can start up MySQL, create some data, and then replicate the changes using `zfs send`/`zfs recv` to the slave to synchronize the changes.

The rate at which you perform the synchronization depends on your application and environment. The limitation is the speed required to perform the snapshot and then to send the changes over the network.

To automate the process, create a script that performs the snapshot, send, and receive operation, and use [cron](#) to synchronize the changes at set times or intervals.

### 17.1.3 Handling MySQL Recovery with ZFS

When using ZFS replication to provide a constant copy of your data, ensure that you can recover your tables, either manually or automatically, in the event of a failure of the original system.

In the event of a failure, follow this sequence:

1. Stop the script on the master, if it is still up and running.
2. Set the slave file system to be read/write:

```
root-shell> zfs set readonly=off slavepool
```

3. Start up [mysqld](#) on the slave. If you are using [InnoDB](#), you get auto-recovery, if it is needed, to make sure the table data is correct, as shown here when I started up from our mid-INSERT snapshot:

```
InnoDB: The log sequence number in ibdata files does not match
InnoDB: the log sequence number in the ib_logfiles!
081109 15:59:59 InnoDB: Database was not shut down normally!
InnoDB: Starting crash recovery.
InnoDB: Reading tablespace information from the .ibd files...
InnoDB: Restoring possible half-written data pages from the doublewrite
InnoDB: buffer...
081109 16:00:03 InnoDB: Started; log sequence number 0 1142807951
081109 16:00:03 [Note] /slavepool/mysql-5.0.67-solaris10-i386/bin/mysqld: ready for connections.
Version: '5.0.67' socket: '/tmp/mysql.sock' port: 3306 MySQL Community Server (GPL)
```

Use [InnoDB](#) tables and a regular synchronization schedule to reduce the risk for significant data loss. On MyISAM tables, you might need to run [REPAIR TABLE](#), and you might even have lost some information.

## 17.2 Using MySQL with [memcached](#)

[memcached](#) is a simple, highly scalable key-based cache that stores data and objects wherever dedicated or spare RAM is available for quick access by applications, without going through layers of parsing or disk I/O. To use, you run the [memcached](#) command on one or more hosts and then use the shared cache to store objects. For more usage instructions, see [Section 17.2.2, “Using memcached”](#)

Benefits of using [memcached](#) include:

- Because all information is stored in RAM, the access speed is faster than loading the information each time from disk.
- Because the “value” portion of the key-value pair does not have any data type restrictions, you can cache data such as complex structures, documents, images, or a mixture of such things.
- If you use the in-memory cache to hold transient information, or as a read-only cache for information also stored in a database, the failure of any [memcached](#) server is not critical. For persistent data, you can fall back to an alternative lookup method using database queries, and reload the data into RAM on a different server.

The typical usage environment is to modify your application so that information is read from the cache provided by [memcached](#). If the information is not in [memcached](#), then the data is loaded from the MySQL database and written into the cache so that future requests for the same object benefit from the cached data.

For a typical deployment layout, see [Figure 17.2, “memcached Architecture Overview”](#).

**Figure 17.2** `memcached` Architecture Overview

In the example structure, any of the clients can contact one of the `memcached` servers to request a given key. Each client is configured to talk to all of the servers shown in the illustration. Within the client, when the request is made to store the information, the key used to reference the data is hashed and this hash is then used to select one of the `memcached` servers. The selection of the `memcached` server takes place on the client before the server is contacted, keeping the process lightweight.

The same algorithm is used again when a client requests the same key. The same key generates the same hash, and the same `memcached` server is selected as the source for the data. Using this method, the cached data is spread among all of the `memcached` servers, and the cached information is accessible from any client. The result is a distributed, memory-based, cache that can return information, particularly complex data and structures, much faster than natively reading the information from the database.

The data held within a traditional `memcached` server is never stored on disk (only in RAM, which means there is no persistence of data), and the RAM cache is always populated from the backing store (a MySQL database). If a `memcached` server fails, the data can always be recovered from the MySQL database.

## 17.2.1 Installing `memcached`

You can build and install `memcached` from the source code directly, or you can use an existing operating system package or installation.

### Installing `memcached` from a Binary Distribution

To install `memcached` on a Red Hat, or Fedora host, use `yum`:

```
root-shell> yum install memcached
```

#### Note

On CentOS, you may be able to obtain a suitable RPM from another source, or use the source tarball.

To install `memcached` on a Debian or Ubuntu host, use `apt-get`:

```
root-shell> apt-get install memcached
```

To install `memcached` on a Gentoo host, use `emerge`:

```
root-shell> emerge install memcached
```

## Building `memcached` from Source

On other Unix-based platforms, including Solaris, AIX, HP-UX and OS X, and Linux distributions not mentioned already, you must install from source. For Linux, make sure you have a 2.6-based kernel, which includes the improved `epoll` interface. For all platforms, ensure that you have `libevent` 1.1 or higher installed. You can obtain `libevent` from [libevent web page](#).

You can obtain the source for `memcached` from [memcached Web site](#).

To build `memcached`, follow these steps:

1. Extract the `memcached` source package:

```
shell> gunzip -c memcached-1.2.5.tar.gz | tar xf -
```

2. Change to the `memcached-1.2.5` directory:

```
shell> cd memcached-1.2.5
```

3. Run `configure`

```
shell> ./configure
```

Some additional options you might specify to the `configure`:

- `--prefix`

To specify a different installation directory, use the `--prefix` option:

```
shell> ./configure --prefix=/opt
```

The default is to use the `/usr/local` directory.

- `--with-libevent`

If you have installed `libevent` and `configure` cannot find the library, use the `--with-libevent` option to specify the location of the installed library.

- `--enable-64bit`

To build a 64-bit version of `memcached` (which enables you to use a single instance with a large RAM allocation), use `--enable-64bit`.

- `--enable-threads`

To enable multi-threading support in `memcached`, which improves the response times on servers with a heavy load, use `--enable-threads`. You must have support for the POSIX threads within your operating system to enable thread support. For more information on the threading support, see [Section 17.2.2.8, “memcached Thread Support”](#).

- `--enable-dtrace`

`memcached` includes a range of DTrace threads that can be used to monitor and benchmark a `memcached` instance. For more information, see [Section 17.2.2.6, “Using memcached and DTrace”](#).

4. Run `make` to build `memcached`:

```
shell> make
```

5. Run `make install` to install `memcached`:

```
shell> make install
```

## 17.2.2 Using `memcached`

To start using `memcached`, start the `memcached` service on one or more servers. Running `memcached` sets up the server, allocates the memory and starts listening for connections from clients.

### Note

You do not need to be a privileged user (`root`) to run `memcached` except to listen on one of the privileged TCP/IP ports (below 1024). You must, however, use a user that has not had their memory limits restricted using `setrlimit` or similar.

To start the server, run `memcached` as a nonprivileged (that is, non-`root`) user:

```
shell> memcached
```

By default, `memcached` uses the following settings:

- Memory allocation of 64MB
- Listens for connections on all network interfaces, using port 11211
- Supports a maximum of 1024 simultaneous connections

Typically, you would specify the full combination of options that you want when starting `memcached`, and normally provide a startup script to handle the initialization of `memcached`. For example, the following line starts `memcached` with a maximum of 1024MB RAM for the cache, listening on port 11211 on the IP address 192.168.0.110, running as a background daemon:

```
shell> memcached -d -m 1024 -p 11211 -l 192.168.0.110
```

To ensure that `memcached` is started up on boot, check the init script and configuration parameters.

### 17.2.2.1 `memcached` Command-Line Options

`memcached` supports the following options:

- `-u user`

If you start `memcached` as `root`, use the `-u` option to specify the user for executing `memcached`:

```
shell> memcached -u memcache
```

- `-m memory`

Set the amount of memory allocated to `memcached` for object storage. Default is 64MB.

To increase the amount of memory allocated for the cache, use the `-m` option to specify the amount of RAM to be allocated (in megabytes). The more RAM you allocate, the more data you can store and therefore the more effective your cache is.

### Warning

Do not specify a memory allocation larger than your available RAM. If you specify too large a value, then some RAM allocated for `memcached` uses swap space, and not physical RAM. This may lead to delays when storing

and retrieving values, because data is swapped to disk, instead of storing the data directly in RAM.

You can use the output of the `vmstat` command to get the free memory, as shown in `free` column:

```
shell> vmstat
kthr    memory             page            disk           faults          cpu
r  b  w    swap  free  re  mf  pi  po  fr  de  sr  sl  s2  --  --    in    sy    cs  us  sy  id
0   0   0  5170504 3450392 2   7   2   0   0   0   4   0   0   0   0   296   54   199   0   0  100
```

For example, to allocate 3GB of RAM:

```
shell> memcached -m 3072
```

On 32-bit x86 systems where you are using PAE to access memory above the 4GB limit, you cannot allocate RAM beyond the maximum process size. You can get around this by running multiple instances of `memcached`, each listening on a different port:

```
shell> memcached -m 1024 -p11211
shell> memcached -m 1024 -p11212
shell> memcached -m 1024 -p11213
```

#### Note

On all systems, particularly 32-bit, ensure that you leave enough room for both `memcached` application in addition to the memory setting. For example, if you have a dedicated `memcached` host with 4GB of RAM, do not set the memory size above 3500MB. Failure to do this may cause either a crash or severe performance issues.

- `-l interface`

Specify a network interface/address to listen for connections. The default is to listen on all available address (`INADDR_ANY`).

```
shell> memcached -l 192.168.0.110
```

Support for IPv6 address support was added in `memcached` 1.2.5.

- `-p port`

Specify the TCP port to use for connections. Default is 18080.

```
shell> memcached -p 18080
```

- `-U port`

Specify the UDP port to use for connections. Default is 11211, 0 switches UDP off.

```
shell> memcached -U 18080
```

- `-s socket`

Specify a Unix socket to listen on.

If you are running `memcached` on the same server as the clients, you can disable the network interface and use a local Unix socket using the `-s` option:

```
shell> memcached -s /tmp/memcached
```

Using a Unix socket automatically disables network support, and saves network ports (allowing more ports to be used by your web server or other process).

- `-a mask`

Specify the access mask to be used for the Unix socket, in octal. Default is 0700.

- `-c connections`

Specify the maximum number of simultaneous connections to the `memcached` service. The default is 1024.

```
shell> memcached -c 2048
```

Use this option, either to reduce the number of connections (to prevent overloading `memcached` service) or to increase the number to make more effective use of the server running `memcached` server.

- `-t threads`

Specify the number of threads to use when processing incoming requests.

By default, `memcached` is configured to use 4 concurrent threads. The threading improves the performance of storing and retrieving data in the cache, using a locking system to prevent different threads overwriting or updating the same values. To increase or decrease the number of threads, use the `-t` option:

```
shell> memcached -t 8
```

- `-d`

Run `memcached` as a daemon (background) process:

```
shell> memcached -d
```

- `-r`

Maximize the size of the core file limit. In the event of a failure, this attempts to dump the entire memory space to disk as a core file, up to any limits imposed by `setrlimit`.

- `-M`

Return an error to the client when the memory has been exhausted. This replaces the normal behavior of removing older items from the cache to make way for new items.

- `-k`

Lock down all paged memory. This reserves the memory before use, instead of allocating new slabs of memory as new items are stored in the cache.

#### Note

There is a user-level limit on how much memory you can lock. Trying to allocate more than the available memory fails. You can set the limit for the user you started the daemon with (not for the `-u user` user) within the shell by using `ulimit -S -l NUM_KB`

- `-v`

Verbose mode. Prints errors and warnings while executing the main event loop.

- `-vv`

Very verbose mode. In addition to information printed by `-v`, also prints each client command and the response.

- `-vvv`

Extremely verbose mode. In addition to information printed by `-vv`, also show the internal state transitions.

- `-h`

Print the help message and exit.

- `-i`

Print the `memcached` and `libevent` license.

- `-I mem`

Specify the maximum size permitted for storing an object within the `memcached` instance. The size supports a unit postfix (`k` for kilobytes, `m` for megabytes). For example, to increase the maximum supported object size to 32MB:

```
shell> memcached -I 32m
```

The maximum object size you can specify is 128MB, the default remains at 1MB.

This option was added in 1.4.2.

- `-b`

Set the backlog queue limit. The backlog queue configures how many network connections can be waiting to be processed by `memcached`. Increasing this limit may reduce errors received by the client that it is not able to connect to the `memcached` instance, but does not improve the performance of the server. The default is 1024.

- `-P pidfile`

Save the process ID of the `memcached` instance into `file`.

- `-f`

Set the chunk size growth factor. When allocating new memory chunks, the allocated size of new chunks is determined by multiplying the default slab size by this factor.

To see the effects of this option without extensive testing, use the `-vv` command-line option to show the calculated slab sizes. For more information, see [Section 17.2.2.9, “memcached Logs”](#).

- `-n bytes`

The minimum space allocated for the key+value+flags information. The default is 48 bytes.

- `-L`

On systems that support large memory pages, enables large memory page use. Using large memory pages enables `memcached` to allocate the item cache in one large chunk, which can improve the performance by reducing the number misses when accessing memory.

- `-C`

Disable the use of compare and swap (CAS) operations.

This option was added in `memcached` 1.3.x.

- `-D char`

Set the default character to be used as a delimiter between the key prefixes and IDs. This is used for the per-prefix statistics reporting (see [Section 17.2.4, “Getting `memcached` Statistics](#)”). The default is the colon (:). If this option is used, statistics collection is turned on automatically. If not used, you can enable stats collection by sending the `stats detail on` command to the server.

This option was added in `memcached` 1.3.x.

- `-R num`

Sets the maximum number of requests per event process. The default is 20.

- `-B protocol`

Set the binding protocol, that is, the default `memcached` protocol support for client connections. Options are `ascii`, `binary` or `auto`. Automatic (`auto`) is the default.

This option was added in `memcached` 1.4.0.

### 17.2.2.2 `memcached` Deployment

When using `memcached` you can use a number of different potential deployment strategies and topologies. The exact strategy to use depends on your application and environment. When developing a system for deploying `memcached` within your system, keep in mind the following points:

- `memcached` is only a caching mechanism. It shouldn't be used to store information that you cannot otherwise afford to lose and then load from a different location.
- There is no security built into the `memcached` protocol. At a minimum, make sure that the servers running `memcached` are only accessible from inside your network, and that the network ports being used are blocked (using a firewall or similar). If the information on the `memcached` servers that is being stored is any sensitive, then encrypt the information before storing it in `memcached`.
- `memcached` does not provide any sort of failover. Because there is no communication between different `memcached` instances. If an instance fails, your application must be capable of removing it from the list, reloading the data and then writing data to another `memcached` instance.
- Latency between the clients and the `memcached` can be a problem if you are using different physical machines for these tasks. If you find that the latency is a problem, move the `memcached` instances to be on the clients.
- Key length is determined by the `memcached` server. The default maximum key size is 250 bytes.
- Try to use at least two `memcached` instances, especially for multiple clients, to avoid having a single point of failure. Ideally, create as many `memcached` nodes as possible. When adding and removing `memcached` instances from a pool, the hashing and distribution of key/value pairs may be affected. For information on how to avoid problems, see [Section 17.2.2.5, “`memcached` Hashing/Distribution Types](#)”.

### 17.2.2.3 Using Namespaces

The `memcached` cache is a very simple massive key/value storage system, and as such there is no way of compartmentalizing data automatically into different sections. For example, if you are storing information by the unique ID returned from a MySQL database, then storing the data from two different tables could run into issues because the same ID might be valid in both tables.

Some interfaces provide an automated mechanism for creating *namespaces* when storing information into the cache. In practice, these namespaces are merely a prefix before a given ID that is applied every time a value is stored or retrieve from the cache.

You can implement the same basic principle by using keys that describe the object and the unique identifier within the key that you supply when the object is stored. For example, when storing user data, prefix the ID of the user with `user:` or `user-`.

**Note**

Using namespaces or prefixes only controls the keys stored/retrieved. There is no security within `memcached`, and therefore no way to enforce that a particular client only accesses keys with a particular namespace. Namespaces are only useful as a method of identifying data and preventing corruption of key/value pairs.

#### 17.2.2.4 Data Expiry

There are two types of data expiry within a `memcached` instance. The first type is applied at the point when you store a new key/value pair into the `memcached` instance. If there is not enough space within a suitable slab to store the value, then an existing least recently used (LRU) object is removed (evicted) from the cache to make room for the new item.

The LRU algorithm ensures that the object that is removed is one that is either no longer in active use or that was used so long ago that its data is potentially out of date or of little value. However, in a system where the memory allocated to `memcached` is smaller than the number of regularly used objects required in the cache, a lot of expired items could be removed from the cache even though they are in active use. You use the statistics mechanism to get a better idea of the level of evictions (expired objects). For more information, see [Section 17.2.4, “Getting `memcached` Statistics”](#).

You can change this eviction behavior by setting the `-M` command-line option when starting `memcached`. This option forces an error to be returned when the memory has been exhausted, instead of automatically evicting older data.

The second type of expiry system is an explicit mechanism that you can set when a key/value pair is inserted into the cache, or when deleting an item from the cache. Using an expiration time can be a useful way of ensuring that the data in the cache is up to date and in line with your application needs and requirements.

A typical scenario for explicitly setting the expiry time might include caching session data for a user when accessing a Web site. `memcached` uses a lazy expiry mechanism where the explicit expiry time that has been set is compared with the current time when the object is requested. Only objects that have not expired are returned.

You can also set the expiry time when explicitly deleting an object from the cache. In this case, the expiry time is really a timeout and indicates the period when any attempts to set the value for a given key are rejected.

#### 17.2.2.5 `memcached` Hashing/Distribution Types

The `memcached` client interface supports a number of different distribution algorithms that are used in multi-server configurations to determine which host should be used when setting or getting data from a given `memcached` instance. When you get or set a value, a hash is constructed from the supplied key and then used to select a host from the list of configured servers. Because the hashing mechanism uses the supplied key as the basis for the hash, the same server is selected during both set and get operations.

You can think of this process as follows. Given an array of servers (a, b, and c), the client uses a hashing algorithm that returns an integer based on the key being stored or retrieved. The resulting value is then used to select a server from the list of servers configured in the client. Most standard

client hashing within memcache clients uses a simple modulus calculation on the value against the number of configured memcached servers. You can summarize the process in pseudocode as:

```
@memcservers = ['a.memc', 'b.memc', 'c.memc'];
$value = hash($key);
$chosen = $value % length(@memcservers);
```

Replacing the above with values:

```
@memcservers = ['a.memc', 'b.memc', 'c.memc'];
$value = hash('myid');
$chosen = 7009 % 3;
```

In the above example, the client hashing algorithm chooses the server at index 1 ( $7009 \% 3 = 1$ ), and store or retrieve the key and value with that server.

#### Note

This selection and hashing process is handled automatically by the memcached client you are using; you need only provide the list of memcached servers to use.

You can see a graphical representation of this below in [Figure 17.3, “memcached Hash Selection”](#).

**Figure 17.3** memcached Hash Selection

The same hashing and selection process takes place during any operation on the specified key within the memcached client.

Using this method provides a number of advantages:

- The hashing and selection of the server to contact is handled entirely within the client. This eliminates the need to perform network communication to determine the right machine to contact.
- Because the determination of the memcached server occurs entirely within the client, the server can be selected automatically regardless of the operation being executed (set, get, increment, etc.).
- Because the determination is handled within the client, the hashing algorithm returns the same value for a given key; values are not affected or reset by differences in the server environment.
- Selection is very fast. The hashing algorithm on the key value is quick and the resulting selection of the server is from a simple array of available machines.
- Using client-side hashing simplifies the distribution of data over each memcached server. Natural distribution of the values returned by the hashing algorithm means that keys are automatically spread over the available servers.

Providing that the list of servers configured within the client remains the same, the same stored key returns the same value, and therefore selects the same server.

However, if you do not use the same hashing mechanism then the same data may be recorded on different servers by different interfaces, both wasting space on your `memcached` and leading to potential differences in the information.

**Note**

One way to use a multi-interface compatible hashing mechanism is to use the `libmemcached` library and the associated interfaces. Because the interfaces for the different languages (including C, Ruby, Perl and Python) use the same client library interface, they always generate the same hash code from the ID.

The problem with client-side selection of the server is that the list of the servers (including their sequential order) *must* remain consistent on each client using the `memcached` servers, and the servers must be available. If you try to perform an operation on a key when:

- A new `memcached` instance has been added to the list of available instances
- A `memcached` instance has been removed from the list of available instances
- The order of the `memcached` instances has changed

When the hashing algorithm is used on the given key, but with a different list of servers, the hash calculation may choose a different server from the list.

If a new `memcached` instance is added into the list of servers, as `new.memc` is in the example below, then a GET operation using the same key, `myid`, can result in a cache-miss. This is because the same value is computed from the key, which selects the same index from the array of servers, but index 2 now points to the new server, not the server `c.memc` where the data was originally stored. This would result in a cache miss, even though the key exists within the cache on another `memcached` instance.

**Figure 17.4** `memcached` Hash Selection with New `memcached` instance

This means that servers `c.memc` and `new.memc` both contain the information for key `myid`, but the information stored against the key in each server may be different in each instance. A more significant problem is a much higher number of cache-misses when retrieving data, as the addition of a new server changes the distribution of keys, and this in turn requires rebuilding the cached data on the `memcached` instances, causing an increase in database reads.

The same effect can occur if you actively manage the list of servers configured in your clients, adding and removing the configured `memcached` instances as each instance is identified as being available. For example, removing a `memcached` instance when the client notices that the instance can no longer be contacted can cause the server selection to fail as described here.

To prevent this causing significant problems and invalidating your cache, you can select the hashing algorithm used to select the server. There are two common types of hashing algorithm, *consistent* and *modula*.

With *consistent* hashing algorithms, the same key when applied to a list of servers always uses the same server to store or retrieve the keys, even if the list of configured servers changes. This means

that you can add and remove servers from the configure list and always use the same server for a given key. There are two types of consistent hashing algorithms available, Ketama and Wheel. Both types are supported by `libmemcached`, and implementations are available for PHP and Java.

Any consistent hashing algorithm has some limitations. When you add servers to an existing list of configured servers, keys are distributed to the new servers as part of the normal distribution. When you remove servers from the list, the keys are re-allocated to another server within the list, meaning that the cache needs to be re-populated with the information. Also, a consistent hashing algorithm does not resolve the issue where you want consistent selection of a server across multiple clients, but where each client contains a different list of servers. The consistency is enforced only within a single client.

With a *modula* hashing algorithm, the client selects a server by first computing the hash and then choosing a server from the list of configured servers. As the list of servers changes, so the server selected when using a modula hashing algorithm also changes. The result is the behavior described above; changes to the list of servers mean that different servers are selected when retrieving data, leading to cache misses and increase in database load as the cache is re-seeded with information.

If you use only a single `memcached` instance for each client, or your list of `memcached` servers configured for a client never changes, then the selection of a hashing algorithm is irrelevant, as it has no noticeable effect.

If you change your servers regularly, or you use a common set of servers that are shared among a large number of clients, then using a consistent hashing algorithm should help to ensure that your cache data is not duplicated and the data is evenly distributed.

### 17.2.2.6 Using `memcached` and DTrace

`memcached` includes a number of different DTrace probes that can be used to monitor the operation of the server. The probes included can monitor individual connections, slab allocations, and modifications to the hash table when a key/value pair is added, updated, or removed.

For more information on DTrace and writing DTrace scripts, read the [DTrace User Guide](#).

Support for DTrace probes was added to `memcached` 1.2.6 includes a number of DTrace probes that can be used to help monitor your application. DTrace is supported on Solaris 10, OpenSolaris, OS X 10.5 and FreeBSD. To enable the DTrace probes in `memcached`, build from source and use the `--enable-dtrace` option. For more information, see [Section 17.2.1, "Installing `memcached`"](#).

The probes supported by `memcached` are:

- `conn-allocate(connid)`

Fired when a connection object is allocated from the connection pool.

- `connid`: The connection ID.

- `conn-release(connid)`

Fired when a connection object is released back to the connection pool.

Arguments:

- `connid`: The connection ID.

- `conn-create(ptr)`

Fired when a new connection object is being created (that is, there are no free connection objects in the connection pool).

Arguments:

- `ptr`: A pointer to the connection. object

- `conn-destroy(ptr)`

Fired when a connection object is being destroyed.

Arguments:

- `ptr`: A pointer to the connection object.

- `conn-dispatch(connid, threadid)`

Fired when a connection is dispatched from the main or connection-management thread to a worker thread.

Arguments:

- `connid`: The connection ID.
- `threadid`: The thread ID.

- `slabs-allocate(size, slabclass, slabsize, ptr)`

Allocate memory from the slab allocator.

Arguments:

- `size`: The requested size.
- `slabclass`: The allocation is fulfilled in this class.
- `slabsize`: The size of each item in this class.
- `ptr`: A pointer to allocated memory.

- `slabs-allocate-failed(size, slabclass)`

Failed to allocate memory (out of memory).

Arguments:

- `size`: The requested size.
- `slabclass`: The class that failed to fulfill the request.

- `slabs-slabclass-allocate(slabclass)`

Fired when a slab class needs more space.

Arguments:

- `slabclass`: The class that needs more memory.

- `slabs-slabclass-allocate-failed(slabclass)`

Failed to allocate memory (out of memory).

Arguments:

- `slabclass`: The class that failed to grab more memory.

- `slabs-free(size, slabclass, ptr)`

Release memory.

Arguments:

- `size`: The amount of memory to release, in bytes.
- `slabclass`: The class the memory belongs to.
- `ptr`: A pointer to the memory to release.
- `assoc-find(key, depth)`

Fired when we have searched the hash table for a named key. These two elements provide an insight into how well the hash function operates. Traversals are a sign of a less optimal function, wasting CPU capacity.

Arguments:

- `key`: The key searched for.
  - `depth`: The depth in the list of hash table.
  - `assoc-insert(key, nokeys)`
- Fired when a new item has been inserted.
- Arguments:
- `key`: The key just inserted.
  - `nokeys`: The total number of keys currently being stored, including the key for which insert was called.
  - `assoc-delete(key, nokeys)`

Fired when a new item has been removed.

Arguments:

- `key`: The key just deleted.
- `nokeys`: The total number of keys currently being stored, excluding the key for which delete was called.
- `item-link(key, size)`

Fired when an item is being linked in the cache.

Arguments:

- `key`: The items key.
- `size`: The size of the data.
- `item-unlink(key, size)`

Fired when an item is being deleted.

Arguments:

- `key`: The items key.
- `size`: The size of the data.
- `item-remove(key, size)`

Fired when the refcount for an item is reduced.

Arguments:

- `key`: The item's key.
- `size`: The size of the data.
- `item-update(key, size)`

Fired when the "last referenced" time is updated.

Arguments:

- `key`: The item's key.
- `size`: The size of the data.
- `item-replace(oldkey, oldsize, newkey, newsize)`

Fired when an item is being replaced with another item.

Arguments:

- `oldkey`: The key of the item to replace.
- `oldsize`: The size of the old item.
- `newkey`: The key of the new item.
- `newsize`: The size of the new item.
- `process-command-start(connid, request, size)`

Fired when the processing of a command starts.

Arguments:

- `connid`: The connection ID.
- `request`: The incoming request.
- `size`: The size of the request.
- `process-command-end(connid, response, size)`

Fired when the processing of a command is done.

Arguments:

- `connid`: The connection ID.
- `response`: The response to send back to the client.
- `size`: The size of the response.
- `command-get(connid, key, size)`

Fired for a `get` command.

Arguments:

- `connid`: The connection ID.
- `key`: The requested key.

- `size`: The size of the key's data (or -1 if not found).

- `command-gets(connid, key, size, casid)`

Fired for a `gets` command.

Arguments:

- `connid`: The connection ID.
- `key`: The requested key.
- `size`: The size of the key's data (or -1 if not found).
- `casid`: The casid for the item.

- `command-add(connid, key, size)`

Fired for a `add` command.

Arguments:

- `connid`: The connection ID.
- `key`: The requested key.
- `size`: The new size of the key's data (or -1 if not found).

- `command-set(connid, key, size)`

Fired for a `set` command.

Arguments:

- `connid`: The connection ID.
- `key`: The requested key.
- `size`: The new size of the key's data (or -1 if not found).

- `command-replace(connid, key, size)`

Fired for a `replace` command.

Arguments:

- `connid`: The connection ID.
- `key`: The requested key.
- `size`: The new size of the key's data (or -1 if not found).

- `command-prepend(connid, key, size)`

Fired for a `prepend` command.

Arguments:

- `connid`: The connection ID.
- `key`: The requested key.
- `size`: The new size of the key's data (or -1 if not found).

- `command-append(connid, key, size)`

Fired for a `append` command.

Arguments:

- `connid`: The connection ID.
- `key`: The requested key.
- `size`: The new size of the key's data (or -1 if not found).

- `command-cas(connid, key, size, casid)`

Fired for a `cas` command.

Arguments:

- `connid`: The connection ID.
- `key`: The requested key.
- `size`: The size of the key's data (or -1 if not found).
- `casid`: The cas ID requested.

- `command-incr(connid, key, val)`

Fired for `incr` command.

Arguments:

- `connid`: The connection ID.
- `key`: The requested key.
- `val`: The new value.

- `command-decr(connid, key, val)`

Fired for `decr` command.

Arguments:

- `connid`: The connection ID.
- `key`: The requested key.
- `val`: The new value.

- `command-delete(connid, key, exptime)`

Fired for a `delete` command.

Arguments:

- `connid`: The connection ID.
- `key`: The requested key.
- `exptime`: The expiry time.

### 17.2.2.7 Memory Allocation within memcached

When you first start `memcached`, the memory that you have configured is not automatically allocated. Instead, `memcached` only starts allocating and reserving physical memory once you start saving information into the cache.

When you start to store data into the cache, `memcached` does not allocate the memory for the data on an item by item basis. Instead, a slab allocation is used to optimize memory usage and prevent memory fragmentation when information expires from the cache.

With slab allocation, memory is reserved in blocks of 1MB. The slab is divided up into a number of blocks of equal size. When you try to store a value into the cache, `memcached` checks the size of the value that you are adding to the cache and determines which slab contains the right size allocation for the item. If a slab with the item size already exists, the item is written to the block within the slab.

If the new item is bigger than the size of any existing blocks, then a new slab is created, divided up into blocks of a suitable size. If an existing slab with the right block size already exists, but there are no free blocks, a new slab is created. If you update an existing item with data that is larger than the existing block allocation for that key, then the key is re-allocated into a suitable slab.

For example, the default size for the smallest block is 88 bytes (40 bytes of value, and the default 48 bytes for the key and flag data). If the size of the first item you store into the cache is less than 40 bytes, then a slab with a block size of 88 bytes is created and the value stored.

If the size of the data that you intend to store is larger than this value, then the block size is increased by the chunk size factor until a block size large enough to hold the value is determined. The block size is always a function of the scale factor, rounded up to a block size which is exactly divisible into the chunk size.

For a sample of the structure, see [Figure 17.5, “Memory Allocation in memcached”](#).

**Figure 17.5 Memory Allocation in memcached**

The result is that you have multiple pages allocated within the range of memory allocated to `memcached`. Each page is 1MB in size (by default), and is split into a different number of chunks, according to the chunk size required to store the key/value pairs. Each instance has multiple pages allocated, and a page is always created when a new item needs to be created requiring a chunk of a particular size. A slab may consist of multiple pages, and each page within a slab contains an equal number of chunks.

The chunk size of a new slab is determined by the base chunk size combined with the chunk size growth factor. For example, if the initial chunks are 104 bytes in size, and the default chunk size growth factor is used (1.25), then the next chunk size allocated would be the best power of 2 fit for  $104 \times 1.25$ , or 136 bytes.

Allocating the pages in this way ensures that memory does not get fragmented. However, depending on the distribution of the objects that you store, it may lead to an inefficient distribution of the slabs and chunks if you have significantly different sized items. For example, having a relatively small number of items within each chunk size may waste a lot of memory with just few chunks in each allocated page.

You can tune the growth factor to reduce this effect by using the `-f` command line option, which adapts the growth factor applied to make more effective use of the chunks and slabs allocated. For information on how to determine the current slab allocation statistics, see [Section 17.2.4.2, “memcached Slabs Statistics”](#).

If your operating system supports it, you can also start `memcached` with the `-L` command line option. This option preallocates all the memory during startup using large memory pages. This can improve performance by reducing the number of misses in the CPU memory cache.

### 17.2.2.8 `memcached` Thread Support

If you enable the thread implementation within when building `memcached` from source, then `memcached` uses multiple threads in addition to the `libevent` system to handle requests.

When enabled, the threading implementation operates as follows:

- Threading is handled by wrapping functions within the code to provide basic protection from updating the same global structures at the same time.
- Each thread uses its own instance of the `libevent` to help improve performance.
- TCP/IP connections are handled with a single thread listening on the TCP/IP socket. Each connection is then distributed to one of the active threads on a simple round-robin basis. Each connection then operates solely within this thread while the connection remains open.
- For UDP connections, all the threads listen to a single UDP socket for incoming requests. Threads that are not currently dealing with another request ignore the incoming packet. One of the remaining, nonbusy, threads reads the request and sends the response. This implementation can lead to increased CPU load as threads wake from sleep to potentially process the request.

Using threads can increase the performance on servers that have multiple CPU cores available, as the requests to update the hash table can be spread between the individual threads. To minimize overhead from the locking mechanism employed, experiment with different thread values to achieve the best performance based on the number and type of requests within your given workload.

### 17.2.2.9 `memcached` Logs

If you enable verbose mode, using the `-v`, `-vv`, or `-vvv` options, then the information output by `memcached` includes details of the operations being performed.

Without the verbose options, `memcached` normally produces no output during normal operating.

- **Output when using `-v`**

The lowest verbosity level shows you:

- Errors and warnings
- Transient errors
- Protocol and socket errors, including exhausting available connections
- Each registered client connection, including the socket descriptor number and the protocol used.

For example:

```
32: Client using the ascii protocol
33: Client using the ascii protocol
```

The socket descriptor is only valid while the client remains connected. Non-persistent connections may not be effectively represented.

Examples of the error messages output at this level include:

```

<%d send buffer was %d, now %d
Can't listen for events on fd %d
Can't read from libevent pipe
Catastrophic: event fd doesn't match conn fd!
Couldn't build response
Couldn't realloc input buffer
Couldn't update event
Failed to build UDP headers
Failed to read, and not due to blocking
Too many open connections
Unexpected state %d

```

- **Output when using `-vv`**

When using the second level of verbosity, you get more detailed information about protocol operations, keys updated, chunk and network operations and details.

During the initial start-up of `memcached` with this level of verbosity, you are shown the sizes of the individual slab classes, the chunk sizes, and the number of entries per slab. These do not show the allocation of the slabs, just the slabs that would be created when data is added. You are also given information about the listen queues and buffers used to send information. A sample of the output generated for a TCP/IP based system with the default memory and growth factors is given below:

```

shell> memcached -vv
slab class 1: chunk size      80 perslab 13107
slab class 2: chunk size     104 perslab 10082
slab class 3: chunk size     136 perslab  7710
slab class 4: chunk size     176 perslab  5957
slab class 5: chunk size     224 perslab  4681
slab class 6: chunk size     280 perslab  3744
slab class 7: chunk size     352 perslab  2978
slab class 8: chunk size     440 perslab  2383
slab class 9: chunk size     552 perslab  1899
slab class 10: chunk size    696 perslab  1506
slab class 11: chunk size    872 perslab  1202
slab class 12: chunk size   1096 perslab   956
slab class 13: chunk size   1376 perslab   762
slab class 14: chunk size   1720 perslab   609
slab class 15: chunk size   2152 perslab   487
slab class 16: chunk size   2696 perslab   388
slab class 17: chunk size   3376 perslab   310
slab class 18: chunk size   4224 perslab   248
slab class 19: chunk size   5280 perslab   198
slab class 20: chunk size   6600 perslab   158
slab class 21: chunk size   8256 perslab   127
slab class 22: chunk size  10320 perslab   101
slab class 23: chunk size  12904 perslab    81
slab class 24: chunk size  16136 perslab    64
slab class 25: chunk size  20176 perslab    51
slab class 26: chunk size  25224 perslab    41
slab class 27: chunk size  31536 perslab    33
slab class 28: chunk size  39424 perslab    26
slab class 29: chunk size  49280 perslab    21
slab class 30: chunk size  61600 perslab    17
slab class 31: chunk size  77000 perslab    13
slab class 32: chunk size  96256 perslab    10
slab class 33: chunk size 120320 perslab     8
slab class 34: chunk size 150400 perslab     6
slab class 35: chunk size 188000 perslab     5
slab class 36: chunk size 235000 perslab     4
slab class 37: chunk size 293752 perslab     3
slab class 38: chunk size 367192 perslab     2
slab class 39: chunk size 458992 perslab     2
<26 server listening (auto-negotiate)
<29 server listening (auto-negotiate)
<30 send buffer was 57344, now 2097152
<31 send buffer was 57344, now 2097152

```

```
<30 server listening (udp)
<30 server listening (udp)
<31 server listening (udp)
<30 server listening (udp)
<30 server listening (udp)
<31 server listening (udp)
<31 server listening (udp)
<31 server listening (udp)
```

Using this verbosity level can be a useful way to check the effects of the growth factor used on slabs with different memory allocations, which in turn can be used to better tune the growth factor to suit the data you are storing in the cache. For example, if you set the growth factor to 4 (quadrupling the size of each slab):

```
shell> memcached -f 4 -m 1g -vv
slab class 1: chunk size 80 perslab 13107
slab class 2: chunk size 320 perslab 3276
slab class 3: chunk size 1280 perslab 819
slab class 4: chunk size 5120 perslab 204
slab class 5: chunk size 20480 perslab 51
slab class 6: chunk size 81920 perslab 12
slab class 7: chunk size 327680 perslab 3
...
```

During use of the cache, this verbosity level also prints out detailed information on the storage and recovery of keys and other information. An example of the output during a typical set/get and increment/decrement operation is shown below.

```
32: Client using the ascii protocol
<32 set my_key 0 0 10
>32 STORED
<32 set object_key 1 0 36
>32 STORED
<32 get my_key
>32 sending key my_key
>32 END
<32 get object_key
>32 sending key object_key
>32 END
<32 set key 0 0 6
>32 STORED
<32 incr key 1
>32 789544
<32 decr key 1
>32 789543
<32 incr key 2
>32 789545
<32 set my_key 0 0 10
>32 STORED
<32 set object_key 1 0 36
>32 STORED
<32 get my_key
>32 sending key my_key
>32 END
<32 get object_key
>32 sending key object_key1 1 36

>32 END
<32 set key 0 0 6
>32 STORED
<32 incr key 1
>32 789544
<32 decr key 1
>32 789543
<32 incr key 2
>32 789545
```

During client communication, for each line, the initial character shows the direction of flow of the information. The < for communication from the client to the `memcached` server and > for communication back to the client. The number is the numeric socket descriptor for the connection.

- **Output when using `-vvv`**

This level of verbosity includes the transitions of connections between different states in the event library while reading and writing content to/from the clients. It should be used to diagnose and identify issues in client communication. For example, you can use this information to determine if `memcached` is taking a long time to return information to the client, during the read of the client operation or before returning and completing the operation. An example of the typical sequence for a set operation is provided below:

```
<32 new auto-negotiating client connection
32: going from conn_new_cmd to conn_waiting
32: going from conn_waiting to conn_read
32: going from conn_read to conn_parse_cmd
32: Client using the ascii protocol
<32 set my_key 0 0 10
32: going from conn_parse_cmd to conn_nread
> NOT FOUND my_key
>32 STORED
32: going from conn_nread to conn_write
32: going from conn_write to conn_new_cmd
32: going from conn_new_cmd to conn_waiting
32: going from conn_waiting to conn_read
32: going from conn_read to conn_closing
<32 connection closed.
```

All of the verbosity levels in `memcached` are designed to be used during debugging or examination of issues. The quantity of information generated, particularly when using `-vvv`, is significant, particularly on a busy server. Also be aware that writing the error information out, especially to disk, may negate some of the performance gains you achieve by using `memcached`. Therefore, use in production or deployment environments is not recommended.

## 17.2.3 Developing a `memcached` Application

A number of language interfaces let applications store and retrieve information with `memcached` servers. You can write `memcached` applications in popular languages such as Perl, PHP, Python, Ruby, C, and Java.

Data stored into a `memcached` server is referred to by a single string (the key), with storage into the cache and retrieval from the cache using the key as the reference. The cache therefore operates like a large associative array or hash table. It is not possible to structure or otherwise organize the information stored in the cache. To emulate database notions such as multiple tables or composite key values, you must encode the extra information into the strings used as keys. For example, to store or look up the address corresponding to a specific latitude and longitude, you might turn those two numeric values into a single comma-separated string to use as a key.

### 17.2.3.1 Basic `memcached` Operations

The interface to `memcached` supports the following methods for storing and retrieving information in the cache, and these are consistent across all the different APIs, although the language specific mechanics might be different:

- `get(key)`: Retrieves information from the cache. Returns the value associated with the key if the specified key exists. Returns `NULL`, `nil`, `undefined`, or the closest equivalent in the corresponding language, if the specified key does not exist.
- `set(key, value [, expiry])`: Sets the item associated with a key in the cache to the specified value. This either updates an existing item if the key already exists, or adds a new key/value pair if

the key doesn't exist. If the expiry time is specified, then the item expires (and is deleted) when the expiry time is reached. The time is specified in seconds, and is taken as a relative time if the value is less than 30 days (30\*24\*60\*60), or an absolute time (epoch) if larger than this value.

- `add(key, value [, expiry])`: Adds the key and associated value to the cache, if the specified key does not already exist.
- `replace(key, value [, expiry])`: Replaces the item associated with the specified `key`, only if the key already exists. The new value is given by the `value` parameter.
- `delete(key [, time])`: Deletes the `key` and its associated item from the cache. If you supply a `time`, then adding another item with the specified `key` is blocked for the specified period.
- `incr(key , value)`: Increments the item associated with the `key` by the specified `value`.
- `decr(key , value)`: Decrements the item associated with the `key` by the specified `value`.
- `flush_all`: Invalidates (or expires) all the current items in the cache. Technically they still exist (they are not deleted), but they are silently destroyed the next time you try to access them.

In all implementations, most or all of these functions are duplicated through the corresponding native language interface.

When practical, use `memcached` to store full items, rather than caching a single column value from the database. For example, when displaying a record about an object (invoice, user history, or blog post), load all the data for the associated entry from the database, and compile it into the internal structure that would normally be required by the application. Save the complete object in the cache.

Complex data structures cannot be stored directly. Most interfaces serialize the data for you, that is, put it in a textual form that can reconstruct the original pointers and nesting. Perl uses `Storable`, PHP uses `serialize`, Python uses `cPickle` (or `Pickle`) and Java uses the `Serializable` interface. In most cases, the serialization interface used is customizable. To share data stored in `memcached` instances between different language interfaces, consider using a common serialization solution such as JSON (Javascript Object Notation).

### 17.2.3.2 Using `memcached` as a MySQL Caching Layer

When using `memcached` to cache MySQL data, your application must retrieve data from the database and load the appropriate key-value pairs into the cache. Then, subsequent lookups can be done directly from the cache.

Because MySQL has its own in-memory caching mechanisms for queried data, such as the `InnoDB buffer pool` and the MySQL query cache, look for opportunities beyond loading individual column values or rows into the cache. Prefer to cache composite values, such as those retrieved from multiple tables through a join query, or result sets assembled from multiple rows.

#### Caution

Limit the information in the cache to non-sensitive data, because there is no security required to access or update the information within a `memcached` instance. Anybody with access to the machine has the ability to read, view and potentially update the information. To keep the data secure, encrypt the information before caching it. To restrict the users capable of connecting to the server, either disable network access, or use IPTables or similar techniques to restrict access to the `memcached` ports to a select set of hosts.

You can introduce `memcached` to an existing application, even if caching was not part of the original design. In many languages and environments the changes to the application will be just a few lines, first to attempt to read from the cache when loading data, fall back to the old method if the information is not cached, and to update the cache with information once the data has been read.

The general sequence for using `memcached` in any language as a caching solution for MySQL is as follows:

1. Request the item from the cache.
2. If the item exists, use the item data.
3. If the item does not exist, load the data from MySQL, and store the value into the cache. This means the value is available to the next client that requests it from the cache.

For a flow diagram of this sequence, see [Figure 17.6, “Typical `memcached` Application Flowchart”](#).

**Figure 17.6 Typical `memcached` Application Flowchart**

## Adapting Database Best Practices to `memcached` Applications

The most direct way to cache MySQL data is to use a 2-column table, where the first column is a [primary key](#). Because of the uniqueness requirements for `memcached` keys, make sure your database schema makes appropriate use of primary keys and [unique constraints](#).

If you combine multiple column values into a single `memcached` item value, choose data types to make it easy to parse the value back into its components, for example by using a separator character between numeric values.

The queries that map most easily to `memcached` lookups are those with a single [WHERE](#) clause, using an `=` or `IN` operator. For complicated [WHERE](#) clauses, or those using operators such as `<`, `>`, [BETWEEN](#), or [LIKE](#), `memcached` does not provide a simple or efficient way to scan through or filter the keys or associated values, so typically you perform those operations as SQL queries on the underlying database.

### 17.2.3.3 Using `libmemcached` with C and C++

The `libmemcached` library provides both C and C++ interfaces to `memcached` and is also the basis for a number of different additional API implementations, including Perl, Python and Ruby. Understanding the core `libmemcached` functions can help when using these other interfaces.

The C library is the most comprehensive interface library for `memcached` and provides functions and operational systems not always exposed in interfaces not based on the `libmemcached` library.

The different functions can be divided up according to their basic operation. In addition to functions that interface to the core API, a number of utility functions provide extended functionality, such as appending and prepending data.

To build and install `libmemcached`, download the `libmemcached` package, run `configure`, and then build and install:

```
shell> tar xjf libmemcached-0.21.tar.gz
shell> cd libmemcached-0.21
shell> ./configure
shell> make
shell> make install
```

On many Linux operating systems, you can install the corresponding `libmemcached` package through the usual `yum`, `apt-get`, or similar commands.

To build an application that uses the library, first set the list of servers. Either directly manipulate the servers configured within the main `memcached_st` structure, or separately populate a list of servers, and then add this list to the `memcached_st` structure. The latter method is used in the following example. Once the server list has been set, you can call the functions to store or retrieve data. A simple application for setting a preset value to `localhost` is provided here:

```
#include <stdio.h>
#include <string.h>
#include <unistd.h>
#include <libmemcached/memcached.h>

int main(int argc, char *argv[])
{
    memcached_server_st *servers = NULL;
    memcached_st *memc;
    memcached_return rc;
    char *key= "keystring";
    char *value= "keyvalue";

    memcached_server_st *memcached_servers_parse (char *server_strings);
    memc= memcached_create(NULL);

    servers= memcached_server_list_append(servers, "localhost", 11211, &rc);
    rc= memcached_server_push(memc, servers);

    if (rc == MEMCACHED_SUCCESS)
        fprintf(stderr,"Added server successfully\n");
    else
        fprintf(stderr,"Couldn't add server: %s\n",memcached_strerror(memc, rc));

    rc= memcached_set(memc, key, strlen(key), value, strlen(value), (time_t)0, (uint32_t)0);

    if (rc == MEMCACHED_SUCCESS)
        fprintf(stderr,"Key stored successfully\n");
    else
        fprintf(stderr,"Couldn't store key: %s\n",memcached_strerror(memc, rc));

    return 0;
}
```

To test the success of an operation, use the return value, or populated result code, for a given function. The value is always set to `MEMCACHED_SUCCESS` if the operation succeeded. In the event of a failure, use the `memcached_strerror()` function to translate the result code into a printable string.

To build the application, specify the `memcached` library:

```
shell> gcc -o memc_basic memc_basic.c -lmemcached
```

Running the above sample application, after starting a `memcached` server, should return a success message:

```
shell> memc_basic
Added server successfully
Key stored successfully
```

## `libmemcached` Base Functions

The base `libmemcached` functions let you create, destroy and clone the main `memcached_st` structure that is used to interface with the `memcached` servers. The main functions are defined below:

```
memcached_st *memcached_create (memcached_st *ptr);
```

Creates a new `memcached_st` structure for use with the other `libmemcached` API functions. You can supply an existing, static, `memcached_st` structure, or `NULL` to have a new structured allocated. Returns a pointer to the created structure, or `NULL` on failure.

```
void memcached_free (memcached_st *ptr);
```

Frees the structure and memory allocated to a previously created `memcached_st` structure.

```
memcached_st *memcached_clone(memcached_st *clone, memcached_st *source);
```

Clones an existing `memcached` structure from the specified `source`, copying the defaults and list of servers defined in the structure.

## `libmemcached` Server Functions

The `libmemcached` API uses a list of servers, stored within the `memcached_server_st` structure, to act as the list of servers used by the rest of the functions. To use `memcached`, you first create the server list, and then apply the list of servers to a valid `libmemcached` object.

Because the list of servers, and the list of servers within an active `libmemcached` object can be manipulated separately, you can update and manage server lists while an active `libmemcached` interface is running.

The functions for manipulating the list of servers within a `memcached_st` structure are:

```
memcached_return
memcached_server_add (memcached_st *ptr,
                     char *hostname,
                     unsigned int port);
```

Adds a server, using the given `hostname` and `port` into the `memcached_st` structure given in `ptr`.

```
memcached_return
memcached_server_add_unix_socket (memcached_st *ptr,
                                char *socket);
```

Adds a Unix socket to the list of servers configured in the `memcached_st` structure.

```
unsigned int memcached_server_count (memcached_st *ptr);
```

Returns a count of the number of configured servers within the `memcached_st` structure.

```
memcached_server_st *
memcached_server_list (memcached_st *ptr);
```

Returns an array of all the defined hosts within a `memcached_st` structure.

```
memcached_return
memcached_server_push (memcached_st *ptr,
                      memcached_server_st *list);
```

Pushes an existing list of servers onto list of servers configured for a current `memcached_st` structure. This adds servers to the end of the existing list, and duplicates are not checked.

The `memcached_server_st` structure can be used to create a list of `memcached` servers which can then be applied individually to `memcached_st` structures.

```
memcached_server_st *
memcached_server_list_append (memcached_server_st *ptr,
                             char *hostname,
                             unsigned int port,
                             memcached_return *error);
```

Adds a server, with `hostname` and `port`, to the server list in `ptr`. The result code is handled by the `error` argument, which should point to an existing `memcached_return` variable. The function returns a pointer to the returned list.

```
unsigned int memcached_server_list_count (memcached_server_st *ptr);
```

Returns the number of the servers in the server list.

```
void memcached_server_list_free (memcached_server_st *ptr);
```

Frees the memory associated with a server list.

```
memcached_server_st *memcached_servers_parse (char *server_strings);
```

Parses a string containing a list of servers, where individual servers are separated by a comma, space, or both, and where individual servers are of the form `server[:port]`. The return value is a server list structure.

## `libmemcached` Set Functions

The set-related functions within `libmemcached` provide the same functionality as the core functions supported by the `memcached` protocol. The full definition for the different functions is the same for all the base functions (`add`, `replace`, `prepend`, `append`). For example, the function definition for `memcached_set()` is:

```
memcached_return
memcached_set (memcached_st *ptr,
              const char *key,
              size_t key_length,
              const char *value,
              size_t value_length,
              time_t expiration,
              uint32_t flags);
```

The `ptr` is the `memcached_st` structure. The `key` and `key_length` define the key name and length, and `value` and `value_length` the corresponding value and length. You can also set the expiration and optional flags. For more information, see [Controlling libmemcached Behaviors](#).

This table outlines the remainder of the set-related `libmemcached` functions and the equivalent core functions supported by the `memcached` protocol.

| <b>libmemcached Function</b>  | <b>Equivalent Core Function</b>   |
|---|---|
| <code>memcached_set(memc, key, key_length, value, value_length, expiration, flags)</code>   | Generic <code>set()</code> operation.   |
| <code>memcached_add(memc, key, key_length, value, value_length, expiration, flags)</code>   | Generic <code>add()</code> function.  |
| <code>memcached_replace(memc, key, key_length, value, value_length, expiration, flags)</code>                                       | Generic <code>replace()</code> .  |
| <code>memcached_prepend(memc, key, key_length, value, value_length, expiration, flags)</code>                                       | Prepends the specified <code>value</code> before the current value of the specified <code>key</code> .  |
| <code>memcached_append(memc, key, key_length, value, value_length, expiration, flags)</code>  | Appends the specified <code>value</code> after the current value of the specified <code>key</code> .  |
| <code>memcached_cas(memc, key, key_length, value, value_length, expiration, flags, cas)</code>                                      | Overwrites the data for a given key as long as the corresponding <code>cas</code> value is still the same within the server.                        |
| <code>memcached_set_by_key(memc, master_key, master_key_length, key, key_length, value, value_length, expiration, flags)</code>     | Similar to the generic <code>set()</code> , but has the option of an additional master key that can be used to identify an individual server.       |
| <code>memcached_add_by_key(memc, master_key, master_key_length, key, key_length, value, value_length, expiration, flags)</code>     | Similar to the generic <code>add()</code> , but has the option of an additional master key that can be used to identify an individual server.       |
| <code>memcached_replace_by_key(memc, master_key, master_key_length, key, key_length, value, value_length, expiration, flags)</code> | Similar to the generic <code>replace()</code> , but has the option of an additional master key that can be used to identify an individual server.   |
| <code>memcached_prepend_by_key(memc, master_key, master_key_length, key, key_length, value, value_length, expiration, flags)</code> | Similar to the <code>memcached_prepend()</code> , but has the option of an additional master key that can be used to identify an individual server. |
| <code>memcached_append_by_key(memc, master_key, master_key_length, key, key_length, value, value_length, expiration, flags)</code>  | Similar to the <code>memcached_append()</code> , but has the option of an additional master key that can be used to identify an individual server.  |
| <code>memcached_cas_by_key(memc, master_key, master_key_length, key, key_length, value, value_length, expiration, flags)</code>     | Similar to the <code>memcached_cas()</code> , but has the option of an additional master key that can be used to identify an individual server.     |

The `by_key` methods add two further arguments that define the master key, to be used and applied during the hashing stage for selecting the servers. You can see this in the following definition:

```
memcached_return
memcached_set_by_key(memcached_st *ptr,
                    const char *master_key,
                    size_t master_key_length,
                    const char *key,
                    size_t key_length,
                    const char *value,
```

```
size_t value_length,
time_t expiration,
uint32_t flags);
```

All the functions return a value of type `memcached_return`, which you can compare against the `MEMCACHED_SUCCESS` constant.

## `libmemcached` Get Functions

The `libmemcached` functions provide both direct access to a single item, and a multiple-key request mechanism that provides much faster responses when fetching a large number of keys simultaneously.

The main get-style function, which is equivalent to the generic `get()` is `memcached_get()`. This function returns a string pointer, pointing to the value associated with the specified key.

```
char *memcached_get (memcached_st *ptr,
                    const char *key, size_t key_length,
                    size_t *value_length,
                    uint32_t *flags,
                    memcached_return *error);
```

A multi-key get, `memcached_mget()`, is also available. Using a multiple key get operation is much quicker to do in one block than retrieving the key values with individual calls to `memcached_get()`. To start the multi-key get, call `memcached_mget()`:

```
memcached_return
memcached_mget (memcached_st *ptr,
               char **keys, size_t *key_length,
               unsigned int number_of_keys);
```

The return value is the success of the operation. The `keys` parameter should be an array of strings containing the keys, and `key_length` an array containing the length of each corresponding key. `number_of_keys` is the number of keys supplied in the array.

To fetch the individual values, use `memcached_fetch()` to get each corresponding value.

```
char *memcached_fetch (memcached_st *ptr,
                     const char *key, size_t *key_length,
                     size_t *value_length,
                     uint32_t *flags,
                     memcached_return *error);
```

The function returns the key value, with the `key`, `key_length` and `value_length` parameters being populated with the corresponding key and length information. The function returns `NULL` when there are no more values to be returned. A full example, including the populating of the key data and the return of the information is provided here.

```
#include <stdio.h>
#include <sstring.h>
#include <unistd.h>
#include <libmemcached/memcached.h>

int main(int argc, char *argv[])
{
    memcached_server_st *servers = NULL;
    memcached_st *memc;
    memcached_return rc;
    char *keys[] = {"huey", "dewey", "louie"};
    size_t key_length[3];
    char *values[] = {"red", "blue", "green"};
    size_t value_length[3];
    unsigned int x;
    uint32_t flags;
```

```

char return_key[MEMCACHED_MAX_KEY];
size_t return_key_length;
char *return_value;
size_t return_value_length;

memc= memcached_create(NULL);

servers= memcached_server_list_append(servers, "localhost", 11211, &rc);
rc= memcached_server_push(memc, servers);

if (rc == MEMCACHED_SUCCESS)
    fprintf(stderr,"Added server successfully\n");
else
    fprintf(stderr,"Couldn't add server: %s\n",memcached_strerror(memc, rc));

for(x= 0; x < 3; x++)
{
    key_length[x] = strlen(keys[x]);
    value_length[x] = strlen(values[x]);

    rc= memcached_set(memc, keys[x], key_length[x], values[x],
                      value_length[x], (time_t)0, (uint32_t)0);
    if (rc == MEMCACHED_SUCCESS)
        fprintf(stderr,"Key %s stored successfully\n",keys[x]);
    else
        fprintf(stderr,"Couldn't store key: %s\n",memcached_strerror(memc, rc));
}

rc= memcached_mget(memc, keys, key_length, 3);

if (rc == MEMCACHED_SUCCESS)
{
    while ((return_value= memcached_fetch(memc, return_key, &return_key_length,
                                          &return_value_length, &flags, &rc)) != NULL)
    {
        if (rc == MEMCACHED_SUCCESS)
        {
            fprintf(stderr,"Key %s returned %s\n",return_key, return_value);
        }
    }
}

return 0;
}

```

Running the above application produces the following output:

```

shell> memc_multi_fetch
Added server successfully
Key huey stored successfully
Key dewey stored successfully
Key louie stored successfully
Key huey returned red
Key dewey returned blue
Key louie returned green

```

## Controlling `libmemcached` Behaviors

The behavior of `libmemcached` can be modified by setting one or more behavior flags. These can either be set globally, or they can be applied during the call to individual functions. Some behaviors also accept an additional setting, such as the hashing mechanism used when selecting servers.

To set global behaviors:

```

memcached_return
    memcached_behavior_set (memcached_st *ptr,
                           memcached_behavior flag,
                           uint64_t data);

```

To get the current behavior setting:

```
uint64_t
memcached_behavior_get (memcached_st *ptr,
                       memcached_behavior flag);
```

The following table describes `libmemcached` behavior flags.

| Behavior  | Description   |
|---|---|
| <code>MEMCACHED_BEHAVIOR_NO_BLOCK</code>        | Caused <code>libmemcached</code> to use asynchronous I/O.   |
| <code>MEMCACHED_BEHAVIOR_TCP_NODELAY</code>     | Turns on no-delay for network sockets.  |
| <code>MEMCACHED_BEHAVIOR_HASH</code>            | Without a value, sets the default hashing algorithm for keys to use MD5. Other valid values include <code>MEMCACHED_HASH_DEFAULT</code> , <code>MEMCACHED_HASH_MD5</code> , <code>MEMCACHED_HASH_CRC</code> , <code>MEMCACHED_HASH_FNV1_64</code> , <code>MEMCACHED_HASH_FNV1A_64</code> , <code>MEMCACHED_HASH_FNV1_32</code> , and <code>MEMCACHED_HASH_FNV1A_32</code> . |
| <code>MEMCACHED_BEHAVIOR_DISTRIBUTION</code>    | Changes the method of selecting the server used to store a given value. The default method is <code>MEMCACHED_DISTRIBUTION_MODULA</code> . You can enable consistent hashing by setting <code>MEMCACHED_DISTRIBUTION_CONSISTENT</code> . <code>MEMCACHED_DISTRIBUTION_CONSISTENT</code> is an alias for the value <code>MEMCACHED_DISTRIBUTION_CONSISTENT_KETAMA</code> .   |
| <code>MEMCACHED_BEHAVIOR_CACHE_LOOKUPS</code>   | Cache the lookups made to the DNS service. This can improve the performance if you are using names instead of IP addresses for individual hosts.  |
| <code>MEMCACHED_BEHAVIOR_SUPPORT_CAS</code>     | Support CAS operations. By default, this is disabled because it imposes a performance penalty.  |
| <code>MEMCACHED_BEHAVIOR_KETAMA</code>          | Sets the default distribution to <code>MEMCACHED_DISTRIBUTION_CONSISTENT_KETAMA</code> and the hash to <code>MEMCACHED_HASH_MD5</code> .  |
| <code>MEMCACHED_BEHAVIOR_POLL_TIMEOUT</code>    | Modify the timeout value used by <code>poll()</code> . Supply a <code>signed int</code> pointer for the timeout value.  |
| <code>MEMCACHED_BEHAVIOR_BUFFER_REQUESTS</code> | Buffers IO requests instead of them being sent. A get operation, or closing the connection causes the data to be flushed.   |
| <code>MEMCACHED_BEHAVIOR_VERIFY_KEY</code>      | Forces <code>libmemcached</code> to verify that a specified key is valid.   |
| <code>MEMCACHED_BEHAVIOR_SORT_HOSTS</code>      | If set, hosts added to the list of configured hosts for a <code>memcached_st</code> structure are placed into the host list in sorted order. This breaks consistent hashing if that behavior has been enabled.  |
| <code>MEMCACHED_BEHAVIOR_CONNECT_TIMEOUT</code> | In nonblocking mode this changes the value of the timeout during socket connection.   |

## `libmemcached` Command-Line Utilities

In addition to the main C library interface, `libmemcached` also includes a number of command-line utilities that can be useful when working with and debugging `memcached` applications.

All of the command-line tools accept a number of arguments, the most critical of which is `servers`, which specifies the list of servers to connect to when returning information.

The main tools are:

- `memcat`: Display the value for each ID given on the command line:

```
shell> memcat --servers=localhost hwkey
Hello world
```

- `memcp`: Copy the contents of a file into the cache, using the file name as the key:

```
shell> echo "Hello World" > hwkey
shell> memcp --servers=localhost hwkey
shell> memcat --servers=localhost hwkey
Hello world
```

- `memrm`: Remove an item from the cache:

```
shell> memcat --servers=localhost hwkey
Hello world
shell> memrm --servers=localhost hwkey
shell> memcat --servers=localhost hwkey
```

- `memslap`: Test the load on one or more `memcached` servers, simulating get/set and multiple client operations. For example, you can simulate the load of 100 clients performing get operations:

```
shell> memslap --servers=localhost --concurrency=100 --flush --test=get
memslap --servers=localhost --concurrency=100 --flush --test=get Threads connecting to servers 100
Took 13.571 seconds to read data
```

- `memflush`: Flush (empty) the contents of the `memcached` cache.

```
shell> memflush --servers=localhost
```

### 17.2.3.4 Using MySQL and `memcached` with Perl

The `Cache::Memcached` module provides a native interface to the Memcache protocol, and provides support for the core functions offered by `memcached`. Install the module using your operating system's package management system, or using `CPAN`:

```
root-shell> perl -MCPAN -e 'install Cache::Memcached'
```

To use `memcached` from Perl through the `Cache::Memcached` module, first create a new `Cache::Memcached` object that defines the list of servers and other parameters for the connection. The only argument is a hash containing the options for the cache interface. For example, to create a new instance that uses three `memcached` servers:

```
use Cache::Memcached;

my $cache = new Cache::Memcached {
    'servers' => [
        '192.168.0.100:11211',
        '192.168.0.101:11211',
        '192.168.0.102:11211',
    ],
};
```

#### Note

When using the `Cache::Memcached` interface with multiple servers, the API automatically performs certain operations across all the servers in the group. For example, getting statistical information through `Cache::Memcached`

returns a hash that contains data on a host-by-host basis, as well as generalized statistics for all the servers in the group.

You can set additional properties on the cache object instance when it is created by specifying the option as part of the option hash. Alternatively, you can use a corresponding method on the instance:

- `servers` or method `set_servers()`: Specifies the list of the servers to be used. The servers list should be a reference to an array of servers, with each element as the address and port number combination (separated by a colon). You can also specify a local connection through a Unix socket (for example `/tmp/sock/memcached`). To specify the server with a weight (indicating how much more frequently the server should be used during hashing), specify an array reference with the `memcached` server instance and a weight number. Higher numbers give higher priority.
- `compress_threshold` or method `set_compress_threshold()`: Specifies the threshold when values are compressed. Values larger than the specified number are automatically compressed (using `zlib`) during storage and retrieval.
- `no_rehash` or method `set_norehash()`: Disables finding a new server if the original choice is unavailable.
- `readonly` or method `set_readonly()`: Disables writes to the `memcached` servers.

Once the `Cache::Memcached` object instance has been configured, you can use the `set()` and `get()` methods to store and retrieve information from the `memcached` servers. Objects stored in the cache are automatically serialized and deserialized using the `Storable` module.

The `Cache::Memcached` interface supports the following methods for storing/retrieving data, and relate to the generic methods as shown in the table.

| Cache::Memcached Function    | Equivalent Generic Method  |
|------------------------------|--|
| <code>get()</code>           | Generic <code>get()</code> .   |
| <code>get_multi(keys)</code> | Gets multiple <code>keys</code> from memcache using just one query. Returns a hash reference of key/value pairs. |
| <code>set()</code>           | Generic <code>set()</code> .   |
| <code>add()</code>           | Generic <code>add()</code> .   |
| <code>replace()</code>       | Generic <code>replace()</code> .   |
| <code>delete()</code>        | Generic <code>delete()</code> .  |
| <code>incr()</code>          | Generic <code>incr()</code> .  |
| <code>decr()</code>          | Generic <code>decr()</code> .  |

Below is a complete example for using `memcached` with Perl and the `Cache::Memcached` module:

```
#!/usr/bin/perl

use Cache::Memcached;
use DBI;
use Data::Dumper;

# Configure the memcached server

my $cache = new Cache::Memcached {
    'servers' => [
        'localhost:11211',
    ],
};
```

```

# Get the film name from the command line
# memcached keys must not contain spaces, so create
# a key name by replacing spaces with underscores

my $filmname = shift or die "Must specify the film name\n";
my $filmkey = $filmname;
$filmkey =~ s/ /_/;

# Load the data from the cache

my $filmdata = $cache->get($filmkey);

# If the data wasn't in the cache, then we load it from the database

if (!defined($filmdata))
{
    $filmdata = load_filmdata($filmname);

    if (defined($filmdata))
    {
# Set the data into the cache, using the key

        if ($cache->set($filmkey,$filmdata))
        {
            print STDERR "Film data loaded from database and cached\n";
        }
        else
        {
            print STDERR "Couldn't store to cache\n";
        }
    }
    else
    {
        die "Couldn't find $filmname\n";
    }
}
else
{
    print STDERR "Film data loaded from Memcached\n";
}

sub load_filmdata
{
    my ($filmname) = @_;

    my $dsn = "DBI:mysql:database=sakila;host=localhost;port=3306";

    $dbh = DBI->connect($dsn, 'sakila','password');

    my ($filmbase) = $dbh->selectrow_hashref(sprintf('select * from film where title = %s',
                                                    $dbh->quote($filmname)));

    if (!defined($filmbase))
    {
        return (undef);
    }

    $filmbase->{stars} =
$dbh->selectall_arrayref(sprintf('select concat(first_name," ",last_name) ' .
                                'from film_actor left join (actor) ' .
                                'on (film_actor.actor_id = actor.actor_id) ' .
                                'where film_id=%s',
                                $dbh->quote($filmbase->{film_id})));

    return($filmbase);
}

```

The example uses the Sakila database, obtaining film data from the database and writing a composite record of the film and actors to [memcached](#). When calling it for a film does not exist, you get this result:

```
shell> memcached-sakila.pl "ROCK INSTINCT"
Film data loaded from database and cached
```

When accessing a film that has already been added to the cache:

```
shell> memcached-sakila.pl "ROCK INSTINCT"
Film data loaded from Memcached
```

### 17.2.3.5 Using MySQL and [memcached](#) with Python

The Python [memcache](#) module interfaces to [memcached](#) servers, and is written in pure Python (that is, without using one of the C APIs). You can download and install a copy from [Python Memcached](#).

To install, download the package and then run the Python installer:

```
python setup.py install
running install
running bdist_egg
running egg_info
creating python_memcached.egg-info
...
removing 'build/bdist.linux-x86_64/egg' (and everything under it)
Processing python_memcached-1.43-py2.4.egg
creating /usr/lib64/python2.4/site-packages/python_memcached-1.43-py2.4.egg
Extracting python_memcached-1.43-py2.4.egg to /usr/lib64/python2.4/site-packages
Adding python-memcached 1.43 to easy-install.pth file

Installed /usr/lib64/python2.4/site-packages/python_memcached-1.43-py2.4.egg
Processing dependencies for python-memcached==1.43
Finished processing dependencies for python-memcached==1.43
```

Once installed, the [memcache](#) module provides a class-based interface to your [memcached](#) servers. When you store Python data structures as [memcached](#) items, they are automatically serialized (turned into string values) using the Python [cPickle](#) or [pickle](#) modules.

To create a new [memcache](#) interface, import the [memcache](#) module and create a new instance of the [memcache.Client](#) class. For example, if the [memcached](#) daemon is running on localhost using the default port:

```
import memcache
memc = memcache.Client(['127.0.0.1:11211'])
```

The first argument is an array of strings containing the server and port number for each [memcached](#) instance to use. To enable debugging, set the optional [debug](#) parameter to 1.

By default, the hashing mechanism used to divide the items among multiple servers is [crc32](#). To change the function used, set the value of [memcache.serverHashFunction](#) to the alternate function to use. For example:

```
from zlib import Adler32
memcache.serverHashFunction = Adler32
```

Once you have defined the servers to use within the [memcache](#) instance, the core functions provide the same functionality as in the generic interface specification. The following table provides a summary of the supported functions:

| Python <a href="#">memcache</a> Function | Equivalent Generic Function     |
|--|---------------------------------|
| <a href="#">get()</a>                    | Generic <a href="#">get()</a> . |

| Python <code>memcache</code> Function                      | Equivalent Generic Function  |
|--|--|
| <code>get_multi(keys)</code>                               | Gets multiple values from the supplied array of <code>keys</code> . Returns a hash reference of key/value pairs. |
| <code>set()</code>   | Generic <code>set()</code> .   |
| <code>set_multi(dict [, expiry [, key_prefix]])</code>     | Sets multiple key/value pairs from the supplied <code>dict</code> .  |
| <code>add()</code>   | Generic <code>add()</code> .   |
| <code>replace()</code>                                     | Generic <code>replace()</code> .   |
| <code>prepend(key, value [, expiry])</code>                | Prepends the supplied <code>value</code> to the value of the existing <code>key</code> .                         |
| <code>append(key, value [, expiry])</code>                 | Appends the supplied <code>value</code> to the value of the existing <code>key</code> .                          |
| <code>delete()</code>                                      | Generic <code>delete()</code> .  |
| <code>delete_multi(keys [, expiry [, key_prefix]] )</code> | Deletes all the keys from the hash matching each string in the array <code>keys</code> .                         |
| <code>incr()</code>  | Generic <code>incr()</code> .  |
| <code>decr()</code>  | Generic <code>decr()</code> .  |

**Note**

Within the Python `memcache` module, all the `*_multi()` functions support an optional `key_prefix` parameter. If supplied, then the string is used as a prefix to all key lookups. For example, if you call:

```
memc.get_multi(['a','b'], key_prefix='users:')
```

The function retrieves the keys `users:a` and `users:b` from the servers.

Here is an example showing the storage and retrieval of information to a `memcache` instance, loading the raw data from MySQL:

```
import sys
import MySQLdb
import memcache

memc = memcache.Client(['127.0.0.1:11211'], debug=1);

try:
    conn = MySQLdb.connect (host = "localhost",
                           user = "sakila",
                           passwd = "password",
                           db = "sakila")
except MySQLdb.Error, e:
    print "Error %d: %s" % (e.args[0], e.args[1])
    sys.exit (1)

popularfilms = memc.get('top5films')

if not popularfilms:
    cursor = conn.cursor()
    cursor.execute('select film_id,title from film order by rental_rate desc limit 5')
    rows = cursor.fetchall()
    memc.set('top5films',rows,60)
    print "Updated memcached with MySQL data"
else:
    print "Loaded data from memcached"
    for row in popularfilms:
        print "%s, %s" % (row[0], row[1])
```

When executed for the first time, the data is loaded from the MySQL database and stored to the [memcached](#) server.

```
shell> python memc_python.py
Updated memcached with MySQL data
```

Because the data is automatically serialized using [cPickle/pickle](#), when you load the data back from [memcached](#), you can use the object directly. In the example above, the information stored to [memcached](#) is in the form of rows from a Python DB cursor. When accessing the information (within the 60 second expiry time), the data is loaded from [memcached](#) and dumped:

```
shell> python memc_python.py
Loaded data from memcached
2, ACE GOLDFINGER
7, AIRPLANE SIERRA
8, AIRPORT POLLOCK
10, ALADDIN CALENDAR
13, ALI FOREVER
```

The serialization and deserialization happens automatically. Because serialization of Python data may be incompatible with other interfaces and languages, you can change the serialization module used during initialization. For example, you might use JSON format when you store complex data structures using a script written in one language, and access them in a script written in a different language.

### 17.2.3.6 Using MySQL and [memcached](#) with PHP

PHP provides support for the Memcache functions through a PECL extension. To enable the PHP [memcache](#) extensions, build PHP using the `--enable-memcache` option to [configure](#) when building from source.

If you are installing on a Red Hat-based server, you can install the [php-pecl-memcache](#) RPM:

```
root-shell> yum --install php-pecl-memcache
```

On Debian-based distributions, use the [php-memcache](#) package.

To set global runtime configuration options, specify the configuration option values within your [php.ini](#) file. The following table provides the name, default value, and a description for each global runtime configuration option.

| Configuration option                           | Default  | Description  |
|--|----------|--|
| <a href="#">memcache.allow_failover</a>        | 1        | Specifies whether another server in the list should be queried if the first server selected fails.   |
| <a href="#">memcache.max_failover_attempts</a> | 20       | Specifies the number of servers to try before returning a failure.   |
| <a href="#">memcache.chunk_size</a>            | 8192     | Defines the size of network chunks used to exchange data with the <a href="#">memcached</a> server.  |
| <a href="#">memcache.default_port</a>          | 11211    | Defines the default port to use when communicating with the <a href="#">memcached</a> servers.   |
| <a href="#">memcache.hash_strategy</a>         | standard | Specifies which hash strategy to use. Set to <a href="#">consistent</a> to enable servers to be added or removed from the pool without causing the keys to be remapped to other servers. When set to <a href="#">standard</a> , an older (modula) strategy |

| Configuration option                | Default            | Description  |
|-------------------------------------|--------------------|--|
|                                     |                    | is used that potentially uses different servers for storage.   |
| <code>memcache.hash_function</code> | <code>crc32</code> | Specifies which function to use when mapping keys to servers. <code>crc32</code> uses the standard CRC32 hash. <code>fnv</code> uses the FNV-1a hashing algorithm. |

To create a connection to a `memcached` server, create a new `Memcache` object and then specify the connection options. For example:

```
<?php
$cache = new Memcache;
$cache->connect('localhost',11211);
?>
```

This opens an immediate connection to the specified server.

To use multiple `memcached` servers, you need to add servers to the `memcache` object using `addServer()`:

```
bool Memcache::addServer ( string $host [, int $port [, bool $persistent
                        [, int $weight [, int $timeout [, int $retry_interval
                        [, bool $status [, callback $failure_callback
                        ]]]]] ] )
```

The server management mechanism within the `php-memcache` module is a critical part of the interface as it controls the main interface to the `memcached` instances and how the different instances are selected through the hashing mechanism.

To create a simple connection to two `memcached` instances:

```
<?php
$cache = new Memcache;
$cache->addServer('192.168.0.100',11211);
$cache->addServer('192.168.0.101',11211);
?>
```

In this scenario, the instance connection is not explicitly opened, but only opened when you try to store or retrieve a value. To enable persistent connections to `memcached` instances, set the `$persistent` argument to true. This is the default setting, and causes the connections to remain open.

To help control the distribution of keys to different instances, use the global `memcache.hash_strategy` setting. This sets the hashing mechanism used to select. You can also add another weight to each server, which effectively increases the number of times the instance entry appears in the instance list, therefore increasing the likelihood of the instance being chosen over other instances. To set the weight, set the value of the `$weight` argument to more than one.

The functions for setting and retrieving information are identical to the generic functional interface offered by `memcached`, as shown in this table:

| PECL <code>memcache</code> Function | Generic Function             |
|-------------------------------------|------------------------------|
| <code>get()</code>                  | Generic <code>get()</code> . |
| <code>set()</code>                  | Generic <code>set()</code> . |
| <code>add()</code>                  | Generic <code>add()</code> . |

| PECL <code>memcache</code> Function | Generic Function                 |
|-------------------------------------|----------------------------------|
| <code>replace()</code>              | Generic <code>replace()</code> . |
| <code>delete()</code>               | Generic <code>delete()</code> .  |
| <code>increment()</code>            | Generic <code>incr()</code> .    |
| <code>decrement()</code>            | Generic <code>decr()</code> .    |

A full example of the PECL `memcache` interface is provided below. The code loads film data from the Sakila database when the user provides a film name. The data stored into the `memcached` instance is recorded as a `mysqli` result row, and the API automatically serializes the information for you.

```
<?php

$memc = new Memcache;
$memc->addServer('localhost','11211');

if(empty($_POST['film'])) {
?>
<html xmlns="http://www.w3.org/1999/xhtml" xml:lang="en" lang="en">
  <head>
    <meta http-equiv="Content-Type" content="text/html; charset=utf-8" />
    <title>Simple Memcache Lookup</title>
  </head>
  <body>
    <form method="post">
      <p><b>Film</b>: <input type="text" size="20" name="film"></p>
      <input type="submit">
    </form>
  </body>
</html>
<?php

} else {

    echo "Loading data...\n";

    $film = htmlspecialchars($_POST['film'], ENT_QUOTES, 'UTF-8');
    $mfilms = $memc->get($film);

    if ($mfilms) {

        printf("<p>Film data for %s loaded from memcache</p>", $mfilms['title']);

        foreach (array_keys($mfilms) as $key) {
            printf("<p><b>%s</b>: %s</p>", $key, $mfilms[$key]);
        }

    } else {

        $mysqli = mysqli('localhost','sakila','password','sakila');

        if (mysqli_connect_error()) {
            sprintf("Database error: (%d) %s", mysqli_connect_errno(), mysqli_connect_error());
            exit;
        }

        $sql = sprintf('SELECT * FROM film WHERE title="%s"', $mysqli->real_escape_string($film));

        $result = $mysqli->query($sql);

        if (!$result) {
            sprintf("Database error: (%d) %s", $mysqli->errno, $mysqli->error);
            exit;
        }

        $row = $result->fetch_assoc();

        $memc->set($row['title'], $row);
    }
}
```

```

        printf("<p>Loaded (%s) from MySQL</p>", htmlspecialchars($row['title'], ENT_QUOTES, 'UTF-8'));
    }
}
?>
</body>
</html>

```

With PHP, the connections to the `memcached` instances are kept open as long as the PHP and associated Apache instance remain running. When adding or removing servers from the list in a running instance (for example, when starting another script that mentions additional servers), the connections are shared, but the script only selects among the instances explicitly configured within the script.

To ensure that changes to the server list within a script do not cause problems, make sure to use the consistent hashing mechanism.

### 17.2.3.7 Using MySQL and `memcached` with Ruby

There are a number of different modules for interfacing to `memcached` within Ruby. The `Ruby-MemCache` client library provides a native interface to `memcached` that does not require any external libraries, such as `libmemcached`. You can obtain the installer package from <http://www.deveiate.org/projects/RMemCache>.

To install, extract the package and then run `install.rb`:

```
shell> install.rb
```

If you have RubyGems, you can install the `Ruby-MemCache` gem:

```

shell> gem install Ruby-MemCache
Bulk updating Gem source index for: http://gems.rubyforge.org
Install required dependency io-reactor? [Yn]  y
Successfully installed Ruby-MemCache-0.0.1
Successfully installed io-reactor-0.05
Installing ri documentation for io-reactor-0.05...
Installing RDoc documentation for io-reactor-0.05...

```

To use a `memcached` instance from within Ruby, create a new instance of the `MemCache` object.

```

require 'memcache'
memc = MemCache::new '192.168.0.100:11211'

```

You can add a weight to each server to increase the likelihood of the server being selected during hashing by appending the weight count to the server host name/port string:

```

require 'memcache'
memc = MemCache::new '192.168.0.100:11211:3'

```

To add servers to an existing list, you can append them directly to the `MemCache` object:

```
memc += ["192.168.0.101:11211"]
```

To set data into the cache, you can just assign a value to a key within the new cache object, which works just like a standard Ruby hash object:

```
memc["key"] = "value"
```

Or to retrieve the value:

```
print memc["key"]
```

For more explicit actions, you can use the method interface, which mimics the main `memcached` API functions, as summarized in the following table:

| Ruby <code>MemCache</code> Method | Equivalent <code>memcached</code> API Functions  |
|-----------------------------------|--|
| <code>get()</code>                | Generic <code>get()</code> .   |
| <code>get_hash(keys)</code>       | Get the values of multiple <code>keys</code> , returning the information as a hash of the keys and their values. |
| <code>set()</code>                | Generic <code>set()</code> .   |
| <code>set_many(pairs)</code>      | Set the values of the keys and values in the hash <code>pairs</code> .   |
| <code>add()</code>                | Generic <code>add()</code> .   |
| <code>replace()</code>            | Generic <code>replace()</code> .   |
| <code>delete()</code>             | Generic <code>delete()</code> .  |
| <code>incr()</code>               | Generic <code>incr()</code> .  |
| <code>decr()</code>               | Generic <code>decr()</code> .  |

### 17.2.3.8 Using MySQL and `memcached` with Java

The `com.danga.MemCached` class within Java provides a native interface to `memcached` instances. You can obtain the client from <https://github.com/gwhalin/Memcached-Java-Client/downloads>. The Java class uses hashes that are compatible with `libmemcached`, so you can mix and match Java and `libmemcached` applications accessing the same `memcached` instances. The serialization between Java and other interfaces are not compatible. If this is a problem, use JSON or a similar nonbinary serialization format.

On most systems, you can download the package and use the `jar` directly.

To use the `com.danga.MemCached` interface, you create a `MemCachedClient` instance and then configure the list of servers by configuring the `SocketIOPool`. Through the pool specification you set up the server list, weighting, and the connection parameters to optimized the connections between your client and the `memcached` instances that you configure.

Generally, you can configure the `memcached` interface once within a single class, then use this interface throughout the rest of your application.

For example, to create a basic interface, first configure the `MemCachedClient` and base `SocketIOPool` settings:

```
public class MyClass {

    protected static MemCachedClient mcc = new MemCachedClient();

    static {

        String[] servers =
        {
            "localhost:11211",
        };

        Integer[] weights = { 1 };

        SocketIOPool pool = SocketIOPool.getInstance();
```

```
pool.setServers( servers );
pool.setWeights( weights );
```

In the above sample, the list of servers is configured by creating an array of the [memcached](#) instances to use. You can then configure individual weights for each server.

The remainder of the properties for the connection are optional, but you can set the connection numbers (initial connections, minimum connections, maximum connections, and the idle timeout) by setting the pool parameters:

```
pool.setInitConn( 5 );
pool.setMinConn( 5 );
pool.setMaxConn( 250 );
pool.setMaxIdle( 1000 * 60 * 60 * 6
```

Once the parameters have been configured, initialize the connection pool:

```
pool.initialize();
```

The pool, and the connection to your [memcached](#) instances should now be ready to use.

To set the hashing algorithm used to select the server used when storing a given key, use [pool.setHashingAlg\(\)](#):

```
pool.setHashingAlg( SockIOPool.NEW_COMPAT_HASH );
```

Valid values are [NEW\\_COMPAT\\_HASH](#), [OLD\\_COMPAT\\_HASH](#) and [NATIVE\\_HASH](#) are also basic modular hashing algorithms. For a consistent hashing algorithm, use [CONSISTENT\\_HASH](#). These constants are equivalent to the corresponding hash settings within [libmemcached](#).

The following table outlines the Java [com.danga.MemCached](#) methods and the equivalent generic methods in the [memcached](#) interface specification.

| Java <a href="#">com.danga.MemCached</a> Method | Equivalent Generic Method  |
|---|--|
| <a href="#">get()</a>                           | Generic <a href="#">get()</a> .  |
| <a href="#">getMulti(keys)</a>                  | Get the values of multiple <a href="#">keys</a> , returning the information as Hash map using <a href="#">java.lang.String</a> for the keys and <a href="#">java.lang.Object</a> for the corresponding values. |
| <a href="#">set()</a>                           | Generic <a href="#">set()</a> .  |
| <a href="#">add()</a>                           | Generic <a href="#">add()</a> .  |
| <a href="#">replace()</a>                       | Generic <a href="#">replace()</a> .  |
| <a href="#">delete()</a>                        | Generic <a href="#">delete()</a> .   |
| <a href="#">incr()</a>                          | Generic <a href="#">incr()</a> .   |
| <a href="#">decr()</a>                          | Generic <a href="#">decr()</a> .   |

### 17.2.3.9 Using the [memcached](#) TCP Text Protocol

Communicating with a [memcached](#) server can be achieved through either the TCP or UDP protocols. When using the TCP protocol, you can use a simple text based interface for the exchange of information.

When communicating with `memcached`, you can connect to the server using the port configured for the server. You can open a connection with the server without requiring authorization or login. As soon as you have connected, you can start to send commands to the server. When you have finished, you can terminate the connection without sending any specific disconnection command. Clients are encouraged to keep their connections open to decrease latency and improve performance.

Data is sent to the `memcached` server in two forms:

- Text lines, which are used to send commands to the server, and receive responses from the server.
- Unstructured data, which is used to receive or send the value information for a given key. Data is returned to the client in exactly the format it was provided.

Both text lines (commands and responses) and unstructured data are always terminated with the string `\r\n`. Because the data being stored may contain this sequence, the length of the data (returned by the client before the unstructured data is transmitted should be used to determine the end of the data.

Commands to the server are structured according to their operation:

- **Storage commands:** `set`, `add`, `replace`, `append`, `prepend`, `cas`

Storage commands to the server take the form:

```
command key [flags] [exptime] length [noreply]
```

Or when using compare and swap (`cas`):

```
cas key [flags] [exptime] length [casunique] [noreply]
```

Where:

- `command`: The command name.
  - `set`: Store value against key
  - `add`: Store this value against key if the key does not already exist
  - `replace`: Store this value against key if the key already exists
  - `append`: Append the supplied value to the end of the value for the specified key. The `flags` and `exptime` arguments should not be used.
  - `prepend`: Append value currently in the cache to the end of the supplied value for the specified key. The `flags` and `exptime` arguments should not be used.
  - `cas`: Set the specified key to the supplied value, only if the supplied `casunique` matches. This is effectively the equivalent of change the information if nobody has updated it since I last fetched it.
- `key`: The key. All data is stored using a the specific key. The key cannot contain control characters or whitespace, and can be up to 250 characters in size.
- `flags`: The flags for the operation (as an integer). Flags in `memcached` are transparent. The `memcached` server ignores the contents of the flags. They can be used by the client to indicate any type of information. In `memcached` 1.2.0 and lower the value is a 16-bit integer value. In `memcached` 1.2.1 and higher the value is a 32-bit integer.
- `exptime`: The expiry time, or zero for no expiry.
- `length`: The length of the supplied value block in bytes, excluding the terminating `\r\n` characters.

- `casunique`: A unique 64-bit value of an existing entry. This is used to compare against the existing value. Use the value returned by the `gets` command when issuing `cas` updates.
- `noreply`: Tells the server not to reply to the command.

For example, to store the value `abcdef` into the key `xyzkey`, you would use:

```
set xyzkey 0 0 6\r\nabcdef\r\n
```

The return value from the server is one line, specifying the status or error information. For more information, see [Table 17.3, “memcached Protocol Responses”](#).

- **Retrieval commands:** `get`, `gets`

Retrieval commands take the form:

```
get key1 [key2 ... keyn]
gets key1 [key2 ... keyn]
```

You can supply multiple keys to the commands, with each requested key separated by whitespace.

The server responds with an information line of the form:

```
VALUE key flags bytes [casunique]
```

Where:

- `key`: The key name.
- `flags`: The value of the flag integer supplied to the `memcached` server when the value was stored.
- `bytes`: The size (excluding the terminating `\r\n` character sequence) of the stored value.
- `casunique`: The unique 64-bit integer that identifies the item.

The information line is immediately followed by the value data block. For example:

```
get xyzkey\r\n
VALUE xyzkey 0 6\r\n
abcdef\r\n
```

If you have requested multiple keys, an information line and data block is returned for each key found. If a requested key does not exist in the cache, no information is returned.

- **Delete commands:** `delete`

Deletion commands take the form:

```
delete key [time] [noreply]
```

Where:

- `key`: The key name.
- `time`: The time in seconds (or a specific Unix time) for which the client wishes the server to refuse `add` or `replace` commands on this key. All `add`, `replace`, `get`, and `gets` commands fail during this period. `set` operations succeed. After this period, the key is deleted permanently and all commands are accepted.

If not supplied, the value is assumed to be zero (delete immediately).

- `noreply`: Tells the server not to reply to the command.

Responses to the command are either `DELETED` to indicate that the key was successfully removed, or `NOT_FOUND` to indicate that the specified key could not be found.

- **Increment/Decrement:** `incr`, `decr`

The increment and decrement commands change the value of a key within the server without performing a separate get/set sequence. The operations assume that the currently stored value is a 64-bit integer. If the stored value is not a 64-bit integer, then the value is assumed to be zero before the increment or decrement operation is applied.

Increment and decrement commands take the form:

```
incr key value [noreply]
decr key value [noreply]
```

Where:

- `key`: The key name.
- `value`: An integer to be used as the increment or decrement value.
- `noreply`: Tells the server not to reply to the command.

The response is:

- `NOT_FOUND`: The specified key could not be located.
- `value`: The new value associated with the specified key.

Values are assumed to be unsigned. For `decr` operations, the value is never decremented below 0. For `incr` operations, the value wraps around the 64-bit maximum.

- **Statistics commands:** `stats`

The `stats` command provides detailed statistical information about the current status of the `memcached` instance and the data it is storing.

Statistics commands take the form:

```
STAT [name] [value]
```

Where:

- `name`: The optional name of the statistics to return. If not specified, the general statistics are returned.
- `value`: A specific value to be used when performing certain statistics operations.

The return value is a list of statistics data, formatted as follows:

```
STAT name value
```

The statistics are terminated with a single line, `END`.

For more information, see [Section 17.2.4, “Getting `memcached` Statistics”](#).

For reference, a list of the different commands supported and their formats is provided below.

**Table 17.2** `memcached` Command Reference

| Command              | Command Formats   |
|----------------------|---|
| <code>set</code>     | <code>set key flags exptime length, set key flags exptime length noreply</code>                     |
| <code>add</code>     | <code>add key flags exptime length, add key flags exptime length noreply</code>                     |
| <code>replace</code> | <code>replace key flags exptime length, replace key flags exptime length noreply</code>             |
| <code>append</code>  | <code>append key length, append key length noreply</code>   |
| <code>prepend</code> | <code>prepend key length, prepend key length noreply</code>   |
| <code>cas</code>     | <code>cas key flags exptime length casunique, cas key flags exptime length casunique noreply</code> |
| <code>get</code>     | <code>get key1 [key2 ... keyn]</code>   |
| <code>gets</code>    |   |
| <code>delete</code>  | <code>delete key, delete key noreply, delete key expiry, delete key expiry noreply</code>           |
| <code>incr</code>    | <code>incr key, incr key noreply, incr key value, incr key value noreply</code>                     |
| <code>decr</code>    | <code>decr key, decr key noreply, decr key value, decr key value noreply</code>                     |
| <code>stat</code>    | <code>stat, stat name, stat name value</code>   |

When sending a command to the server, the response from the server is one of the settings in the following table. All response values from the server are terminated by `\r\n`:

**Table 17.3** `memcached` Protocol Responses

| String   | Description   |
|--|---|
| <code>STORED</code>  | Value has successfully been stored.   |
| <code>NOT_STORED</code>  | The value was not stored, but not because of an error. For commands where you are adding a or updating a value if it exists (such as <code>add</code> and <code>replace</code> ), or where the item has already been set to be deleted. |
| <code>EXISTS</code>  | When using a <code>cas</code> command, the item you are trying to store already exists and has been modified since you last checked it.   |
| <code>NOT_FOUND</code>   | The item you are trying to store, update or delete does not exist or has already been deleted.  |
| <code>ERROR</code>   | You submitted a nonexistent command name.   |
| <code>CLIENT_ERROR</code><br><code>errorstring</code>                          | There was an error in the input line, the detail is contained in <code>errorstring</code> .   |
| <code>SERVER_ERROR</code><br><code>errorstring</code>                          | There was an error in the server that prevents it from returning the information. In extreme conditions, the server may disconnect the client after this error occurs.  |
| <code>VALUE</code> <code>keys</code> <code>flags</code><br><code>length</code> | The requested key has been found, and the stored <code>key</code> , <code>flags</code> and data block are returned, of the specified <code>length</code> .  |
| <code>DELETED</code>   | The requested key was deleted from the server.  |
| <code>STAT</code> <code>name</code> <code>value</code>                         | A line of statistics data.  |

| String           | Description                     |
|------------------|---------------------------------|
| <code>END</code> | The end of the statistics data. |

## 17.2.4 Getting `memcached` Statistics

The `memcached` system has a built-in statistics system that collects information about the data being stored into the cache, cache hit ratios, and detailed information on the memory usage and distribution of information through the slab allocation used to store individual items. Statistics are provided at both a basic level that provide the core statistics, and more specific statistics for specific areas of the `memcached` server.

This information can be useful to ensure that you are getting the correct level of cache and memory usage, and that your slab allocation and configuration properties are set at an optimal level.

The stats interface is available through the standard `memcached` protocol, so the reports can be accessed by using `telnet` to connect to the `memcached`. The supplied `memcached-tool` includes support for obtaining the [Section 17.2.4.2, “memcached Slabs Statistics”](#) and [Section 17.2.4.1, “memcached General Statistics”](#) information. For more information, see [Section 17.2.4.6, “Using memcached-tool”](#).

Alternatively, most of the language API interfaces provide a function for obtaining the statistics from the server.

For example, to get the basic stats using `telnet`:

```
shell> telnet localhost 11211
Trying ::1...
Connected to localhost.
Escape character is '^]'.
stats
STAT pid 23599
STAT uptime 675
STAT time 1211439587
STAT version 1.2.5
STAT pointer_size 32
STAT rusage_user 1.404992
STAT rusage_system 4.694685
STAT curr_items 32
STAT total_items 56361
STAT bytes 2642
STAT curr_connections 53
STAT total_connections 438
STAT connection_structures 55
STAT cmd_get 113482
STAT cmd_set 80519
STAT get_hits 78926
STAT get_misses 34556
STAT evictions 0
STAT bytes_read 6379783
STAT bytes_written 4860179
STAT limit_maxbytes 67108864
STAT threads 1
END
```

When using Perl and the `Cache::Memcached` module, the `stats()` function returns information about all the servers currently configured in the connection object, and total statistics for all the `memcached` servers as a whole.

For example, the following Perl script obtains the stats and dumps the hash reference that is returned:

```
use Cache::Memcached;
use Data::Dumper;

my $memc = new Cache::Memcached;
```

```
$memc->set_servers(\@ARGV);

print Dumper($memc->stats());
```

When executed on the same `memcached` as used in the `Telnet` example above we get a hash reference with the host by host and total statistics:

```
$VAR1 = {
  'hosts' => {
    'localhost:11211' => {
      'misc' => {
        'bytes' => '2421',
        'curr_connections' => '3',
        'connection_structures' => '56',
        'pointer_size' => '32',
        'time' => '1211440166',
        'total_items' => '410956',
        'cmd_set' => '588167',
        'bytes_written' => '35715151',
        'evictions' => '0',
        'curr_items' => '31',
        'pid' => '23599',
        'limit_maxbytes' => '67108864',
        'uptime' => '1254',
        'rusage_user' => '9.857805',
        'cmd_get' => '838451',
        'rusage_system' => '34.096988',
        'version' => '1.2.5',
        'get_hits' => '581511',
        'bytes_read' => '46665716',
        'threads' => '1',
        'total_connections' => '3104',
        'get_misses' => '256940'
      },
      'sizes' => {
        '128' => '16',
        '64' => '15'
      }
    }
  },
  'self' => {},
  'total' => {
    'cmd_get' => 838451,
    'bytes' => 2421,
    'get_hits' => 581511,
    'connection_structures' => 56,
    'bytes_read' => 46665716,
    'total_items' => 410956,
    'total_connections' => 3104,
    'cmd_set' => 588167,
    'bytes_written' => 35715151,
    'curr_items' => 31,
    'get_misses' => 256940
  }
};
```

The statistics are divided up into a number of distinct sections, and then can be requested by adding the type to the `stats` command. Each statistics output is covered in more detail in the following sections.

- General statistics, see [Section 17.2.4.1, “memcached General Statistics”](#).
- Slab statistics (`slabs`), see [Section 17.2.4.2, “memcached Slabs Statistics”](#).
- Item statistics (`items`), see [Section 17.2.4.3, “memcached Item Statistics”](#).
- Size statistics (`sizes`), see [Section 17.2.4.4, “memcached Size Statistics”](#).
- Detailed status (`detail`), see [Section 17.2.4.5, “memcached Detail Statistics”](#).

### 17.2.4.1 `memcached` General Statistics

The output of the general statistics provides an overview of the performance and use of the `memcached` instance. The statistics returned by the command and their meaning is shown in the following table.

The following terms are used to define the value type for each statistics value:

- `32u`: 32-bit unsigned integer
- `64u`: 64-bit unsigned integer
- `32u:32u`: Two 32-bit unsigned integers separated by a colon
- `String`: Character string

| Statistic                          | Data type            | Description  | Version |
|------------------------------------|----------------------|--|---------|
| <code>pid</code>                   | <code>32u</code>     | Process ID of the <code>memcached</code> instance.                   |         |
| <code>uptime</code>                | <code>32u</code>     | Uptime (in seconds) for this <code>memcached</code> instance.        |         |
| <code>time</code>                  | <code>32u</code>     | Current time (as epoch).   |         |
| <code>version</code>               | string               | Version string of this instance.                                     |         |
| <code>pointer_size</code>          | string               | Size of pointers for this host specified in bits (32 or 64).         |         |
| <code>rusage_user</code>           | <code>32u:32u</code> | Total user time for this instance (seconds:microseconds).            |         |
| <code>rusage_system</code>         | <code>32u:32u</code> | Total system time for this instance (seconds:microseconds).          |         |
| <code>curr_items</code>            | <code>32u</code>     | Current number of items stored by this instance.                     |         |
| <code>total_items</code>           | <code>32u</code>     | Total number of items stored during the life of this instance.       |         |
| <code>bytes</code>                 | <code>64u</code>     | Current number of bytes used by this server to store items.          |         |
| <code>curr_connections</code>      | <code>32u</code>     | Current number of open connections.                                  |         |
| <code>total_connections</code>     | <code>32u</code>     | Total number of connections opened since the server started running. |         |
| <code>connection_structures</code> | <code>32u</code>     | Number of connection structures allocated by the server.             |         |
| <code>cmd_get</code>               | <code>64u</code>     | Total number of retrieval requests ( <code>get</code> operations).   |         |
| <code>cmd_set</code>               | <code>64u</code>     | Total number of storage requests ( <code>set</code> operations).     |         |
| <code>get_hits</code>              | <code>64u</code>     | Number of keys that have been requested and found present.           |         |
| <code>get_misses</code>            | <code>64u</code>     | Number of items that have been requested and not found.              |         |
| <code>delete_hits</code>           | <code>64u</code>     | Number of keys that have been deleted and found present.             | 1.3.x   |
| <code>delete_misses</code>         | <code>64u</code>     | Number of items that have been delete and not found.                 | 1.3.x   |
| <code>incr_hits</code>             | <code>64u</code>     | Number of keys that have been incremented and found present.         | 1.3.x   |
| <code>incr_misses</code>           | <code>64u</code>     | Number of items that have been incremented and not found.            | 1.3.x   |
| <code>decr_hits</code>             | <code>64u</code>     | Number of keys that have been decremented and found present.         | 1.3.x   |

| Statistic                   | Data type | Description   | Version |
|-----------------------------|-----------|---|---------|
| <code>decr_misses</code>    | 64u       | Number of items that have been decremented and not found.   | 1.3.x   |
| <code>cas_hits</code>       | 64u       | Number of keys that have been compared and swapped and found present.   | 1.3.x   |
| <code>cas_misses</code>     | 64u       | Number of items that have been compared and swapped and not found.  | 1.3.x   |
| <code>cas_badvalue</code>   | 64u       | Number of keys that have been compared and swapped, but the comparison (original) value did not match the supplied value. | 1.3.x   |
| <code>evictions</code>      | 64u       | Number of valid items removed from cache to free memory for new items.  |         |
| <code>bytes_read</code>     | 64u       | Total number of bytes read by this server from network.   |         |
| <code>bytes_written</code>  | 64u       | Total number of bytes sent by this server to network.   |         |
| <code>limit_maxbytes</code> | 32u       | Number of bytes this server is permitted to use for storage.  |         |
| <code>threads</code>        | 32u       | Number of worker threads requested.   |         |
| <code>conn_yields</code>    | 64u       | Number of yields for connections (related to the <code>-R</code> option).   | 1.4.0   |

The most useful statistics from those given here are the number of cache hits, misses, and evictions.

A large number of `get_misses` may just be an indication that the cache is still being populated with information. The number should, over time, decrease in comparison to the number of cache `get_hits`. If, however, you have a large number of cache misses compared to cache hits after an extended period of execution, it may be an indication that the size of the cache is too small and you either need to increase the total memory size, or increase the number of the `memcached` instances to improve the hit ratio.

A large number of `evictions` from the cache, particularly in comparison to the number of items stored is a sign that your cache is too small to hold the amount of information that you regularly want to keep cached. Instead of items being retained in the cache, items are being evicted to make way for new items keeping the turnover of items in the cache high, reducing the efficiency of the cache.

#### 17.2.4.2 `memcached` Slabs Statistics

To get the `slabs` statistics, use the `stats slabs` command, or the API equivalent.

The slab statistics provide you with information about the slabs that have created and allocated for storing information within the cache. You get information both on each individual slab-class and total statistics for the whole slab.

```

STAT 1:chunk_size 104
STAT 1:chunks_per_page 10082
STAT 1:total_pages 1
STAT 1:total_chunks 10082
STAT 1:used_chunks 10081
STAT 1:free_chunks 1
STAT 1:free_chunks_end 10079
STAT 9:chunk_size 696
STAT 9:chunks_per_page 1506
STAT 9:total_pages 63
STAT 9:total_chunks 94878
STAT 9:used_chunks 94878
STAT 9:free_chunks 0
STAT 9:free_chunks_end 0
STAT active_slabs 2

```

```
STAT total_malloced 67083616
END
```

Individual stats for each slab class are prefixed with the slab ID. A unique ID is given to each allocated slab from the smallest size up to the largest. The prefix number indicates the slab class number in relation to the calculated chunk from the specified growth factor. Hence in the example, 1 is the first chunk size and 9 is the 9th chunk allocated size.

The parameters returned for each chunk size and a description of each parameter are provided in the following table.

| Statistic                    | Description   | Version |
|------------------------------|---|---------|
| <code>chunk_size</code>      | Space allocated to each chunk within this slab class.                   |         |
| <code>chunks_per_page</code> | Number of chunks within a single page for this slab class.              |         |
| <code>total_pages</code>     | Number of pages allocated to this slab class.                           |         |
| <code>total_chunks</code>    | Number of chunks allocated to the slab class.                           |         |
| <code>used_chunks</code>     | Number of chunks allocated to an item..                                 |         |
| <code>free_chunks</code>     | Number of chunks not yet allocated to items.                            |         |
| <code>free_chunks_end</code> | Number of free chunks at the end of the last allocated page.            |         |
| <code>get_hits</code>        | Number of get hits to this chunk  | 1.3.x   |
| <code>cmd_set</code>         | Number of set commands on this chunk                                    | 1.3.x   |
| <code>delete_hits</code>     | Number of delete hits to this chunk                                     | 1.3.x   |
| <code>incr_hits</code>       | Number of increment hits to this chunk                                  | 1.3.x   |
| <code>decr_hits</code>       | Number of decrement hits to this chunk                                  | 1.3.x   |
| <code>cas_hits</code>        | Number of CAS hits to this chunk  | 1.3.x   |
| <code>cas_badval</code>      | Number of CAS hits on this chunk where the existing value did not match | 1.3.x   |
| <code>mem_requested</code>   | The true amount of memory of memory requested within this chunk         | 1.4.1   |

The following additional statistics cover the information for the entire server, rather than on a chunk by chunk basis:

| Statistic                   | Description                                     | Version |
|-----------------------------|---|---------|
| <code>active_slabs</code>   | Total number of slab classes allocated.         |         |
| <code>total_malloced</code> | Total amount of memory allocated to slab pages. |         |

The key values in the slab statistics are the `chunk_size`, and the corresponding `total_chunks` and `used_chunks` parameters. These given an indication of the size usage of the chunks within the system. Remember that one key/value pair is placed into a chunk of a suitable size.

From these stats, you can get an idea of your size and chunk allocation and distribution. If you store many items with a number of largely different sizes, consider adjusting the chunk size growth factor to increase in larger steps to prevent chunk and memory wastage. A good indication of a bad growth factor is a high number of different slab classes, but with relatively few chunks actually in use within each slab. Increasing the growth factor creates fewer slab classes and therefore makes better use of the allocated pages.

### 17.2.4.3 `memcached` Item Statistics

To get the `items` statistics, use the `stats items` command, or the API equivalent.

The `items` statistics give information about the individual items allocated within a given slab class.

```
STAT items:2:number 1
STAT items:2:age 452
STAT items:2:evicted 0
STAT items:2:evicted_nonzero 0
STAT items:2:evicted_time 2
STAT items:2:outofmemory 0
STAT items:2:tailrepairs 0
...
STAT items:27:number 1
STAT items:27:age 452
STAT items:27:evicted 0
STAT items:27:evicted_nonzero 0
STAT items:27:evicted_time 2
STAT items:27:outofmemory 0
STAT items:27:tailrepairs 0
```

The prefix number against each statistics relates to the corresponding chunk size, as returned by the `stats slabs` statistics. The result is a display of the number of items stored within each chunk within each slab size, and specific statistics about their age, eviction counts, and out of memory counts. A summary of the statistics is given in the following table.

| Statistic                    | Description  |       |
|------------------------------|--|-------|
| <code>number</code>          | The number of items currently stored in this slab class.   |       |
| <code>age</code>             | The age of the oldest item within the slab class, in seconds.  |       |
| <code>evicted</code>         | The number of items evicted to make way for new entries.   |       |
| <code>evicted_time</code>    | The time of the last evicted entry   |       |
| <code>evicted_nonzero</code> | The time of the last evicted non-zero entry  | 1.4.0 |
| <code>outofmemory</code>     | The number of items for this slab class that have triggered an out of memory error (only value when the <code>-M</code> command line option is in effect). |       |
| <code>tailrepairs</code>     | Number of times the entries for a particular ID need repairing   |       |

Item level statistics can be used to determine how many items are stored within a given slab and their freshness and recycle rate. You can use this to help identify whether there are certain slab classes that are triggering a much larger number of evictions than others.

#### 17.2.4.4 `memcached` Size Statistics

To get size statistics, use the `stats sizes` command, or the API equivalent.

The size statistics provide information about the sizes and number of items of each size within the cache. The information is returned as two columns, the first column is the size of the item (rounded up to the nearest 32 byte boundary), and the second column is the count of the number of items of that size within the cache:

```
96 35
128 38
160 807
192 804
224 410
256 222
288 83
320 39
352 53
384 33
416 64
448 51
```

```
480 30
512 54
544 39
576 10065
```

### Caution

Running this statistic locks up your cache as each item is read from the cache and its size calculated. On a large cache, this may take some time and prevent any set or get operations until the process completes.

The item size statistics are useful only to determine the sizes of the objects you are storing. Since the actual memory allocation is relevant only in terms of the chunk size and page size, the information is only useful during a careful debugging or diagnostic session.

## 17.2.4.5 `memcached` Detail Statistics

For `memcached` 1.3.x and higher, you can enable and obtain detailed statistics about the `get`, `set`, and `del` operations on the individual keys stored in the cache, and determine whether the attempts hit (found) a particular key. These operations are only recorded while the detailed stats analysis is turned on.

To enable detailed statistics, you must send the `stats detail on` command to the `memcached` server:

```
$ telnet localhost 11211
Trying 127.0.0.1...
Connected to tiger.
Escape character is '^]'.
stats detail on
OK
```

Individual statistics are recorded for every `get`, `set` and `del` operation on a key, including keys that are not currently stored in the server. For example, if an attempt is made to obtain the value of key `abckey` and it does not exist, the `get` operating on the specified key are recorded while detailed statistics are in effect, even if the key is not currently stored. The `hits`, that is, the number of `get` or `del` operations for a key that exists in the server are also counted.

To turn detailed statistics off, send the `stats detail off` command to the `memcached` server:

```
$ telnet localhost 11211
Trying 127.0.0.1...
Connected to tiger.
Escape character is '^]'.
stats detail off
OK
```

To obtain the detailed statistics recorded during the process, send the `stats detail dump` command to the `memcached` server:

```
stats detail dump
PREFIX hykkey get 0 hit 0 set 1 del 0
PREFIX xyzkey get 0 hit 0 set 1 del 0
PREFIX yukkey get 1 hit 0 set 0 del 0
PREFIX abckey get 3 hit 3 set 1 del 0
END
```

You can use the detailed statistics information to determine whether your `memcached` clients are using a large number of keys that do not exist in the server by comparing the `hit` and `get` or `del` counts. Because the information is recorded by key, you can also determine whether the failures or operations are clustered around specific keys.

### 17.2.4.6 Using memcached-tool

The `memcached-tool`, located within the `scripts` directory within the `memcached` source directory. The tool provides convenient access to some reports and statistics from any `memcached` instance.

The basic format of the command is:

```
shell> ./memcached-tool hostname:port [command]
```

The default output produces a list of the slab allocations and usage. For example:

```
shell> memcached-tool localhost:11211 display
```

| #  | Item_Size | Max_age | Pages | Count | Full? | Evicted | Evict_Time | OOM |
|----|-----------|---------|-------|-------|-------|---------|------------|-----|
| 1  | 80B       | 93s     | 1     | 20    | no    | 0       | 0          | 0   |
| 2  | 104B      | 93s     | 1     | 16    | no    | 0       | 0          | 0   |
| 3  | 136B      | 1335s   | 1     | 28    | no    | 0       | 0          | 0   |
| 4  | 176B      | 1335s   | 1     | 24    | no    | 0       | 0          | 0   |
| 5  | 224B      | 1335s   | 1     | 32    | no    | 0       | 0          | 0   |
| 6  | 280B      | 1335s   | 1     | 34    | no    | 0       | 0          | 0   |
| 7  | 352B      | 1335s   | 1     | 36    | no    | 0       | 0          | 0   |
| 8  | 440B      | 1335s   | 1     | 46    | no    | 0       | 0          | 0   |
| 9  | 552B      | 1335s   | 1     | 58    | no    | 0       | 0          | 0   |
| 10 | 696B      | 1335s   | 1     | 66    | no    | 0       | 0          | 0   |
| 11 | 872B      | 1335s   | 1     | 89    | no    | 0       | 0          | 0   |
| 12 | 1.1K      | 1335s   | 1     | 112   | no    | 0       | 0          | 0   |
| 13 | 1.3K      | 1335s   | 1     | 145   | no    | 0       | 0          | 0   |
| 14 | 1.7K      | 1335s   | 1     | 123   | no    | 0       | 0          | 0   |
| 15 | 2.1K      | 1335s   | 1     | 198   | no    | 0       | 0          | 0   |
| 16 | 2.6K      | 1335s   | 1     | 199   | no    | 0       | 0          | 0   |
| 17 | 3.3K      | 1335s   | 1     | 229   | no    | 0       | 0          | 0   |
| 18 | 4.1K      | 1335s   | 1     | 248   | yes   | 36      | 2          | 0   |
| 19 | 5.2K      | 1335s   | 2     | 328   | no    | 0       | 0          | 0   |
| 20 | 6.4K      | 1335s   | 2     | 316   | yes   | 387     | 1          | 0   |
| 21 | 8.1K      | 1335s   | 3     | 381   | yes   | 492     | 1          | 0   |
| 22 | 10.1K     | 1335s   | 3     | 303   | yes   | 598     | 2          | 0   |
| 23 | 12.6K     | 1335s   | 5     | 405   | yes   | 605     | 1          | 0   |
| 24 | 15.8K     | 1335s   | 6     | 384   | yes   | 766     | 2          | 0   |
| 25 | 19.7K     | 1335s   | 7     | 357   | yes   | 908     | 170        | 0   |
| 26 | 24.6K     | 1336s   | 7     | 287   | yes   | 1012    | 1          | 0   |
| 27 | 30.8K     | 1336s   | 7     | 231   | yes   | 1193    | 169        | 0   |
| 28 | 38.5K     | 1336s   | 4     | 104   | yes   | 1323    | 169        | 0   |
| 29 | 48.1K     | 1336s   | 1     | 21    | yes   | 1287    | 1          | 0   |
| 30 | 60.2K     | 1336s   | 1     | 17    | yes   | 1093    | 169        | 0   |
| 31 | 75.2K     | 1337s   | 1     | 13    | yes   | 713     | 168        | 0   |
| 32 | 94.0K     | 1337s   | 1     | 10    | yes   | 278     | 168        | 0   |
| 33 | 117.5K    | 1336s   | 1     | 3     | no    | 0       | 0          | 0   |

This output is the same if you specify the `command` as `display`:

```
shell> memcached-tool localhost:11211 display
```

| #   | Item_Size | Max_age | Pages | Count | Full? | Evicted | Evict_Time | OOM |
|-----|-----------|---------|-------|-------|-------|---------|------------|-----|
| 1   | 80B       | 93s     | 1     | 20    | no    | 0       | 0          | 0   |
| 2   | 104B      | 93s     | 1     | 16    | no    | 0       | 0          | 0   |
| ... |           |         |       |       |       |         |            |     |

The output shows a summarized version of the output from the `slabs` statistics. The columns provided in the output are shown below:

- `#`: The slab number
- `Item_Size`: The size of the slab
- `Max_age`: The age of the oldest item in the slab
- `Pages`: The number of pages allocated to the slab

- **Count**: The number of items in this slab
- **Full?**: Whether the slab is fully populated
- **Evicted**: The number of objects evicted from this slab
- **Evict\_Time**: The time (in seconds) since the last eviction
- **OOM**: The number of items that have triggered an out of memory error

You can also obtain a dump of the general statistics for the server using the `stats` command:

```
shell> memcached-tool localhost:11211 stats
#localhost:11211  Field      Value
      accepting_conns      1
      bytes                162
      bytes_read           485
      bytes_written        6820
      cas_badval            0
      cas_hits              0
      cas_misses            0
      cmd_flush             0
      cmd_get               4
      cmd_set               2
      conn_yields           0
      connection_structures 11
      curr_connections      10
      curr_items            2
      decr_hits             0
      decr_misses           1
      delete_hits           0
      delete_misses         0
      evictions             0
      get_hits              4
      get_misses            0
      incr_hits             0
      incr_misses           2
      limit_maxbytes        67108864
      listen_disabled_num   0
      pid                  12981
      pointer_size          32
      rusage_system         0.013911
      rusage_user           0.011876
      threads               4
      time                  1255518565
      total_connections     20
      total_items           2
      uptime                880
      version               1.4.2
```

## 17.2.5 memcached FAQ

- 17.2.5.1 Can memcached be run on a Windows environment? ..... 2617
- 17.2.5.2 What is the maximum size of an object you can store in memcached? Is that  
configurable? ..... 2617

| 17.2.5.13 | Can we implement different types of <a href="#">memcached</a> as different nodes in the same server, so can there be deterministic and non-deterministic in the same server? .....   | 2618 |
| 17.2.5.14 | What are best practices for testing an implementation, to ensure that it improves performance, and to measure the impact of <a href="#">memcached</a> configuration changes? And would you recommend keeping the configuration very simple to start? ..... | 2619 |

#### 17.2.5.15 Can memcached be run on a Windows environment?

No. Currently [memcached](#) is available only on the Unix/Linux platform. There is an unofficial port available, see <http://www.codeplex.com/memcachedproviders>.

#### 17.2.5.16 What is the maximum size of an object you can store in memcached? Is that configurable?

The default maximum object size is 1MB. In [memcached](#) 1.4.2 and later, you can change the maximum size of an object using the `-I` command line option.

For versions before this, to increase this size, you have to re-compile [memcached](#). You can modify the value of the `POWER_BLOCK` within the `slabs.c` file within the source.

In [memcached](#) 1.4.2 and higher, you can configure the maximum supported object size by using the `-I` command-line option. For example, to increase the maximum object size to 5MB:

```
$ memcached -I 5m
```

If an object is larger than the maximum object size, you must manually split it. [memcached](#) is very simple: you give it a key and some data, it tries to cache it in RAM. If you try to store more than the default maximum size, the value is just truncated for speed reasons.

#### 17.2.5.17 Is it true [memcached](#) will be much more effective with db-read-intensive applications than with db-write-intensive applications?

Yes. [memcached](#) plays no role in database writes, it is a method of caching data already read from the database in RAM.

#### 17.2.5.18 Are there any overhead in not using persistent connections? If persistent is always recommended, what are the downsides (for example, locking up)?

If you don't use persistent connections when communicating with [memcached](#), there will be a small increase in the latency of opening the connection each time. The effect is comparable to use nonpersistent connections with MySQL.

In general, the chance of locking or other issues with persistent connections is minimal, because there is very little locking within [memcached](#). If there is a problem, eventually your request will time out and return no result, so your application will need to load from MySQL again.

#### 17.2.5.19 How is an event such as a crash of one of the [memcached](#) servers handled by the [memcached](#) client?

There is no automatic handling of this. If your client fails to get a response from a server, code a fallback mechanism to load the data from the MySQL database.

The client APIs all provide the ability to add and remove [memcached](#) instances on the fly. If within your application you notice that [memcached](#) server is no longer responding, you can remove the server from the list of servers, and keys will automatically be redistributed to another [memcached](#) server in the list. If retaining the cache content on all your servers is important, make sure you use an API that supports a consistent hashing algorithm. For more information, see [Section 17.2.2.5](#), "[memcached Hashing/Distribution Types](#)".

**17.2.5.6** What is a recommended hardware configuration for a memcached server?

memcached has a very low processing overhead. All that is required is spare physical RAM capacity. A memcached server does not require a dedicated machine. If you have web, application, or database servers that have spare RAM capacity, then use them with memcached.

To build and deploy a dedicated memcached server, use a relatively low-power CPU, lots of RAM, and one or more Gigabit Ethernet interfaces.

**17.2.5.7** Is memcached more effective for video and audio as opposed to textual read/writes?

memcached works equally well for all kinds of data. To memcached, any value you store is just a stream of data. Remember, though, that the maximum size of an object you can store in memcached is 1MB, but can be configured to be larger by using the `-I` option in memcached 1.4.2 and later, or by modifying the source in versions before 1.4.2. If you plan on using memcached with audio and video content, you will probably want to increase the maximum object size. Also remember that memcached is a solution for caching information for reading. It shouldn't be used for writes, except when updating the information in the cache.

**17.2.5.8** Can memcached work with ASPX?

There are ports and interfaces for many languages and environments. ASPX relies on an underlying language such as C# or VisualBasic, and if you are using ASP.NET then there is a C# memcached library. For more information, see <https://sourceforge.net/projects/memcacheddotnet/>.

**17.2.5.9** How expensive is it to establish a memcache connection? Should those connections be pooled?

Opening the connection is relatively inexpensive, because there is no security, authentication or other handshake taking place before you can start sending requests and getting results. Most APIs support a persistent connection to a memcached instance to reduce the latency. Connection pooling would depend on the API you are using, but if you are communicating directly over TCP/IP, then connection pooling would provide some small performance benefit.

**17.2.5.10** How is the data handled when the memcached server is down?

The behavior is entirely application dependent. Most applications fall back to loading the data from the database (just as if they were updating the memcached information). If you are using multiple memcached servers, you might also remove a downed server from the list to prevent it from affecting performance. Otherwise, the client will still attempt to communicate with the memcached server that corresponds to the key you are trying to load.

**17.2.5.11** How are auto-increment columns in the MySQL database coordinated across multiple instances of memcached?

They aren't. There is no relationship between MySQL and memcached unless your application (or, if you are using the MySQL UDFs for memcached, your database definition) creates one.

If you are storing information based on an auto-increment key into multiple instances of memcached, the information is only stored on one of the memcached instances anyway. The client uses the key value to determine which memcached instance to store the information. It doesn't store the same information across all the instances, as that would be a waste of cache memory.

**17.2.5.12** Is compression available?

Yes. Most of the client APIs support some sort of compression, and some even allow you to specify the threshold at which a value is deemed appropriate for compression during storage.

**17.2.5.13** Can we implement different types of memcached as different nodes in the same server, so can there be deterministic and non-deterministic in the same server?

Yes. You can run multiple instances of [memcached](#) on a single server, and in your client configuration you choose the list of servers you want to use.

**17.2.5.** What are best practices for testing an implementation, to ensure that it improves performance, and to measure the impact of [memcached](#) configuration changes? And would you recommend keeping the configuration very simple to start?

The best way to test the performance is to start up a [memcached](#) instance. First, modify your application so that it stores the data just before the data is about to be used or displayed into [memcached](#). Since the APIs handle the serialization of the data, it should just be a one-line modification to your code. Then, modify the start of the process that would normally load that information from MySQL with the code that requests the data from [memcached](#). If the data cannot be loaded from [memcached](#), default to the MySQL process.

All of the changes required will probably amount to just a few lines of code. To get the best benefit, make sure you cache entire objects (for example, all the components of a web page, blog post, discussion thread, and so on), rather than using [memcached](#) as a simple cache of individual rows of MySQL tables.

Keeping the configuration simple at the start, or even over the long term, is easy with [memcached](#). Once you have the basic structure up and running, often the only ongoing change is to add more servers into the list of servers used by your applications. You don't need to manage the [memcached](#) servers, and there is no complex configuration; just add more servers to the list and let the client API and the [memcached](#) servers make the decisions.

Replication enables data from one MySQL database server (the master) to be copied to one or more MySQL database servers (the slaves). Replication is asynchronous by default; slaves do not need to be connected permanently to receive updates from the master. Depending on the configuration, you can replicate all databases, selected databases, or even selected tables within a database.

Advantages of replication in MySQL include:

- Scale-out solutions - spreading the load among multiple slaves to improve performance. In this environment, all writes and updates must take place on the master server. Reads, however, may take place on one or more slaves. This model can improve the performance of writes (since the master is dedicated to updates), while dramatically increasing read speed across an increasing number of slaves.
- Data security - because data is replicated to the slave, and the slave can pause the replication process, it is possible to run backup services on the slave without corrupting the corresponding master data.
- Analytics - live data can be created on the master, while the analysis of the information can take place on the slave without affecting the performance of the master.
- Long-distance data distribution - you can use replication to create a local copy of data for a remote site to use, without permanent access to the master.

For information on how to use replication in such scenarios, see [Section 18.3, “Replication Solutions”](#).

MySQL 5.7 supports different methods of replication. The traditional method is based on replicating events from the master's binary log, and requires the log files and positions in them to be synchronized between master and slave. The newer method based on *global transaction identifiers* (GTIDs) is transactional and therefore does not require working with log files or positions within these files, which greatly simplifies many common replication tasks. Replication using GTIDs guarantees consistency between master and slave as long as all transactions committed on the master have also been applied on the slave. For more information about GTIDs and GTID-based replication in MySQL, see [Section 18.1.3, “Replication with Global Transaction Identifiers”](#). For information on using binary log file position based replication, see [Section 18.1, “Configuring Replication”](#).

Replication in MySQL supports different types of synchronization. The original type of synchronization is one-way, asynchronous replication, in which one server acts as the master, while one or more other servers act as slaves. This is in contrast to the *synchronous* replication which is a characteristic of MySQL Cluster (see [Chapter 20, MySQL NDB Cluster 7.5](#)). In MySQL 5.7, semisynchronous replication is supported in addition to the built-in asynchronous replication. With semisynchronous replication, a commit performed on the master blocks before returning to the session that performed the transaction until at least one slave acknowledges that it has received and logged the events for the transaction; see [Section 18.3.9, “Semisynchronous Replication”](#). MySQL 5.7 also supports delayed replication such that a slave server deliberately lags behind the master by at least a specified amount of time; see [Section 18.3.10, “Delayed Replication”](#). For scenarios where *synchronous* replication is required, use MySQL Cluster (see [Chapter 20, MySQL NDB Cluster 7.5](#)).

There are a number of solutions available for setting up replication between servers, and the best method to use depends on the presence of data and the engine types you are using. For more information on the available options, see [Section 18.1.2, “Setting Up Binary Log File Position Based Replication”](#).

There are two core types of replication format, Statement Based Replication (SBR), which replicates entire SQL statements, and Row Based Replication (RBR), which replicates only the changed rows. You can also use a third variety, Mixed Based Replication (MBR). For more information on the different replication formats, see [Section 18.2.1, “Replication Formats”](#).

Replication is controlled through a number of different options and variables. For more information, see [Section 18.1.6, “Replication and Binary Logging Options and Variables”](#).

You can use replication to solve a number of different problems, including performance, supporting the backup of different databases, and as part of a larger solution to alleviate system failures. For information on how to address these issues, see [Section 18.3, “Replication Solutions”](#).

For notes and tips on how different data types and statements are treated during replication, including details of replication features, version compatibility, upgrades, and potential problems and their resolution, see [Section 18.4, “Replication Notes and Tips”](#). For answers to some questions often asked by those who are new to MySQL Replication, see [Section A.13, “MySQL 5.7 FAQ: Replication”](#).

For detailed information on the implementation of replication, how replication works, the process and contents of the binary log, background threads and the rules used to decide how statements are recorded and replicated, see [Section 18.2, “Replication Implementation”](#).

## 18.1 Configuring Replication

This section describes how to configure the different types of replication available in MySQL and includes the setup and configuration required for a replication environment, including step-by-step instructions for creating a new replication environment. The major components of this section are:

- For a guide to setting up two or more servers for replication using binary log file positions, [Section 18.1.2, “Setting Up Binary Log File Position Based Replication”](#), deals with the configuration of the servers and provides methods for copying data between the master and slaves.

- For a guide to setting up two or more servers for replication using GTID transactions, [Section 18.1.3, “Replication with Global Transaction Identifiers”](#), deals with the configuration of the servers.
- Events in the binary log are recorded using a number of formats. These are referred to as statement-based replication (SBR) or row-based replication (RBR). A third type, mixed-format replication (MIXED), uses SBR or RBR replication automatically to take advantage of the benefits of both SBR and RBR formats when appropriate. The different formats are discussed in [Section 18.2.1, “Replication Formats”](#).
- Detailed information on the different configuration options and variables that apply to replication is provided in [Section 18.1.6, “Replication and Binary Logging Options and Variables”](#).
- Once started, the replication process should require little administration or monitoring. However, for advice on common tasks that you may want to execute, see [Section 18.1.7, “Common Replication Administration Tasks”](#).

### 18.1.1 Binary Log File Position Based Replication Configuration Overview

This section describes replication between MySQL servers based on the binary log file position method, where the MySQL instance operating as the master (the source of the database changes) writes updates and changes as “events” to the binary log. The information in the binary log is stored in different logging formats according to the database changes being recorded. Slaves are configured to read the binary log from the master and to execute the events in the binary log on the slave’s local database.

Each slave receives a copy of the entire contents of the binary log. It is the responsibility of the slave to decide which statements in the binary log should be executed. Unless you specify otherwise, all events in the master binary log are executed on the slave. If required, you can configure the slave to process only events that apply to particular databases or tables.

#### Important

You cannot configure the master to log only certain events.

Each slave keeps a record of the binary log coordinates: the file name and position within the file that it has read and processed from the master. This means that multiple slaves can be connected to the master and executing different parts of the same binary log. Because the slaves control this process, individual slaves can be connected and disconnected from the server without affecting the master’s operation. Also, because each slave records the current position within the binary log, it is possible for slaves to be disconnected, reconnect and then resume processing.

The master and each slave must be configured with a unique ID (using the `server-id` option). In addition, each slave must be configured with information about the master host name, log file name, and position within that file. These details can be controlled from within a MySQL session using the `CHANGE MASTER TO` statement on the slave. The details are stored within the slave’s master info repository, which can be either a file or a table (see [Section 18.2.4, “Replication Relay and Status Logs”](#)).

### 18.1.2 Setting Up Binary Log File Position Based Replication

This section describes how to set up a MySQL server to use binary log file position based replication. There are a number of different methods for setting up replication, and the exact method to use depends on how you are setting up replication, and whether you already have data within your master database.

There are some generic tasks that are common to all setups:

- On the master, you must enable binary logging and configure a unique server ID. This might require a server restart. See [Section 18.1.2.1, “Setting the Replication Master Configuration”](#).

- On each slave that you want to connect to the master, you must configure a unique server ID. This might require a server restart. See [Setting the Replication Slave Configuration](#).
- Optionally, create a separate user for your slaves to use during authentication with the master when reading the binary log for replication. See [Section 18.1.2.2, “Creating a User for Replication”](#).
- Before creating a data snapshot or starting the replication process, on the master you should record the current position in the binary log. You need this information when configuring the slave so that the slave knows where within the binary log to start executing events. See [Section 18.1.2.3, “Obtaining the Replication Master Binary Log Coordinates”](#).
- If you already have data on the master and want to use it to synchronize the slave, you need to create a data snapshot to copy the data to the slave. The storage engine you are using has an impact on how you create the snapshot. When you are using [MyISAM](#), you must stop processing statements on the master to obtain a read-lock, then obtain its current binary log coordinates and dump its data, before permitting the master to continue executing statements. If you do not stop the execution of statements, the data dump and the master status information will not match, resulting in inconsistent or corrupted databases on the slaves. For more information on replicating a [MyISAM](#) master, see [Section 18.1.2.3, “Obtaining the Replication Master Binary Log Coordinates”](#). If you are using [InnoDB](#), you do not need a read-lock and a transaction that is long enough to transfer the data snapshot is sufficient. For more information, see [Section 15.19, “InnoDB and MySQL Replication”](#).
- Configure the slave with settings for connecting to the master, such as the host name, login credentials, and binary log file name and position. See [Setting the Master Configuration on the Slave](#).

**Note**

Certain steps within the setup process require the [SUPER](#) privilege. If you do not have this privilege, it might not be possible to enable replication.

After configuring the basic options, select your scenario:

- To set up replication for a fresh installation of a master and slaves that contain no data, see [Setting Up Replication between a New Master and Slaves](#).
- To set up replication of a new master using the data from an existing MySQL server, see [Setting Up Replication with Existing Data](#).
- To add replication slaves to an existing replication environment, see [Section 18.1.2.6, “Adding Slaves to a Replication Environment”](#).

Before administering MySQL replication servers, read this entire chapter and try all statements mentioned in [Section 14.4.1, “SQL Statements for Controlling Master Servers”](#), and [Section 14.4.2, “SQL Statements for Controlling Slave Servers”](#). Also familiarize yourself with the replication startup options described in [Section 18.1.6, “Replication and Binary Logging Options and Variables”](#).

### 18.1.2.1 Setting the Replication Master Configuration

To configure a master to use binary log file position based replication, you must enable binary logging and establish a unique server ID. If this has not already been done, a server restart is required.

Binary logging *must* be enabled on the master because the binary log is the basis for replicating changes from the master to its slaves. If binary logging is not enabled on the master using the [log-bin](#) option, replication is not possible.

Each server within a replication group must be configured with a unique server ID. This ID is used to identify individual servers within the group, and must be a positive integer between 1 and  $(2^{32})-1$ . How you organize and select the numbers is your choice.

To configure the binary log and server ID options, shut down the MySQL server and edit the [my.cnf](#) or [my.ini](#) file. Within the [\[mysqld\]](#) section of the configuration file, add the [log-bin](#) and [server-id](#)

options. If these options already exist, but are commented out, uncomment the options and alter them according to your needs. For example, to enable binary logging using a log file name prefix of `mysql-bin`, and configure a server ID of 1, use these lines:

```
[mysqld]
log-bin=mysql-bin
server-id=1
```

After making the changes, restart the server.

#### Note

The following options have an impact on this procedure:

- if you omit `server-id` (or set it explicitly to its default value of 0), the master refuses any connections from slaves.
- For the greatest possible durability and consistency in a replication setup using `InnoDB` with transactions, you should use `innodb_flush_log_at_trx_commit=1` and `sync_binlog=1` in the master `my.cnf` file.
- Ensure that the `skip-networking` option is not enabled on your replication master. If networking has been disabled, the slave can not communicate with the master and replication fails.

### 18.1.2.2 Creating a User for Replication

Each slave connects to the master using a MySQL user name and password, so there must be a user account on the master that the slave can use to connect. Any account can be used for this operation, providing it has been granted the `REPLICATION SLAVE` privilege. You can choose to create a different account for each slave, or connect to the master using the same account for each slave.

Although you do not have to create an account specifically for replication, you should be aware that the replication user name and password are stored in plain text in the master info repository file or table (see [Section 18.2.4.2, “Slave Status Logs”](#)). Therefore, you may want to create a separate account that has privileges only for the replication process, to minimize the possibility of compromise to other accounts.

To create a new account, use `CREATE USER`. To grant this account the privileges required for replication, use the `GRANT` statement. If you create an account solely for the purposes of replication, that account needs only the `REPLICATION SLAVE` privilege. For example, to set up a new user, `repl`, that can connect for replication from any host within the `mydomain.com` domain, issue these statements on the master:

```
mysql> CREATE USER 'repl'@'%.mydomain.com' IDENTIFIED BY 'slavepass';
mysql> GRANT REPLICATION SLAVE ON *.* TO 'repl'@'%.mydomain.com';
```

See [Section 14.7.1, “Account Management Statements”](#), for more information on statements for manipulation of user accounts.

### 18.1.2.3 Obtaining the Replication Master Binary Log Coordinates

To configure the slave to start the replication process at the correct point, you need the master's current coordinates within its binary log.

If the master has been running previously without binary logging enabled, the log file name and position values displayed by `SHOW MASTER STATUS` or `mysqldump --master-data` are empty. In that case, the values that you need to use later when specifying the slave's log file and position are the empty string ( `' '` ) and `4`.

If the master has been binary logging previously, use this procedure to obtain the master binary log coordinates:

### Warning

This procedure uses `FLUSH TABLES WITH READ LOCK`, which blocks `COMMIT` operations for `InnoDB` tables.

1. Start a session on the master by connecting to it with the command-line client, and flush all tables and block write statements by executing the `FLUSH TABLES WITH READ LOCK` statement:

```
mysql> FLUSH TABLES WITH READ LOCK;
```

### Warning

Leave the client from which you issued the `FLUSH TABLES` statement running so that the read lock remains in effect. If you exit the client, the lock is released.

2. In a different session on the master, use the `SHOW MASTER STATUS` statement to determine the current binary log file name and position:

```
mysql > SHOW MASTER STATUS;
```

| File             | Position | Binlog_Do_DB | Binlog_Ignore_DB |
|------------------|----------|--------------|------------------|
| mysql-bin.000003 | 73       | test         | manual,mysql     |

The `File` column shows the name of the log file and the `Position` column shows the position within the file. In this example, the binary log file is `mysql-bin.000003` and the position is 73. Record these values. You need them later when you are setting up the slave. They represent the replication coordinates at which the slave should begin processing new updates from the master.

You now have the information you need to enable the slave to start reading from the binary log in the correct place to start replication.

The next step depends on whether you have existing data on the master. Choose one of the following options:

- If you have existing data that needs to be synchronized with the slave before you start replication, leave the client running so that the lock remains in place. This prevents any further changes being made, so that the data copied to the slave is in synchrony with the master. Proceed to [Section 18.1.2.4, "Choosing a Method for Data Snapshots"](#).
- If you are setting up a new master and slave replication group, you can exit the first session to release the read lock. See [Setting Up Replication between a New Master and Slaves](#) for how to proceed.

## 18.1.2.4 Choosing a Method for Data Snapshots

If the master database contains existing data it is necessary to copy this data to each slave. There are different ways to dump the data from the master database. The following sections describe possible options.

To select the appropriate method of dumping the database, choose between these options:

- Use the `mysqldump` tool to create a dump of all the databases you want to replicate. This is the recommended method, especially when using `InnoDB`.
- If your database is stored in binary portable files, you can copy the raw data files to a slave. This can be more efficient than using `mysqldump` and importing the file on each slave, because it skips the

overhead of updating indexes as the `INSERT` statements are replayed. With storage engines such as `InnoDB` this is not recommended.

## Creating a Data Snapshot Using `mysqldump`

To create a snapshot of the data in an existing master database, use the `mysqldump` tool. Once the data dump has been completed, import this data into the slave before starting the replication process.

The following example dumps all databases to a file named `dbdump.db`, and includes the `--master-data` option which automatically appends the `CHANGE MASTER TO` statement required on the slave to start the replication process:

```
shell> mysqldump --all-databases --master-data > dbdump.db
```

### Note

If you do not use `--master-data`, then it is necessary to lock all tables in a separate session manually. See [Section 18.1.2.3, “Obtaining the Replication Master Binary Log Coordinates”](#).

It is possible to exclude certain databases from the dump using the `mysqldump` tool. If you want to choose which databases to include in the dump, do not use `--all-databases`. Choose one of these options:

- Exclude all the tables in the database using `--ignore-table` option.
- Name only those databases which you want dumped using the `--databases` option.

For more information, see [Section 5.5.4, “mysqldump — A Database Backup Program”](#).

To import the data, either copy the dump file to the slave, or access the file from the master when connecting remotely to the slave.

## Creating a Data Snapshot Using Raw Data Files

This section describes how to create a data snapshot using the raw files which make up the database. Employing this method with a table using a storage engine that has complex caching or logging algorithms requires extra steps to produce a perfect “point in time” snapshot: the initial copy command could leave out cache information and logging updates, even if you have acquired a global read lock. How the storage engine responds to this depends on its crash recovery abilities.

If you use `InnoDB` tables, you can use the `mysqlbackup` command from the MySQL Enterprise Backup component to produce a consistent snapshot. This command records the log name and offset corresponding to the snapshot to be used on the slave. MySQL Enterprise Backup is a commercial product that is included as part of a MySQL Enterprise subscription. See [Section 28.2, “MySQL Enterprise Backup Overview”](#) for detailed information.

This method also does not work reliably if the master and slave have different values for `ft_stopword_file`, `ft_min_word_len`, or `ft_max_word_len` and you are copying tables having full-text indexes.

Assuming the above exceptions do not apply to your database, use the [cold backup](#) technique to obtain a reliable binary snapshot of `InnoDB` tables: do a [slow shutdown](#) of the MySQL Server, then copy the data files manually.

To create a raw data snapshot of `MyISAM` tables when your MySQL data files exist on a single file system, you can use standard file copy tools such as `cp` or `copy`, a remote copy tool such as `scp` or `rsync`, an archiving tool such as `zip` or `tar`, or a file system snapshot tool such as `dump`. If you are replicating only certain databases, copy only those files that relate to those tables. For `InnoDB`, all tables in all databases are stored in the `system tablespace` files, unless you have the `innodb_file_per_table` option enabled.

The following files are not required for replication:

- Files relating to the `mysql` database.
- The master info repository file, if used (see [Section 18.2.4, “Replication Relay and Status Logs”](#)).
- The master's binary log files.
- Any relay log files.

Depending on whether you are using `InnoDB` tables or not, choose one of the following:

If you are using `InnoDB` tables, and also to get the most consistent results with a raw data snapshot, shut down the master server during the process, as follows:

1. Acquire a read lock and get the master's status. See [Section 18.1.2.3, “Obtaining the Replication Master Binary Log Coordinates”](#).
2. In a separate session, shut down the master server:

```
shell> mysqladmin shutdown
```

3. Make a copy of the MySQL data files. The following examples show common ways to do this. You need to choose only one of them:

```
shell> tar cf /tmp/db.tar ./data
shell> zip -r /tmp/db.zip ./data
shell> rsync --recursive ./data /tmp/dbdata
```

4. Restart the master server.

If you are not using `InnoDB` tables, you can get a snapshot of the system from a master without shutting down the server as described in the following steps:

1. Acquire a read lock and get the master's status. See [Section 18.1.2.3, “Obtaining the Replication Master Binary Log Coordinates”](#).
2. Make a copy of the MySQL data files. The following examples show common ways to do this. You need to choose only one of them:

```
shell> tar cf /tmp/db.tar ./data
shell> zip -r /tmp/db.zip ./data
shell> rsync --recursive ./data /tmp/dbdata
```

3. In the client where you acquired the read lock, release the lock:

```
mysql> UNLOCK TABLES;
```

Once you have created the archive or copy of the database, copy the files to each slave before starting the slave replication process.

### 18.1.2.5 Setting Up Replication Slaves

The following sections describe how to set up slaves. Before you proceed, ensure that you have:

- Configured the MySQL master with the necessary configuration properties. See [Section 18.1.2.1, “Setting the Replication Master Configuration”](#).
- Obtained the master status information. See [Section 18.1.2.3, “Obtaining the Replication Master Binary Log Coordinates”](#).
- On the master, released the read lock:

```
mysql> UNLOCK TABLES;
```

## Setting the Replication Slave Configuration

Each replication slave *must* have a unique server ID. If this has not already been done, this part of slave setup requires a server restart.

If the slave server ID is not already set, or the current value conflicts with the value that you have chosen for the master server, shut down the slave server and edit the `[mysqld]` section of the configuration file to specify a unique server ID. For example:

```
[mysqld]
server-id=2
```

After making the changes, restart the server.

If you are setting up multiple slaves, each one must have a unique `server-id` value that differs from that of the master and from any of the other slaves.

### Note

If you omit `server-id` (or set it explicitly to its default value of 0), the slave refuses to connect to a master.

You do not have to enable binary logging on the slave for replication to be set up. However, if you enable binary logging on the slave, you can use the slave's binary log for data backups and crash recovery, and also use the slave as part of a more complex replication topology. For example, where this slave then acts as a master to other slaves.

## Setting the Master Configuration on the Slave

To set up the slave to communicate with the master for replication, configure the slave with the necessary connection information. To do this, execute the following statement on the slave, replacing the option values with the actual values relevant to your system:

```
mysql> CHANGE MASTER TO
->     MASTER_HOST='master_host_name',
->     MASTER_USER='replication_user_name',
->     MASTER_PASSWORD='replication_password',
->     MASTER_LOG_FILE='recorded_log_file_name',
->     MASTER_LOG_POS=recorded_log_position;
```

### Note

Replication cannot use Unix socket files. You must be able to connect to the master MySQL server using TCP/IP.

The `CHANGE MASTER TO` statement has other options as well. For example, it is possible to set up secure replication using SSL. For a full list of options, and information about the maximum permissible length for the string-valued options, see [Section 14.4.2.1, “CHANGE MASTER TO Syntax”](#).

The next steps depend on whether you have existing data to import to the slave or not. See [Section 18.1.2.4, “Choosing a Method for Data Snapshots”](#) for more information. Choose one of the following:

- If you do not have a snapshot of a database to import, see [Setting Up Replication between a New Master and Slaves](#).
- If you have a snapshot of a database to import, see [Setting Up Replication with Existing Data](#).

## Setting Up Replication between a New Master and Slaves

When there is no snapshot of a previous database to import, configure the slave to start the replication from the new master.

To set up replication between a master and a new slave:

1. Start up the MySQL slave and connect to it.
2. Execute a `CHANGE MASTER TO` statement to set the master replication server configuration. See [Setting the Master Configuration on the Slave](#).

Perform these slave setup steps on each slave.

This method can also be used if you are setting up new servers but have an existing dump of the databases from a different server that you want to load into your replication configuration. By loading the data into a new master, the data is automatically replicated to the slaves.

If you are setting up a new replication environment using the data from a different existing database server to create a new master, run the dump file generated from that server on the new master. The database updates are automatically propagated to the slaves:

```
shell> mysql -h master < fulldb.dump
```

## Setting Up Replication with Existing Data

When setting up replication with existing data, transfer the snapshot from the master to the slave before starting replication. The process for importing data to the slave depends on how you created the snapshot of data on the master.

Choose one of the following:

If you used `mysqldump`:

1. Start the slave, using the `--skip-slave-start` option so that replication does not start.
2. Import the dump file:

```
shell> mysql < fulldb.dump
```

If you created a snapshot using the raw data files:

1. Extract the data files into your slave data directory. For example:

```
shell> tar xvf dbdump.tar
```

You may need to set permissions and ownership on the files so that the slave server can access and modify them.

2. Start the slave, using the `--skip-slave-start` option so that replication does not start.
3. Configure the slave with the replication coordinates from the master. This tells the slave the binary log file and position within the file where replication needs to start. Also, configure the slave with the login credentials and host name of the master. For more information on the `CHANGE MASTER TO` statement required, see [Setting the Master Configuration on the Slave](#).
4. Start the slave threads:

```
mysql> START SLAVE;
```

After you have performed this procedure, the slave connects to the master and replicates any updates that have occurred on the master since the snapshot was taken.

If the `server-id` option for the master is not correctly set, slaves cannot connect to it. Similarly, if you have not set the `server-id` option correctly for the slave, you get the following error in the slave's error log:

Warning: You should set `server-id` to a non-0 value if `master_host` is set; we will force server id to 2, but this MySQL server will not act as a slave.

You also find error messages in the slave's error log if it is not able to replicate for any other reason.

The slave stores information about the master you have configured in its master info repository. The master info repository can be in the form of files or a table, as determined by the value set for `--master-info-repository`. When a slave uses `--master-info-repository=FILE`, two files are stored in the data directory, named `master.info` and `relay-log.info`. If `--master-info-repository=TABLE` instead, this information is saved in the `master_slave_info` table in the `mysql` database. In either case, do *not* remove or edit the files or table. Always use the `CHANGE MASTER TO` statement to change replication parameters. The slave can use the values specified in the statement to update the status files automatically. See [Section 18.2.4, “Replication Relay and Status Logs”](#), for more information.

#### Note

The contents of the master info repository override some of the server options specified on the command line or in `my.cnf`. See [Section 18.1.6, “Replication and Binary Logging Options and Variables”](#), for more details.

A single snapshot of the master suffices for multiple slaves. To set up additional slaves, use the same master snapshot and follow the slave portion of the procedure just described.

### 18.1.2.6 Adding Slaves to a Replication Environment

You can add another slave to an existing replication configuration without stopping the master. Instead, set up the new slave by making a copy of an existing slave, except that you configure the new slave with a different `server-id` value.

To duplicate an existing slave:

1. Shut down the existing slave:

```
shell> mysqladmin shutdown
```

2. Copy the data directory from the existing slave to the new slave. You can do this by creating an archive using `tar` or `WinZip`, or by performing a direct copy using a tool such as `cp` or `rsync`. Ensure that you also copy the log files and relay log files.

A common problem that is encountered when adding new replication slaves is that the new slave fails with a series of warning and error messages like these:

```
071118 16:44:10 [Warning] Neither --relay-log nor --relay-log-index were used; so
replication may break when this MySQL server acts as a slave and has his hostname
changed!! Please use '--relay-log=new_slave_hostname-relay-bin' to avoid this problem.
071118 16:44:10 [ERROR] Failed to open the relay log './old_slave_hostname-relay-bin.003525'
(relay_log_pos 22940879)
071118 16:44:10 [ERROR] Could not find target log during relay log initialization
071118 16:44:10 [ERROR] Failed to initialize the master info structure
```

This situation can occur if the `--relay-log` option is not specified, as the relay log files contain the host name as part of their file names. This is also true of the relay log index file if the `--relay-log-index` option is not used. See [Section 18.1.6, “Replication and Binary Logging Options and Variables”](#), for more information about these options.

To avoid this problem, use the same value for `--relay-log` on the new slave that was used on the existing slave. If this option was not set explicitly on the existing slave, use `existing_slave_hostname-relay-bin`. If this is not possible, copy the existing slave's relay log index file to the new slave and set the `--relay-log-index` option on the new slave to match

what was used on the existing slave. If this option was not set explicitly on the existing slave, use `existing_slave_hostname-relay-bin.index`. Alternatively, if you have already tried to start the new slave after following the remaining steps in this section and have encountered errors like those described previously, then perform the following steps:

- a. If you have not already done so, issue a `STOP SLAVE` on the new slave.  
  
If you have already started the existing slave again, issue a `STOP SLAVE` on the existing slave as well.
  - b. Copy the contents of the existing slave's relay log index file into the new slave's relay log index file, making sure to overwrite any content already in the file.
  - c. Proceed with the remaining steps in this section.
3. Copy the master info and relay log info repositories (see [Section 18.2.4, “Replication Relay and Status Logs”](#)) from the existing slave to the new slave. These hold the current log coordinates for the master's binary log and the slave's relay log.
  4. Start the existing slave.
  5. On the new slave, edit the configuration and give the new slave a unique `server-id` not used by the master or any of the existing slaves.
  6. Start the new slave. The slave uses the information in its master info repository to start the replication process.

### 18.1.3 Replication with Global Transaction Identifiers

This section explains transaction-based replication using *global transaction identifiers* (GTIDs). When using GTIDs, each transaction can be identified and tracked as it is committed on the originating server and applied by any slaves; this means that it is not necessary when using GTIDs to refer to log files or positions within those files when starting a new slave or failing over to a new master, which greatly simplifies these tasks. Because GTID-based replication is completely transaction-based, it is simple to determine whether masters and slaves are consistent; as long as all transactions committed on a master are also committed on a slave, consistency between the two is guaranteed. You can use either statement-based or row-based replication with GTIDs (see [Section 18.2.1, “Replication Formats”](#)); however, for best results, we recommend that you use the row-based format.

This section discusses the following topics:

- How GTIDs are defined and created, and how they are represented in the MySQL Server (see [Section 18.1.3.1, “GTID Concepts”](#)).
- A general procedure for setting up and starting GTID-based replication (see [Section 18.1.3.2, “Setting Up Replication Using GTIDs”](#)).
- Suggested methods for provisioning new replication servers when using GTIDs (see [Section 18.1.3.3, “Using GTIDs for Failover and Scaleout”](#)).
- Restrictions and limitations that you should be aware of when using GTID-based replication (see [Section 18.1.3.4, “Restrictions on Replication with GTIDs”](#)).

For information about MySQL Server options and variables relating to GTID-based replication, see [Section 18.1.6.5, “Global Transaction ID Options and Variables”](#). See also [Section 13.17, “Functions Used with Global Transaction IDs”](#), which describes SQL functions supported by MySQL 5.7 for use with GTIDs.

#### 18.1.3.1 GTID Concepts

A global transaction identifier (GTID) is a unique identifier created and associated with each transaction committed on the server of origin (master). This identifier is unique not only to the server on which

it originated, but is unique across all servers in a given replication setup. There is a 1-to-1 mapping between all transactions and all GTIDs.

The following paragraphs provide a basic description of GTIDs. More advanced concepts are covered later in the following sections:

- [GTID Sets](#)
- [mysql.gtid\\_executed Table](#)
- [mysql.gtid\\_executed Table Compression](#)

A GTID is represented as a pair of coordinates, separated by a colon character (:), as shown here:

```
GTID = source_id:transaction_id
```

The *source\_id* identifies the originating server. Normally, the server's *server\_uuid* is used for this purpose. The *transaction\_id* is a sequence number determined by the order in which the transaction was committed on this server; for example, the first transaction to be committed has *1* as its *transaction\_id*, and the tenth transaction to be committed on the same originating server is assigned a *transaction\_id* of *10*. It is not possible for a transaction to have *0* as a sequence number in a GTID. For example, the twenty-third transaction to be committed originally on the server with the UUID *3E11FA47-71CA-11E1-9E33-C80AA9429562* has this GTID:

```
3E11FA47-71CA-11E1-9E33-C80AA9429562:23
```

This format is used to represent GTIDs in the output of statements such as `SHOW SLAVE STATUS` as well as in the binary log. They can also be seen when viewing the log file with `mysqlbinlog --base64-output=DECODE-ROWS` or in the output from `SHOW BINLOG EVENTS`.

As written in the output of statements such as `SHOW MASTER STATUS` or `SHOW SLAVE STATUS`, a sequence of GTIDs originating from the same server may be collapsed into a single expression, as shown here.

```
3E11FA47-71CA-11E1-9E33-C80AA9429562:1-5
```

The example just shown represents the first through fifth transactions originating on the MySQL Server whose *server\_uuid* is *3E11FA47-71CA-11E1-9E33-C80AA9429562*.

This format is also used to supply the argument required by the `START SLAVE` options `SQL_BEFORE_GTIDS` and `SQL_AFTER_GTIDS`.

## GTID Sets

A GTID set is a set of global transaction identifiers which is represented as shown here:

```
gtid_set:
    uuid_set [, uuid_set] ...
    | ''

uuid_set:
    uuid:interval[:interval]...

uuid:
    hhhh-hhhh-hhhh-hhhh-hhhh-hhhh-hhhh-hhhh-hhhh-hhhh

h:
    [0-9|A-F]

interval:
    n[-n]

    (n >= 1)
```

GTID sets are used in the MySQL Server in several ways. For example, the values stored by the `gtid_executed` and `gtid_purged` system variables are represented as GTID sets. In addition, the functions `GTID_SUBSET()` and `GTID_SUBTRACT()` require GTID sets as input. When GTID sets are returned from server variables, UUIDs are in alphabetical order and numeric intervals are merged and in ascending order.

GTIDs are always preserved between master and slave. This means that you can always determine the source for any transaction applied on any slave by examining its binary log. In addition, once a transaction with a given GTID is committed on a given server, any subsequent transaction having the same GTID is ignored by that server. Thus, a transaction committed on the master can be applied no more than once on the slave, which helps to guarantee consistency.

When GTIDs are in use, the slave has no need for any nonlocal data, such as the name of a file on the master and a position within that file. All necessary information for synchronizing with the master is obtained directly from the replication data stream. GTIDs replace the file-offset pairs previously required to determine points for starting, stopping, or resuming the flow of data between master and slave. therefore, do not include `MASTER_LOG_FILE` or `MASTER_LOG_POS` options in the `CHANGE MASTER TO` statement used to direct a slave to replicate from a given master; instead it is necessary only to enable the `MASTER_AUTO_POSITION` option. For the exact steps needed to configure and start masters and slaves using GTID-based replication, see [Section 18.1.3.2, “Setting Up Replication Using GTIDs”](#).

The generation and life cycle of a GTID consist of the following steps:

1. A transaction is executed and committed on the master.

This transaction is assigned a GTID using the master's UUID and the smallest nonzero transaction sequence number not yet used on this server; the GTID is written to the master's binary log (immediately preceding the transaction itself in the log).

2. After the binary log data is transmitted to the slave and stored in the slave's relay log (using established mechanisms for this process—see [Section 18.2, “Replication Implementation”](#), for details), the slave reads the GTID and sets the value of its `gtid_next` system variable as this GTID. This tells the slave that the next transaction must be logged using this GTID.

It is important to note that the slave sets `gtid_next` in a session context.

3. The slave verifies that this GTID has not already been used to log a transaction in its own binary log. If this GTID has not been used, the slave then writes the GTID, applies the transaction, and writes the transaction to its binary log. By reading and checking the transaction's GTID first, before processing the transaction itself, the slave guarantees not only that no previous transaction having this GTID has been applied on the slave, but also that no other session has already read this GTID but has not yet committed the associated transaction. In other words, multiple clients are not permitted to apply the same transaction concurrently.
4. Because `gtid_next` is not empty, the slave does not attempt to generate a GTID for this transaction but instead writes the GTID stored in this variable—that is, the GTID obtained from the master—immediately preceding the transaction in its binary log.

## mysql.gtid\_executed Table

Beginning with MySQL 5.7.5, GTIDs are stored in a table named `gtid_executed`, in the `mysql` database. A row in this table contains, for each GTID or set of GTIDs that it represents, the UUID of the originating server, and the starting and ending transaction IDs of the set; for a row referencing only a single GTID, these last two values are the same.

The `mysql.gtid_executed` table is created (if it does not already exist) when the MySQL Server is installed or upgraded, using a `CREATE TABLE` statement similar to that shown here:

```
CREATE TABLE gtid_executed (
  source_uuid CHAR(36) NOT NULL,
```

```
interval_start BIGINT(20) NOT NULL,
interval_end BIGINT(20) NOT NULL,
PRIMARY KEY (source_uuid, interval_start)
)
```

### Warning

As with other MySQL system tables, do not attempt to create or modify this table yourself.

GTIDs are stored in the `mysql.gtid_executed` table only when `gtid_mode` is `ON` or `ON_PERMISSIVE`. GTIDs are stored in this table without regard to whether binary logging is enabled. However, the manner in which they are stored differs depending on whether `log_bin` is `ON` or `OFF`:

- If binary logging is disabled (`log_bin` is `OFF`), the server stores the GTID belonging to each transaction together with the transaction in the table.

In addition, when binary logging is disabled, this table is compressed periodically at a user-configurable rate; see [mysql.gtid\\_executed Table Compression](#), for more information.

- If binary logging is enabled (`log_bin` is `ON`), then in addition to storing the GTIDs in `mysql.gtid_executed`, whenever the binary log is rotated or the server is shut down, the server writes GTIDs for all transactions that were written into the previous binary log into the new binary log.

In the event of the server stopping unexpectedly, the set of GTIDs from the previous binary log is not saved in the `mysql.gtid_executed` table. In this case, these GTIDs are added to the table and to the set of GTIDs in the `gtid_executed` system variable during recovery.

The `mysql.gtid_executed` table is reset by `RESET MASTER`.

## mysql.gtid\_executed Table Compression

Over the course of time, the `mysql.gtid_executed` table can become filled with many rows referring to individual GTIDs that originate on the same server, and whose transaction IDs make up a sequence, similar to what is shown here:

```
mysql> SELECT * FROM mysql.gtid_executed;
```

| source_uuid                          | interval_start | interval_end |
|--------------------------------------|----------------|--------------|
| 3E11FA47-71CA-11E1-9E33-C80AA9429562 | 37             | 37           |
| 3E11FA47-71CA-11E1-9E33-C80AA9429562 | 38             | 38           |
| 3E11FA47-71CA-11E1-9E33-C80AA9429562 | 39             | 39           |
| 3E11FA47-71CA-11E1-9E33-C80AA9429562 | 40             | 40           |
| 3E11FA47-71CA-11E1-9E33-C80AA9429562 | 41             | 41           |
| 3E11FA47-71CA-11E1-9E33-C80AA9429562 | 42             | 42           |
| 3E11FA47-71CA-11E1-9E33-C80AA9429562 | 43             | 43           |
| ...                                  |                |              |

Considerable space can be saved if this table is compressed periodically by replacing each such set of rows with a single row that spans the entire interval of transaction identifiers, like this:

| source_uuid                          | interval_start | interval_end |
|--------------------------------------|----------------|--------------|
| 3E11FA47-71CA-11E1-9E33-C80AA9429562 | 37             | 43           |
| ...                                  |                |              |

When GTIDs are enabled, the server performs this type of compression on the `mysql.gtid_executed` table periodically. You can control the number of transactions that are allowed to elapse before the table is compressed, and thus the compression rate, by setting the `executed_gtid_compression_period` system variable. This variable's default value is 1000; this means that, by default, compression of the table is performed after each 1000 transactions. Setting

`executed_gtid_compression_period` to 0 prevents the compression from being performed at all; however, you should be prepared for a potentially large increase in the amount of disk space that may be required by the `gtid_executed` table if you do this.

#### Note

When binary logging is enabled, the value of `executed_gtid_compression_period` is *not* used and the `mysql.gtid_executed` table is compressed on each binary log rotation.

Compression of the `mysql.gtid_executed` table is performed by a dedicated foreground thread that is created whenever GTIDs are enabled on the server. This thread is not listed in the output of `SHOW PROCESSLIST`, but it can be viewed as a row in the `threads` table, as shown here:

```
mysql> SELECT * FROM PERFORMANCE_SCHEMA.THREADS WHERE NAME LIKE '%gtid%'\G
***** 1. row *****
      THREAD_ID: 21
        NAME: thread/sql/compress_gtid_table
         TYPE: FOREGROUND
PROCESSLIST_ID: 139635685943104
PROCESSLIST_USER: NULL
PROCESSLIST_HOST: NULL
PROCESSLIST_DB: NULL
PROCESSLIST_COMMAND: Daemon
PROCESSLIST_TIME: 611
PROCESSLIST_STATE: Suspending
PROCESSLIST_INFO: NULL
PARENT_THREAD_ID: 1
          ROLE: NULL
    INSTRUMENTED: YES
```

This thread has the name `thread/sql/compress_gtid_table`, and normally sleeps until `executed_gtid_compression_period` transactions have been executed, then wakes up to perform compression of the `mysql.gtid_executed` table as described previously. It then sleeps until another `executed_gtid_compression_period` transactions have taken place, then wakes up to perform the compression again, repeating this loop indefinitely. Setting this value to 0 when binary logging is disabled means that the thread always sleeps and never wakes up.

### 18.1.3.2 Setting Up Replication Using GTIDs

This section describes a process for configuring and starting GTID-based replication in MySQL 5.7. This is a “cold start” procedure that assumes either that you are starting the replication master for the first time, or that it is possible to stop it; for information about provisioning replication slaves using GTIDs from a running master, see [Section 18.1.3.3, “Using GTIDs for Failover and Scaleout”](#). For information about changing GTID mode on servers online, see [Section 18.1.5, “Changing Replication Modes on Online Servers”](#).

The key steps in this startup process for the simplest possible GTID replication topology—consisting of one master and one slave—are as follows:

1. If replication is already running, synchronize both servers by making them read-only.
2. Stop both servers.
3. Restart both servers with GTIDs enabled and the correct options configured.

The `mysqld` options necessary to start the servers as described are discussed in the example that follows later in this section.

#### Note

`server_uuid` must exist for GTIDs to function correctly.

4. Instruct the slave to use the master as the replication data source and to use auto-positioning, and then start the slave.

The SQL statements needed to accomplish this step are described in the example that follows later in this section.

5. Enable read mode again on both servers, so that they can accept updates.

In the following example, two servers are already running as master and slave, using MySQL's binary log position-based replication protocol. If you are starting with new servers, see [Section 18.1.2.2, “Creating a User for Replication”](#) for information about adding a specific user for replication connections and [Section 18.1.2.1, “Setting the Replication Master Configuration”](#) for information about setting the server-id. The following examples show how to use startup options when running `mysqld`. Alternatively you can store startup options in an option file, see [Section 5.2.6, “Using Option Files”](#) for more information.

Most of the steps that follow require the use of the MySQL `root` account or another MySQL user account that has the `SUPER` privilege. `mysqladmin shutdown` requires either the `SUPER` privilege or the `SHUTDOWN` privilege.

**Step 1: Synchronize the servers.** Make the servers read-only. To do this, enable the `read_only` system variable by executing the following statement on both servers:

```
mysql> SET @@global.read_only = ON;
```

Then, allow the slave to catch up with the master. *It is extremely important that you make sure the slave has processed all updates before continuing.*

**Step 2: Stop both servers.** Stop each server using `mysqladmin` as shown here, where `username` is the user name for a MySQL user having sufficient privileges to shut down the server:

```
shell> mysqladmin -uusername -p shutdown
```

Then supply this user's password at the prompt.

**Step 3: Restart both servers with GTIDs enabled.** To enable GTID-based replication, each server must be started with GTID mode enabled, by setting the `--gtid-mode` option to `ON`, and with the `--enforce-gtid-consistency` option enabled to ensure that only statements which are safe for GTID-based replication are logged. In addition, you should start the slave with the `--skip-slave-start` option before configuring the slave settings. For more information on GTID related options, see [Section 18.1.6.5, “Global Transaction ID Options and Variables”](#).

It is not mandatory to have binary logging enabled in order to use GTIDs due to the addition of the `mysql.gtid_executed` Table in MySQL 5.7.5. This means that you can have slave servers using GTIDs but without binary logging. Masters *must* always have binary logging enabled in order to be able to replicate. For example, to start a slave with GTIDs enabled but without binary logging, use at least these options:

```
shell> mysqld --gtid-mode=ON --enforce-gtid-consistency &
```

In MySQL 5.7.4 and earlier, binary logging is required to use GTIDs and both master and slave servers must be started with at least these options:

```
shell> mysqld --gtid-mode=ON --log-bin --enforce-gtid-consistency &
```

Depending on your configuration, supply additional options to `mysqld`.

**Step 4: Direct the slave to use the master.** Tell the slave to use the master as the replication data source, and to use GTID-based auto-positioning rather than file-based positioning. Execute a `CHANGE`

`MASTER TO` statement on the slave, using the `MASTER_AUTO_POSITION` option to tell the slave that transactions will be identified by GTIDs.

You may also need to supply appropriate values for the master's host name and port number as well as the user name and password for a replication user account which can be used by the slave to connect to the master; if these have already been set prior to Step 1 and no further changes need to be made, the corresponding options can safely be omitted from the statement shown here.

```
mysql> CHANGE MASTER TO
>     MASTER_HOST = host,
>     MASTER_PORT = port,
>     MASTER_USER = user,
>     MASTER_PASSWORD = password,
>     MASTER_AUTO_POSITION = 1;
```

Neither the `MASTER_LOG_FILE` option nor the `MASTER_LOG_POS` option may be used with `MASTER_AUTO_POSITION` set equal to 1. Attempting to do so causes the `CHANGE MASTER TO` statement to fail with an error.

Assuming that the `CHANGE MASTER TO` statement has succeeded, you can then start the slave, like this:

```
mysql> START SLAVE;
```

**Step 5: Disable read-only mode.** Allow the master to begin accepting updates once again by running the following statement:

```
mysql> SET @@global.read_only = OFF;
```

GTID-based replication should now be running, and you can begin (or resume) activity on the master as before. [Section 18.1.3.3, “Using GTIDs for Failover and Scaleout”](#), discusses creation of new slaves when using GTIDs.

### 18.1.3.3 Using GTIDs for Failover and Scaleout

There are a number of techniques when using MySQL Replication with Global Transaction Identifiers (GTIDs) for provisioning a new slave which can then be used for scaleout, being promoted to master as necessary for failover. This section describes the following techniques:

- [Simple replication](#)
- [Copying data and transactions to the slave](#)
- [Injecting empty transactions](#)
- [Excluding transactions with `gtid\_purged`](#)
- [Restoring GTID mode slaves](#)

Global transaction identifiers were added to MySQL Replication for the purpose of simplifying in general management of the replication data flow and of failover activities in particular. Each identifier uniquely identifies a set of binary log events that together make up a transaction. GTIDs play a key role in applying changes to the database: the server automatically skips any transaction having an identifier which the server recognizes as one that it has processed before. This behavior is critical for automatic replication positioning and correct failover.

The mapping between identifiers and sets of events comprising a given transaction is captured in the binary log. This poses some challenges when provisioning a new server with data from another existing server. To reproduce the identifier set on the new server, it is necessary to copy the identifiers from the old server to the new one, and to preserve the relationship between the identifiers and the actual events. This is necessary for restoring a slave that is immediately available as a candidate to become a new master on failover or switchover.

**Simple replication.** The easiest way to reproduce all identifiers and transactions on a new server is to make the new server into the slave of a master that has the entire execution history, and enable global transaction identifiers on both servers. See [Section 18.1.3.2, “Setting Up Replication Using GTIDs”](#), for more information.

Once replication is started, the new server copies the entire binary log from the master and thus obtains all information about all GTIDs.

This method is simple and effective, but requires the slave to read the binary log from the master; it can sometimes take a comparatively long time for the new slave to catch up with the master, so this method is not suitable for fast failover or restoring from backup. This section explains how to avoid fetching all of the execution history from the master by copying binary log files to the new server.

**Copying data and transactions to the slave.** Playing back the entire transaction history can be time-consuming, and represents a major bottleneck when setting up a new replication slave. To eliminate this requirement, a snapshot of the data set, the binary logs and the global transaction information the master contains is imported to the slave. The binary log is played back, after which replication can be started, allowing the slave to become current with any remaining transactions.

There are several variants of this method, the difference being in the manner in which data dumps and transactions from binary logs are transferred to the slave, as outlined here:

| Data Set   | Transaction History   |
|--|---|
| <ul style="list-style-type: none"> <li>Use the <code>mysql</code> client to import a dump file created with <code>mysqldump</code>. Use the <code>--master-data</code> option to include binary logging information and <code>--set-gtid-purged</code> to <code>AUTO</code> (the default) or <code>ON</code>, to include information about executed transactions. You should have <code>--gtid-mode=ON</code> while importing the dump on the slave.</li> <li>Stop the slave, copy the contents of the master's data directory to the slave's data directory, then restart the slave.</li> </ul> | <p>If <code>gtid_mode</code> is not <code>ON</code>, restart the server with GTID mode enabled.</p> <ul style="list-style-type: none"> <li>Import the binary log using <code>mysqlbinlog</code>, with the <code>--read-from-remote-server</code> and <code>--read-from-remote-master</code> options.</li> <li>Copy the master's binary log files to the slave. You can make copies from the slave using <code>mysqlbinlog --read-from-remote-server --raw</code>. These can be read in to the slave in either of the following ways: <ul style="list-style-type: none"> <li>Update the slave's <code>binlog.index</code> file to point to the copied log files. Then execute a <code>CHANGE MASTER TO</code> statement in the <code>mysql</code> client to point to the first log file, and <code>START SLAVE</code> to read them.</li> <li>Use <code>mysqlbinlog &gt; file</code> (without the <code>--raw</code> option) to export the binary log files to SQL files that can be processed by the <code>mysql</code> client.</li> </ul> </li> </ul> |

See also [Section 5.6.7.3, “Using mysqlbinlog to Back Up Binary Log Files”](#).

This method has the advantage that a new server is available almost immediately; only those transactions that were committed while the snapshot or dump file was being replayed still need to be obtained from the existing master. This means that the slave's availability is not instantaneous—but only a relatively short amount of time should be required for the slave to catch up with these few remaining transactions.

Copying over binary logs to the target server in advance is usually faster than reading the entire transaction execution history from the master in real time. However, it may not always be feasible to move these files to the target when required, due to size or other considerations. The two remaining methods for provisioning a new slave discussed in this section use other means to transfer information about transactions to the new slave.

**Injecting empty transactions.** The master's global `gtid_executed` variable contains the set of all transactions executed on the master. Rather than copy the binary logs when taking a snapshot to provision a new server, you can instead note the content of `gtid_executed` on the server from which the snapshot was taken. Before adding the new server to the replication chain, simply commit an empty transaction on the new server for each transaction identifier contained in the master's `gtid_executed`, like this:

```
SET GTID_NEXT='aaa-bbb-ccc-ddd:N';

BEGIN;
COMMIT;

SET GTID_NEXT='AUTOMATIC';
```

Once all transaction identifiers have been reinstated in this way using empty transactions, you must flush and purge the slave's binary logs, as shown here, where `N` is the nonzero suffix of the current binary log file name:

```
FLUSH LOGS;
PURGE BINARY LOGS TO 'master-bin.00000N';
```

You should do this to prevent this server from flooding the replication stream with false transactions in the event that it is later promoted to master. (The `FLUSH LOGS` statement forces the creation of a new binary log file; `PURGE BINARY LOGS` purges the empty transactions, but retains their identifiers.)

This method creates a server that is essentially a snapshot, but in time is able to become a master as its binary log history converges with that of the replication stream (that is, as it catches up with the master or masters). This outcome is similar in effect to that obtained using the remaining provisioning method, which we discuss in the next few paragraphs.

**Excluding transactions with `gtid_purged`.** The master's global `gtid_purged` variable contains the set of all transactions that have been purged from the master's binary log. As with the method discussed previously (see [Injecting empty transactions](#)), you can record the value of `gtid_executed` on the server from which the snapshot was taken (in place of copying the binary logs to the new server). Unlike the previous method, there is no need to commit empty transactions (or to issue `PURGE BINARY LOGS`); instead, you can set `gtid_purged` on the slave directly, based on the value of `gtid_executed` on the server from which the backup or snapshot was taken.

As with the method using empty transactions, this method creates a server that is functionally a snapshot, but in time is able to become a master as its binary log history converges with that of the replication master or group.

**Restoring GTID mode slaves.** When restoring a slave in a GTID based replication setup that has encountered an error, injecting an empty transaction may not solve the problem because an event does not have a GTID.

Use `mysqlbinlog` to find the next transaction, which is probably the first transaction in the next log file after the event. Copy everything up to the `COMMIT` for that transaction, being sure to include the `SET @@SESSION.GTID_NEXT`. Even if you are not using row-based replication, you can still run binary log row events in the command line client.

Stop the slave and run the transaction you copied. The `mysqlbinlog` output sets the delimiter to `/*! */;`, so set it back:

```
mysql> DELIMITER ;
```

Restart replication from the correct position automatically:

```
mysql> SET GTID_NEXT=automatic;
mysql> RESET SLAVE;
```

```
mysql> START SLAVE;
```

### 18.1.3.4 Restrictions on Replication with GTIDs

Because GTID-based replication is dependent on transactions, some features otherwise available in MySQL are not supported when using it. This section provides information about restrictions on and limitations of replication with GTIDs.

**Updates involving nontransactional storage engines.** When using GTIDs, updates to tables using nontransactional storage engines such as [MyISAM](#) cannot be made in the same statement or transaction as updates to tables using transactional storage engines such as [InnoDB](#).

This restriction is due to the fact that updates to tables that use a nontransactional storage engine mixed with updates to tables that use a transactional storage engine within the same transaction can result in multiple GTIDs being assigned to the same transaction.

Such problems can also occur when the master and the slave use different storage engines for their respective versions of the same table, where one storage engine is transactional and the other is not.

In any of the cases just mentioned, the one-to-one correspondence between transactions and GTIDs is broken, with the result that GTID-based replication cannot function correctly.

**CREATE TABLE ... SELECT statements.** `CREATE TABLE ... SELECT` is not safe for statement-based replication. When using row-based replication, this statement is actually logged as two separate events—one for the creation of the table, and another for the insertion of rows from the source table into the new table just created. When this statement is executed within a transaction, it is possible in some cases for these two events to receive the same transaction identifier, which means that the transaction containing the inserts is skipped by the slave. Therefore, `CREATE TABLE ... SELECT` is not supported when using GTID-based replication.

**Temporary tables.** `CREATE TEMPORARY TABLE` and `DROP TEMPORARY TABLE` statements are not supported inside transactions when using GTIDs (that is, when the server was started with the `--enforce-gtid-consistency` option). It is possible to use these statements with GTIDs enabled, but only outside of any transaction, and only with `autocommit=1`.

**Preventing execution of unsupported statements.** To prevent execution of statements that would cause GTID-based replication to fail, all servers must be started with the `--enforce-gtid-consistency` option when enabling GTIDs. This causes statements of any of the types discussed previously in this section to fail with an error.

For information about other required startup options when enabling GTIDs, see [Section 18.1.3.2, “Setting Up Replication Using GTIDs”](#).

`sql_slave_skip_counter` is not supported when using GTIDs. If you need to skip transactions, use the value of the master's `gtid_executed` variable instead; see [Injecting empty transactions](#), for more information.

**GTID mode and mysqldump.** It is possible to import a dump made using `mysqldump` into a MySQL Server running with GTID mode enabled, provided that there are no GTIDs in the target server's binary log.

**GTID mode and mysql\_upgrade.** It is not recommended to use `mysql_upgrade` with the `--write-binlog` option on a MySQL Server running with `--gtid-mode=ON` because `mysql_upgrade` can make changes to system tables that use the [MyISAM](#) storage engine, which is non-transactional.

## 18.1.4 MySQL Multi-Source Replication

This section describes MySQL Multi-Source Replication, included in MySQL 5.7.6 and later. Multi-source replication enables you to replicate from multiple immediate masters in parallel. This section describes multi-source replication, and how to configure, monitor and troubleshoot it.

### 18.1.4.1 MySQL Multi-Source Replication Overview

MySQL Multi-Source Replication enables a replication slave to receive transactions from multiple sources simultaneously. Multi-source replication can be used to back up multiple servers to a single server, to merge table shards, and consolidate data from multiple servers to a single server. Multi-source replication does not implement any conflict detection or resolution when applying the transactions, and those tasks are left to the application if required. In a multi-source replication topology, a slave creates a replication channel for each master that it should receive transactions from. See [Section 18.2.3, “Replication Channels”](#). The following sections describe how to set up multi-source replication.

### 18.1.4.2 Multi-Source Replication Tutorials

This section provides tutorials on how to configure masters and slaves for multi-source replication, and how to start, stop and reset multi-source slaves.

#### Configuring Multi-Source Replication

This section explains how to configure a multi-source replication topology, and provides details about configuring masters and slaves. Such a topology requires at least two masters and one slave configured.

Masters in a multi-source replication topology can be configured to use either global transaction identifier (GTID) based replication, or binary log position-based replication. See [Section 18.1.3.2, “Setting Up Replication Using GTIDs”](#) for how to configure a master using GTID based replication. See [Section 18.1.2.1, “Setting the Replication Master Configuration”](#) for how to configure a master using file position based replication.

Slaves in a multi-source replication topology require `TABLE` based repositories. Multi-source replication is not compatible with `FILE` based repositories. The type of repository being used by `mysqld` can be configured either at startup, or dynamically.

To configure the type of repository used by a replication slave at startup, start `mysqld` with the following options:

```
--master-info-repository=TABLE --relay-log-info-repository=TABLE
```

To modify an existing replication slave that is using a `FILE` repository to use `TABLE` repositories, convert the existing replication repositories dynamically by running the following commands:

```
STOP SLAVE;  
SET GLOBAL master_info_repository = 'TABLE';  
SET GLOBAL relay_log_info_repository = 'TABLE';
```

#### Adding a GTID Based Master to a Multi-Source Replication Slave

This section assumes you have enabled GTID based transactions on the master using `gtid_mode=ON`, enabled a replication user, and ensured that the slave is using `TABLE` based replication repositories. Use the `CHANGE MASTER TO` statement to add a new master to a channel by using a `FOR CHANNEL channel` clause. For more information on replication channels, see [Section 18.2.3, “Replication Channels”](#)

For example, to add a new master with the host name `master1` using port `3451` to a channel called `master-1`:

```
CHANGE MASTER TO MASTER_HOST='master1', MASTER_USER='rpl', MASTER_PORT=3451, MASTER_PASSWORD='', \  
MASTER_AUTO_POSITION = 1 FOR CHANNEL 'master-1';
```

Multi-source replication is compatible with auto-positioning. See [Section 14.4.2.1, “CHANGE MASTER TO Syntax”](#) for more information.

Repeat this process for each extra master that you want to add to a channel, changing the host name, port and channel as appropriate.

## Adding a Binary Log Based Master to a Multi-Source Replication Slave

This section assumes you have enabled binary logging on the master using `--log-bin`, enabled a replication user, noted the current binary log position, and ensured that the slave is using `TABLE` based replication repositories. You need to know the current `MASTER_LOG_FILE` and `MASTER_LOG_POSITION`. Use the `CHANGE MASTER TO` statement to add a new master to a channel by specifying a `FOR CHANNEL channel` clause. For example, to add a new master with the host name `master1` using port `3451` to a channel called `master-1`:

```
CHANGE MASTER TO MASTER_HOST='master1', MASTER_USER='rpl', MASTER_PORT=3451, MASTER_PASSWORD='' \
MASTER_LOG_FILE='master1-bin.000006', MASTER_LOG_POS=628 FOR CHANNEL 'master-1';
```

Repeat this process for each extra master that you want to add to a channel, changing the host name, port and channel as appropriate.

## Starting Multi-Source Replication Slaves

Once you have added all of the channels you want to use as replication masters, use a `START SLAVE thread_types` statement to start replication. When you have enabled multiple channels on a slave, you can choose to either start all channels, or select a specific channel to start.

- To start all currently configured replication channels:

```
START SLAVE thread_types;
```

- To start only a named channel, use a `FOR CHANNEL channel` clause:

```
START SLAVE thread_types FOR CHANNEL channel;
```

Use the `thread_types` option to choose specific threads you want the above statements to start on the slave. See [Section 14.4.2.6, “START SLAVE Syntax”](#) for more information.

## Stopping Multi-Source Replication Slaves

The `STOP SLAVE` statement can be used to stop a multi-source replication slave. By default, if you use the `STOP SLAVE` statement on a multi-source replication slave all channels are stopped. Optionally, use the `FOR CHANNEL channel` clause to stop only a specific channel.

- To stop all currently configured replication channels:

```
STOP SLAVE thread_types;
```

- To stop only a named channel, use a `FOR CHANNEL channel` clause:

```
STOP SLAVE thread_types FOR CHANNEL channel;
```

Use the `thread_types` option to choose specific threads you want the above statements to stop on the slave. See [Section 14.4.2.7, “STOP SLAVE Syntax”](#) for more information.

## Resetting Multi-Source Replication Slaves

The `RESET SLAVE` statement can be used to reset a multi-source replication slave. By default, if you use the `RESET SLAVE` statement on a multi-source replication slave all channels are reset. Optionally, use the `FOR CHANNEL channel` clause to reset only a specific channel.

- To reset all currently configured replication channels:

```
RESET SLAVE;
```

- To reset only a named channel, use a `FOR CHANNEL channel` clause:

```
RESET SLAVE FOR CHANNEL channel;
```

See [Section 14.4.2.4, “RESET SLAVE Syntax”](#) for more information.

### 18.1.4.3 Multi-Source Replication Monitoring

To monitor the status of replication channels the following options exist:

- Using the replication Performance Schema tables. The first column of these tables is `Channel_Name`. This enables you to write complex queries based on `Channel_Name` as a key. See [Section 24.10.11, “Performance Schema Replication Tables”](#).
- Using `SHOW SLAVE STATUS FOR CHANNEL channel_name`. By default, if the `FOR CHANNEL channel_name` clause is not used, this statement shows the slave status for all channels with one row per channel. The identifier `channel_name` is added as a column in the result set. If a `FOR CHANNEL channel_name` clause is provided, the results show the status of only the named replication channel.

#### Note

The `SHOW VARIABLES` statement does not work with multiple replication channels. The information that was available through these variables has been migrated to the replication performance tables. Using a `SHOW VARIABLES` statement in a topology with multiple channels shows the status of only the default channel.

### Monitoring Channels Using Performance Schema Tables

This section explains how to use the replication Performance Schema tables to monitor channels. You can choose to monitor all channels, or a subset of the existing channels.

To monitor the connection status of all channels:

```
mysql> SELECT * FROM replication_connection_status\G;
***** 1. row *****
CHANNEL_NAME: master1
GROUP_NAME:
SOURCE_UUID: 046e41f8-a223-11e4-a975-0811960cc264
THREAD_ID: 24
SERVICE_STATE: ON
COUNT_RECEIVED_HEARTBEATS: 0
LAST_HEARTBEAT_TIMESTAMP: 0000-00-00 00:00:00
RECEIVED_TRANSACTION_SET: 046e41f8-a223-11e4-a975-0811960cc264:4-37
LAST_ERROR_NUMBER: 0
LAST_ERROR_MESSAGE:
LAST_ERROR_TIMESTAMP: 0000-00-00 00:00:00
***** 2. row *****
CHANNEL_NAME: master2
GROUP_NAME:
SOURCE_UUID: 7475e474-a223-11e4-a978-0811960cc264
THREAD_ID: 26
SERVICE_STATE: ON
COUNT_RECEIVED_HEARTBEATS: 0
LAST_HEARTBEAT_TIMESTAMP: 0000-00-00 00:00:00
RECEIVED_TRANSACTION_SET: 7475e474-a223-11e4-a978-0811960cc264:4-6
LAST_ERROR_NUMBER: 0
LAST_ERROR_MESSAGE:
LAST_ERROR_TIMESTAMP: 0000-00-00 00:00:00
2 rows in set (0.00 sec)
```

In the above output there are two channels enabled, and as shown by the `CHANNEL_NAME` field they are called `master1` and `master2`.

The addition of the `CHANNEL_NAME` field enables you to query the Performance Schema tables for a specific channel. To monitor the connection status of a named channel, use a `WHERE channel_name=channel` clause:

```
mysql> SELECT * FROM replication_connection_status WHERE channel_name='master1'\G
***** 1. row *****
CHANNEL_NAME: master1
GROUP_NAME:
SOURCE_UUID: 046e41f8-a223-11e4-a975-0811960cc264
THREAD_ID: 24
SERVICE_STATE: ON
COUNT_RECEIVED_HEARTBEATS: 0
LAST_HEARTBEAT_TIMESTAMP: 0000-00-00 00:00:00
RECEIVED_TRANSACTION_SET: 046e41f8-a223-11e4-a975-0811960cc264:4-37
LAST_ERROR_NUMBER: 0
LAST_ERROR_MESSAGE:
LAST_ERROR_TIMESTAMP: 0000-00-00 00:00:00
1 row in set (0.00 sec)
```

Similarly, the `WHERE channel_name=channel` clause can be used to monitor the other replication Performance Schema tables for a specific channel. For more information, see [Section 24.10.11, “Performance Schema Replication Tables”](#).

#### 18.1.4.4 Multi-Source Replication Error Messages

New error codes and messages have been added to MySQL 5.7.6 to provide information about errors encountered in a multi-source replication topology. These error codes and messages are only emitted when multi-source replication is enabled, and provide information related to the channel which generated the error. For example:

`Slave is already running` and `Slave is already stopped` have been replaced with `Replication thread(s) for channel channel_name are already running` and `Replication threads(s) for channel channel_name are already stopped` respectively.

The server log messages have also been changed to indicate which channel the log messages relate to. This makes debugging and tracing easier.

### 18.1.5 Changing Replication Modes on Online Servers

This section describes how to change the mode of replication being used without having to take the server offline. This is new functionality added in MySQL 5.7.6.

#### 18.1.5.1 Replication Mode Concepts

To be able to safely configure the replication mode of an online server it is important to understand some key concepts of replication. This section explains these concepts and is essential reading before attempting to modify the replication mode of an online server.

The modes of replication available in MySQL rely on different techniques for identifying transactions which are logged. The types of transactions used by replication are as follows:

- GTID transactions are identified by a global transaction identifier (GTID) in the form `UUID:NUMBER`. Every GTID transaction in a log is always preceded by a `Gtid_log_event`. GTID transactions can be addressed using either the GTID or using the file name and position.
- Anonymous transactions do not have a GTID assigned, and MySQL 5.7.6 and later ensures that every anonymous transaction in a log is preceded by an `Anonymous_gtid_log_event`. In previous versions, anonymous transactions were not preceded by any particular event. Anonymous transactions can only be addressed using file name and position.

When using GTIDs you can take advantage of auto-positioning and automatic fail-over, as well as use `WAIT_FOR_EXECUTED_GTID_SET()`, `session_track_gtids`, and monitor replicated transactions using Performance Schema tables. With GTIDs enabled you cannot use `sql_slave_skip_counter`, instead use empty transactions.

The changes introduced by MySQL 5.7.6 mean that transactions in a relay log that was received from a master running a previous version of MySQL may not be preceded by any particular event at all, but after being replayed and logged in the slave's binary log, they are preceded with an `Anonymous_gtid_log_event`.

The ability to configure the replication mode online means that the `gtid_mode` and `enforce_gtid_consistency` variables are now both dynamic and can be set by `SUPER` from a top-level statement. In previous versions, both of these variables could only be configured using the appropriate option at server start, meaning that changes to the replication mode required a server restart. In all versions `gtid_mode` could be set to `ON` or `OFF`, which corresponded to whether GTIDs were used to identify transactions or not. When `gtid_mode=ON` it is not possible to replicate anonymous transactions, and when `gtid_mode=OFF` only anonymous transactions can be replicated. As of MySQL 5.7.6, the `gtid_mode` variable has two additional states, `OFF_PERMISSIVE` and `ON_PERMISSIVE`. When `gtid_mode=OFF_PERMISSIVE` then *new* transactions are anonymous while permitting replicated transactions to be either GTID or anonymous transactions. When `gtid_mode=ON_PERMISSIVE` then *new* transactions use GTIDs while permitting replicated transactions to be either GTID or anonymous transactions. This means it is possible to have a replication topology that has servers using both anonymous and GTID transactions. For example a master with `gtid_mode=ON` could be replicating to a slave with `gtid_mode=ON_PERMISSIVE`. The valid values for `gtid_mode` are as follows and in this order:

- `OFF`
- `OFF_PERMISSIVE`
- `ON_PERMISSIVE`
- `ON`

It is important to note that the state of `gtid_mode` can only be changed by one step at a time based on the above order. For example, if `gtid_mode` is currently set to `OFF_PERMISSIVE`, it is possible to change to `OFF` or `ON_PERMISSIVE` but not to `ON`. This is to ensure that the process of changing from anonymous transactions to GTID transactions online is correctly handled by the server. When you switch between `gtid_mode=ON` and `gtid_mode=OFF`, the GTID state (in other words the value of `gtid_executed`) is persistent. This ensures that the GTID set that has been applied by the server is always retained, regardless of changes between types of `gtid_mode`.

As part of the changes introduced by MySQL 5.7.6, the fields related to GTIDs have been modified so that they display the correct information regardless of the currently selected `gtid_mode`. This means that fields which display GTID sets, such as `gtid_executed`, `gtid_purged`, `RECEIVED_TRANSACTION_SET` in the `replication_connection_status` Performance Schema table, and the GTID related results of `SHOW SLAVE STATUS`, now return the empty string when there are no GTIDs present. Fields that display a single GTID, such as `CURRENT_TRANSACTION` in the `replication_applier_status_by_worker` Performance Schema table, now display `ANONYMOUS` when GTID transactions are not being used.

Replication from a master using `gtid_mode=ON` provides the ability to use auto-positioning, configured using the `CHANGE MASTER TO MASTER_AUTO_POSITION = 1;` statement. The replication topology being used impacts on whether it is possible to enable auto-positioning or not, as this feature relies on GTIDs and is not compatible with anonymous transactions. An error is generated if auto-positioning is enabled and an anonymous transaction is encountered. It is strongly recommended to ensure there are no anonymous transactions remaining in the topology before enabling auto-positioning, see [Section 18.1.5.2, “Enabling GTID Transactions Online”](#). The valid combinations of `gtid_mode` and auto-positioning on master and slave are shown in the following table, where the master's `gtid_mode` is shown on the horizontal and the slave's `gtid_mode` is on the vertical:

**Table 18.1 Valid Combinations of Master and Slave `gtid_mode`**

| Master/Slave<br><code>gtid_mode</code> | <code>OFF</code> | <code>OFF_PERMISSIVE</code> | <code>ON_PERMISSIVE</code> | <code>ON</code> |
|--|------------------|-----------------------------|----------------------------|-----------------|
| <code>OFF</code>                       | Y                | Y                           | N                          | N               |
| <code>OFF_PERMISSIVE</code>            | Y                | Y                           | Y                          | Y*              |
| <code>ON_PERMISSIVE</code>             | Y                | Y                           | Y                          | Y*              |
| <code>ON</code>                        | N                | N                           | Y                          | Y*              |

In the above table, the entries are:

- **Y**: the `gtid_mode` of master and slave is compatible
- **N**: the `gtid_mode` of master and slave is not compatible
- **\***: auto-positioning can be used

The currently selected `gtid_mode` also impacts on the `gtid_next` variable. The following table shows the behavior of the server for the different values of `gtid_mode` and `gtid_next`.

**Table 18.2 Valid Combinations of `gtid_mode` and `gtid_next`**

| <code>gtid_next</code>      | <b>AUTOMATIC<br/>binary log<br/>on</b> | <b>AUTOMATIC<br/>binary log off<br/>on</b> | <b>ANONYMOUS</b> | <b>UUID:NUMBER</b> |
|-----------------------------|--|--|------------------|--------------------|
| <code>OFF</code>            | ANONYMOUS                              | ANONYMOUS                                  | ANONYMOUS        | Error              |
| <code>OFF_PERMISSIVE</code> | ANONYMOUS                              | ANONYMOUS                                  | ANONYMOUS        | UUID:NUMBER        |
| <code>ON_PERMISSIVE</code>  | New GTID                               | ANONYMOUS                                  | ANONYMOUS        | UUID:NUMBER        |
| <code>ON</code>             | New GTID                               | ANONYMOUS                                  | Error            | UUID:NUMBER        |

In the above table, the entries are:

- **ANONYMOUS**: generate an anonymous transaction.
- **Error**: generate an error and fail to execute `SET GTID_NEXT`.
- **UUID:NUMBER**: generate a GTID with the specified UUID:NUMBER.
- **New GTID**: generate a GTID with an automatically generated number.

When the binary log is off and `gtid_next` is set to **AUTOMATIC**, then no GTID is generated. This is consistent with the behavior of previous versions.

### 18.1.5.2 Enabling GTID Transactions Online

This section describes how to enable GTID transactions, and optionally auto-positioning, on servers that are already online and using anonymous transactions. This procedure does not require taking the server offline and is suited to use in production. However, if you have the possibility to take the servers offline when enabling GTID transactions that process is easier.

Before you start, ensure that the servers meet the following pre-conditions:

- All servers in your topology must use MySQL 5.7.6 or later. You cannot enable GTID transactions online on any single server unless all servers which are in the topology are using this version.
- All servers have `gtid_mode` set to the default value `OFF`.

The following procedure can be paused at any time and later resumed where it was, or reversed by jumping to the corresponding step of [Section 18.1.5.3, “Disabling GTID Transactions Online”](#), the

online procedure to disable GTIDs. This makes the procedure fault-tolerant because any unrelated issues that may appear in the middle of the procedure can be handled as usual, and then the procedure continued where it was left off.

**Note**

It is crucial that you complete every step before continuing to the next step.

To enable GTID transactions:

1. On each server, execute:

```
SET @@GLOBAL.ENFORCE_GTID_CONSISTENCY = WARN;
```

Let the server run for a while with your normal workload and monitor the logs. If this step causes any warnings in the log, adjust your application so that it only uses GTID-compatible features and does not generate any warnings.

**Important**

This is the first important step. You must ensure that no warnings are being generated in the error logs before going to the next step.

2. On each server, execute:

```
SET @@GLOBAL.ENFORCE_GTID_CONSISTENCY = ON;
```

3. On each server, execute:

```
SET @@GLOBAL.GTID_MODE = OFF_PERMISSIVE;
```

It does not matter which server executes this statement first, but it is important that all servers complete this step before any server begins the next step.

4. On each server, execute:

```
SET @@GLOBAL.GTID_MODE = ON_PERMISSIVE;
```

It does not matter which server executes this statement first.

5. On each server, wait until the status variable `ONGOING_ANONYMOUS_TRANSACTION_COUNT` is zero. This can be checked using:

```
SHOW STATUS LIKE 'ONGOING_ANONYMOUS_TRANSACTION_COUNT';
```

**Note**

On a replication slave, it is theoretically possible that this shows zero and then non-zero again. This is not a problem, it suffices that it shows zero once.

6. Wait for all transactions generated up to step 5 to replicate to all servers. You can do this without stopping updates: the only important thing is that all anonymous transactions get replicated.

See [Section 18.1.5.4, “Verifying Replication of Anonymous Transactions”](#) for one method of checking that all anonymous transactions have replicated to all servers.

7. If you use binary logs for anything other than replication, for example point in time backup and restore, wait until you do not need the old binary logs having transactions without GTIDs.

For instance, after step 6 has completed, you can execute `FLUSH LOGS` on the server where you are taking backups. Then either explicitly take a backup or wait for the next iteration of any periodic backup routine you may have set up.

Ideally, wait for the server to purge all binary logs that existed when step 6 was completed. Also wait for any backup taken before step 6 to expire.

### Important

This is the second important point. It is vital to understand that binary logs containing anonymous transactions, without GTIDs cannot be used after the next step. After this step, you must be sure that transactions without GTIDs do not exist anywhere in the topology.

8. On each server, execute:

```
SET @@GLOBAL.GTID_MODE = ON;
```

9. On each server, add `gtid-mode=ON` to `my.cnf`.

You are now guaranteed that all transactions have a GTID (except transactions generated in step 5 or earlier, which have already been processed). To start using the GTID protocol so that you can later perform automatic fail-over, execute the following on each slave. Optionally, if you use multi-source replication, do this for each channel and include the `FOR CHANNEL channel` clause:

```
STOP SLAVE [FOR CHANNEL 'channel'];
CHANGE MASTER TO MASTER_AUTO_POSITION = 1 [FOR CHANNEL 'channel'];
START SLAVE [FOR CHANNEL 'channel'];
```

### 18.1.5.3 Disabling GTID Transactions Online

This section describes how to disable GTID transactions on servers that are already online. This procedure does not require taking the server offline and is suited to use in production. However, if you have the possibility to take the servers offline when disabling GTIDs mode that process is easier.

The process is similar to enabling GTID transactions while the server is online, but reversing the steps. The only thing that differs is the point at which you wait for logged transactions to replicate.

Before you start, ensure that the servers meet the following pre-conditions:

- All servers in your topology must use MySQL 5.7.6 or later. You cannot disable GTID transactions online on any single server unless *all* servers which are in the topology are using this version.
  - All servers have `gtid_mode` set to `ON`.
1. Execute the following on each slave, and if you using multi-source replication, do it for each channel and include the `FOR CHANNEL channel` clause:

```
STOP SLAVE [FOR CHANNEL 'channel'];
CHANGE MASTER TO MASTER_AUTO_POSITION = 0, MASTER_LOG_FILE = file, \
MASTER_LOG_POS = position [FOR CHANNEL 'channel'];
START SLAVE [FOR CHANNEL 'channel'];
```

2. On each server, execute:

```
SET @@GLOBAL.GTID_MODE = ON_PERMISSIVE;
```

3. On each server, execute:

```
SET @@GLOBAL.GTID_MODE = OFF_PERMISSIVE;
```

4. On each server, wait until the variable `@@GLOBAL.GTID_OWNED` is equal to the empty string. This can be checked using:

```
SELECT @@GLOBAL.GTID_OWNED;
```

On a replication slave, it is theoretically possible that this is empty and then nonempty again. This is not a problem, it suffices that it is empty once.

5. Wait for all transactions that currently exist in any binary log to replicate to all slaves. See [Section 18.1.5.4, “Verifying Replication of Anonymous Transactions”](#) for one method of checking that all anonymous transactions have replicated to all servers.
6. If you use binary logs for anything else than replication, for example to do point in time backup or restore: wait until you do not need the old binary logs having GTID transactions.

For instance, after step 5 has completed, you can execute `FLUSH LOGS` on the server where you are taking the backup. Then either explicitly take a backup or wait for the next iteration of any periodic backup routine you may have set up.

Ideally, wait for the server to purge all binary logs that existed when step 5 was completed. Also wait for any backup taken before step 5 to expire.

#### Important

This is the one important point during this procedure. It is important to understand that logs containing GTID transactions cannot be used after the next step. Before proceeding you must be sure that GTID transactions do not exist anywhere in the topology.

7. On each server, execute:

```
SET @@GLOBAL.GTID_MODE = OFF;
```

8. On each server, set `gtid-mode=OFF` in `my.cnf`.

If you want to set `enforce_gtid_consistency=OFF`, you can do so now. After setting it, you should add `enforce_gtid_consistency=OFF` to your configuration file.

If you want to downgrade to an earlier version of MySQL, you can do so now, using the normal downgrade procedure.

### 18.1.5.4 Verifying Replication of Anonymous Transactions

This section explains how to monitor a replication topology and verify that all anonymous transactions have been replicated. This is helpful when changing the replication mode online as you can verify that it is safe to change to GTID transactions.

There are several possible ways to wait for transactions to replicate:

The simplest method, which works regardless of your topology but relies on timing is as follows: if you are sure that the slave never lags more than N seconds, just wait for a bit more than N seconds. Or wait for a day, or whatever time period you consider safe for your deployment.

A safer method in the sense that it does not depend on timing: if you only have a master with one or more slaves, do the following:

1. On the master, execute:

```
SHOW MASTER STATUS;
```

Note down the values in the `File` and `Position` column.

2. On every slave, use the file and position information from the master to execute:

```
SELECT MASTER_POS_WAIT(file, position);
```

If you have a master and multiple levels of slaves, or in other words you have slaves of slaves, repeat step 2 on each level, starting from the master, then all the direct slaves, then all the slaves of slaves, and so on.

If you use a circular replication topology where multiple servers may have write clients, perform step 2 for each master-slave connection, until you have completed the full circle. Repeat the whole process so that you do the full circle *twice*.

For example, suppose you have three servers A, B, and C, replicating in a circle so that A -> B -> C -> A. The procedure is then:

- Do step 1 on A and step 2 on B.
- Do step 1 on B and step 2 on C.
- Do step 1 on C and step 2 on A.
- Do step 1 on A and step 2 on B.
- Do step 1 on B and step 2 on C.
- Do step 1 on C and step 2 on A.

## 18.1.6 Replication and Binary Logging Options and Variables

The following sections contain information about `mysqld` options and server variables that are used in replication and for controlling the binary log. Options and variables for use on replication masters and replication slaves are covered separately, as are options and variables relating to binary logging and global transaction identifiers (GTIDs). A set of quick-reference tables providing basic information about these options and variables is also included.

Of particular importance is the `--server-id` option.

|                            |                            |                        |
|----------------------------|----------------------------|------------------------|
| <b>Command-Line Format</b> | <code>--server-id=#</code> |                        |
| <b>System Variable</b>     | <b>Name</b>                | <code>server_id</code> |
|                            | <b>Variable Scope</b>      | Global                 |
|                            | <b>Dynamic Variable</b>    | Yes                    |
| <b>Permitted Values</b>    | <b>Type</b>                | integer                |
|                            | <b>Default</b>             | 0                      |
|                            | <b>Min Value</b>           | 0                      |
|                            | <b>Max Value</b>           | 4294967295             |

This option is common to both master and slave replication servers, and is used in replication to enable master and slave servers to identify themselves uniquely. For additional information, see [Section 18.1.6.2, “Replication Master Options and Variables”](#), and [Section 18.1.6.3, “Replication Slave Options and Variables”](#).

On the master and each slave, you *must* use the `--server-id` option to establish a unique replication ID in the range from 1 to  $2^{32} - 1$ . “Unique”, means that each ID must be different from every other ID in use by any other replication master or slave. For example, `server-id=3`.

In MySQL 5.7.2 and earlier, if you start a master server without using `--server-id` to set its ID, the default ID is 0. In this case, the master refuses connections from all slaves, slaves refuse to connect to the master, and the server sets the `server_id` system variable to 1. In MySQL 5.7.3 and later, the `--server-id` must be used if binary logging is enabled, and a value of 0 is not changed by the server.

If you specify `--server-id` without an argument, the effect is the same as using 0. In either case, if the `server_id` is 0, binary logging takes place, but slaves cannot connect to the master, nor can any other servers connect to it as slaves. (Bug #11763963, Bug #56718)

For more information, see [Setting the Replication Slave Configuration](#).

### `server_uuid`

In MySQL 5.7, the server generates a true UUID in addition to the `--server-id` supplied by the user. This is available as the global, read-only variable `server_uuid`.

#### Note

The presence of the `server_uuid` system variable in MySQL 5.7 does not change the requirement for setting a unique `--server-id` for each MySQL server as part of preparing and running MySQL replication, as described earlier in this section.

|                  |                  |                          |
|------------------|------------------|--------------------------|
| System Variable  | Name             | <code>server_uuid</code> |
|                  | Variable Scope   | Global                   |
|                  | Dynamic Variable | No                       |
| Permitted Values | Type             | string                   |

When starting, the MySQL server automatically obtains a UUID as follows:

1. Attempt to read and use the UUID written in the file `data_dir/auto.cnf` (where `data_dir` is the server's data directory).
2. If `data_dir/auto.cnf` is not found, generate a new UUID and save it to this file, creating the file if necessary.

The `auto.cnf` file has a format similar to that used for `my.cnf` or `my.ini` files. In MySQL 5.7, `auto.cnf` has only a single `[auto]` section containing a single `server_uuid` setting and value; the file's contents appear similar to what is shown here:

```
[auto]
server_uuid=8a94f357-aab4-11df-86ab-c80aa9429562
```

#### Important

The `auto.cnf` file is automatically generated; do not attempt to write or modify this file.

When using MySQL replication, masters and slaves know each other's UUIDs. The value of a slave's UUID can be seen in the output of `SHOW SLAVE HOSTS`. Once `START SLAVE` has been executed, the value of the master's UUID is available on the slave in the output of `SHOW SLAVE STATUS`.

#### Note

Issuing a `STOP SLAVE` or `RESET SLAVE` statement does *not* reset the master's UUID as used on the slave.

A server's `server_uuid` is also used in GTIDs for transactions originating on that server. For more information, see [Section 18.1.3, “Replication with Global Transaction Identifiers”](#).

When starting, the slave I/O thread generates an error and aborts if its master's UUID is equal to its own unless the `--replicate-same-server-id` option has been set. In addition, the slave I/O thread generates a warning if either of the following is true:

- No master having the expected `server_uuid` exists.

- The master's `server_uuid` has changed, although no `CHANGE MASTER TO` statement has ever been executed.

### 18.1.6.1 Replication and Binary Logging Option and Variable Reference

The following tables list basic information about the MySQL command-line options and system variables applicable to replication and the binary log.

**Table 18.3 Summary of Replication options and variables in MySQL 5.7**

| Option or Variable Name   |                 |                 |
|---|-----------------|-----------------|
| Command Line  | System Variable | Status Variable |
| Option File   | Scope           | Dynamic         |
| <b>Notes</b>  |                 |                 |
| <code>abort-slave-event-count</code>  |                 |                 |
| Yes   | No              | No              |
| Yes   |                 | No              |
| DESCRIPTION: Option used by mysql-test for debugging and testing of replication |                 |                 |
| <code>binlog_gtid_simple_recovery</code>  |                 |                 |
| Yes   | Yes             | No              |
| Yes   | Global          | No              |

| No   | Yes             | No              |
| No   | Global          | Yes             |
| DESCRIPTION: Controls whether GTID based logging is enabled and what type of transactions the logs can contain   |                 |                 |
| <a href="#">gtid_next</a>  |                 |                 |
| No   | Yes             | No              |
| No   | Session         | Yes             |
| DESCRIPTION: Specifies the GTID for the next statement to execute. See documentation for details.  |                 |                 |
| <a href="#">gtid_owned</a>   |                 |                 |
| No   | Yes             | No              |
| No   | Both            | No              |
| DESCRIPTION: The set of GTIDs owned by this client (session), or by all clients, together with the thread ID of the owner (global). Read-only.                             |                 |                 |
| <a href="#">gtid_purged</a>  |                 |                 |
| No   | Yes             | No              |
| No   | Global          | Yes             |
| DESCRIPTION: The set of all GTIDs that have been purged from the binary log.   |                 |                 |
| <a href="#">init_slave</a>   |                 |                 |
| Yes  | Yes             | No              |
| Yes  | Global          | Yes             |
| DESCRIPTION: Statements that are executed when a slave connects to a master  |                 |                 |
| <a href="#">log-slave-updates</a>  |                 |                 |
| Yes  | Yes             | No              |
| Yes  | Global          | No              |
| DESCRIPTION: Tells the slave to log the updates performed by its SQL thread to its own binary log  |                 |                 |

| Option or Variable Name  |                 |                 |
|--|-----------------|-----------------|
| Command Line   | System Variable | Status Variable |
| Option File  | Scope           | Dynamic         |
| <b>Notes</b>   |                 |                 |
| <a href="#">log_slave_updates</a>  |                 |                 |
| Yes  | Yes             | No              |
| Yes  | Global          | No              |
| DESCRIPTION: Whether the slave should log the updates performed by its SQL thread to its own binary log. Read-only; set using the --log-slave-updates server option. |                 |                 |
| <a href="#">log_statements_unsafe_for_binlog</a>   |                 |                 |
| No   | Yes             | No              |
| No   | Global          | Yes             |
| DESCRIPTION: Disables error 1592 warnings being written to the error log   |                 |                 |
| <a href="#">master-info-file</a>   |                 |                 |
| Yes  | No              | No              |
| Yes  |                 | No              |
| DESCRIPTION: The location and name of the file that remembers the master and where the I/O replication thread is in the master's binary logs                         |                 |                 |
| <a href="#">master-info-repository</a>   |                 |                 |
| Yes  | No              | No              |
| Yes  |                 | No              |
| DESCRIPTION: Whether to write master status information and replication I/O thread location in the master's binary logs to a file or table.                          |                 |                 |
| <a href="#">master-retry-count</a>   |                 |                 |
| Yes  | No              | No              |
| Yes  |                 | No              |
| DESCRIPTION: Number of tries the slave makes to connect to the master before giving up   |                 |                 |
| <a href="#">master_info_repository</a>   |                 |                 |
| Yes  | Yes             | No              |
| Yes  | Global          | Yes             |
| DESCRIPTION: Whether to write master status information and replication I/O thread location in the master's binary logs to a file or table                           |                 |                 |
| <a href="#">relay-log</a>  |                 |                 |
| Yes  | Yes             | No              |
| Yes  | Global          | No              |
| DESCRIPTION: The location and base name to use for relay logs  |                 |                 |
| <a href="#">relay-log-index</a>  |                 |                 |
| Yes  | Yes             | No              |
| Yes  | Global          | No              |
| DESCRIPTION: The location and name to use for the file that keeps a list of the last relay logs  |                 |                 |
| <a href="#">relay-log-info-file</a>  |                 |                 |
| Yes  | No              | No              |
| Yes  |                 | No              |

| Option or Variable Name   |                 |                 |
|---|-----------------|-----------------|
| Command Line  | System Variable | Status Variable |
| Option File   | Scope           | Dynamic         |
| <b>Notes</b>  |                 |                 |
| DESCRIPTION: The location and name of the file that remembers where the SQL replication thread is in the relay logs                   |                 |                 |
| <a href="#">relay-log-info-repository</a>   |                 |                 |
| Yes   | No              | No              |
| Yes   |                 | No              |
| DESCRIPTION: Whether to write the replication SQL thread's location in the relay logs to a file or a table.                           |                 |                 |
| <a href="#">relay-log-recovery</a>  |                 |                 |
| Yes   | No              | No              |
| Yes   |                 | No              |
| DESCRIPTION: Enables automatic recovery of relay log files from master at startup   |                 |                 |
| <a href="#">relay_log_basename</a>  |                 |                 |
| No  | Yes             | No              |
| No  | Global          | No              |
| DESCRIPTION: Complete path to relay log, including filename   |                 |                 |
| <a href="#">relay_log_index</a>   |                 |                 |
| Yes   | Yes             | No              |
| Yes   | Global          | No              |
| DESCRIPTION: The name of the relay log index file   |                 |                 |
| <a href="#">relay_log_info_file</a>   |                 |                 |
| Yes   | Yes             | No              |
| Yes   | Global          | No              |
| DESCRIPTION: The name of the file in which the slave records information about the relay logs   |                 |                 |
| <a href="#">relay_log_info_repository</a>   |                 |                 |
| No  | Yes             | No              |
| No  | Global          | Yes             |
| DESCRIPTION: Whether to write the replication SQL thread's location in the relay logs to a file or a table                            |                 |                 |
| <a href="#">relay_log_purge</a>   |                 |                 |
| Yes   | Yes             | No              |
| Yes   | Global          | Yes             |
| DESCRIPTION: Determines whether relay logs are purged   |                 |                 |
| <a href="#">relay_log_recovery</a>  |                 |                 |
| Yes   | Yes             | No              |
| Yes   | Global          | Yes             |
| DESCRIPTION: Whether automatic recovery of relay log files from master at startup is enabled; must be enabled for a crash-safe slave. |                 |                 |
| <a href="#">relay_log_space_limit</a>   |                 |                 |
| Yes   | Yes             | No              |

| Option or Variable Name   |                 |                 |
|---|-----------------|-----------------|
| Command Line  | System Variable | Status Variable |
| Option File   | Scope           | Dynamic         |
| <b>Notes</b>  |                 |                 |
| Yes   | Global          | No              |
| DESCRIPTION: Maximum space to use for all relay logs<br><code>replicate-do-db</code>  |                 |                 |
| Yes   | No              | No              |
| Yes   |                 | No              |
| DESCRIPTION: Tells the slave SQL thread to restrict replication to the specified database<br><code>replicate-do-table</code>                                    |                 |                 |
| Yes   | No              | No              |
| Yes   |                 | No              |
| DESCRIPTION: Tells the slave SQL thread to restrict replication to the specified table<br><code>replicate-ignore-db</code>                                      |                 |                 |
| Yes   | No              | No              |
| Yes   |                 | No              |
| DESCRIPTION: Tells the slave SQL thread not to replicate to the specified database<br><code>replicate-ignore-table</code>                                       |                 |                 |
| Yes   | No              | No              |
| Yes   |                 | No              |
| DESCRIPTION: Tells the slave SQL thread not to replicate to the specified table<br><code>replicate-rewrite-db</code>  |                 |                 |
| Yes   | No              | No              |
| Yes   |                 | No              |
| DESCRIPTION: Updates to a database with a different name than the original<br><code>replicate-same-server-id</code>   |                 |                 |
| Yes   | No              | No              |
| Yes   |                 | No              |
| DESCRIPTION: In replication, if set to 1, do not skip events having our server id<br><code>replicate-wild-do-table</code>                                       |                 |                 |
| Yes   | No              | No              |
| Yes   |                 | No              |
| DESCRIPTION: Tells the slave thread to restrict replication to the tables that match the specified wildcard pattern<br><code>replicate-wild-ignore-table</code> |                 |                 |
| Yes   | No              | No              |
| Yes   |                 | No              |
| DESCRIPTION: Tells the slave thread not to replicate to the tables that match the given wildcard pattern<br><code>report-host</code>                            |                 |                 |
| Yes   | Yes             | No              |
| Yes   | Global          | No              |

| Option or Variable Name   |                 |                 |
|---|-----------------|-----------------|
| Command Line  | System Variable | Status Variable |
| Option File   | Scope           | Dynamic         |
| <b>Notes</b>  |                 |                 |
| DESCRIPTION: Host name or IP of the slave to be reported to the master during slave registration  |                 |                 |
| <a href="#">report-password</a>   |                 |                 |
| Yes   | Yes             | No              |
| Yes   | Global          | No              |
| DESCRIPTION: An arbitrary password that the slave server should report to the master. Not the same as the password for the MySQL replication user account.  |                 |                 |
| <a href="#">report-port</a>   |                 |                 |
| Yes   | Yes             | No              |
| Yes   | Global          | No              |
| DESCRIPTION: Port for connecting to slave reported to the master during slave registration  |                 |                 |
| <a href="#">report-user</a>   |                 |                 |
| Yes   | Yes             | No              |
| Yes   | Global          | No              |
| DESCRIPTION: An arbitrary user name that a slave server should report to the master. Not the same as the name used with the MySQL replication user account. |                 |                 |
| <a href="#">Rpl_semi_sync_master_clients</a>  |                 |                 |
| No  | No              | Yes             |
| No  | Global          | No              |
| DESCRIPTION: Number of semisynchronous slaves   |                 |                 |
| <a href="#">rpl_semi_sync_master_enabled</a>  |                 |                 |
| No  | Yes             | No              |
| No  | Global          | Yes             |
| DESCRIPTION: Whether semisynchronous replication is enabled on the master   |                 |                 |
| <a href="#">Rpl_semi_sync_master_net_avg_wait_time</a>  |                 |                 |
| No  | No              | Yes             |
| No  | Global          | No              |
| DESCRIPTION: The average time the master waited for a slave reply   |                 |                 |
| <a href="#">Rpl_semi_sync_master_net_wait_time</a>  |                 |                 |
| No  | No              | Yes             |
| No  | Global          | No              |
| DESCRIPTION: The total time the master waited for slave replies   |                 |                 |
| <a href="#">Rpl_semi_sync_master_net_waits</a>  |                 |                 |
| No  | No              | Yes             |
| No  | Global          | No              |
| DESCRIPTION: The total number of times the master waited for slave replies  |                 |                 |
| <a href="#">Rpl_semi_sync_master_no_times</a>   |                 |                 |
| No  | No              | Yes             |
| No  | Global          | No              |
| DESCRIPTION: Number of times the master turned off semisynchronous replication  |                 |                 |

| Option or Variable Name   |                 |                 |
|---|-----------------|-----------------|
| Command Line  | System Variable | Status Variable |
| Option File   | Scope           | Dynamic         |
| <b>Notes</b>  |                 |                 |
| <a href="#">Rpl_semi_sync_master_no_tx</a>  |                 |                 |
| No  | No              | Yes             |
| No  | Global          | No              |
| DESCRIPTION: Number of commits not acknowledged successfully  |                 |                 |
| <a href="#">Rpl_semi_sync_master_status</a>   |                 |                 |
| No  | No              | Yes             |
| No  | Global          | No              |
| DESCRIPTION: Whether semisynchronous replication is operational on the master                         |                 |                 |
| <a href="#">Rpl_semi_sync_master_timefunc_failures</a>  |                 |                 |
| No  | No              | Yes             |
| No  | Global          | No              |
| DESCRIPTION: Number of times the master failed when calling time functions                            |                 |                 |
| <a href="#">rpl_semi_sync_master_timeout</a>  |                 |                 |
| No  | Yes             | No              |
| No  | Global          | Yes             |
| DESCRIPTION: Number of milliseconds to wait for slave acknowledgment                                  |                 |                 |
| <a href="#">rpl_semi_sync_master_trace_level</a>  |                 |                 |
| No  | Yes             | No              |
| No  | Global          | Yes             |
| DESCRIPTION: The semisynchronous replication debug trace level on the master                          |                 |                 |
| <a href="#">Rpl_semi_sync_master_tx_avg_wait_time</a>   |                 |                 |
| No  | No              | Yes             |
| No  | Global          | No              |
| DESCRIPTION: The average time the master waited for each transaction                                  |                 |                 |
| <a href="#">Rpl_semi_sync_master_tx_wait_time</a>   |                 |                 |

| <b>Notes</b>  |                 |                 |
| No  | Global          | No              |
| DESCRIPTION: The server's globally unique ID, automatically (re)generated at server start<br><a href="#">show-slave-auth-info</a>   |                 |                 |
| Yes   | No              | No              |
| Yes   |                 | No              |
| DESCRIPTION: Show user name and password in SHOW SLAVE HOSTS on this master<br><a href="#">simplified_binlog_gtid_recovery</a>  |                 |                 |
| Yes   | Yes             | No              |
| Yes   | Global          | No              |
| DESCRIPTION: Controls how binary logs are iterated during GTID recovery<br><a href="#">skip-slave-start</a>   |                 |                 |
| Yes   | No              | No              |
| Yes   |                 | No              |
| DESCRIPTION: If set, slave is not autostarted<br><a href="#">slave-checkpoint-group</a>   |                 |                 |
| Yes   | No              | No              |
| Yes   |                 | No              |
| DESCRIPTION: Maximum number of transactions processed by a multi-threaded slave before a checkpoint operation is called to update progress status. Not supported by MySQL Cluster.<br><a href="#">slave-checkpoint-period</a> |                 |                 |
| Yes   | No              | No              |
| Yes   |                 | No              |
| DESCRIPTION: Update progress status of multi-threaded slave and flush relay log info to disk after this number of milliseconds. Not supported by MySQL Cluster.<br><a href="#">slave-load-tmpdir</a>                          |                 |                 |
| Yes   | Yes             | No              |
| Yes   | Global          | No              |
| DESCRIPTION: The location where the slave should put its temporary files when replicating a LOAD DATA INFILE statement<br><a href="#">slave-max-allowed-packet</a>  |                 |                 |
| Yes   | No              | No              |
| Yes   |                 | No              |
| DESCRIPTION: Maximum size, in bytes, of a packet that can be sent from a replication master to a slave; overrides max_allowed_packet.<br><a href="#">slave_net_timeout</a>  |                 |                 |
| Yes   | Yes             | No              |
| Yes   | Global          | Yes             |
| DESCRIPTION: Number of seconds to wait for more data from a master/slave connection before aborting the read  |                 |                 |

| Option or Variable Name   |                 |                 |
|---|-----------------|-----------------|
| Command Line  | System Variable | Status Variable |
| Option File   | Scope           | Dynamic         |
| <b>Notes</b>  |                 |                 |
| <a href="#">slave-parallel-type</a>   |                 |                 |
| Yes   | No              | No              |
| Yes   |                 | No              |
| DESCRIPTION: Tells the slave to use database partitioning (DATABASE) or timestamp information (LOGICAL_CLOCK) from the master to parallelize transactions. The default is DATABASE. |                 |                 |
| <a href="#">slave-parallel-workers</a>  |                 |                 |
| Yes   | No              | No              |
| Yes   |                 | No              |
| DESCRIPTION: Number of worker threads for executing events in parallel. Set to 0 (the default) to disable slave multi-threading. Not supported by MySQL Cluster.                    |                 |                 |
| <a href="#">slave-pending-jobs-size-max</a>   |                 |                 |
| Yes   | No              | No              |
| No  |                 | No              |
| DESCRIPTION: Maximum size of slave worker queues holding events not yet applied.  |                 |                 |
| <a href="#">slave-rows-search-algorithms</a>  |                 |                 |
| Yes   | No              | No              |
| Yes   |                 | No              |
| DESCRIPTION: Determines search algorithms used for slave update batching. Any 2 or 3 from the list INDEX_SEARCH, TABLE_SCAN, HASH_SCAN; the default is TABLE_SCAN,INDEX_SCAN.       |                 |                 |
| <a href="#">slave-skip-errors</a>   |                 |                 |
| Yes   | Yes             | No              |
| Yes   | Global          | No              |
| DESCRIPTION: Tells the slave thread to continue replication when a query returns an error from the provided list  |                 |                 |
| <a href="#">slave_checkpoint_group</a>  |                 |                 |
| Yes   | Yes             | No              |
| Yes   | Global          | Yes             |
| DESCRIPTION: Maximum number of transactions processed by a multi-threaded slave before a checkpoint operation is called to update progress status. Not supported by MySQL Cluster.  |                 |                 |
| <a href="#">slave_checkpoint_period</a>   |                 |                 |
| Yes   | Yes             | No              |
| Yes   | Global          | Yes             |
| DESCRIPTION: Update progress status of multi-threaded slave and flush relay log info to disk after this number of milliseconds. Not supported by MySQL Cluster.                     |                 |                 |
| <a href="#">slave_compressed_protocol</a>   |                 |                 |
| Yes   | Yes             | No              |
| Yes   | Global          | Yes             |
| DESCRIPTION: Use compression on master/slave protocol   |                 |                 |
| <a href="#">slave_exec_mode</a>   |                 |                 |
| Yes   | Yes             | No              |

| Option or Variable Name  |                 |                 |
|--|-----------------|-----------------|
| Command Line   | System Variable | Status Variable |
| Option File  | Scope           | Dynamic         |
| <b>Notes</b>   |                 |                 |
| Yes  | Global          | Yes             |
| DESCRIPTION: Allows for switching the slave thread between IDEMPOTENT mode (key and some other errors suppressed) and STRICT mode; STRICT mode is the default, except for MySQL Cluster, where IDEMPOTENT is always used |                 |                 |
| <a href="#">Slave_heartbeat_period</a>   |                 |                 |
| No   | No              | Yes             |
| No   | Global          | No              |
| DESCRIPTION: The slave's replication heartbeat interval, in seconds  |                 |                 |
| <a href="#">slave_max_allowed_packet</a>   |                 |                 |
| No   | Yes             | No              |
| No   | Global          | Yes             |
| DESCRIPTION: Maximum size, in bytes, of a packet that can be sent from a replication master to a slave; overrides max_allowed_packet.  |                 |                 |
| <a href="#">Slave_open_temp_tables</a>   |                 |                 |
| No   | No              | Yes             |
| No   | Global          | No              |
| DESCRIPTION: Number of temporary tables that the slave SQL thread currently has open   |                 |                 |
| <a href="#">slave_parallel_type</a>  |                 |                 |
| No   | Yes             | No              |
| No   | Global          | Yes             |
| DESCRIPTION: Tells the slave to use database partitioning (DATABASE) or information (LOGICAL_CLOCK) from master to parallelize transactions. The default is DATABASE.  |                 |                 |
| <a href="#">slave_parallel_workers</a>   |                 |                 |
| Yes  | Yes             | No              |
| No   | Global          | Yes             |
| DESCRIPTION: Number of worker threads for executing events in parallel. Set to 0 (the default) to disable slave multi-threading. Not supported by MySQL Cluster.   |                 |                 |
| <a href="#">slave_pending_jobs_size_max</a>  |                 |                 |
| No   | Yes             | No              |
| No   | Global          | Yes             |
| DESCRIPTION: Maximum size of slave worker queues holding events not yet applied.   |                 |                 |
| <a href="#">slave_preserve_commit_order</a>  |                 |                 |
| Yes  | Yes             | No              |
| No   | Global          | Yes             |
| DESCRIPTION: Ensures that all commits by slave workers happen in the same order as on the master to maintain consistency when using parallel worker threads.   |                 |                 |
| <a href="#">Slave_retried_transactions</a>   |                 |                 |
| No   | No              | Yes             |
| No   | Global          | No              |

| Option or Variable Name  |                 |                 |
|--|-----------------|-----------------|
| Command Line   | System Variable | Status Variable |
| Option File  | Scope           | Dynamic         |
| <b>Notes</b>   |                 |                 |
| DESCRIPTION: The total number of times since startup that the replication slave SQL thread has retried transactions  |                 |                 |
| <a href="#">slave_rows_search_algorithms</a>   |                 |                 |
| No   | Yes             | No              |
| No   | Global          | Yes             |
| DESCRIPTION: Determines search algorithms used for slave update batching. Any 2 or 3 from the list INDEX_SEARCH, TABLE_SCAN, HASH_SCAN; the default is TABLE_SCAN, INDEX_SCAN.   |                 |                 |
| <a href="#">Slave_running</a>  |                 |                 |
| No   | No              | Yes             |
| No   | Global          | No              |
| DESCRIPTION: The state of this server as a replication slave (slave I/O thread status)   |                 |                 |
| <a href="#">slave_transaction_retries</a>  |                 |                 |
| Yes  | Yes             | No              |
| Yes  | Global          | Yes             |
| DESCRIPTION: Number of times the slave SQL thread will retry a transaction in case it failed with a deadlock or elapsed lock wait timeout, before giving up and stopping   |                 |                 |
| <a href="#">slave_type_conversions</a>   |                 |                 |
| Yes  | Yes             | No              |
| Yes  | Global          | No              |
| DESCRIPTION: Controls type conversion mode on replication slave. Value is a list of zero or more elements from the list: ALL_LOSSY, ALL_NON_LOSSY. Set to an empty string to disallow type conversions between master and slave. |                 |                 |
| <a href="#">sql_slave_skip_counter</a>   |                 |                 |
| No   | Yes             | No              |
| No   | Global          | Yes             |
| DESCRIPTION: Number of events from the master that a slave server should skip. Not compatible with GTID replication.   |                 |                 |
| <a href="#">sync_binlog</a>  |                 |                 |
| Yes  | Yes             | No              |
| Yes  | Global          | Yes             |
| DESCRIPTION: Synchronously flush binary log to disk after every #th event  |                 |                 |
| <a href="#">sync_master_info</a>   |                 |                 |
| Yes  | Yes             | No              |
| Yes  | Global          | Yes             |
| DESCRIPTION: Synchronize master.info to disk after every #th event.  |                 |                 |
| <a href="#">sync_relay_log</a>   |                 |                 |
| Yes  | Yes             | No              |
| Yes  | Global          | Yes             |
| DESCRIPTION: Synchronize relay log to disk after every #th event.  |                 |                 |
| <a href="#">sync_relay_log_info</a>  |                 |                 |

| Option or Variable Name   |                 |                 |
|---|-----------------|-----------------|
| Command Line  | System Variable | Status Variable |
| Option File   | Scope           | Dynamic         |
| <b>Notes</b>  |                 |                 |
| Yes   | Yes             | No              |
| Yes   | Global          | Yes             |
| DESCRIPTION: Synchronize relay.info file to disk after every #th event. |                 |                 |

Section 18.1.6.2, “Replication Master Options and Variables”, provides more detailed information about options and variables relating to replication master servers. For more information about options and variables relating to replication slaves, see Section 18.1.6.3, “Replication Slave Options and Variables”.

**Table 18.4 Summary of Binary Logging options and variables in MySQL 5.7**

| Option or Variable Name  |                 |                 |
|--|-----------------|-----------------|
| Command Line   | System Variable | Status Variable |
| Option File  | Scope           | Dynamic         |
| <b>Notes</b>   |                 |                 |
| <a href="#">binlog-checksum</a>  |                 |                 |
| Yes  | No              | No              |
| Yes  |                 | No              |
| DESCRIPTION: Enable/disable binary log checksums   |                 |                 |
| <a href="#">binlog-do-db</a>   |                 |                 |
| Yes  | No              | No              |
| Yes  |                 | No              |
| DESCRIPTION: Limits binary logging to specific databases   |                 |                 |
| <a href="#">binlog_format</a>  |                 |                 |
| Yes  | Yes             | No              |
| Yes  | Both            | Yes             |
| DESCRIPTION: Specifies the format of the binary log  |                 |                 |
| <a href="#">binlog-ignore-db</a>   |                 |                 |
| Yes  | No              | No              |
| Yes  |                 | No              |
| DESCRIPTION: Tells the master that updates to the given database should not be logged to the binary log  |                 |                 |
| <a href="#">binlog-row-event-max-size</a>  |                 |                 |
| Yes  | No              | No              |
| Yes  |                 | No              |
| DESCRIPTION: Binary log max event size   |                 |                 |
| <a href="#">binlog-rows-query-log-events</a>   |                 |                 |
| Yes  | No              | No              |
| Yes  |                 | No              |
| DESCRIPTION: Enables logging of rows query log events when using row-based logging. Disabled by default. Do not enable when producing logs for pre-5.6.2 slaves/readers. |                 |                 |
| <a href="#">Binlog_cache_disk_use</a>  |                 |                 |
| No   | No              | Yes             |

| Option or Variable Name  |                 |                 |
|--|-----------------|-----------------|
| Command Line   | System Variable | Status Variable |
| Option File  | Scope           | Dynamic         |
| <b>Notes</b>   |                 |                 |
| No   | Global          | No              |
| DESCRIPTION: Number of transactions that used a temporary file instead of the binary log cache<br><a href="#">binlog_cache_size</a>  |                 |                 |
| Yes  | Yes             | No              |
| Yes  | Global          | Yes             |
| DESCRIPTION: Size of the cache to hold the SQL statements for the binary log during a transaction<br><a href="#">Binlog_cache_use</a>  |                 |                 |
| No   | No              | Yes             |
| No   | Global          | No              |
| DESCRIPTION: Number of transactions that used the temporary binary log cache<br><a href="#">binlog_checksum</a>  |                 |                 |
| No   | Yes             | No              |
| No   | Global          | Yes             |
| DESCRIPTION: Enable/disable binary log checksums<br><a href="#">binlog_direct_non_transactional_updates</a>  |                 |                 |
| Yes  | Yes             | No              |
| Yes  | Both            | Yes             |
| DESCRIPTION: Causes updates using statement format to nontransactional engines to be written directly to binary log. See documentation before using.<br><a href="#">binlog_error_action</a>                  |                 |                 |
| Yes  | Yes             | No              |
| Yes  | Both            | Yes             |
| DESCRIPTION: Controls what happens when the server cannot write to the binary log.<br><a href="#">binlog_group_commit_sync_delay</a>   |                 |                 |
| Yes  | Yes             | No              |
| Yes  | Global          | Yes             |
| DESCRIPTION: Sets the number of microseconds to wait before synchronizing transactions to disk.<br><a href="#">binlog_group_commit_sync_no_delay_count</a>   |                 |                 |
| Yes  | Yes             | No              |
| Yes  | Global          | Yes             |
| DESCRIPTION: Sets the maximum number of transactions to wait for before aborting the current delay specified by <code>binlog_group_commit_sync_delay</code> .<br><a href="#">binlog_max_flush_queue_time</a> |                 |                 |
| No   | Yes             | No              |
| No   | Global          | Yes             |
| DESCRIPTION: How long to read transactions before flushing to binary log<br><a href="#">binlog_order_commits</a>   |                 |                 |
| No   | Yes             | No              |
| No   | Global          | Yes             |

| Option or Variable Name  |                 |                 |
|--|-----------------|-----------------|
| Command Line   | System Variable | Status Variable |
| Option File  | Scope           | Dynamic         |
| <b>Notes</b>   |                 |                 |
| DESCRIPTION: Whether to commit in same order as writes to binary log   |                 |                 |
| <a href="#">binlog_row_image</a>   |                 |                 |
| Yes  | Yes             | No              |
| Yes  | Both            | Yes             |
| DESCRIPTION: Use full or minimal images when logging row changes. Allowed values are full, minimal, and noblob.  |                 |                 |
| <a href="#">binlog_rows_query_log_events</a>   |                 |                 |
| No   | Yes             | No              |
| No   | Both            | Yes             |
| DESCRIPTION: When TRUE, enables logging of rows query log events in row-based logging mode. FALSE by default. Do not enable when producing logs for pre-5.6.2 replication slaves or other readers. |                 |                 |
| <a href="#">Binlog_stmt_cache_disk_use</a>   |                 |                 |
| No   | No              | Yes             |
| No   | Global          | No              |
| DESCRIPTION: Number of nontransactional statements that used a temporary file instead of the binary log statement cache  |                 |                 |
| <a href="#">binlog_stmt_cache_size</a>   |                 |                 |
| Yes  | Yes             | No              |
| Yes  | Global          | Yes             |
| DESCRIPTION: Size of the cache to hold nontransactional statements for the binary log during a transaction   |                 |                 |
| <a href="#">Binlog_stmt_cache_use</a>  |                 |                 |
| No   | No              | Yes             |
| No   | Global          | No              |
| DESCRIPTION: Number of statements that used the temporary binary log statement cache   |                 |                 |
| <a href="#">binlogging_impossible_mode</a>   |                 |                 |
| Yes  | Yes             | No              |
| Yes  | Both            | Yes             |
| DESCRIPTION: Deprecated and will be removed in a future version. Use the renamed binlog_error_action instead.  |                 |                 |
| <a href="#">Com_show_binlog_events</a>   |                 |                 |
| No   | No              | Yes             |
| No   | Both            | No              |
| DESCRIPTION: Count of SHOW BINLOG EVENTS statements  |                 |                 |
| <a href="#">Com_show_binlogs</a>   |                 |                 |
| No   | No              | Yes             |
| No   | Both            | No              |
| DESCRIPTION: Count of SHOW BINLOGS statements  |                 |                 |

| DESCRIPTION: Option used by mysql-test for debugging and testing of replication  |                 |                 |

Section 18.1.6.4, “Binary Logging Options and Variables”, provides more detailed information about options and variables relating to binary logging. For additional general information about the binary log, see Section 6.4.4, “The Binary Log”.

For information about the [sql\\_log\\_bin](#) and [sql\\_log\\_off](#) variables, see Section 6.1.5, “Server System Variables”.

For a table showing *all* command-line options, system and status variables used with [mysqld](#), see Section 6.1.3, “Server Option and Variable Reference”.

### 18.1.6.2 Replication Master Options and Variables

This section describes the server options and system variables that you can use on replication master servers. You can specify the options either on the [command line](#) or in an [option file](#). You can specify system variable values using [SET](#).

On the master and each slave, you must use the [server-id](#) option to establish a unique replication ID. For each server, you should pick a unique positive integer in the range from 1 to  $2^{32} - 1$ , and each ID must be different from every other ID in use by any other replication master or slave. Example:  
[server-id=3](#).

For options used on the master for controlling binary logging, see Section 18.1.6.4, “Binary Logging Options and Variables”.

### System Variables Used on Replication Masters

The following system variables are used to control replication masters:

- [auto\\_increment\\_increment](#)

|                         |                         |  |
|-------------------------|-------------------------|--|
| <b>System Variable</b>  | <b>Name</b>             | <a href="#">auto_increment_increment</a> |
|                         | <b>Variable Scope</b>   | Global, Session                          |
|                         | <b>Dynamic Variable</b> | Yes                                      |
| <b>Permitted Values</b> | <b>Type</b>             | integer                                  |
|                         | <b>Default</b>          | <a href="#">1</a>                        |

|  |                  |       |
|--|------------------|-------|
|  | <b>Min Value</b> | 1     |
|  | <b>Max Value</b> | 65535 |

`auto_increment_increment` and `auto_increment_offset` are intended for use with master-to-master replication, and can be used to control the operation of `AUTO_INCREMENT` columns. Both variables have global and session values, and each can assume an integer value between 1 and 65,535 inclusive. Setting the value of either of these two variables to 0 causes its value to be set to 1 instead. Attempting to set the value of either of these two variables to an integer greater than 65,535 or less than 0 causes its value to be set to 65,535 instead. Attempting to set the value of `auto_increment_increment` or `auto_increment_offset` to a noninteger value produces an error, and the actual value of the variable remains unchanged.

#### Note

`auto_increment_increment` is also supported for use with `NDB` tables.

These two variables affect `AUTO_INCREMENT` column behavior as follows:

- `auto_increment_increment` controls the interval between successive column values. For example:

```
mysql> SHOW VARIABLES LIKE 'auto_inc%';
+-----+-----+
| Variable_name | Value |
+-----+-----+
| auto_increment_increment | 1 |
| auto_increment_offset | 1 |
+-----+-----+
2 rows in set (0.00 sec)

mysql> CREATE TABLE autoinc1
-> (col INT NOT NULL AUTO_INCREMENT PRIMARY KEY);
Query OK, 0 rows affected (0.04 sec)

mysql> SET @@auto_increment_increment=10;
Query OK, 0 rows affected (0.00 sec)

mysql> SHOW VARIABLES LIKE 'auto_inc%';
+-----+-----+
| Variable_name | Value |
+-----+-----+
| auto_increment_increment | 10 |
| auto_increment_offset | 1 |
+-----+-----+
2 rows in set (0.01 sec)

mysql> INSERT INTO autoinc1 VALUES (NULL), (NULL), (NULL), (NULL);
Query OK, 4 rows affected (0.00 sec)
Records: 4 Duplicates: 0 Warnings: 0

mysql> SELECT col FROM autoinc1;
+-----+
| col |
+-----+
| 1 |
| 11 |
| 21 |
| 31 |
+-----+
4 rows in set (0.00 sec)
```

- `auto_increment_offset` determines the starting point for the `AUTO_INCREMENT` column value. Consider the following, assuming that these statements are executed during the same session as the example given in the description for `auto_increment_increment`:

```
mysql> SET @@auto_increment_offset=5;
Query OK, 0 rows affected (0.00 sec)

mysql> SHOW VARIABLES LIKE 'auto_inc%';
+-----+-----+
| Variable_name | Value |
+-----+-----+
| auto_increment_increment | 10 |
| auto_increment_offset   | 5   |
+-----+-----+
2 rows in set (0.00 sec)

mysql> CREATE TABLE autoinc2
  -> (col INT NOT NULL AUTO_INCREMENT PRIMARY KEY);
Query OK, 0 rows affected (0.06 sec)

mysql> INSERT INTO autoinc2 VALUES (NULL), (NULL), (NULL), (NULL);
Query OK, 4 rows affected (0.00 sec)
Records: 4  Duplicates: 0  Warnings: 0

mysql> SELECT col FROM autoinc2;
+-----+
| col |
+-----+
| 5 |
| 15 |
| 25 |
| 35 |
+-----+
4 rows in set (0.02 sec)
```

When the value of `auto_increment_offset` is greater than that of `auto_increment_increment`, the value of `auto_increment_offset` is ignored.

If either of these variables is changed, and then new rows inserted into a table containing an `AUTO_INCREMENT` column, the results may seem counterintuitive because the series of `AUTO_INCREMENT` values is calculated without regard to any values already present in the column, and the next value inserted is the least value in the series that is greater than the maximum existing value in the `AUTO_INCREMENT` column. The series is calculated like this:

$$\text{auto\_increment\_offset} + N \times \text{auto\_increment\_increment}$$

where  $N$  is a positive integer value in the series [1, 2, 3, ...]. For example:

```
mysql> SHOW VARIABLES LIKE 'auto_inc%';
+-----+-----+
| Variable_name | Value |
+-----+-----+
| auto_increment_increment | 10 |
| auto_increment_offset   | 5   |
+-----+-----+
2 rows in set (0.00 sec)

mysql> SELECT col FROM autoinc1;
+-----+
| col |
+-----+
| 1 |
| 11 |
| 21 |
| 31 |
+-----+
```

```
4 rows in set (0.00 sec)

mysql> INSERT INTO autoinc1 VALUES (NULL), (NULL), (NULL), (NULL);
Query OK, 4 rows affected (0.00 sec)
Records: 4  Duplicates: 0  Warnings: 0

mysql> SELECT col FROM autoinc1;
+-----+
| col |
+-----+
| 1 |
| 11 |
| 21 |
| 31 |
| 35 |
| 45 |
| 55 |
| 65 |
+-----+
8 rows in set (0.00 sec)
```

The values shown for `auto_increment_increment` and `auto_increment_offset` generate the series  $5 + N \times 10$ , that is, [5, 15, 25, 35, 45, ...]. The highest value present in the `col` column prior to the `INSERT` is 31, and the next available value in the `AUTO_INCREMENT` series is 35, so the inserted values for `col` begin at that point and the results are as shown for the `SELECT` query.

It is not possible to restrict the effects of these two variables to a single table; these variables control the behavior of all `AUTO_INCREMENT` columns in *all* tables on the MySQL server. If the global value of either variable is set, its effects persist until the global value is changed or overridden by setting the session value, or until `mysqld` is restarted. If the local value is set, the new value affects `AUTO_INCREMENT` columns for all tables into which new rows are inserted by the current user for the duration of the session, unless the values are changed during that session.

The default value of `auto_increment_increment` is 1. See [Section 18.4.1.1, “Replication and AUTO\\_INCREMENT”](#).

- `auto_increment_offset`

|                  |                  |                                    |
|------------------|------------------|------------------------------------|
| System Variable  | Name             | <code>auto_increment_offset</code> |
|                  | Variable Scope   | Global, Session                    |
|                  | Dynamic Variable | Yes                                |
| Permitted Values | Type             | integer                            |
|                  | Default          | 1                                  |
|                  | Min Value        | 1                                  |
|                  | Max Value        | 65535                              |

This variable has a default value of 1. For more information, see the description for `auto_increment_increment`.

**Note**

`auto_increment_offset` is also supported for use with `NDB` tables.

### 18.1.6.3 Replication Slave Options and Variables

This section explains the server options and system variables that apply to slave replication servers and contains the following:

[Startup Options for Replication Slaves](#)

[Options for Logging Slave Status to Tables](#)

[System Variables Used on Replication Slaves](#)

Specify the options either on the [command line](#) or in an [option file](#). Many of the options can be set while the server is running by using the [CHANGE MASTER TO](#) statement. Specify system variable values using [SET](#).

**Server ID.** On the master and each slave, you must use the [server-id](#) option to establish a unique replication ID in the range from 1 to  $2^{32} - 1$ . “Unique” means that each ID must be different from every other ID in use by any other replication master or slave. Example [my.cnf](#) file:

```
[mysqld]
server-id=3
```

#### Startup Options for Replication Slaves

This section explains startup options for controlling replication slave servers. Many of these options can be set while the server is running by using the [CHANGE MASTER TO](#) statement. Others, such as the [--replicate-\\*](#) options, can be set only when the slave server starts. Replication-related system variables are discussed later in this section.

- [--log-slave-updates](#)

|                            |                                     |                                   |
|----------------------------|-------------------------------------|-----------------------------------|
| <b>Command-Line Format</b> | <a href="#">--log-slave-updates</a> |                                   |
| <b>System Variable</b>     | <b>Name</b>                         | <a href="#">log_slave_updates</a> |
|                            | <b>Variable Scope</b>               | Global                            |
|                            | <b>Dynamic Variable</b>             | No                                |
| <b>Permitted Values</b>    | <b>Type</b>                         | boolean                           |
|                            | <b>Default</b>                      | <a href="#">OFF</a>               |

Normally, a slave does not write any updates that are received from a master server to its own binary log. This option causes the slave to write the updates performed by its SQL thread to its own binary log. For this option to have any effect, the slave must also be started with the [--log-bin](#) option to enable binary logging. [--log-slave-updates](#) is used when you want to chain replication servers. For example, you might want to set up replication servers using this arrangement:

```
A -> B -> C
```

Here, [A](#) serves as the master for the slave [B](#), and [B](#) serves as the master for the slave [C](#). For this to work, [B](#) must be both a master *and* a slave. You must start both [A](#) and [B](#) with [--log-bin](#) to enable binary logging, and [B](#) with the [--log-slave-updates](#) option so that updates received from [A](#) are logged by [B](#) to its binary log.

- [--log-slow-slave-statements](#)

|                            |   |
|----------------------------|---|
| <b>Removed</b>             | 5.7.1   |
| <b>Command-Line Format</b> | <a href="#">--log-slow-slave-statements</a> (5.7.0) |

|                         |                |         |
|-------------------------|----------------|---------|
| <b>Permitted Values</b> | <b>Type</b>    | boolean |
|                         | <b>Default</b> | OFF     |

When the slow query log is enabled, this option enables logging for queries that have taken more than `long_query_time` seconds to execute on the slave.

This command-line option was removed in MySQL 5.7.1 and replaced by the `log_slow_slave_statements` system variable. The system variable can be set on the command line or in option files the same way as the option, so there is no need for any changes at server startup, but the system variable also makes it possible to examine or set the value at runtime.

- `--log-warnings[=level]`

|  |                                 |                           |
|--|---------------------------------|---------------------------|
| <b>Deprecated</b>                                    | 5.7.2                           |                           |
| <b>Command-Line Format</b>                           | <code>--log-warnings[=#]</code> |                           |
| <b>System Variable</b>                               | <b>Name</b>                     | <code>log_warnings</code> |
|  | <b>Variable Scope</b>           | Global                    |
|  | <b>Dynamic Variable</b>         | Yes                       |
| <b>Permitted Values</b> (32-bit platforms, <= 5.7.1) | <b>Type</b>                     | integer                   |
|  | <b>Default</b>                  | 1                         |
|  | <b>Min Value</b>                | 0                         |
|  | <b>Max Value</b>                | 4294967295                |
| <b>Permitted Values</b> (32-bit platforms, >= 5.7.2) | <b>Type</b>                     | integer                   |
|  | <b>Default</b>                  | 2                         |
|  | <b>Min Value</b>                | 0                         |
|  | <b>Max Value</b>                | 4294967295                |
| <b>Permitted Values</b> (64-bit platforms, <= 5.7.1) | <b>Type</b>                     | integer                   |
|  | <b>Default</b>                  | 1                         |
|  | <b>Min Value</b>                | 0                         |
|  | <b>Max Value</b>                | 18446744073709551615      |
| <b>Permitted Values</b> (64-bit platforms, >= 5.7.2) | <b>Type</b>                     | integer                   |
|  | <b>Default</b>                  | 2                         |
|  | <b>Min Value</b>                | 0                         |
|  | <b>Max Value</b>                | 18446744073709551615      |

#### Note

As of MySQL 5.7.2, the `log_error_verbosity` system variable is preferred over, and should be used instead of, the `--log-warnings` option or `log_warnings` system variable. For more information, see the

descriptions of `log_error_verbosity` and `log_warnings`. The `--log-warnings` command-line option and `log_warnings` system variable are deprecated and will be removed in a future MySQL release.

Causes the server to record more messages to the error log about what it is doing. With respect to replication, the server generates warnings that it succeeded in reconnecting after a network or connection failure, and provides information about how each slave thread started. This variable is enabled by default (the default is 1 before MySQL 5.7.2, 2 as of 5.7.2). To disable it, set it to 0. The server logs messages about statements that are unsafe for statement-based logging if the value is greater than 0. Aborted connections and access-denied errors for new connection attempts are logged if the value is greater than 1. See [Section B.5.2.11, “Communication Errors and Aborted Connections”](#).

#### Note

The effects of this option are not limited to replication. It produces warnings across a spectrum of server activities.

- `--master-info-file=file_name`

|                            |   |                          |
|----------------------------|---|--------------------------|
| <b>Command-Line Format</b> | <code>--master-info-file=file_name</code> |                          |
| <b>Permitted Values</b>    | <b>Type</b>                               | file name                |
|                            | <b>Default</b>                            | <code>master.info</code> |

The name to use for the file in which the slave records information about the master. The default name is `master.info` in the data directory. For information about the format of this file, see [Section 18.2.4.2, “Slave Status Logs”](#).

- `--master-retry-count=count`

|  |                                     |                                   |
|--|-------------------------------------|-----------------------------------|
| <b>Deprecated</b>                          | 5.6.1                               |                                   |
| <b>Command-Line Format</b>                 | <code>--master-retry-count=#</code> |                                   |
| <b>Permitted Values</b> (32-bit platforms) | <b>Type</b>                         | integer                           |
|  | <b>Default</b>                      | <code>86400</code>                |
|  | <b>Min Value</b>                    | <code>0</code>                    |
|  | <b>Max Value</b>                    | <code>4294967295</code>           |
| <b>Permitted Values</b> (64-bit platforms) | <b>Type</b>                         | integer                           |
|  | <b>Default</b>                      | <code>86400</code>                |
|  | <b>Min Value</b>                    | <code>0</code>                    |
|  | <b>Max Value</b>                    | <code>18446744073709551615</code> |

The number of times that the slave tries to connect to the master before giving up. Reconnects are attempted at intervals set by the `MASTER_CONNECT_RETRY` option of the `CHANGE MASTER TO` statement (default 60). Reconnects are triggered when data reads by the slave time out according to the `--slave-net-timeout` option. The default value is 86400. A value of 0 means “infinite”; the slave attempts to connect forever.

This option is deprecated and will be removed in a future MySQL release. Applications should be updated to use the `MASTER_RETRY_COUNT` option of the `CHANGE MASTER TO` statement instead.

- `--max-relay-log-size=size`

|                            |                                     |                                 |
|----------------------------|-------------------------------------|---------------------------------|
| <b>Command-Line Format</b> | <code>--max_relay_log_size=#</code> |                                 |
| <b>System Variable</b>     | <b>Name</b>                         | <code>max_relay_log_size</code> |
|                            | <b>Variable Scope</b>               | Global                          |
|                            | <b>Dynamic Variable</b>             | Yes                             |
| <b>Permitted Values</b>    | <b>Type</b>                         | integer                         |
|                            | <b>Default</b>                      | 0                               |
|                            | <b>Min Value</b>                    | 0                               |
|                            | <b>Max Value</b>                    | 1073741824                      |

The size at which the server rotates relay log files automatically. If this value is nonzero, the relay log is rotated automatically when its size exceeds this value. If this value is zero (the default), the size at which relay log rotation occurs is determined by the value of `max_binlog_size`. For more information, see [Section 18.2.4.1, “The Slave Relay Log”](#).

- `--relay-log=file_name`

|                            |                                    |                        |
|----------------------------|------------------------------------|------------------------|
| <b>Command-Line Format</b> | <code>--relay-log=file_name</code> |                        |
| <b>System Variable</b>     | <b>Name</b>                        | <code>relay_log</code> |
|                            | <b>Variable Scope</b>              | Global                 |
|                            | <b>Dynamic Variable</b>            | No                     |
| <b>Permitted Values</b>    | <b>Type</b>                        | file name              |

The base name for the relay log. For the default replication channel, the default base name for relay logs is `host_name-relay-bin`. For non-default replication channels, the default base name for relay logs is `host_name-channel-relay-bin`, where `channel` is the name of the replication channel recorded in this relay log. The server writes the file in the data directory unless the base name is given with a leading absolute path name to specify a different directory. The server creates relay log files in sequence by adding a numeric suffix to the base name.

Due to the manner in which MySQL parses server options, if you specify this option, you must supply a value; *the default base name is used only if the option is not actually specified*. If you use the `--relay-log` option without specifying a value, unexpected behavior is likely to result; this behavior depends on the other options used, the order in which they are specified, and whether they are specified on the command line or in an option file. For more information about how MySQL handles server options, see [Section 5.2.3, “Specifying Program Options”](#).

If you specify this option, the value specified is also used as the base name for the relay log index file. You can override this behavior by specifying a different relay log index file base name using the `--relay-log-index` option.

When the server reads an entry from the index file, it checks whether the entry contains a relative path. If it does, the relative part of the path is replaced with the absolute path set using the `--relay-log` option. An absolute path remains unchanged; in such a case, the index must be edited manually to enable the new path or paths to be used. Previously, manual intervention was required whenever relocating the binary log or relay log files. (Bug #11745230, Bug #12133)

You may find the `--relay-log` option useful in performing the following tasks:

- Creating relay logs whose names are independent of host names.
- If you need to put the relay logs in some area other than the data directory because your relay logs tend to be very large and you do not want to decrease `max_relay_log_size`.
- To increase speed by using load-balancing between disks.

You can obtain the relay log file name (and path) from the `relay_log_basename` system variable.

- `--relay-log-index=file_name`

|                            |  |                              |
|----------------------------|--|------------------------------|
| <b>Command-Line Format</b> | <code>--relay-log-index=file_name</code> |                              |
| <b>System Variable</b>     | <b>Name</b>                              | <code>relay_log_index</code> |
|                            | <b>Variable Scope</b>                    | Global                       |
|                            | <b>Dynamic Variable</b>                  | No                           |
| <b>Permitted Values</b>    | <b>Type</b>                              | file name                    |

The name to use for the relay log index file. The default name is `host_name-relay-bin.index` in the data directory, where `host_name` is the name of the server. For the default replication channel, the default name is `host_name-relay-bin.index`. For non-default replication channels, the default name is `host_name-channel-relay-bin.index`, where `channel` is the name of the replication channel recorded in this relay log index.

Due to the manner in which MySQL parses server options, if you specify this option, you must supply a value; *the default base name is used only if the option is not actually specified*. If you use the `--relay-log-index` option without specifying a value, unexpected behavior is likely to result; this behavior depends on the other options used, the order in which they are specified, and whether they are specified on the command line or in an option file. For more information about how MySQL handles server options, see [Section 5.2.3, “Specifying Program Options”](#).

If you specify this option, the value specified is also used as the base name for the relay logs. You can override this behavior by specifying a different relay log file base name using the `--relay-log` option.

- `--relay-log-info-file=file_name`

|                            |  |                             |
|----------------------------|--|-----------------------------|
| <b>Command-Line Format</b> | <code>--relay-log-info-file=file_name</code> |                             |
| <b>Permitted Values</b>    | <b>Type</b>                                  | file name                   |
|                            | <b>Default</b>                               | <code>relay-log.info</code> |

The name to use for the file in which the slave records information about the relay logs. The default name is `relay-log.info` in the data directory. For information about the format of this file, see [Section 18.2.4.2, “Slave Status Logs”](#).

- `--relay-log-purge={0|1}`

|                            |                                |                              |
|----------------------------|--------------------------------|------------------------------|
| <b>Command-Line Format</b> | <code>--relay_log_purge</code> |                              |
| <b>System Variable</b>     | <b>Name</b>                    | <code>relay_log_purge</code> |
|                            | <b>Variable Scope</b>          | Global                       |
|                            | <b>Dynamic Variable</b>        | Yes                          |
| <b>Permitted Values</b>    | <b>Type</b>                    | boolean                      |

|  |                |      |
|--|----------------|------|
|  | <b>Default</b> | TRUE |
|--|----------------|------|

Disable or enable automatic purging of relay logs as soon as they are no longer needed. The default value is 1 (enabled). This is a global variable that can be changed dynamically with `SET GLOBAL relay_log_purge = N`. Disabling purging of relay logs when using the `--relay-log-recovery` option puts data consistency at risk.

- `--relay-log-recovery={0|1}`

|                            |                                   |         |
|----------------------------|-----------------------------------|---------|
| <b>Command-Line Format</b> | <code>--relay-log-recovery</code> |         |
| <b>Permitted Values</b>    | <b>Type</b>                       | boolean |
|                            | <b>Default</b>                    | FALSE   |

Enables automatic relay log recovery immediately following server startup. The recovery process creates a new relay log file, initializes the SQL thread position to this new relay log, and initializes the I/O thread to the SQL thread position. Reading of the relay log from the master then continues. This should be used following an unexpected halt of a replication slave to ensure that no possibly corrupted relay logs are processed. The default value is 0 (disabled).

This variable can be set to 1 to make a slave resilient to unexpected halts, see [Section 18.3.2, “Handling an Unexpected Halt of a Replication Slave”](#) for more information. Enabling the `--relay-log-recovery` option when `relay-log-purge` is disabled risks reading the relay log from files that were not purged, leading to data inconsistency.

When using a multi-threaded slave (in other words `slave_parallel_workers` is greater than 0), inconsistencies such as gaps can occur in the sequence of transactions that have been executed from the relay log. Enabling the `--relay-log-recovery` option when there are inconsistencies causes an error and the option has no effect. The solution in this situation is to issue `START SLAVE UNTIL SQL_AFTER_MTS_GAPS`, which brings the server to a more consistent state, then issue `RESET SLAVE` to remove the relay logs. See [Section 18.4.1.34, “Replication and Transaction Inconsistencies”](#) for more information.

- `--relay-log-space-limit=size`

|  |  |                                    |
|--|--|------------------------------------|
| <b>Command-Line Format</b>                 | <code>--relay_log_space_limit=#</code> |                                    |
| <b>System Variable</b>                     | <b>Name</b>                            | <code>relay_log_space_limit</code> |
|  | <b>Variable Scope</b>                  | Global                             |
|  | <b>Dynamic Variable</b>                | No                                 |
| <b>Permitted Values</b> (32-bit platforms) | <b>Type</b>                            | integer                            |
|  | <b>Default</b>                         | 0                                  |
|  | <b>Min Value</b>                       | 0                                  |
|  | <b>Max Value</b>                       | 4294967295                         |
| <b>Permitted Values</b> (64-bit platforms) | <b>Type</b>                            | integer                            |
|  | <b>Default</b>                         | 0                                  |
|  | <b>Min Value</b>                       | 0                                  |
|  | <b>Max Value</b>                       | 18446744073709551615               |

This option places an upper limit on the total size in bytes of all relay logs on the slave. A value of 0 means “no limit”. This is useful for a slave server host that has limited disk space. When the limit is reached, the I/O thread stops reading binary log events from the master server until the SQL thread has caught up and deleted some unused relay logs. Note that this limit is not absolute: There are cases where the SQL thread needs more events before it can delete relay logs. In that case, the I/O thread exceeds the limit until it becomes possible for the SQL thread to delete some relay logs because not doing so would cause a deadlock. You should not set `--relay-log-space-limit` to less than twice the value of `--max-relay-log-size` (or `--max-binlog-size` if `--max-relay-log-size` is 0). In that case, there is a chance that the I/O thread waits for free space because `--relay-log-space-limit` is exceeded, but the SQL thread has no relay log to purge and is unable to satisfy the I/O thread. This forces the I/O thread to ignore `--relay-log-space-limit` temporarily.

- `--replicate-do-db=db_name`

|                            |                                     |        |
|----------------------------|-------------------------------------|--------|
| <b>Command-Line Format</b> | <code>--replicate-do-db=name</code> |        |
| <b>Permitted Values</b>    | <b>Type</b>                         | string |

Creates a replication filter using the name of a database. In MySQL 5.7.3 and later, such filters can also be created using `CHANGE REPLICATION FILTER REPLICATE_DO_DB`. The precise effect of this filtering depends on whether statement-based or row-based replication is in use, and are described in the next several paragraphs.

**Statement-based replication.** Tell the slave SQL thread to restrict replication to statements where the default database (that is, the one selected by `USE`) is `db_name`. To specify more than one database, use this option multiple times, once for each database; however, doing so does *not* replicate cross-database statements such as `UPDATE some_db.some_table SET foo='bar'` while a different database (or no database) is selected.

#### Warning

To specify multiple databases you *must* use multiple instances of this option. Because database names can contain commas, if you supply a comma separated list then the list will be treated as the name of a single database.

An example of what does not work as you might expect when using statement-based replication: If the slave is started with `--replicate-do-db=sales` and you issue the following statements on the master, the `UPDATE` statement is *not* replicated:

```
USE prices;
UPDATE sales.january SET amount=amount+1000;
```

The main reason for this “check just the default database” behavior is that it is difficult from the statement alone to know whether it should be replicated (for example, if you are using multiple-table `DELETE` statements or multiple-table `UPDATE` statements that act across multiple databases). It is also faster to check only the default database rather than all databases if there is no need.

**Row-based replication.** Tells the slave SQL thread to restrict replication to database `db_name`. Only tables belonging to `db_name` are changed; the current database has no effect on this. Suppose that the slave is started with `--replicate-do-db=sales` and row-based replication is in effect, and then the following statements are run on the master:

```
USE prices;
UPDATE sales.february SET amount=amount+100;
```

The `february` table in the `sales` database on the slave is changed in accordance with the `UPDATE` statement; this occurs whether or not the `USE` statement was issued. However, issuing the following

statements on the master has no effect on the slave when using row-based replication and `--replicate-do-db=sales`:

```
USE prices;
UPDATE prices.march SET amount=amount-25;
```

Even if the statement `USE prices` were changed to `USE sales`, the `UPDATE` statement's effects would still not be replicated.

Another important difference in how `--replicate-do-db` is handled in statement-based replication as opposed to row-based replication occurs with regard to statements that refer to multiple databases. Suppose that the slave is started with `--replicate-do-db=db1`, and the following statements are executed on the master:

```
USE db1;
UPDATE db1.table1 SET col1 = 10, db2.table2 SET col2 = 20;
```

If you are using statement-based replication, then both tables are updated on the slave. However, when using row-based replication, only `table1` is affected on the slave; since `table2` is in a different database, `table2` on the slave is not changed by the `UPDATE`. Now suppose that, instead of the `USE db1` statement, a `USE db4` statement had been used:

```
USE db4;
UPDATE db1.table1 SET col1 = 10, db2.table2 SET col2 = 20;
```

In this case, the `UPDATE` statement would have no effect on the slave when using statement-based replication. However, if you are using row-based replication, the `UPDATE` would change `table1` on the slave, but not `table2`—in other words, only tables in the database named by `--replicate-do-db` are changed, and the choice of default database has no effect on this behavior.

If you need cross-database updates to work, use `--replicate-wild-do-table=db_name.%` instead. See [Section 18.2.5, “How Servers Evaluate Replication Filtering Rules”](#).

#### Note

This option affects replication in the same manner that `--binlog-do-db` affects binary logging, and the effects of the replication format on how `--replicate-do-db` affects replication behavior are the same as those of the logging format on the behavior of `--binlog-do-db`.

This option has no effect on `BEGIN`, `COMMIT`, or `ROLLBACK` statements.

- `--replicate-ignore-db=db_name`

|                            |   |        |
|----------------------------|---|--------|
| <b>Command-Line Format</b> | <code>--replicate-ignore-db=name</code> |        |
| <b>Permitted Values</b>    | <b>Type</b>                             | string |

Creates a replication filter using the name of a database. In MySQL 5.7.3 and later, such filters can also be created using `CHANGE REPLICATION FILTER REPLICATE_IGNORE_DB`. As with `--replicate-do-db`, the precise effect of this filtering depends on whether statement-based or row-based replication is in use, and are described in the next several paragraphs.

**Statement-based replication.** Tells the slave SQL thread not to replicate any statement where the default database (that is, the one selected by `USE`) is `db_name`.

**Row-based replication.** Tells the slave SQL thread not to update any tables in the database `db_name`. The default database has no effect.

When using statement-based replication, the following example does not work as you might expect. Suppose that the slave is started with `--replicate-ignore-db=sales` and you issue the following statements on the master:

```
USE prices;
UPDATE sales.january SET amount=amount+1000;
```

The `UPDATE` statement *is* replicated in such a case because `--replicate-ignore-db` applies only to the default database (determined by the `USE` statement). Because the `sales` database was specified explicitly in the statement, the statement has not been filtered. However, when using row-based replication, the `UPDATE` statement's effects are *not* propagated to the slave, and the slave's copy of the `sales.january` table is unchanged; in this instance, `--replicate-ignore-db=sales` causes *all* changes made to tables in the master's copy of the `sales` database to be ignored by the slave.

To specify more than one database to ignore, use this option multiple times, once for each database. Because database names can contain commas, if you supply a comma separated list then the list will be treated as the name of a single database.

You should not use this option if you are using cross-database updates and you do not want these updates to be replicated. See [Section 18.2.5, “How Servers Evaluate Replication Filtering Rules”](#).

If you need cross-database updates to work, use `--replicate-wild-ignore-table=db_name.%` instead. See [Section 18.2.5, “How Servers Evaluate Replication Filtering Rules”](#).

#### Note

This option affects replication in the same manner that `--binlog-ignore-db` affects binary logging, and the effects of the replication format on how `--replicate-ignore-db` affects replication behavior are the same as those of the logging format on the behavior of `--binlog-ignore-db`.

This option has no effect on `BEGIN`, `COMMIT`, or `ROLLBACK` statements.

- `--replicate-do-table=db_name.tbl_name`

|                            |  |        |
|----------------------------|--|--------|
| <b>Command-Line Format</b> | <code>--replicate-do-table=name</code> |        |
| <b>Permitted Values</b>    | <b>Type</b>                            | string |

Creates a replication filter by telling the slave SQL thread to restrict replication to a given table. To specify more than one table, use this option multiple times, once for each table. This works for both cross-database updates and default database updates, in contrast to `--replicate-do-db`. See [Section 18.2.5, “How Servers Evaluate Replication Filtering Rules”](#).

In MySQL 5.7.3 and later, you can also create such a filter by issuing a `CHANGE REPLICATION FILTER REPLICATE_DO_TABLE` statement.

This option affects only statements that apply to tables. It does not affect statements that apply only to other database objects, such as stored routines. To filter statements operating on stored routines, use one or more of the `--replicate-*db` options.

- `--replicate-ignore-table=db_name.tbl_name`

|                            |  |        |
|----------------------------|--|--------|
| <b>Command-Line Format</b> | <code>--replicate-ignore-table=name</code> |        |
| <b>Permitted Values</b>    | <b>Type</b>                                | string |

Creates a replication filter by telling the slave SQL thread not to replicate any statement that updates the specified table, even if any other tables might be updated by the same statement. To specify

more than one table to ignore, use this option multiple times, once for each table. This works for cross-database updates, in contrast to `--replicate-ignore-db`. See [Section 18.2.5, “How Servers Evaluate Replication Filtering Rules”](#).

In MySQL 5.7.3 and later, you can also create such a filter by issuing a `CHANGE REPLICATION FILTER REPLICATE_IGNORE_TABLE` statement.

This option affects only statements that apply to tables. It does not affect statements that apply only to other database objects, such as stored routines. To filter statements operating on stored routines, use one or more of the `--replicate-*--db` options.

- `--replicate-rewrite-db=from_name->to_name`

|                            |   |        |
|----------------------------|---|--------|
| <b>Command-Line Format</b> | <code>--replicate-rewrite-db=old_name-&gt;new_name</code> |        |
| <b>Permitted Values</b>    | <b>Type</b>   | string |

Tells the slave to create a replication filter that translates the default database (that is, the one selected by `USE`) to `to_name` if it was `from_name` on the master. Only statements involving tables are affected (not statements such as `CREATE DATABASE`, `DROP DATABASE`, and `ALTER DATABASE`), and only if `from_name` is the default database on the master. To specify multiple rewrites, use this option multiple times. The server uses the first one with a `from_name` value that matches. The database name translation is done *before* the `--replicate-*` rules are tested.

In MySQL 5.7.3 and later, you can also create such a filter by issuing a `CHANGE REPLICATION FILTER REPLICATE_REWRITE_DB` statement.

Statements in which table names are qualified with database names when using this option do not work with table-level replication filtering options such as `--replicate-do-table`. Suppose we have a database named `a` on the master, one named `b` on the slave, each containing a table `t`, and have started the master with `--replicate-rewrite-db='a->b'`. At a later point in time, we execute `DELETE FROM a.t`. In this case, no relevant filtering rule works, for the reasons shown here:

1. `--replicate-do-table=a.t` does not work because the slave has table `t` in database `b`.
2. `--replicate-do-table=b.t` does not match the original statement and so is ignored.
3. `--replicate-do-table=*.t` is handled identically to `--replicate-do-table=a.t`, and thus does not work, either.

Similarly, the `--replication-rewrite-db` option does not work with cross-database updates.

If you use this option on the command line and the `>` character is special to your command interpreter, quote the option value. For example:

```
shell> mysqld --replicate-rewrite-db="olddb->newdb"
```

- `--replicate-same-server-id`

|                            |   |                    |
|----------------------------|---|--------------------|
| <b>Command-Line Format</b> | <code>--replicate-same-server-id</code> |                    |
| <b>Permitted Values</b>    | <b>Type</b>                             | boolean            |
|                            | <b>Default</b>                          | <code>FALSE</code> |

To be used on slave servers. Usually you should use the default setting of 0, to prevent infinite loops caused by circular replication. If set to 1, the slave does not skip events having its own server ID. Normally, this is useful only in rare configurations. Cannot be set to 1 if `--log-slave-updates` is used. By default, the slave I/O thread does not write binary log events to the relay log if they have the slave's server ID (this optimization helps `save` disk usage). If you want to use `--replicate-same-`

`server-id`, be sure to start the slave with this option before you make the slave read its own events that you want the slave SQL thread to execute.

- `--replicate-wild-do-table=db_name.tbl_name`

|                            |   |        |
|----------------------------|---|--------|
| <b>Command-Line Format</b> | <code>--replicate-wild-do-table=name</code> |        |
| <b>Permitted Values</b>    | <b>Type</b>                                 | string |

Creates a replication filter by telling the slave thread to restrict replication to statements where any of the updated tables match the specified database and table name patterns. Patterns can contain the `%` and `_` wildcard characters, which have the same meaning as for the [LIKE](#) pattern-matching operator. To specify more than one table, use this option multiple times, once for each table. This works for cross-database updates. See [Section 18.2.5, “How Servers Evaluate Replication Filtering Rules”](#).

In MySQL 5.7.3 and later, you can also create such a filter by issuing a `CHANGE REPLICATION FILTER REPLICATE_WILD_DO_TABLE` statement.

This option applies to tables, views, and triggers. It does not apply to stored procedures and functions, or events. To filter statements operating on the latter objects, use one or more of the `--replicate-*-db` options.

Example: `--replicate-wild-do-table=foo%.bar%` replicates only updates that use a table where the database name starts with `foo` and the table name starts with `bar`.

If the table name pattern is `%`, it matches any table name and the option also applies to database-level statements (`CREATE DATABASE`, `DROP DATABASE`, and `ALTER DATABASE`). For example, if you use `--replicate-wild-do-table=foo%.%`, database-level statements are replicated if the database name matches the pattern `foo%`.

To include literal wildcard characters in the database or table name patterns, escape them with a backslash. For example, to replicate all tables of a database that is named `my_own%db`, but not replicate tables from the `my1ownAABCdb` database, you should escape the `_` and `%` characters like this: `--replicate-wild-do-table=my\_own\%db`. If you use the option on the command line, you might need to double the backslashes or quote the option value, depending on your command interpreter. For example, with the `bash` shell, you would need to type `--replicate-wild-do-table=my\\\_own\\%db`.

- `--replicate-wild-ignore-table=db_name.tbl_name`

|                            |   |        |
|----------------------------|---|--------|
| <b>Command-Line Format</b> | <code>--replicate-wild-ignore-table=name</code> |        |
| <b>Permitted Values</b>    | <b>Type</b>                                     | string |

Creates a replication filter which keeps the slave thread from replicating a statement in which any table matches the given wildcard pattern. To specify more than one table to ignore, use this option multiple times, once for each table. This works for cross-database updates. See [Section 18.2.5, “How Servers Evaluate Replication Filtering Rules”](#).

In MySQL 5.7.3 and later, you can also create such a filter by issuing a `CHANGE REPLICATION FILTER REPLICATE_WILD_IGNORE_TABLE` statement.

Example: `--replicate-wild-ignore-table=foo%.bar%` does not replicate updates that use a table where the database name starts with `foo` and the table name starts with `bar`.

For information about how matching works, see the description of the `--replicate-wild-do-table` option. The rules for including literal wildcard characters in the option value are the same as for `--replicate-wild-ignore-table` as well.

- `--report-host=host_name`

|                            |                                      |                          |
|----------------------------|--------------------------------------|--------------------------|
| <b>Command-Line Format</b> | <code>--report-host=host_name</code> |                          |
| <b>System Variable</b>     | <b>Name</b>                          | <code>report_host</code> |
|                            | <b>Variable Scope</b>                | Global                   |
|                            | <b>Dynamic Variable</b>              | No                       |
| <b>Permitted Values</b>    | <b>Type</b>                          | string                   |

The host name or IP address of the slave to be reported to the master during slave registration. This value appears in the output of `SHOW SLAVE HOSTS` on the master server. Leave the value unset if you do not want the slave to register itself with the master.

#### Note

It is not sufficient for the master to simply read the IP address of the slave from the TCP/IP socket after the slave connects. Due to NAT and other routing issues, that IP may not be valid for connecting to the slave from the master or other hosts.

- `--report-password=password`

|                            |                                     |                              |
|----------------------------|-------------------------------------|------------------------------|
| <b>Command-Line Format</b> | <code>--report-password=name</code> |                              |
| <b>System Variable</b>     | <b>Name</b>                         | <code>report_password</code> |
|                            | <b>Variable Scope</b>               | Global                       |
|                            | <b>Dynamic Variable</b>             | No                           |
| <b>Permitted Values</b>    | <b>Type</b>                         | string                       |

The account password of the slave to be reported to the master during slave registration. This value appears in the output of `SHOW SLAVE HOSTS` on the master server if the `--show-slave-auth-info` option is given.

Although the name of this option might imply otherwise, `--report-password` is not connected to the MySQL user privilege system and so is not necessarily (or even likely to be) the same as the password for the MySQL replication user account.

- `--report-port=slave_port_num`

|                            |                              |                           |
|----------------------------|------------------------------|---------------------------|
| <b>Command-Line Format</b> | <code>--report-port=#</code> |                           |
| <b>System Variable</b>     | <b>Name</b>                  | <code>report_port</code>  |
|                            | <b>Variable Scope</b>        | Global                    |
|                            | <b>Dynamic Variable</b>      | No                        |
| <b>Permitted Values</b>    | <b>Type</b>                  | integer                   |
|                            | <b>Default</b>               | <code>[slave_port]</code> |
|                            | <b>Min Value</b>             | 0                         |
|                            | <b>Max Value</b>             | 65535                     |

The TCP/IP port number for connecting to the slave, to be reported to the master during slave registration. Set this only if the slave is listening on a nondefault port or if you have a special tunnel from the master or other clients to the slave. If you are not sure, do not use this option.

The default value for this option is the port number actually used by the slave (Bug #13333431). This is also the default value displayed by `SHOW SLAVE HOSTS`.

- `--report-user=user_name`

|                            |                                 |                          |
|----------------------------|---------------------------------|--------------------------|
| <b>Command-Line Format</b> | <code>--report-user=name</code> |                          |
| <b>System Variable</b>     | <b>Name</b>                     | <code>report_user</code> |
|                            | <b>Variable Scope</b>           | Global                   |
|                            | <b>Dynamic Variable</b>         | No                       |
| <b>Permitted Values</b>    | <b>Type</b>                     | string                   |

The account user name of the slave to be reported to the master during slave registration. This value appears in the output of `SHOW SLAVE HOSTS` on the master server if the `--show-slave-auth-info` option is given.

Although the name of this option might imply otherwise, `--report-user` is not connected to the MySQL user privilege system and so is not necessarily (or even likely to be) the same as the name of the MySQL replication user account.

- `--show-slave-auth-info`

|                            |                                     |                    |
|----------------------------|-------------------------------------|--------------------|
| <b>Command-Line Format</b> | <code>--show-slave-auth-info</code> |                    |
| <b>Permitted Values</b>    | <b>Type</b>                         | boolean            |
|                            | <b>Default</b>                      | <code>FALSE</code> |

Display slave user names and passwords in the output of `SHOW SLAVE HOSTS` on the master server for slaves started with the `--report-user` and `--report-password` options.

- `--slave-checkpoint-group=#`

|                            |   |                     |
|----------------------------|---|---------------------|
| <b>Command-Line Format</b> | <code>--slave-checkpoint-group=#</code> |                     |
| <b>Permitted Values</b>    | <b>Type</b>                             | integer             |
|                            | <b>Default</b>                          | <code>512</code>    |
|                            | <b>Min Value</b>                        | <code>32</code>     |
|                            | <b>Max Value</b>                        | <code>524280</code> |
|                            | <b>Block Size</b>                       | <code>8</code>      |

Sets the maximum number of transactions that can be processed by a multi-threaded slave before a checkpoint operation is called to update its status as shown by `SHOW SLAVE STATUS`. Setting this option has no effect on slaves for which multi-threading is not enabled.

**Note**

Multi-threaded slaves are not currently supported by MySQL Cluster, which silently ignores the setting for this option. See [Section 20.6.3, “Known Issues in NDB Cluster Replication”](#), for more information.

This option works in combination with the `--slave-checkpoint-period` option in such a way that, when either limit is exceeded, the checkpoint is executed and the counters tracking both the number of transactions and the time elapsed since the last checkpoint are reset.

The minimum allowed value for this option is 32, unless the server was built using `-DWITH_DEBUG`, in which case the minimum value is 1. The effective value is always a multiple of 8; you can set it to a value that is not such a multiple, but the server rounds it down to the next lower multiple of 8 before storing the value. (*Exception:* No such rounding is performed by the debug server.) Regardless of how the server was built, the default value is 512, and the maximum allowed value is 524280.

- `--slave-checkpoint-period=#`

|                            |  |         |
|----------------------------|--|---------|
| <b>Command-Line Format</b> | <code>--slave-checkpoint-period=#</code> |         |
| <b>Permitted Values</b>    | <b>Type</b>                              | integer |
|                            | <b>Default</b>                           | 300     |
|                            | <b>Min Value</b>                         | 1       |
|                            | <b>Max Value</b>                         | 4G      |

Sets the maximum time (in milliseconds) that is allowed to pass before a checkpoint operation is called to update the status of a multi-threaded slave as shown by `SHOW SLAVE STATUS`. Setting this option has no effect on slaves for which multi-threading is not enabled.

**Note**

Multi-threaded slaves are not currently supported by MySQL Cluster, which silently ignores the setting for this option. See [Section 20.6.3, “Known Issues in NDB Cluster Replication”](#), for more information.

This option works in combination with the `--slave-checkpoint-group` option in such a way that, when either limit is exceeded, the checkpoint is executed and the counters tracking both the number of transactions and the time elapsed since the last checkpoint are reset.

The minimum allowed value for this option is 1, unless the server was built using `-DWITH_DEBUG`, in which case the minimum value is 0. Regardless of how the server was built, the default value is 300, and the maximum possible value is 4294967296 (4GB).

- `--slave-parallel-workers`

|                            |   |         |
|----------------------------|---|---------|
| <b>Command-Line Format</b> | <code>--slave-parallel-workers=#</code> |         |
| <b>Permitted Values</b>    | <b>Type</b>                             | integer |
|                            | <b>Default</b>                          | 0       |
|                            | <b>Min Value</b>                        | 0       |
|                            | <b>Max Value</b>                        | 1024    |

Sets the number of slave applier threads for executing replication transactions in parallel. Setting this variable to a number greater than 0 creates a multi-threaded slave with this number of applier

threads. When set to 0 (the default) parallel execution is disabled and the slave uses a single applier thread.

A multi-threaded slave provides parallel execution by using a coordinator thread and the number of applier threads configured by this option. The way which transactions are distributed among applier threads is configured by `--slave-parallel-type`. For more information about multi-threaded slaves see [slave-parallel-workers](#).

#### Note

Multi-threaded slaves are not currently supported by MySQL Cluster, which silently ignores the setting for this option. See [Section 20.6.3, “Known Issues in NDB Cluster Replication”](#), for more information.

- `--slave-pending-jobs-size-max=#`

|                            |  |         |
|----------------------------|--|---------|
| <b>Command-Line Format</b> | <code>--slave-pending-jobs-size-max=#</code> |         |
| <b>Permitted Values</b>    | <b>Type</b>                                  | integer |
|                            | <b>Default</b>                               | 16M     |
|                            | <b>Min Value</b>                             | 1024    |
|                            | <b>Max Value</b>                             | 18EB    |
|                            | <b>Block Size</b>                            | 1024    |

For multi-threaded slaves, this option sets the maximum amount of memory (in bytes) available to slave worker queues holding events not yet applied. Setting this option has no effect on slaves for which multi-threading is not enabled.

The minimum possible value for this option is 1024; the default is 16MB. The maximum possible value is 18446744073709551615 (16 exabytes). Values that are not exact multiples of 1024 are rounded down to the next-highest multiple of 1024 prior to being stored.

#### Important

The value for this option must not be less than the master's value for [max\\_allowed\\_packet](#); otherwise a slave worker queue may become full while there remain events coming from the master to be processed.

- `--skip-slave-start`

|                            |                                 |         |
|----------------------------|---------------------------------|---------|
| <b>Command-Line Format</b> | <code>--skip-slave-start</code> |         |
| <b>Permitted Values</b>    | <b>Type</b>                     | boolean |
|                            | <b>Default</b>                  | FALSE   |

Tells the slave server not to start the slave threads when the server starts. To start the threads later, use a `START SLAVE` statement.

- `--slave_compressed_protocol={0|1}`

|                            |  |  |
|----------------------------|--|--|
| <b>Command-Line Format</b> | <code>--slave_compressed_protocol</code> |  |
| <b>System Variable</b>     | <b>Name</b>                              | <code>slave_compressed_protocol</code> |
|                            | <b>Variable Scope</b>                    | Global                                 |
|                            |  | 2688                                   |

|                         |                         |         |
|-------------------------|-------------------------|---------|
|                         | <b>Dynamic Variable</b> | Yes     |
| <b>Permitted Values</b> | <b>Type</b>             | boolean |
|                         | <b>Default</b>          | OFF     |

If this option is set to 1, use compression for the slave/master protocol if both the slave and the master support it. The default is 0 (no compression).

- `--slave-load-tmpdir=dir_name`

|                            |   |                                |
|----------------------------|---|--------------------------------|
| <b>Command-Line Format</b> | <code>--slave-load-tmpdir=dir_name</code> |                                |
| <b>System Variable</b>     | <b>Name</b>                               | <code>slave_load_tmpdir</code> |
|                            | <b>Variable Scope</b>                     | Global                         |
|                            | <b>Dynamic Variable</b>                   | No                             |
| <b>Permitted Values</b>    | <b>Type</b>                               | directory name                 |
|                            | <b>Default</b>                            | <code>/tmp</code>              |

The name of the directory where the slave creates temporary files. This option is by default equal to the value of the `tmpdir` system variable. When the slave SQL thread replicates a `LOAD DATA INFILE` statement, it extracts the file to be loaded from the relay log into temporary files, and then loads these into the table. If the file loaded on the master is huge, the temporary files on the slave are huge, too. Therefore, it might be advisable to use this option to tell the slave to put temporary files in a directory located in some file system that has a lot of available space. In that case, the relay logs are huge as well, so you might also want to use the `--relay-log` option to place the relay logs in that file system.

The directory specified by this option should be located in a disk-based file system (not a memory-based file system) because the temporary files used to replicate `LOAD DATA INFILE` must survive machine restarts. The directory also should not be one that is cleared by the operating system during the system startup process.

- `slave-max-allowed-packet=bytes`

|                            |   |                         |
|----------------------------|---|-------------------------|
| <b>Command-Line Format</b> | <code>--slave-max-allowed-packet=#</code> |                         |
| <b>Permitted Values</b>    | <b>Type</b>                               | integer                 |
|                            | <b>Default</b>                            | <code>1073741824</code> |
|                            | <b>Min Value</b>                          | <code>1024</code>       |
|                            | <b>Max Value</b>                          | <code>1073741824</code> |

This option sets the maximum packet size in bytes for the slave SQL and I/O threads, so that large updates using row-based replication do not cause replication to fail because an update exceeded `max_allowed_packet`. (Bug #12400221, Bug #60926)

The corresponding server variable `slave_max_allowed_packet` always has a value that is a positive integer multiple of 1024; if you set it to some value that is not such a multiple, the value is automatically rounded down to the next highest multiple of 1024. (For example, if you start the server with `--slave-max-allowed-packet=10000`, the value used is 9216; setting 0 as the value causes 1024 to be used.) A truncation warning is issued in such cases.

The maximum (and default) value is 1073741824 (1 GB); the minimum is 1024.

- `--slave-net-timeout=seconds`

|                                       |                                    |                                |
|---------------------------------------|------------------------------------|--------------------------------|
| <b>Command-Line Format</b>            | <code>--slave-net-timeout=#</code> |                                |
| <b>System Variable</b>                | <b>Name</b>                        | <code>slave_net_timeout</code> |
|                                       | <b>Variable Scope</b>              | Global                         |
|                                       | <b>Dynamic Variable</b>            | Yes                            |
| <b>Permitted Values</b>               | <b>Type</b>                        | integer                        |
|                                       | <b>Default</b>                     | 3600                           |
|                                       | <b>Min Value</b>                   | 1                              |
| <b>Permitted Values (&gt;= 5.7.7)</b> | <b>Type</b>                        | integer                        |
|                                       | <b>Default</b>                     | 60                             |
|                                       | <b>Min Value</b>                   | 1                              |

The number of seconds to wait for more data from the master before the slave considers the connection broken, aborts the read, and tries to reconnect. The first retry occurs immediately after the timeout. The interval between retries is controlled by the `MASTER_CONNECT_RETRY` option for the `CHANGE MASTER TO` statement, and the number of reconnection attempts is limited by the `--master-retry-count` option. Prior to MySQL 5.7.7, the default was 3600 seconds (one hour). In MySQL 5.7.7 and later the default is 60 (one minute).

- `--slave-parallel-type=type`

|                            |   |                            |
|----------------------------|---|----------------------------|
| <b>Introduced</b>          | 5.7.2                                   |                            |
| <b>Command-Line Format</b> | <code>--slave-parallel-type=type</code> |                            |
| <b>Permitted Values</b>    | <b>Type</b>                             | enumeration                |
|                            | <b>Default</b>                          | <code>DATABASE</code>      |
|                            | <b>Valid Values</b>                     | <code>DATABASE</code>      |
|                            |   | <code>LOGICAL_CLOCK</code> |

When using a multi-threaded slave (`slave_parallel_workers` is greater than 0), this option specifies the policy used to decide which transactions are allowed to execute in parallel on the slave. The possible values are:

- `DATABASE`: Transactions that update different databases are applied in parallel. This value is only appropriate if data is partitioned into multiple databases which are being updated independently and concurrently on the master. Only recommended if there are no cross-database constraints, as such constraints may be violated on the slave.
- `LOGICAL_CLOCK`: Transactions that are part of the same binary log group commit on a master are applied in parallel on a slave. There are no cross-database constraints, and data does not need to be partitioned into multiple databases.

Regardless of the value of this variable, there is no special configuration required on the master. When `slave_preserve_commit_order=1`, you can only use `LOGICAL_CLOCK`. If your replication topology uses multiple levels of slaves, `LOGICAL_CLOCK` may achieve less parallelization for each level the slave is away from the master.

- `slave-rows-search-algorithms=list`

|                            |  |  |
|----------------------------|--|--|
| <b>Command-Line Format</b> | <code>--slave-rows-search-algorithms=list</code> |  |
| <b>Permitted Values</b>    | <b>Type</b>                                      | set  |
|                            | <b>Default</b>                                   | <code>TABLE_SCAN, INDEX_SCAN</code>  |
|                            | <b>Valid Values</b>                              | <code>TABLE_SCAN, INDEX_SCAN</code>  |
|                            |  | <code>INDEX_SCAN, HASH_SCAN</code>   |
|                            |  | <code>TABLE_SCAN, HASH_SCAN</code>   |
