- The row was last modified by the primary. It is possible that the modification was accomplished through the execution of a reflected operation.

If both of the conditions are not met, the reflected operation is discarded by the secondary.

**Conflict resolution exceptions table.** To use the `NDB$OLD()` conflict resolution function, it is also necessary to create an exceptions table corresponding to each NDB table for which this type of conflict resolution is to be employed. This is also true when using `NDB$EPOCH()` or `NDB$EPOCH_TRANS()`. The name of this table is that of the table for which conflict resolution is to be applied, with the string `$EX` appended. (For example, if the name of the original table is `mytable`, the name of the corresponding exceptions table name should be `mytable$EX`.) The syntax for creating the exceptions table is as shown here:

```
CREATE TABLE original_table$EX (
  [NDB$]server_id INT UNSIGNED,
  [NDB$]master_server_id INT UNSIGNED,
  [NDB$]master_epoch BIGINT UNSIGNED,
  [NDB$]count INT UNSIGNED,

  [NDB$OP_TYPE ENUM('WRITE_ROW', 'UPDATE_ROW', 'DELETE_ROW',
    'REFRESH_ROW', 'READ_ROW') NOT NULL,]
  [NDB$CFT_CAUSE ENUM('ROW_DOES_NOT_EXIST', 'ROW_ALREADY_EXISTS',
    'DATA_IN_CONFLICT', 'TRANS_IN_CONFLICT') NOT NULL,]
  [NDB$ORIG_TRANSID BIGINT UNSIGNED NOT NULL,]

  original_table_pk_columns,

  [orig_table_column|orig_table_column$OLD|orig_table_column$NEW,]

  [additional_columns,]

  PRIMARY KEY([NDB$]server_id, [NDB$]master_server_id, [NDB$]master_epoch, [NDB$]count)
) ENGINE=NDB;
```

The first four columns are required. The names of the first four columns and the columns matching the original table's primary key columns are not critical; however, we suggest for reasons of clarity and consistency, that you use the names shown here for the `server_id`, `master_server_id`, `master_epoch`, and `count` columns, and that you use the same names as in the original table for the columns matching those in the original table's primary key.

If the exceptions table uses one or more of the optional columns `NDB$OP_TYPE`, `NDB$CFT_CAUSE`, or `NDB$ORIG_TRANSID` discussed later in this section, then each of the required columns must also be named using the prefix `NDB$`. If desired, you can use the `NDB$` prefix to name the required columns even if you do not define any optional columns, but in this case, all four of the required columns must be named using the prefix.

Following these columns, the columns making up the original table's primary key should be copied in the order in which they are used to define the primary key of the original table. The data types for the columns duplicating the primary key columns of the original table should be the same as (or larger than) those of the original columns. A subset of the primary key columns may be used.

Regardless of the NDB Cluster version employed, the exceptions table must use the NDB storage engine. (An example that uses `NDB$OLD()` with an exceptions table is shown later in this section.)

Additional columns may optionally be defined following the copied primary key columns, but not before any of them; any such extra columns cannot be `NOT NULL`. NDB Cluster supports three additional, predefined optional columns `NDB$OP_TYPE`, `NDB$CFT_CAUSE`, and `NDB$ORIG_TRANSID`, which are described in the next few paragraphs.

**`NDB$OP_TYPE`:** This column can be used to obtain the type of operation causing the conflict. If you use this column, define it as shown here:

```
NDB$OP_TYPE ENUM('WRITE_ROW', 'UPDATE_ROW', 'DELETE_ROW',
  'REFRESH_ROW', 'READ_ROW') NOT NULL
```

The `WRITE_ROW`, `UPDATE_ROW`, and `DELETE_ROW` operation types represent user-initiated operations. `REFRESH_ROW` operations are operations generated by conflict resolution in compensating transactions sent back to the originating cluster from the cluster that detected the conflict. `READ_ROW` operations are user-initiated read tracking operations defined with exclusive row locks.

**`NDB$CFT_CAUSE`:** You can define an optional column `NDB$CFT_CAUSE` which provides the cause of the registered conflict. This column, if used, is defined as shown here:

```
NDB$CFT_CAUSE ENUM('ROW_DOES_NOT_EXIST', 'ROW_ALREADY_EXISTS',
  'DATA_IN_CONFLICT', 'TRANS_IN_CONFLICT') NOT NULL
```

`ROW_DOES_NOT_EXIST` can be reported as the cause for `UPDATE_ROW` and `WRITE_ROW` operations; `ROW_ALREADY_EXISTS` can be reported for `WRITE_ROW` events. `DATA_IN_CONFLICT` is reported when a row-based conflict function detects a conflict; `TRANS_IN_CONFLICT` is reported when a transactional conflict function rejects all of the operations belonging to a complete transaction.

**`NDB$ORIG_TRANSID`:** The `NDB$ORIG_TRANSID` column, if used, contains the ID of the originating transaction. This column should be defined as follows:

```
NDB$ORIG_TRANSID BIGINT UNSIGNED NOT NULL
```

`NDB$ORIG_TRANSID` is a 64-bit value generated by NDB. This value can be used to correlate multiple exceptions table entries belonging to the same conflicting transaction from the same or different exceptions tables.

Additional reference columns which are not part of the original table's primary key can be named `colname$OLD` or `colname$NEW`. `colname$OLD` references old values in update and delete operations—that is, operations containing `DELETE_ROW` events. `colname$NEW` can be used to reference new values in insert and update operations—in other words, operations using `WRITE_ROW` events, `UPDATE_ROW` events, or both types of events. Where a conflicting operation does not supply a value for a given non-primary-key reference column, the exceptions table row contains either `NULL`, or a defined default value for that column.

### Important

The `mysql.ndb_replication` table is read when a data table is set up for replication, so the row corresponding to a table to be replicated must be inserted into `mysql.ndb_replication` *before* the table to be replicated is created.

## Examples

The following examples assume that you have already a working NDB Cluster replication setup, as described in [Section 20.6.5, “Preparing the NDB Cluster for Replication”](#), and [Section 20.6.6, “Starting NDB Cluster Replication \(Single Replication Channel\)”](#).

**`NDB$MAX()` example.** Suppose you wish to enable “greatest timestamp wins” conflict resolution on table `test.t1`, using column `mycol` as the “timestamp”. This can be done using the following steps:

1. Make sure that you have started the master `mysqld` with `--ndb-log-update-as-write=OFF`.
2. On the master, perform this `INSERT` statement:

```
INSERT INTO mysql.ndb_replication
VALUES ('test', 't1', 0, NULL, 'NDB$MAX(mycol)');
```

Inserting a 0 into the `server_id` indicates that all SQL nodes accessing this table should use conflict resolution. If you want to use conflict resolution on a specific `mysqld` only, use the actual server ID.

Inserting `NULL` into the `binlog_type` column has the same effect as inserting 0 (`NBT_DEFAULT`); the server default is used.

3. Create the `test.t1` table:

```
CREATE TABLE test.t1 (
  columns
  mycol INT UNSIGNED,
  columns
) ENGINE=NDB;
```

Now, when updates are done on this table, conflict resolution is applied, and the version of the row having the greatest value for `mycol` is written to the slave.

#### Note

Other `binlog_type` options—such as `NBT_UPDATED_ONLY_USE_UPDATE`—should be used to control logging on the master using the `ndb_replication` table rather than by using command-line options.

**NDB\$OLD() example.** Suppose an `NDB` table such as the one defined here is being replicated, and you wish to enable “same timestamp wins” conflict resolution for updates to this table:

```
CREATE TABLE test.t2 (
  a INT UNSIGNED NOT NULL,
  b CHAR(25) NOT NULL,
  columns,
  mycol INT UNSIGNED NOT NULL,
  columns,
  PRIMARY KEY pk (a, b)
) ENGINE=NDB;
```

The following steps are required, in the order shown:

1. First—and *prior* to creating `test.t2`—you must insert a row into the `mysql.ndb_replication` table, as shown here:

```
INSERT INTO mysql.ndb_replication
VALUES ('test', 't2', 0, NULL, 'NDB$OLD(mycol)');
```

Possible values for the `binlog_type` column are shown earlier in this section. The value `'NDB$OLD(mycol)'` should be inserted into the `conflict_fn` column.

2. Create an appropriate exceptions table for `test.t2`. The table creation statement shown here includes all required columns; any additional columns must be declared following these columns, and before the definition of the table's primary key.

```
CREATE TABLE test.t2$EX (
  server_id SMALLINT UNSIGNED,
  master_server_id INT UNSIGNED,
```

```

master_epoch BIGINT UNSIGNED,
count BIGINT UNSIGNED,
a INT UNSIGNED NOT NULL,
b CHAR(25) NOT NULL,

[additional_columns,]

PRIMARY KEY(server_id, master_server_id, master_epoch, count)
) ENGINE=NDB;

```

We can include additional columns for information about the type, cause, and originating transaction ID for a given conflict. We are also not required to supply matching columns for all primary key columns in the original table. This means you can create the exceptions table like this:

```

CREATE TABLE test.t2$EX (
    NDB$server_id SMALLINT UNSIGNED,
    NDB$master_server_id INT UNSIGNED,
    NDB$master_epoch BIGINT UNSIGNED,
    NDB$count BIGINT UNSIGNED,
    a INT UNSIGNED NOT NULL,

    NDB$OP_TYPE ENUM('WRITE_ROW', 'UPDATE_ROW', 'DELETE_ROW',
        'REFRESH_ROW', 'READ_ROW') NOT NULL,
    NDB$CFT_CAUSE ENUM('ROW_DOES_NOT_EXIST', 'ROW_ALREADY_EXISTS',
        'DATA_IN_CONFLICT', 'TRANS_IN_CONFLICT') NOT NULL,
    NDB$ORIG_TRANSID BIGINT UNSIGNED NOT NULL,

    [additional_columns,]

    PRIMARY KEY(NDB$server_id, NDB$master_server_id, NDB$master_epoch, NDB$count)
) ENGINE=NDB;

```

#### Note

The `NDB$` prefix is required for the four required columns since we included at least one of the columns `NDB$OP_TYPE`, `NDB$CFT_CAUSE`, or `NDB$ORIG_TRANSID` in the table definition.

3. Create the table `test.t2` as shown previously.

These steps must be followed for every table for which you wish to perform conflict resolution using `NDB$OLD()`. For each such table, there must be a corresponding row in `mysql.ndb_replication`, and there must be an exceptions table in the same database as the table being replicated.

**Read conflict detection and resolution.** NDB Cluster also supports tracking of read operations, which makes it possible in circular replication setups to manage conflicts between reads of a given row in one cluster and updates or deletes of the same row in another. This example uses `employee` and `department` tables to model a scenario in which an employee is moved from one department to another on the master cluster (which we refer to hereafter as cluster *A*) while the slave cluster (hereafter *B*) updates the employee count of the employee's former department in an interleaved transaction.

The data tables have been created using the following SQL statements:

```

# Employee table
CREATE TABLE employee (
    id INT PRIMARY KEY,
    name VARCHAR(2000),
    dept INT NOT NULL
) ENGINE=NDB;

# Department table
CREATE TABLE department (
    id INT PRIMARY KEY,
    name VARCHAR(2000),
    members INT
) ENGINE=NDB;

```

```
) ENGINE=NDB;
```

The contents of the two tables include the rows shown in the (partial) output of the following `SELECT` statements:

```
mysql> SELECT id, name, dept FROM employee;
+-----+-----+-----+
| id   | name  | dept |
+-----+-----+-----+
...
| 998  | Mike  | 3    |
| 999  | Joe   | 3    |
| 1000 | Mary  | 3    |
...
+-----+-----+-----+

mysql> SELECT id, name, members FROM department;
+-----+-----+-----+
| id   | name          | members |
+-----+-----+-----+
...
| 3    | Old project   | 24      |
...
+-----+-----+-----+
```

We assume that we are already using an exceptions table that includes the four required columns (and these are used for this table's primary key), the optional columns for operation type and cause, and the original table's primary key column, created using the SQL statement shown here:

```
CREATE TABLE employee$EX (
  NDB$server_id INT UNSIGNED,
  NDB$master_server_id INT UNSIGNED,
  NDB$master_epoch BIGINT UNSIGNED,
  NDB$count INT UNSIGNED,

  NDB$OP_TYPE ENUM( 'WRITE_ROW', 'UPDATE_ROW', 'DELETE_ROW',
    'REFRESH_ROW', 'READ_ROW') NOT NULL,
  NDB$CFT_CAUSE ENUM( 'ROW_DOES_NOT_EXIST',
    'ROW_ALREADY_EXISTS',
    'DATA_IN_CONFLICT',
    'TRANS_IN_CONFLICT') NOT NULL,

  id INT NOT NULL,

  PRIMARY KEY(NDB$server_id, NDB$master_server_id, NDB$master_epoch, NDB$count)
) ENGINE=NDB;
```

Suppose there occur the two simultaneous transactions on the two clusters. On cluster *A*, we create a new department, then move employee number 999 into that department, using the following SQL statements:

```
BEGIN;
  INSERT INTO department VALUES (4, "New project", 1);
  UPDATE employee SET dept = 4 WHERE id = 999;
COMMIT;
```

At the same time, on cluster *B*, another transaction reads from `employee`, as shown here:

```
BEGIN;
  SELECT name FROM employee WHERE id = 999;
  UPDATE department SET members = members - 1 WHERE id = 3;
commit;
```

The conflicting transactions are not normally detected by the conflict resolution mechanism, since the conflict is between a read (`SELECT`) and an update operation. You can circumvent this issue by

executing `SET ndb_log_exclusive_reads = 1` on the slave cluster. Acquiring exclusive read locks in this way causes any rows read on the master to be flagged as needing conflict resolution on the slave cluster. If we enable exclusive reads in this way prior to the logging of these transactions, the read on cluster *B* is tracked and sent to cluster *A* for resolution; the conflict on the employee row will be detected and the transaction on cluster *B* is aborted.

The conflict is registered in the exceptions table (on cluster *A*) as a `READ_ROW` operation (see [Conflict resolution exceptions table](#), for a description of operation types), as shown here:

```
mysql> SELECT id, NDB$OP_TYPE, NDB$CFT_CAUSE FROM employee$EX;
+-----+-----+-----+
| id    | NDB$OP_TYPE | NDB$CFT_CAUSE |
+-----+-----+-----+
...
| 999   | READ_ROW    | TRANS_IN_CONFLICT |
+-----+-----+-----+
```

Any existing rows found in the read operation are flagged. This means that multiple rows resulting from the same conflict may be logged in the exception table, as shown by examining the effects a conflict between an update on cluster *A* and a read of multiple rows on cluster *B* from the same table in simultaneous transactions. The transaction executed on cluster *A* is shown here:

```
BEGIN;
  INSERT INTO department VALUES (4, "New project", 0);
  UPDATE employee SET dept = 4 WHERE dept = 3;
  SELECT COUNT(*) INTO @count FROM employee WHERE dept = 4;
  UPDATE department SET members = @count WHERE id = 4;
COMMIT;
```

Concurrently a transaction containing the statements shown here runs on cluster *B*:

```
SET ndb_log_exclusive_reads = 1; # Must be set if not already enabled
...
BEGIN;
  SELECT COUNT(*) INTO @count FROM employee WHERE dept = 3 FOR UPDATE;
  UPDATE department SET members = @count WHERE id = 3;
COMMIT;
```

In this case, all three rows matching the `WHERE` condition in the second transaction's `SELECT` are read, and are thus flagged in the exceptions table, as shown here:

```
mysql> SELECT id, NDB$OP_TYPE, NDB$CFT_CAUSE FROM employee$EX;
+-----+-----+-----+
| id    | NDB$OP_TYPE | NDB$CFT_CAUSE |
+-----+-----+-----+
...
| 998   | READ_ROW    | TRANS_IN_CONFLICT |
| 999   | READ_ROW    | TRANS_IN_CONFLICT |
| 1000  | READ_ROW    | TRANS_IN_CONFLICT |
...
+-----+-----+-----+
```

Read tracking is performed on the basis of existing rows only. A read based on a given condition track conflicts only of any rows that are *found* and not of any rows that are inserted in an interleaved transaction. This is similar to how exclusive row locking is performed in a single instance of NDB Cluster .

## 20.7 NDB Cluster Release Notes

Changes in NDB Cluster releases are documented separately from this reference manual; you can find release notes for the changes in each NDB Cluster 7.5 release at [NDB 7.5 Release Notes](#).

You can obtain release notes for older versions of NDB Cluster from [NDB Cluster Release Notes](#).

| 21.6.2 Partitioning Limitations Relating to Storage Engines ..... | 3435 |
| 21.6.3 Partitioning Limitations Relating to Functions .....       | 3436 |
| 21.6.4 Partitioning and Locking .....                             | 3437 |

This chapter discusses MySQL's implementation of *user-defined partitioning*.

### Note

As of MySQL 5.7.17, the generic partitioning handler in the MySQL server is deprecated, and is removed in MySQL 8.0, when the storage engine used for a given table is expected to provide its own (“native”) partitioning handler. Currently, only the [InnoDB](#) and [NDB](#) storage engines do.

Use of tables with nonnative partitioning results in an [ER\\_WARN\\_DEPRECATED\\_SYNTAX](#) warning. Also, the server performs a check at startup to identify tables that use nonnative partitioning; for any found, the server writes a message to its error log. To disable this check, use the [--disable-partition-engine-check](#) option.

To prepare for migration to MySQL 8.0, any table with nonnative partitioning should be changed to use an engine that provides native partitioning, or be made nonpartitioned. For example, to change a table to [InnoDB](#), execute this statement:

```
ALTER TABLE table_name ENGINE = INNODB;
```

You can determine whether your MySQL Server supports partitioning by checking the output of the [SHOW PLUGINS](#) statement, like this:

```
mysql> SHOW PLUGINS;
+-----+-----+-----+-----+-----+
|
```

| Name             | Status        | Type                  | Library     | License    |
|------------------|---------------|-----------------------|-------------|------------|
| binlog           | ACTIVE        | STORAGE ENGINE        | NULL        | GPL        |
| <b>partition</b> | <b>ACTIVE</b> | <b>STORAGE ENGINE</b> | <b>NULL</b> | <b>GPL</b> |
| ARCHIVE          | ACTIVE        | STORAGE ENGINE        | NULL        | GPL        |
| BLACKHOLE        | ACTIVE        | STORAGE ENGINE        | NULL        | GPL        |
| CSV              | ACTIVE        | STORAGE ENGINE        | NULL        | GPL        |
| FEDERATED        | DISABLED      | STORAGE ENGINE        | NULL        | GPL        |
| MEMORY           | ACTIVE        | STORAGE ENGINE        | NULL        | GPL        |
| InnoDB           | ACTIVE        | STORAGE ENGINE        | NULL        | GPL        |
| MRG_MYISAM       | ACTIVE        | STORAGE ENGINE        | NULL        | GPL        |
| MyISAM           | ACTIVE        | STORAGE ENGINE        | NULL        | GPL        |
| ndbcluster       | DISABLED      | STORAGE ENGINE        | NULL        | GPL        |

11 rows in set (0.00 sec)

You can also check the `INFORMATION_SCHEMA.PLUGINS` table with a query similar to this one:

```
mysql> SELECT
->     PLUGIN_NAME as Name,
->     PLUGIN_VERSION as Version,
->     PLUGIN_STATUS as Status
-> FROM INFORMATION_SCHEMA.PLUGINS
-> WHERE PLUGIN_TYPE='STORAGE ENGINE';
```

| Name               | Version    | Status        |
|--------------------|------------|---------------|
| binlog             | 1.0        | ACTIVE        |
| CSV                | 1.0        | ACTIVE        |
| MEMORY             | 1.0        | ACTIVE        |
| MRG_MYISAM         | 1.0        | ACTIVE        |
| MyISAM             | 1.0        | ACTIVE        |
| PERFORMANCE_SCHEMA | 0.1        | ACTIVE        |
| BLACKHOLE          | 1.0        | ACTIVE        |
| ARCHIVE            | 3.0        | ACTIVE        |
| InnoDB             | 5.7        | ACTIVE        |
| <b>partition</b>   | <b>1.0</b> | <b>ACTIVE</b> |

10 rows in set (0.00 sec)

In either case, if you do not see the `partition` plugin listed with the value `ACTIVE` for the `Status` column in the output (shown in bold text in each of the examples just given), then your version of MySQL was not built with partitioning support.

MySQL 5.7 Community binaries provided by Oracle include partitioning support. For information about partitioning support offered in MySQL Enterprise Edition binaries, see [Chapter 28, MySQL Enterprise Edition](#).

To enable partitioning if you are compiling MySQL 5.7 from source, the build must be configured with the `-DWITH_PARTITION_STORAGE_ENGINE` option. For more information, see [Section 2.9, “Installing MySQL from Source”](#).

If your MySQL binary is built with partitioning support, nothing further needs to be done to enable it (for example, no special entries are required in your `my.cnf` file).

If you want to disable partitioning support, you can start the MySQL Server with the `--skip-partition` option. When partitioning support is disabled, you can see any existing partitioned tables and drop them (although doing this is not advised), but you cannot otherwise manipulate them or access their data.

See [Section 21.1, “Overview of Partitioning in MySQL”](#), for an introduction to partitioning and partitioning concepts.

MySQL supports several types of partitioning as well as subpartitioning; see [Section 21.2, “Partitioning Types”](#), and [Section 21.2.6, “Subpartitioning”](#).

[Section 21.3, “Partition Management”](#), covers methods of adding, removing, and altering partitions in existing partitioned tables.

[Section 21.3.4, “Maintenance of Partitions”](#), discusses table maintenance commands for use with partitioned tables.

The `PARTITIONS` table in the `INFORMATION_SCHEMA` database provides information about partitions and partitioned tables. See [Section 23.15, “The INFORMATION\\_SCHEMA PARTITIONS Table”](#), for more information; for some examples of queries against this table, see [Section 21.2.7, “How MySQL Partitioning Handles NULL”](#).

For known issues with partitioning in MySQL 5.7, see [Section 21.6, “Restrictions and Limitations on Partitioning”](#).

You may also find the following resources to be useful when working with partitioned tables.

**Additional Resources.** Other sources of information about user-defined partitioning in MySQL include the following:

- [MySQL Partitioning Forum](#)

This is the official discussion forum for those interested in or experimenting with MySQL Partitioning technology. It features announcements and updates from MySQL developers and others. It is monitored by members of the Partitioning Development and Documentation Teams.

- [Mikael Ronström's Blog](#)

MySQL Partitioning Architect and Lead Developer Mikael Ronström frequently posts articles here concerning his work with MySQL Partitioning and MySQL Cluster.

- [PlanetMySQL](#)

A MySQL news site featuring MySQL-related blogs, which should be of interest to anyone using my MySQL. We encourage you to check here for links to blogs kept by those working with MySQL Partitioning, or to have your own blog added to those covered.

MySQL 5.7 binaries are available from <http://dev.mysql.com/downloads/mysql/5.7.html>. However, for the latest partitioning bugfixes and feature additions, you can obtain the source from our GitHub repository. To enable partitioning, the build must be configured with the `-DWITH_PARTITION_STORAGE_ENGINE` option. For more information about building MySQL, see [Section 2.9, “Installing MySQL from Source”](#). If you have problems compiling a partitioning-enabled MySQL 5.7 build, check the [MySQL Partitioning Forum](#) and ask for assistance there if you do not find a solution to your problem already posted.

## 21.1 Overview of Partitioning in MySQL

This section provides a conceptual overview of partitioning in MySQL 5.7.

For information on partitioning restrictions and feature limitations, see [Section 21.6, “Restrictions and Limitations on Partitioning”](#).

The SQL standard does not provide much in the way of guidance regarding the physical aspects of data storage. The SQL language itself is intended to work independently of any data structures or media underlying the schemas, tables, rows, or columns with which it works. Nonetheless, most advanced database management systems have evolved some means of determining the physical location to be used for storing specific pieces of data in terms of the file system, hardware or even both. In MySQL, the `InnoDB` storage engine has long supported the notion of a tablespace, and the MySQL Server, even prior to the introduction of partitioning, could be configured to employ different physical directories for storing different databases (see [Section 9.12.3, “Using Symbolic Links”](#), for an explanation of how this is done).

*Partitioning* takes this notion a step further, by enabling you to distribute portions of individual tables across a file system according to rules which you can set largely as needed. In effect, different portions of a table are stored as separate tables in different locations. The user-selected rule by which the division of data is accomplished is known as a *partitioning function*, which in MySQL can be the modulus, simple matching against a set of ranges or value lists, an internal hashing function, or a linear hashing function. The function is selected according to the partitioning type specified by the user, and takes as its parameter the value of a user-supplied expression. This expression can be a column value, a function acting on one or more column values, or a set of one or more column values, depending on the type of partitioning that is used.

In the case of [RANGE](#), [LIST](#), and [\[LINEAR\] HASH](#) partitioning, the value of the partitioning column is passed to the partitioning function, which returns an integer value representing the number of the partition in which that particular record should be stored. This function must be nonconstant and nonrandom. It may not contain any queries, but may use an SQL expression that is valid in MySQL, as long as that expression returns either [NULL](#) or an integer *intval* such that

```
-MAXVALUE <= intval <= MAXVALUE
```

([MAXVALUE](#) is used to represent the least upper bound for the type of integer in question. [-MAXVALUE](#) represents the greatest lower bound.)

For [\[LINEAR\] KEY](#), [RANGE COLUMNS](#), and [LIST COLUMNS](#) partitioning, the partitioning expression consists of a list of one or more columns.

For [\[LINEAR\] KEY](#) partitioning, the partitioning function is supplied by MySQL.

For more information about permitted partitioning column types and partitioning functions, see [Section 21.2, “Partitioning Types”](#), as well as [Section 14.1.18, “CREATE TABLE Syntax”](#), which provides partitioning syntax descriptions and additional examples. For information about restrictions on partitioning functions, see [Section 21.6.3, “Partitioning Limitations Relating to Functions”](#).

This is known as *horizontal partitioning*—that is, different rows of a table may be assigned to different physical partitions. MySQL 5.7 does not support *vertical partitioning*, in which different columns of a table are assigned to different physical partitions. There are no plans at this time to introduce vertical partitioning into MySQL.

For information about determining whether your MySQL Server binary supports user-defined partitioning, see [Chapter 21, Partitioning](#).

For creating partitioned tables, you can use most storage engines that are supported by your MySQL server; the MySQL partitioning engine runs in a separate layer and can interact with any of these. In MySQL 5.7, all partitions of the same partitioned table must use the same storage engine; for example, you cannot use [MyISAM](#) for one partition and [InnoDB](#) for another. However, there is nothing preventing you from using different storage engines for different partitioned tables on the same MySQL server or even in the same database.

MySQL partitioning cannot be used with the [MERGE](#), [CSV](#), or [FEDERATED](#) storage engines.

Partitioning by [KEY](#) or [LINEAR KEY](#) is possible with [NDB](#), but other types of user-defined partitioning are not supported for tables using this storage engine. In addition, an [NDB](#) table that employs user-defined partitioning must have an explicit primary key, and any columns referenced in the table's partitioning expression must be part of the primary key. However, if no columns are listed in the [PARTITION BY KEY](#) or [PARTITION BY LINEAR KEY](#) clause of the [CREATE TABLE](#) or [ALTER TABLE](#) statement used to create or modify a user-partitioned [NDB](#) table, then the table is not required to have an explicit primary key. For more information, see [Section 20.1.6.1, “Noncompliance with SQL Syntax in NDB Cluster”](#).

To employ a particular storage engine for a partitioned table, it is necessary only to use the [\[STORAGE\] ENGINE](#) option just as you would for a nonpartitioned table. However, you should keep

in mind that `[STORAGE] ENGINE` (and other table options) need to be listed *before* any partitioning options are used in a `CREATE TABLE` statement. This example shows how to create a table that is partitioned by hash into 6 partitions and which uses the `InnoDB` storage engine:

```
CREATE TABLE ti (id INT, amount DECIMAL(7,2), tr_date DATE)
ENGINE=INNODB
PARTITION BY HASH( MONTH(tr_date) )
PARTITIONS 6;
```

Each `PARTITION` clause can include a `[STORAGE] ENGINE` option, but in MySQL 5.7 this has no effect.

### Important

Partitioning applies to all data and indexes of a table; you cannot partition only the data and not the indexes, or vice versa, nor can you partition only a portion of the table.

Data and indexes for each partition can be assigned to a specific directory using the `DATA DIRECTORY` and `INDEX DIRECTORY` options for the `PARTITION` clause of the `CREATE TABLE` statement used to create the partitioned table.

`DATA DIRECTORY` and `INDEX DIRECTORY` are not supported for individual partitions or subpartitions of `MyISAM` tables on Windows. They are supported for individual partitions and subpartitions of `InnoDB` tables (as on all platforms).

All columns used in the table's partitioning expression must be part of every unique key that the table may have, including any primary key. This means that a table such as this one, created by the following SQL statement, cannot be partitioned:

```
CREATE TABLE tnp (
  id INT NOT NULL AUTO_INCREMENT,
  ref BIGINT NOT NULL,
  name VARCHAR(255),
  PRIMARY KEY pk (id),
  UNIQUE KEY uk (name)
);
```

Because the keys `pk` and `uk` have no columns in common, there are no columns available for use in a partitioning expression. Possible workarounds in this situation include adding the `name` column to the table's primary key, adding the `id` column to `uk`, or simply removing the unique key altogether. See [Section 21.6.1, “Partitioning Keys, Primary Keys, and Unique Keys”](#), for more information.

In addition, `MAX_ROWS` and `MIN_ROWS` can be used to determine the maximum and minimum numbers of rows, respectively, that can be stored in each partition. See [Section 21.3, “Partition Management”](#), for more information on these options.

The `MAX_ROWS` option can also be useful for creating MySQL Cluster tables with extra partitions, thus allowing for greater storage of hash indexes. See the documentation for the `DataMemory` data node configuration parameter, as well as [Section 20.1.2, “NDB Cluster Nodes, Node Groups, Replicas, and Partitions”](#), for more information.

Some advantages of partitioning are listed here:

- Partitioning makes it possible to store more data in one table than can be held on a single disk or file system partition.
- Data that loses its usefulness can often be easily removed from a partitioned table by dropping the partition (or partitions) containing only that data. Conversely, the process of adding new data can in some cases be greatly facilitated by adding one or more new partitions for storing specifically that data.

- Some queries can be greatly optimized in virtue of the fact that data satisfying a given `WHERE` clause can be stored only on one or more partitions, which automatically excludes any remaining partitions from the search. Because partitions can be altered after a partitioned table has been created, you can reorganize your data to enhance frequent queries that may not have been often used when the partitioning scheme was first set up. This ability to exclude non-matching partitions (and thus any rows they contain) is often referred to as *partition pruning*. For more information, see [Section 21.4, “Partition Pruning”](#).

In addition, MySQL 5.7 supports explicit partition selection for queries. For example, `SELECT * FROM t PARTITION (p0,p1) WHERE c < 5` selects only those rows in partitions `p0` and `p1` that match the `WHERE` condition. In this case, MySQL does not check any other partitions of table `t`; this can greatly speed up queries when you already know which partition or partitions you wish to examine. Partition selection is also supported for the data modification statements `DELETE`, `INSERT`, `REPLACE`, `UPDATE`, and `LOAD DATA`, `LOAD XML`. See the descriptions of these statements for more information and examples.

Other benefits usually associated with partitioning include those in the following list. These features are not currently implemented in MySQL Partitioning, but are high on our list of priorities.

- Queries involving aggregate functions such as `SUM()` and `COUNT()` can easily be parallelized. A simple example of such a query might be `SELECT salesperson_id, COUNT(orders) as order_total FROM sales GROUP BY salesperson_id`. By “parallelized,” we mean that the query can be run simultaneously on each partition, and the final result obtained merely by summing the results obtained for all partitions.
- Achieving greater query throughput in virtue of spreading data seeks over multiple disks.

Be sure to check this section and chapter frequently for updates as MySQL Partitioning development continues.

## 21.2 Partitioning Types

This section discusses the types of partitioning which are available in MySQL 5.7. These include the types listed here:

- **RANGE partitioning.** This type of partitioning assigns rows to partitions based on column values falling within a given range. See [Section 21.2.1, “RANGE Partitioning”](#). For information about an extension to this type, `RANGE COLUMNS`, see [Section 21.2.3.1, “RANGE COLUMNS partitioning”](#).
- **LIST partitioning.** Similar to partitioning by `RANGE`, except that the partition is selected based on columns matching one of a set of discrete values. See [Section 21.2.2, “LIST Partitioning”](#). For information about an extension to this type, `LIST COLUMNS`, see [Section 21.2.3.2, “LIST COLUMNS partitioning”](#).
- **HASH partitioning.** With this type of partitioning, a partition is selected based on the value returned by a user-defined expression that operates on column values in rows to be inserted into the table. The function may consist of any expression valid in MySQL that yields a nonnegative integer value. An extension to this type, `LINEAR HASH`, is also available. See [Section 21.2.4, “HASH Partitioning”](#).
- **KEY partitioning.** This type of partitioning is similar to partitioning by `HASH`, except that only one or more columns to be evaluated are supplied, and the MySQL server provides its own hashing function. These columns can contain other than integer values, since the hashing function supplied by MySQL guarantees an integer result regardless of the column data type. An extension to this type, `LINEAR KEY`, is also available. See [Section 21.2.5, “KEY Partitioning”](#).

A very common use of database partitioning is to segregate data by date. Some database systems support explicit date partitioning, which MySQL does not implement in 5.7. However, it is not difficult

in MySQL to create partitioning schemes based on [DATE](#), [TIME](#), or [DATETIME](#) columns, or based on expressions making use of such columns.

When partitioning by [KEY](#) or [LINEAR KEY](#), you can use a [DATE](#), [TIME](#), or [DATETIME](#) column as the partitioning column without performing any modification of the column value. For example, this table creation statement is perfectly valid in MySQL:

```
CREATE TABLE members (  
    firstname VARCHAR(25) NOT NULL,  
    lastname VARCHAR(25) NOT NULL,  
    username VARCHAR(16) NOT NULL,  
    email VARCHAR(35),  
    joined DATE NOT NULL  
)  
PARTITION BY KEY(joined)  
PARTITIONS 6;
```

In MySQL 5.7, it is also possible to use a [DATE](#) or [DATETIME](#) column as the partitioning column using [RANGE COLUMNS](#) and [LIST COLUMNS](#) partitioning.

MySQL's other partitioning types, however, require a partitioning expression that yields an integer value or [NULL](#). If you wish to use date-based partitioning by [RANGE](#), [LIST](#), [HASH](#), or [LINEAR HASH](#), you can simply employ a function that operates on a [DATE](#), [TIME](#), or [DATETIME](#) column and returns such a value, as shown here:

```
CREATE TABLE members (  
    firstname VARCHAR(25) NOT NULL,  
    lastname VARCHAR(25) NOT NULL,  
    username VARCHAR(16) NOT NULL,  
    email VARCHAR(35),  
    joined DATE NOT NULL  
)  
PARTITION BY RANGE( YEAR(joined) ) (  
    PARTITION p0 VALUES LESS THAN (1960),  
    PARTITION p1 VALUES LESS THAN (1970),  
    PARTITION p2 VALUES LESS THAN (1980),  
    PARTITION p3 VALUES LESS THAN (1990),  
    PARTITION p4 VALUES LESS THAN MAXVALUE  
);
```

Additional examples of partitioning using dates may be found in the following sections of this chapter:

- [Section 21.2.1, “RANGE Partitioning”](#)
- [Section 21.2.4, “HASH Partitioning”](#)
- [Section 21.2.4.1, “LINEAR HASH Partitioning”](#)

For more complex examples of date-based partitioning, see the following sections:

- [Section 21.4, “Partition Pruning”](#)
- [Section 21.2.6, “Subpartitioning”](#)

MySQL partitioning is optimized for use with the [TO\\_DAYS\(\)](#), [YEAR\(\)](#), and [TO\\_SECONDS\(\)](#) functions. However, you can use other date and time functions that return an integer or [NULL](#), such as [WEEKDAY\(\)](#), [DAYOFYEAR\(\)](#), or [MONTH\(\)](#). See [Section 13.7, “Date and Time Functions”](#), for more information about such functions.

It is important to remember—regardless of the type of partitioning that you use—that partitions are always numbered automatically and in sequence when created, starting with 0. When a new row is inserted into a partitioned table, it is these partition numbers that are used in identifying the correct partition. For example, if your table uses 4 partitions, these partitions are numbered 0, 1, 2, and 3. For the [RANGE](#) and [LIST](#) partitioning types, it is necessary to ensure that there is a partition defined for

each partition number. For [HASH](#) partitioning, the user-supplied expression must evaluate to an integer value greater than 0. For [KEY](#) partitioning, this issue is taken care of automatically by the hashing function which the MySQL server employs internally.

Names of partitions generally follow the rules governing other MySQL identifiers, such as those for tables and databases. However, you should note that partition names are not case-sensitive. For example, the following [CREATE TABLE](#) statement fails as shown:

```
mysql> CREATE TABLE t2 (val INT)
-> PARTITION BY LIST(val)(
->     PARTITION mypart VALUES IN (1,3,5),
->     PARTITION MyPart VALUES IN (2,4,6)
-> );
ERROR 1488 (HY000): Duplicate partition name mypart
```

Failure occurs because MySQL sees no difference between the partition names `mypart` and `MyPart`.

When you specify the number of partitions for the table, this must be expressed as a positive, nonzero integer literal with no leading zeros, and may not be an expression such as `0.8E+01` or `6-2`, even if it evaluates to an integer value. Decimal fractions are not permitted.

In the sections that follow, we do not necessarily provide all possible forms for the syntax that can be used for creating each partition type; this information may be found in [Section 14.1.18, "CREATE TABLE Syntax"](#).

## 21.2.1 RANGE Partitioning

A table that is partitioned by range is partitioned in such a way that each partition contains rows for which the partitioning expression value lies within a given range. Ranges should be contiguous but not overlapping, and are defined using the [VALUES LESS THAN](#) operator. For the next few examples, suppose that you are creating a table such as the following to hold personnel records for a chain of 20 video stores, numbered 1 through 20:

```
CREATE TABLE employees (
  id INT NOT NULL,
  fname VARCHAR(30),
  lname VARCHAR(30),
  hired DATE NOT NULL DEFAULT '1970-01-01',
  separated DATE NOT NULL DEFAULT '9999-12-31',
  job_code INT NOT NULL,
  store_id INT NOT NULL
);
```

### Note

The `employees` table used here has no primary or unique keys. While the examples work as shown for purposes of the present discussion, you should keep in mind that tables are extremely likely in practice to have primary keys, unique keys, or both, and that allowable choices for partitioning columns depend on the columns used for these keys, if any are present. For a discussion of these issues, see [Section 21.6.1, "Partitioning Keys, Primary Keys, and Unique Keys"](#).

This table can be partitioned by range in a number of ways, depending on your needs. One way would be to use the `store_id` column. For instance, you might decide to partition the table 4 ways by adding a [PARTITION BY RANGE](#) clause as shown here:

```
CREATE TABLE employees (
  id INT NOT NULL,
  fname VARCHAR(30),
  lname VARCHAR(30),
```

```

        hired DATE NOT NULL DEFAULT '1970-01-01',
        separated DATE NOT NULL DEFAULT '9999-12-31',
        job_code INT NOT NULL,
        store_id INT NOT NULL
    )
    PARTITION BY RANGE (store_id) (
        PARTITION p0 VALUES LESS THAN (6),
        PARTITION p1 VALUES LESS THAN (11),
        PARTITION p2 VALUES LESS THAN (16),
        PARTITION p3 VALUES LESS THAN (21)
    );

```

In this partitioning scheme, all rows corresponding to employees working at stores 1 through 5 are stored in partition `p0`, to those employed at stores 6 through 10 are stored in partition `p1`, and so on. Note that each partition is defined in order, from lowest to highest. This is a requirement of the `PARTITION BY RANGE` syntax; you can think of it as being analogous to a series of `if ... elseif ...` statements in C or Java in this regard.

It is easy to determine that a new row containing the data (72, 'Mitchell', 'Wilson', '1998-06-25', NULL, 13) is inserted into partition `p2`, but what happens when your chain adds a 21<sup>st</sup> store? Under this scheme, there is no rule that covers a row whose `store_id` is greater than 20, so an error results because the server does not know where to place it. You can keep this from occurring by using a “catchall” `VALUES LESS THAN` clause in the `CREATE TABLE` statement that provides for all values greater than the highest value explicitly named:

```

CREATE TABLE employees (
    id INT NOT NULL,
    fname VARCHAR(30),
    lname VARCHAR(30),
    hired DATE NOT NULL DEFAULT '1970-01-01',
    separated DATE NOT NULL DEFAULT '9999-12-31',
    job_code INT NOT NULL,
    store_id INT NOT NULL
)
PARTITION BY RANGE (store_id) (
    PARTITION p0 VALUES LESS THAN (6),
    PARTITION p1 VALUES LESS THAN (11),
    PARTITION p2 VALUES LESS THAN (16),
    PARTITION p3 VALUES LESS THAN MAXVALUE
);

```

### Note

Another way to avoid an error when no matching value is found is to use the `IGNORE` keyword as part of the `INSERT` statement. For an example, see [Section 21.2.2, “LIST Partitioning”](#). Also see [Section 14.2.5, “INSERT Syntax”](#), for general information about `IGNORE`.

`MAXVALUE` represents an integer value that is always greater than the largest possible integer value (in mathematical language, it serves as a *least upper bound*). Now, any rows whose `store_id` column value is greater than or equal to 16 (the highest value defined) are stored in partition `p3`. At some point in the future—when the number of stores has increased to 25, 30, or more—you can use an `ALTER TABLE` statement to add new partitions for stores 21-25, 26-30, and so on (see [Section 21.3, “Partition Management”](#), for details of how to do this).

In much the same fashion, you could partition the table based on employee job codes—that is, based on ranges of `job_code` column values. For example—assuming that two-digit job codes are used for regular (in-store) workers, three-digit codes are used for office and support personnel, and four-digit codes are used for management positions—you could create the partitioned table using the following statement:

```

CREATE TABLE employees (
    id INT NOT NULL,
    fname VARCHAR(30),

```

```

    lname VARCHAR(30),
    hired DATE NOT NULL DEFAULT '1970-01-01',
    separated DATE NOT NULL DEFAULT '9999-12-31',
    job_code INT NOT NULL,
    store_id INT NOT NULL
)
PARTITION BY RANGE (job_code) (
    PARTITION p0 VALUES LESS THAN (100),
    PARTITION p1 VALUES LESS THAN (1000),
    PARTITION p2 VALUES LESS THAN (10000)
);

```

In this instance, all rows relating to in-store workers would be stored in partition **p0**, those relating to office and support staff in **p1**, and those relating to managers in partition **p2**.

It is also possible to use an expression in **VALUES LESS THAN** clauses. However, MySQL must be able to evaluate the expression's return value as part of a **LESS THAN (<)** comparison.

Rather than splitting up the table data according to store number, you can use an expression based on one of the two **DATE** columns instead. For example, let us suppose that you wish to partition based on the year that each employee left the company; that is, the value of **YEAR(separated)**. An example of a **CREATE TABLE** statement that implements such a partitioning scheme is shown here:

```

CREATE TABLE employees (
    id INT NOT NULL,
    fname VARCHAR(30),
    lname VARCHAR(30),
    hired DATE NOT NULL DEFAULT '1970-01-01',
    separated DATE NOT NULL DEFAULT '9999-12-31',
    job_code INT,
    store_id INT
)
PARTITION BY RANGE ( YEAR(separated) ) (
    PARTITION p0 VALUES LESS THAN (1991),
    PARTITION p1 VALUES LESS THAN (1996),
    PARTITION p2 VALUES LESS THAN (2001),
    PARTITION p3 VALUES LESS THAN MAXVALUE
);

```

In this scheme, for all employees who left before 1991, the rows are stored in partition **p0**; for those who left in the years 1991 through 1995, in **p1**; for those who left in the years 1996 through 2000, in **p2**; and for any workers who left after the year 2000, in **p3**.

It is also possible to partition a table by **RANGE**, based on the value of a **TIMESTAMP** column, using the **UNIX\_TIMESTAMP( )** function, as shown in this example:

```

CREATE TABLE quarterly_report_status (
    report_id INT NOT NULL,
    report_status VARCHAR(20) NOT NULL,
    report_updated TIMESTAMP NOT NULL DEFAULT CURRENT_TIMESTAMP ON UPDATE CURRENT_TIMESTAMP
)
PARTITION BY RANGE ( UNIX_TIMESTAMP(report_updated) ) (
    PARTITION p0 VALUES LESS THAN ( UNIX_TIMESTAMP('2008-01-01 00:00:00') ),
    PARTITION p1 VALUES LESS THAN ( UNIX_TIMESTAMP('2008-04-01 00:00:00') ),
    PARTITION p2 VALUES LESS THAN ( UNIX_TIMESTAMP('2008-07-01 00:00:00') ),
    PARTITION p3 VALUES LESS THAN ( UNIX_TIMESTAMP('2008-10-01 00:00:00') ),
    PARTITION p4 VALUES LESS THAN ( UNIX_TIMESTAMP('2009-01-01 00:00:00') ),
    PARTITION p5 VALUES LESS THAN ( UNIX_TIMESTAMP('2009-04-01 00:00:00') ),
    PARTITION p6 VALUES LESS THAN ( UNIX_TIMESTAMP('2009-07-01 00:00:00') ),
    PARTITION p7 VALUES LESS THAN ( UNIX_TIMESTAMP('2009-10-01 00:00:00') ),
    PARTITION p8 VALUES LESS THAN ( UNIX_TIMESTAMP('2010-01-01 00:00:00') ),
    PARTITION p9 VALUES LESS THAN (MAXVALUE)
);

```

Any other expressions involving **TIMESTAMP** values are not permitted. (See Bug #42849.)

Range partitioning is particularly useful when one or more of the following conditions is true:

- You want or need to delete “old” data. If you are using the partitioning scheme shown previously for the `employees` table, you can simply use `ALTER TABLE employees DROP PARTITION p0;` to delete all rows relating to employees who stopped working for the firm prior to 1991. (See [Section 14.1.8, “ALTER TABLE Syntax”](#), and [Section 21.3, “Partition Management”](#), for more information.) For a table with a great many rows, this can be much more efficient than running a `DELETE` query such as `DELETE FROM employees WHERE YEAR(separated) <= 1990;`.
- You want to use a column containing date or time values, or containing values arising from some other series.
- You frequently run queries that depend directly on the column used for partitioning the table. For example, when executing a query such as `EXPLAIN PARTITIONS SELECT COUNT(*) FROM employees WHERE separated BETWEEN '2000-01-01' AND '2000-12-31' GROUP BY store_id;`, MySQL can quickly determine that only partition `p2` needs to be scanned because the remaining partitions cannot contain any records satisfying the `WHERE` clause. See [Section 21.4, “Partition Pruning”](#), for more information about how this is accomplished.

A variant on this type of partitioning is `RANGE COLUMNS` partitioning. Partitioning by `RANGE COLUMNS` makes it possible to employ multiple columns for defining partitioning ranges that apply both to placement of rows in partitions and for determining the inclusion or exclusion of specific partitions when performing partition pruning. See [Section 21.2.3.1, “RANGE COLUMNS partitioning”](#), for more information.

**Partitioning schemes based on time intervals.** If you wish to implement a partitioning scheme based on ranges or intervals of time in MySQL 5.7, you have two options:

1. Partition the table by `RANGE`, and for the partitioning expression, employ a function operating on a `DATE`, `TIME`, or `DATETIME` column and returning an integer value, as shown here:

```
CREATE TABLE members (
  firstname VARCHAR(25) NOT NULL,
  lastname VARCHAR(25) NOT NULL,
  username VARCHAR(16) NOT NULL,
  email VARCHAR(35),
  joined DATE NOT NULL
)
PARTITION BY RANGE( YEAR(joined) ) (
  PARTITION p0 VALUES LESS THAN (1960),
  PARTITION p1 VALUES LESS THAN (1970),
  PARTITION p2 VALUES LESS THAN (1980),
  PARTITION p3 VALUES LESS THAN (1990),
  PARTITION p4 VALUES LESS THAN MAXVALUE
);
```

In MySQL 5.7, it is also possible to partition a table by `RANGE` based on the value of a `TIMESTAMP` column, using the `UNIX_TIMESTAMP()` function, as shown in this example:

```
CREATE TABLE quarterly_report_status (
  report_id INT NOT NULL,
  report_status VARCHAR(20) NOT NULL,
  report_updated TIMESTAMP NOT NULL DEFAULT CURRENT_TIMESTAMP ON UPDATE CURRENT_TIMESTAMP
)
PARTITION BY RANGE ( UNIX_TIMESTAMP(report_updated) ) (
  PARTITION p0 VALUES LESS THAN ( UNIX_TIMESTAMP('2008-01-01 00:00:00') ),
  PARTITION p1 VALUES LESS THAN ( UNIX_TIMESTAMP('2008-04-01 00:00:00') ),
  PARTITION p2 VALUES LESS THAN ( UNIX_TIMESTAMP('2008-07-01 00:00:00') ),
  PARTITION p3 VALUES LESS THAN ( UNIX_TIMESTAMP('2008-10-01 00:00:00') ),
  PARTITION p4 VALUES LESS THAN ( UNIX_TIMESTAMP('2009-01-01 00:00:00') ),
  PARTITION p5 VALUES LESS THAN ( UNIX_TIMESTAMP('2009-04-01 00:00:00') ),
  PARTITION p6 VALUES LESS THAN ( UNIX_TIMESTAMP('2009-07-01 00:00:00') ),
  PARTITION p7 VALUES LESS THAN ( UNIX_TIMESTAMP('2009-10-01 00:00:00') ),
  PARTITION p8 VALUES LESS THAN ( UNIX_TIMESTAMP('2010-01-01 00:00:00') ),
  PARTITION p9 VALUES LESS THAN (MAXVALUE)
);
```

In MySQL 5.7, any other expressions involving `TIMESTAMP` values are not permitted. (See Bug #42849.)

#### Note

It is also possible in MySQL 5.7 to use `UNIX_TIMESTAMP(timestamp_column)` as a partitioning expression for tables that are partitioned by `LIST`. However, it is usually not practical to do so.

2. Partition the table by `RANGE COLUMNS`, using a `DATE` or `DATETIME` column as the partitioning column. For example, the `members` table could be defined using the `joined` column directly, as shown here:

```
CREATE TABLE members (
  firstname VARCHAR(25) NOT NULL,
  lastname VARCHAR(25) NOT NULL,
  username VARCHAR(16) NOT NULL,
  email VARCHAR(35),
  joined DATE NOT NULL
)
PARTITION BY RANGE COLUMNS(joined) (
  PARTITION p0 VALUES LESS THAN ('1960-01-01'),
  PARTITION p1 VALUES LESS THAN ('1970-01-01'),
  PARTITION p2 VALUES LESS THAN ('1980-01-01'),
  PARTITION p3 VALUES LESS THAN ('1990-01-01'),
  PARTITION p4 VALUES LESS THAN MAXVALUE
);
```

#### Note

The use of partitioning columns employing date or time types other than `DATE` or `DATETIME` is not supported with `RANGE COLUMNS`.

## 21.2.2 LIST Partitioning

List partitioning in MySQL is similar to range partitioning in many ways. As in partitioning by `RANGE`, each partition must be explicitly defined. The chief difference between the two types of partitioning is that, in list partitioning, each partition is defined and selected based on the membership of a column value in one of a set of value lists, rather than in one of a set of contiguous ranges of values. This is done by using `PARTITION BY LIST(expr)` where `expr` is a column value or an expression based on a column value and returning an integer value, and then defining each partition by means of a `VALUES IN (value_list)`, where `value_list` is a comma-separated list of integers.

#### Note

In MySQL 5.7, it is possible to match against only a list of integers (and possibly `NULL`—see Section 21.2.7, “How MySQL Partitioning Handles `NULL`”) when partitioning by `LIST`.

However, other column types may be used in value lists when employing `LIST COLUMN` partitioning, which is described later in this section.

Unlike the case with partitions defined by range, list partitions do not need to be declared in any particular order. For more detailed syntactical information, see Section 14.1.18, “`CREATE TABLE Syntax`”.

For the examples that follow, we assume that the basic definition of the table to be partitioned is provided by the `CREATE TABLE` statement shown here:

```
CREATE TABLE employees (
```

```

    id INT NOT NULL,
    fname VARCHAR(30),
    lname VARCHAR(30),
    hired DATE NOT NULL DEFAULT '1970-01-01',
    separated DATE NOT NULL DEFAULT '9999-12-31',
    job_code INT,
    store_id INT
);

```

(This is the same table used as a basis for the examples in [Section 21.2.1, “RANGE Partitioning”](#).)

Suppose that there are 20 video stores distributed among 4 franchises as shown in the following table.

| Region  | Store ID Numbers     |
|---------|----------------------|
| North   | 3, 5, 6, 9, 17       |
| East    | 1, 2, 10, 11, 19, 20 |
| West    | 4, 12, 13, 14, 18    |
| Central | 7, 8, 15, 16         |

To partition this table in such a way that rows for stores belonging to the same region are stored in the same partition, you could use the `CREATE TABLE` statement shown here:

```

CREATE TABLE employees (
    id INT NOT NULL,
    fname VARCHAR(30),
    lname VARCHAR(30),
    hired DATE NOT NULL DEFAULT '1970-01-01',
    separated DATE NOT NULL DEFAULT '9999-12-31',
    job_code INT,
    store_id INT
)
PARTITION BY LIST(store_id) (
    PARTITION pNorth VALUES IN (3,5,6,9,17),
    PARTITION pEast VALUES IN (1,2,10,11,19,20),
    PARTITION pWest VALUES IN (4,12,13,14,18),
    PARTITION pCentral VALUES IN (7,8,15,16)
);

```

This makes it easy to add or drop employee records relating to specific regions to or from the table. For instance, suppose that all stores in the West region are sold to another company. In MySQL 5.7, all rows relating to employees working at stores in that region can be deleted with the query `ALTER TABLE employees TRUNCATE PARTITION pWest`, which can be executed much more efficiently than the equivalent `DELETE FROM employees WHERE store_id IN (4,12,13,14,18);`. (Using `ALTER TABLE employees DROP PARTITION pWest` would also delete all of these rows, but would also remove the partition `pWest` from the definition of the table; you would need to use an `ALTER TABLE ... ADD PARTITION` statement to restore the table's original partitioning scheme.)

As with [RANGE](#) partitioning, it is possible to combine [LIST](#) partitioning with partitioning by hash or key to produce a composite partitioning (subpartitioning). See [Section 21.2.6, “Subpartitioning”](#).

Unlike the case with [RANGE](#) partitioning, there is no “catch-all” such as `MAXVALUE`; all expected values for the partitioning expression should be covered in `PARTITION ... VALUES IN (...)` clauses. An `INSERT` statement containing an unmatched partitioning column value fails with an error, as shown in this example:

```

mysql> CREATE TABLE h2 (
->   c1 INT,
->   c2 INT
-> )
-> PARTITION BY LIST(c1) (

```

```

-> PARTITION p0 VALUES IN (1, 4, 7),
-> PARTITION p1 VALUES IN (2, 5, 8)
-> );
Query OK, 0 rows affected (0.11 sec)

mysql> INSERT INTO h2 VALUES (3, 5);
ERROR 1525 (HY000): Table has no partition for value 3

```

When inserting multiple rows using a single `INSERT` statement the behavior depends on whether the table uses a transactional storage engine. For an `InnoDB` table, the statement is considered a single transaction, so the presence of any unmatched values causes the statement to fail completely, and no rows are inserted. For a table using a nontransactional storage engine such as `MyISAM`, any rows coming before the row containing the unmatched value are inserted, but any coming after it are not.

You can cause this type of error to be ignored by using the `IGNORE` keyword. If you do so, rows containing unmatched partitioning column values are not inserted, but any rows with matching values *are* inserted, and no errors are reported:

```

mysql> TRUNCATE h2;
Query OK, 1 row affected (0.00 sec)

mysql> SELECT * FROM h2;
Empty set (0.00 sec)

mysql> INSERT IGNORE INTO h2 VALUES (2, 5), (6, 10), (7, 5), (3, 1), (1, 9);
Query OK, 3 rows affected (0.00 sec)
Records: 5  Duplicates: 2  Warnings: 0

mysql> SELECT * FROM h2;
+-----+-----+
| c1    | c2    |
+-----+-----+
| 7     | 5     |
| 1     | 9     |
| 2     | 5     |
+-----+-----+
3 rows in set (0.00 sec)

```

MySQL 5.7 provides support for `LIST COLUMNS` partitioning. This is a variant of `LIST` partitioning that enables you to use columns of types other than integer types for partitioning columns, as well as to use multiple columns as partitioning keys. For more information, see [Section 21.2.3.2, “LIST COLUMNS partitioning”](#).

## 21.2.3 COLUMNS Partitioning

The next two sections discuss *COLUMNS partitioning*, which are variants on `RANGE` and `LIST` partitioning. `COLUMNS` partitioning enables the use of multiple columns in partitioning keys. All of these columns are taken into account both for the purpose of placing rows in partitions and for the determination of which partitions are to be checked for matching rows in partition pruning.

In addition, both `RANGE COLUMNS` partitioning and `LIST COLUMNS` partitioning support the use of non-integer columns for defining value ranges or list members. The permitted data types are shown in the following list:

- All integer types: `TINYINT`, `SMALLINT`, `MEDIUMINT`, `INT (INTEGER)`, and `BIGINT`. (This is the same as with partitioning by `RANGE` and `LIST`.)

Other numeric data types (such as `DECIMAL` or `FLOAT`) are not supported as partitioning columns.

- `DATE` and `DATETIME`.

Columns using other data types relating to dates or times are not supported as partitioning columns.

- The following string types: `CHAR`, `VARCHAR`, `BINARY`, and `VARBINARY`.

`TEXT` and `BLOB` columns are not supported as partitioning columns.

The discussions of `RANGE COLUMNS` and `LIST COLUMNS` partitioning in the next two sections assume that you are already familiar with partitioning based on ranges and lists as supported in MySQL 5.1 and later; for more information about these, see [Section 21.2.1, “RANGE Partitioning”](#), and [Section 21.2.2, “LIST Partitioning”](#), respectively.

### 21.2.3.1 RANGE COLUMNS partitioning

Range columns partitioning is similar to range partitioning, but enables you to define partitions using ranges based on multiple column values. In addition, you can define the ranges using columns of types other than integer types.

`RANGE COLUMNS` partitioning differs significantly from `RANGE` partitioning in the following ways:

- `RANGE COLUMNS` does not accept expressions, only names of columns.
- `RANGE COLUMNS` accepts a list of one or more columns.

`RANGE COLUMNS` partitions are based on comparisons between *tuples* (lists of column values) rather than comparisons between scalar values. Placement of rows in `RANGE COLUMNS` partitions is also based on comparisons between tuples; this is discussed further later in this section.

- `RANGE COLUMNS` partitioning columns are not restricted to integer columns; string, `DATE` and `DATETIME` columns can also be used as partitioning columns. (See [Section 21.2.3, “COLUMNS Partitioning”](#), for details.)

The basic syntax for creating a table partitioned by `RANGE COLUMNS` is shown here:

```
CREATE TABLE table_name
PARTITIONED BY RANGE COLUMNS(column_list) (
    PARTITION partition_name VALUES LESS THAN (value_list)[,
    PARTITION partition_name VALUES LESS THAN (value_list)][,
    ...]
)

column_list:
    column_name[, column_name][, ...]

value_list:
    value[, value][, ...]
```

#### Note

Not all `CREATE TABLE` options that can be used when creating partitioned tables are shown here. For complete information, see [Section 14.1.18, “CREATE TABLE Syntax”](#).

In the syntax just shown, *column\_list* is a list of one or more columns (sometimes called a *partitioning column list*), and *value\_list* is a list of values (that is, it is a *partition definition value list*). A *value\_list* must be supplied for each partition definition, and each *value\_list* must have the same number of values as the *column\_list* has columns. Generally speaking, if you use *N* columns in the `COLUMNS` clause, then each `VALUES LESS THAN` clause must also be supplied with a list of *N* values.

The elements in the partitioning column list and in the value list defining each partition must occur in the same order. In addition, each element in the value list must be of the same data type as the corresponding element in the column list. However, the order of the column names in the partitioning column list and the value lists does not have to be the same as the order of the table column definitions in the main part of the `CREATE TABLE` statement. As with table partitioned by `RANGE`, you can use `MAXVALUE` to represent a value such that any legal value inserted into a given column is always less

than this value. Here is an example of a `CREATE TABLE` statement that helps to illustrate all of these points:

```
mysql> CREATE TABLE rcx (
->     a INT,
->     b INT,
->     c CHAR(3),
->     d INT
-> )
-> PARTITION BY RANGE COLUMNS(a,d,c) (
->     PARTITION p0 VALUES LESS THAN (5,10,'ggg'),
->     PARTITION p1 VALUES LESS THAN (10,20,'mmmm'),
->     PARTITION p2 VALUES LESS THAN (15,30,'sss'),
->     PARTITION p3 VALUES LESS THAN (MAXVALUE,MAXVALUE,MAXVALUE)
-> );
Query OK, 0 rows affected (0.15 sec)
```

Table `rcx` contains the columns `a`, `b`, `c`, `d`. The partitioning column list supplied to the `COLUMNS` clause uses 3 of these columns, in the order `a`, `d`, `c`. Each value list used to define a partition contains 3 values in the same order; that is, each value list tuple has the form `(INT, INT, CHAR(3))`, which corresponds to the data types used by columns `a`, `d`, and `c` (in that order).

Placement of rows into partitions is determined by comparing the tuple from a row to be inserted that matches the column list in the `COLUMNS` clause with the tuples used in the `VALUES LESS THAN` clauses to define partitions of the table. Because we are comparing tuples (that is, lists or sets of values) rather than scalar values, the semantics of `VALUES LESS THAN` as used with `RANGE COLUMNS` partitions differs somewhat from the case with simple `RANGE` partitions. In `RANGE` partitioning, a row generating an expression value that is equal to a limiting value in a `VALUES LESS THAN` is never placed in the corresponding partition; however, when using `RANGE COLUMNS` partitioning, it is sometimes possible for a row whose partitioning column list's first element is equal in value to the that of the first element in a `VALUES LESS THAN` value list to be placed in the corresponding partition.

Consider the `RANGE` partitioned table created by this statement:

```
CREATE TABLE r1 (
  a INT,
  b INT
)
PARTITION BY RANGE (a) (
  PARTITION p0 VALUES LESS THAN (5),
  PARTITION p1 VALUES LESS THAN (MAXVALUE)
);
```

If we insert 3 rows into this table such that the column value for `a` is 5 for each row, all 3 rows are stored in partition `p1` because the `a` column value is in each case not less than 5, as we can see by executing the proper query against the `INFORMATION_SCHEMA.PARTITIONS` table:

```
mysql> INSERT INTO r1 VALUES (5,10), (5,11), (5,12);
Query OK, 3 rows affected (0.00 sec)
Records: 3  Duplicates: 0  Warnings: 0

mysql> SELECT PARTITION_NAME, TABLE_ROWS
->     FROM INFORMATION_SCHEMA.PARTITIONS
->     WHERE TABLE_NAME = 'r1';
+-----+-----+
| PARTITION_NAME | TABLE_ROWS |
+-----+-----+
| p0             |            0 |
| p1             |            3 |
+-----+-----+
2 rows in set (0.00 sec)
```

Now consider a similar table `rc1` that uses `RANGE COLUMNS` partitioning with both columns `a` and `b` referenced in the `COLUMNS` clause, created as shown here:

```
CREATE TABLE rc1 (
  a INT,
  b INT
)
PARTITION BY RANGE COLUMNS(a, b) (
  PARTITION p0 VALUES LESS THAN (5, 12),
  PARTITION p3 VALUES LESS THAN (MAXVALUE, MAXVALUE)
);
```

If we insert exactly the same rows into `rc1` as we just inserted into `r1`, the distribution of the rows is quite different:

```
mysql> INSERT INTO rc1 VALUES (5,10), (5,11), (5,12);
Query OK, 3 rows affected (0.00 sec)
Records: 3  Duplicates: 0  Warnings: 0

mysql> SELECT PARTITION_NAME, TABLE_ROWS
       -> FROM INFORMATION_SCHEMA.PARTITIONS
       -> WHERE TABLE_NAME = 'rc1';
+-----+-----+-----+
| TABLE_SCHEMA | PARTITION_NAME | TABLE_ROWS |
+-----+-----+-----+
| p             | p0             |           2 |
| p             | p1             |           1 |
+-----+-----+-----+
2 rows in set (0.00 sec)
```

This is because we are comparing rows rather than scalar values. We can compare the row values inserted with the limiting row value from the `VALUES THAN LESS THAN` clause used to define partition `p0` in table `rc1`, like this:

```
mysql> SELECT (5,10) < (5,12), (5,11) < (5,12), (5,12) < (5,12);
+-----+-----+-----+
| (5,10) < (5,12) | (5,11) < (5,12) | (5,12) < (5,12) |
+-----+-----+-----+
| 1               | 1               | 0               |
+-----+-----+-----+
1 row in set (0.00 sec)
```

The 2 tuples `(5,10)` and `(5,11)` evaluate as less than `(5,12)`, so they are stored in partition `p0`. Since 5 is not less than 5 and 12 is not less than 12, `(5,12)` is considered not less than `(5,12)`, and is stored in partition `p1`.

The `SELECT` statement in the preceding example could also have been written using explicit row constructors, like this:

```
SELECT ROW(5,10) < ROW(5,12), ROW(5,11) < ROW(5,12), ROW(5,12) < ROW(5,12);
```

For more information about the use of row constructors in MySQL, see [Section 14.2.10.5, “Row Subqueries”](#).

For a table partitioned by `RANGE COLUMNS` using only a single partitioning column, the storing of rows in partitions is the same as that of an equivalent table that is partitioned by `RANGE`. The following `CREATE TABLE` statement creates a table partitioned by `RANGE COLUMNS` using 1 partitioning column:

```
CREATE TABLE rx (
  a INT,
  b INT
)
PARTITION BY RANGE COLUMNS (a) (
  PARTITION p0 VALUES LESS THAN (5),
  PARTITION p1 VALUES LESS THAN (MAXVALUE)
);
```

If we insert the rows (5,10), (5,11), and (5,12) into this table, we can see that their placement is the same as it is for the table `r` we created and populated earlier:

```
mysql> INSERT INTO rx VALUES (5,10), (5,11), (5,12);
Query OK, 3 rows affected (0.00 sec)
Records: 3  Duplicates: 0  Warnings: 0

mysql> SELECT PARTITION_NAME, TABLE_ROWS
-> FROM INFORMATION_SCHEMA.PARTITIONS
-> WHERE TABLE_NAME = 'rx';
+-----+-----+-----+
| TABLE_SCHEMA | PARTITION_NAME | TABLE_ROWS |
+-----+-----+-----+
| p             | p0             | 0           |
| p             | p1             | 3           |
+-----+-----+-----+
2 rows in set (0.00 sec)
```

It is also possible to create tables partitioned by `RANGE COLUMNS` where limiting values for one or more columns are repeated in successive partition definitions. You can do this as long as the tuples of column values used to define the partitions are strictly increasing. For example, each of the following `CREATE TABLE` statements is valid:

```
CREATE TABLE rc2 (
  a INT,
  b INT
)
PARTITION BY RANGE COLUMNS(a,b) (
  PARTITION p0 VALUES LESS THAN (0,10),
  PARTITION p1 VALUES LESS THAN (10,20),
  PARTITION p2 VALUES LESS THAN (10,30),
  PARTITION p3 VALUES LESS THAN (MAXVALUE,MAXVALUE)
);

CREATE TABLE rc3 (
  a INT,
  b INT
)
PARTITION BY RANGE COLUMNS(a,b) (
  PARTITION p0 VALUES LESS THAN (0,10),
  PARTITION p1 VALUES LESS THAN (10,20),
  PARTITION p2 VALUES LESS THAN (10,30),
  PARTITION p3 VALUES LESS THAN (10,35),
  PARTITION p4 VALUES LESS THAN (20,40),
  PARTITION p5 VALUES LESS THAN (MAXVALUE,MAXVALUE)
);
```

The following statement also succeeds, even though it might appear at first glance that it would not, since the limiting value of column `b` is 25 for partition `p0` and 20 for partition `p1`, and the limiting value of column `c` is 100 for partition `p1` and 50 for partition `p2`:

```
CREATE TABLE rc4 (
  a INT,
  b INT,
  c INT
)
PARTITION BY RANGE COLUMNS(a,b,c) (
  PARTITION p0 VALUES LESS THAN (0,25,50),
  PARTITION p1 VALUES LESS THAN (10,20,100),
  PARTITION p2 VALUES LESS THAN (10,30,50)
  PARTITION p3 VALUES LESS THAN (MAXVALUE,MAXVALUE,MAXVALUE)
);
```

When designing tables partitioned by `RANGE COLUMNS`, you can always test successive partition definitions by comparing the desired tuples using the `mysql` client, like this:

```
mysql> SELECT (0,25,50) < (10,20,100), (10,20,100) < (10,30,50);
+-----+-----+
| (0,25,50) < (10,20,100) | (10,20,100) < (10,30,50) |
+-----+-----+
| 1 | 1 |
+-----+-----+
1 row in set (0.00 sec)
```

If a `CREATE TABLE` statement contains partition definitions that are not in strictly increasing order, it fails with an error, as shown in this example:

```
mysql> CREATE TABLE rcf (
->   a INT,
->   b INT,
->   c INT
-> )
-> PARTITION BY RANGE COLUMNS(a,b,c) (
->   PARTITION p0 VALUES LESS THAN (0,25,50),
->   PARTITION p1 VALUES LESS THAN (20,20,100),
->   PARTITION p2 VALUES LESS THAN (10,30,50),
->   PARTITION p3 VALUES LESS THAN (MAXVALUE,MAXVALUE,MAXVALUE)
-> );
ERROR 1493 (HY000): VALUES LESS THAN value must be strictly increasing for each partition
```

When you get such an error, you can deduce which partition definitions are invalid by making “less than” comparisons between their column lists. In this case, the problem is with the definition of partition `p2` because the tuple used to define it is not less than the tuple used to define partition `p3`, as shown here:

```
mysql> SELECT (0,25,50) < (20,20,100), (20,20,100) < (10,30,50);
+-----+-----+
| (0,25,50) < (20,20,100) | (20,20,100) < (10,30,50) |
+-----+-----+
| 1 | 0 |
+-----+-----+
1 row in set (0.00 sec)
```

It is also possible for `MAXVALUE` to appear for the same column in more than one `VALUES LESS THAN` clause when using `RANGE COLUMNS`. However, the limiting values for individual columns in successive partition definitions should otherwise be increasing, there should be no more than one partition defined where `MAXVALUE` is used as the upper limit for all column values, and this partition definition should appear last in the list of `PARTITION ... VALUES LESS THAN` clauses. In addition, you cannot use `MAXVALUE` as the limiting value for the first column in more than one partition definition.

As stated previously, it is also possible with `RANGE COLUMNS` partitioning to use non-integer columns as partitioning columns. (See [Section 21.2.3, “COLUMNS Partitioning”](#), for a complete listing of these.) Consider a table named `employees` (which is not partitioned), created using the following statement:

```
CREATE TABLE employees (
  id INT NOT NULL,
  fname VARCHAR(30),
  lname VARCHAR(30),
  hired DATE NOT NULL DEFAULT '1970-01-01',
  separated DATE NOT NULL DEFAULT '9999-12-31',
  job_code INT NOT NULL,
  store_id INT NOT NULL
);
```

Using `RANGE COLUMNS` partitioning, you can create a version of this table that stores each row in one of four partitions based on the employee's last name, like this:

```
CREATE TABLE employees_by_lname (
  id INT NOT NULL,
  fname VARCHAR(30),
```

```

lname VARCHAR(30),
hired DATE NOT NULL DEFAULT '1970-01-01',
separated DATE NOT NULL DEFAULT '9999-12-31',
job_code INT NOT NULL,
store_id INT NOT NULL
)
PARTITION BY RANGE COLUMNS (lname) (
    PARTITION p0 VALUES LESS THAN ('g'),
    PARTITION p1 VALUES LESS THAN ('m'),
    PARTITION p2 VALUES LESS THAN ('t'),
    PARTITION p3 VALUES LESS THAN (MAXVALUE)
);

```

Alternatively, you could cause the `employees` table as created previously to be partitioned using this scheme by executing the following `ALTER TABLE` statement:

```

ALTER TABLE employees PARTITION BY RANGE COLUMNS (lname) (
    PARTITION p0 VALUES LESS THAN ('g'),
    PARTITION p1 VALUES LESS THAN ('m'),
    PARTITION p2 VALUES LESS THAN ('t'),
    PARTITION p3 VALUES LESS THAN (MAXVALUE)
);

```

#### Note

Because different character sets and collations have different sort orders, the character sets and collations in use may effect which partition of a table partitioned by `RANGE COLUMNS` a given row is stored in when using string columns as partitioning columns. In addition, changing the character set or collation for a given database, table, or column after such a table is created may cause changes in how rows are distributed. For example, when using a case-sensitive collation, `'and'` sorts before `'Andersen'`, but when using a collation that is case insensitive, the reverse is true.

For information about how MySQL handles character sets and collations, see [Section 11.1, “Character Set Support”](#).

Similarly, you can cause the `employees` table to be partitioned in such a way that each row is stored in one of several partitions based on the decade in which the corresponding employee was hired using the `ALTER TABLE` statement shown here:

```

ALTER TABLE employees PARTITION BY RANGE COLUMNS (hired) (
    PARTITION p0 VALUES LESS THAN ('1970-01-01'),
    PARTITION p1 VALUES LESS THAN ('1980-01-01'),
    PARTITION p2 VALUES LESS THAN ('1990-01-01'),
    PARTITION p3 VALUES LESS THAN ('2000-01-01'),
    PARTITION p4 VALUES LESS THAN ('2010-01-01'),
    PARTITION p5 VALUES LESS THAN (MAXVALUE)
);

```

See [Section 14.1.18, “CREATE TABLE Syntax”](#), for additional information about `PARTITION BY RANGE COLUMNS` syntax.

### 21.2.3.2 LIST COLUMNS partitioning

MySQL 5.7 provides support for `LIST COLUMNS` partitioning. This is a variant of `LIST` partitioning that enables the use of multiple columns as partition keys, and for columns of data types other than integer types to be used as partitioning columns; you can use string types, `DATE`, and `DATETIME` columns. (For more information about permitted data types for `COLUMNS` partitioning columns, see [Section 21.2.3, “COLUMNS Partitioning”](#).)

Suppose that you have a business that has customers in 12 cities which, for sales and marketing purposes, you organize into 4 regions of 3 cities each as shown in the following table:

| Region | Cities                         |
|--------|--------------------------------|
| 1      | Oskarshamn, Högsby, Mönsterås  |
| 2      | Vimmerby, Hultsfred, Västervik |
| 3      | Nässjö, Eksjö, Vetlanda        |
| 4      | Uppvidinge, Alvesta, Växjö     |

With [LIST COLUMNS](#) partitioning, you can create a table for customer data that assigns a row to any of 4 partitions corresponding to these regions based on the name of the city where a customer resides, as shown here:

```
CREATE TABLE customers_1 (
  first_name VARCHAR(25),
  last_name VARCHAR(25),
  street_1 VARCHAR(30),
  street_2 VARCHAR(30),
  city VARCHAR(15),
  renewal DATE
)
PARTITION BY LIST COLUMNS(city) (
  PARTITION pRegion_1 VALUES IN('Oskarshamn', 'Högsby', 'Mönsterås'),
  PARTITION pRegion_2 VALUES IN('Vimmerby', 'Hultsfred', 'Västervik'),
  PARTITION pRegion_3 VALUES IN('Nässjö', 'Eksjö', 'Vetlanda'),
  PARTITION pRegion_4 VALUES IN('Uppvidinge', 'Alvesta', 'Växjö')
);
```

As with partitioning by [RANGE COLUMNS](#), you do not need to use expressions in the [COLUMNS\(\)](#) clause to convert column values into integers. (In fact, the use of expressions other than column names is not permitted with [COLUMNS\(\)](#).)

It is also possible to use [DATE](#) and [DATETIME](#) columns, as shown in the following example that uses the same name and columns as the `customers_1` table shown previously, but employs [LIST COLUMNS](#) partitioning based on the `renewal` column to store rows in one of 4 partitions depending on the week in February 2010 the customer's account is scheduled to renew:

```
CREATE TABLE customers_2 (
  first_name VARCHAR(25),
  last_name VARCHAR(25),
  street_1 VARCHAR(30),
  street_2 VARCHAR(30),
  city VARCHAR(15),
  renewal DATE
)
PARTITION BY LIST COLUMNS(renewal) (
  PARTITION pWeek_1 VALUES IN('2010-02-01', '2010-02-02', '2010-02-03',
    '2010-02-04', '2010-02-05', '2010-02-06', '2010-02-07'),
  PARTITION pWeek_2 VALUES IN('2010-02-08', '2010-02-09', '2010-02-10',
    '2010-02-11', '2010-02-12', '2010-02-13', '2010-02-14'),
  PARTITION pWeek_3 VALUES IN('2010-02-15', '2010-02-16', '2010-02-17',
    '2010-02-18', '2010-02-19', '2010-02-20', '2010-02-21'),
  PARTITION pWeek_4 VALUES IN('2010-02-22', '2010-02-23', '2010-02-24',
    '2010-02-25', '2010-02-26', '2010-02-27', '2010-02-28')
);
```

This works, but becomes cumbersome to define and maintain if the number of dates involved grows very large; in such cases, it is usually more practical to employ [RANGE](#) or [RANGE COLUMNS](#) partitioning instead. In this case, since the column we wish to use as the partitioning key is a [DATE](#) column, we use [RANGE COLUMNS](#) partitioning, as shown here:

```
CREATE TABLE customers_3 (
  first_name VARCHAR(25),
  last_name VARCHAR(25),
  street_1 VARCHAR(30),
  street_2 VARCHAR(30),
```

```

    city VARCHAR(15),
    renewal DATE
)
PARTITION BY RANGE COLUMNS(renewal) (
    PARTITION pWeek_1 VALUES LESS THAN('2010-02-09'),
    PARTITION pWeek_2 VALUES LESS THAN('2010-02-15'),
    PARTITION pWeek_3 VALUES LESS THAN('2010-02-22'),
    PARTITION pWeek_4 VALUES LESS THAN('2010-03-01')
);

```

See [Section 21.2.3.1, “RANGE COLUMNS partitioning”](#), for more information.

In addition (as with [RANGE COLUMNS](#) partitioning), you can use multiple columns in the [COLUMNS\(\)](#) clause.

See [Section 14.1.18, “CREATE TABLE Syntax”](#), for additional information about [PARTITION BY LIST COLUMNS\(\)](#) syntax.

## 21.2.4 HASH Partitioning

Partitioning by [HASH](#) is used primarily to ensure an even distribution of data among a predetermined number of partitions. With range or list partitioning, you must specify explicitly into which partition a given column value or set of column values is to be stored; with hash partitioning, MySQL takes care of this for you, and you need only specify a column value or expression based on a column value to be hashed and the number of partitions into which the partitioned table is to be divided.

To partition a table using [HASH](#) partitioning, it is necessary to append to the [CREATE TABLE](#) statement a [PARTITION BY HASH \(expr\)](#) clause, where *expr* is an expression that returns an integer. This can simply be the name of a column whose type is one of MySQL's integer types. In addition, you most likely want to follow this with [PARTITIONS num](#), where *num* is a positive integer representing the number of partitions into which the table is to be divided.

### Note

For simplicity, the tables in the examples that follow do not use any keys. You should be aware that, if a table has any unique keys, every column used in the partitioning expression for this table must be part of every unique key, including the primary key. See [Section 21.6.1, “Partitioning Keys, Primary Keys, and Unique Keys”](#), for more information.

The following statement creates a table that uses hashing on the [store\\_id](#) column and is divided into 4 partitions:

```

CREATE TABLE employees (
    id INT NOT NULL,
    fname VARCHAR(30),
    lname VARCHAR(30),
    hired DATE NOT NULL DEFAULT '1970-01-01',
    separated DATE NOT NULL DEFAULT '9999-12-31',
    job_code INT,
    store_id INT
)
PARTITION BY HASH(store_id)
PARTITIONS 4;

```

If you do not include a [PARTITIONS](#) clause, the number of partitions defaults to 1.

Using the [PARTITIONS](#) keyword without a number following it results in a syntax error.

You can also use an SQL expression that returns an integer for *expr*. For instance, you might want to partition based on the year in which an employee was hired. This can be done as shown here:

```

CREATE TABLE employees (

```

```

    id INT NOT NULL,
    fname VARCHAR(30),
    lname VARCHAR(30),
    hired DATE NOT NULL DEFAULT '1970-01-01',
    separated DATE NOT NULL DEFAULT '9999-12-31',
    job_code INT,
    store_id INT
)
PARTITION BY HASH( YEAR(hired) )
PARTITIONS 4;

```

*expr* must return a nonconstant, nonrandom integer value (in other words, it should be varying but deterministic), and must not contain any prohibited constructs as described in [Section 21.6, “Restrictions and Limitations on Partitioning”](#). You should also keep in mind that this expression is evaluated each time a row is inserted or updated (or possibly deleted); this means that very complex expressions may give rise to performance issues, particularly when performing operations (such as batch inserts) that affect a great many rows at one time.

The most efficient hashing function is one which operates upon a single table column and whose value increases or decreases consistently with the column value, as this allows for “pruning” on ranges of partitions. That is, the more closely that the expression varies with the value of the column on which it is based, the more efficiently MySQL can use the expression for hash partitioning.

For example, where *date\_col* is a column of type *DATE*, then the expression *TO\_DAYS(date\_col)* is said to vary directly with the value of *date\_col*, because for every change in the value of *date\_col*, the value of the expression changes in a consistent manner. The variance of the expression *YEAR(date\_col)* with respect to *date\_col* is not quite as direct as that of *TO\_DAYS(date\_col)*, because not every possible change in *date\_col* produces an equivalent change in *YEAR(date\_col)*. Even so, *YEAR(date\_col)* is a good candidate for a hashing function, because it varies directly with a portion of *date\_col* and there is no possible change in *date\_col* that produces a disproportionate change in *YEAR(date\_col)*.

By way of contrast, suppose that you have a column named *int\_col* whose type is *INT*. Now consider the expression *POW(5-int\_col,3) + 6*. This would be a poor choice for a hashing function because a change in the value of *int\_col* is not guaranteed to produce a proportional change in the value of the expression. Changing the value of *int\_col* by a given amount can produce widely differing changes in the value of the expression. For example, changing *int\_col* from 5 to 6 produces a change of -1 in the value of the expression, but changing the value of *int\_col* from 6 to 7 produces a change of -7 in the expression value.

In other words, the more closely the graph of the column value versus the value of the expression follows a straight line as traced by the equation  $y=cx$  where *c* is some nonzero constant, the better the expression is suited to hashing. This has to do with the fact that the more nonlinear an expression is, the more uneven the distribution of data among the partitions it tends to produce.

In theory, pruning is also possible for expressions involving more than one column value, but determining which of such expressions are suitable can be quite difficult and time-consuming. For this reason, the use of hashing expressions involving multiple columns is not particularly recommended.

When *PARTITION BY HASH* is used, MySQL determines which partition of *num* partitions to use based on the modulus of the result of the expression. In other words, for a given expression *expr*, the partition in which the record is stored is partition number *N*, where  $N = \text{MOD}(\text{expr}, \text{num})$ . Suppose that table *t1* is defined as follows, so that it has 4 partitions:

```

CREATE TABLE t1 (col1 INT, col2 CHAR(5), col3 DATE)
PARTITION BY HASH( YEAR(col3) )
PARTITIONS 4;

```

If you insert a record into *t1* whose *col3* value is '2005-09-15', then the partition in which it is stored is determined as follows:

```
MOD(YEAR('2005-09-01'),4)
= MOD(2005,4)
= 1
```

MySQL 5.7 also supports a variant of [HASH](#) partitioning known as *linear hashing* which employs a more complex algorithm for determining the placement of new rows inserted into the partitioned table. See [Section 21.2.4.1, “LINEAR HASH Partitioning”](#), for a description of this algorithm.

The user-supplied expression is evaluated each time a record is inserted or updated. It may also—depending on the circumstances—be evaluated when records are deleted.

### 21.2.4.1 LINEAR HASH Partitioning

MySQL also supports linear hashing, which differs from regular hashing in that linear hashing utilizes a linear powers-of-two algorithm whereas regular hashing employs the modulus of the hashing function's value.

Syntactically, the only difference between linear-hash partitioning and regular hashing is the addition of the [LINEAR](#) keyword in the [PARTITION BY](#) clause, as shown here:

```
CREATE TABLE employees (
  id INT NOT NULL,
  fname VARCHAR(30),
  lname VARCHAR(30),
  hired DATE NOT NULL DEFAULT '1970-01-01',
  separated DATE NOT NULL DEFAULT '9999-12-31',
  job_code INT,
  store_id INT
)
PARTITION BY LINEAR HASH( YEAR(hired) )
PARTITIONS 4;
```

Given an expression *expr*, the partition in which the record is stored when linear hashing is used is partition number *N* from among *num* partitions, where *N* is derived according to the following algorithm:

1. Find the next power of 2 greater than *num*. We call this value *V*; it can be calculated as:

```
V = POWER(2, CEILING(LOG(2, num)))
```

(Suppose that *num* is 13. Then  $\text{LOG}(2, 13)$  is 3.7004397181411.  $\text{CEILING}(3.7004397181411)$  is 4, and  $V = \text{POWER}(2, 4)$ , which is 16.)

2. Set  $N = F(\text{column\_list}) \& (V - 1)$ .
3. While  $N \geq \text{num}$ :
  - Set  $V = V / 2$
  - Set  $N = N \& (V - 1)$

Suppose that the table `t1`, using linear hash partitioning and having 6 partitions, is created using this statement:

```
CREATE TABLE t1 (col1 INT, col2 CHAR(5), col3 DATE)
PARTITION BY LINEAR HASH( YEAR(col3) )
PARTITIONS 6;
```

Now assume that you want to insert two records into `t1` having the `col3` column values '2003-04-14' and '1998-10-19'. The partition number for the first of these is determined as follows:

```
V = POWER(2, CEILING( LOG(2,6) )) = 8
```

```
N = YEAR('2003-04-14') & (8 - 1)
  = 2003 & 7
  = 3

(3 >= 6 is FALSE: record stored in partition #3)
```

The number of the partition where the second record is stored is calculated as shown here:

```
V = 8
N = YEAR('1998-10-19') & (8 - 1)
  = 1998 & 7
  = 6

(6 >= 6 is TRUE: additional step required)

N = 6 & ((8 / 2) - 1)
  = 6 & 3
  = 2

(2 >= 6 is FALSE: record stored in partition #2)
```

The advantage in partitioning by linear hash is that the adding, dropping, merging, and splitting of partitions is made much faster, which can be beneficial when dealing with tables containing extremely large amounts (terabytes) of data. The disadvantage is that data is less likely to be evenly distributed between partitions as compared with the distribution obtained using regular hash partitioning.

## 21.2.5 KEY Partitioning

Partitioning by key is similar to partitioning by hash, except that where hash partitioning employs a user-defined expression, the hashing function for key partitioning is supplied by the MySQL server. MySQL Cluster uses `MD5()` for this purpose; for tables using other storage engines, the server employs its own internal hashing function which is based on the same algorithm as `PASSWORD()`.

The syntax rules for `CREATE TABLE ... PARTITION BY KEY` are similar to those for creating a table that is partitioned by hash. The major differences are listed here:

- `KEY` is used rather than `HASH`.
- `KEY` takes only a list of zero or more column names. Any columns used as the partitioning key must comprise part or all of the table's primary key, if the table has one. Where no column name is specified as the partitioning key, the table's primary key is used, if there is one. For example, the following `CREATE TABLE` statement is valid in MySQL 5.7:

```
CREATE TABLE k1 (
  id INT NOT NULL PRIMARY KEY,
  name VARCHAR(20)
)
PARTITION BY KEY()
PARTITIONS 2;
```

If there is no primary key but there is a unique key, then the unique key is used for the partitioning key:

```
CREATE TABLE k1 (
  id INT NOT NULL,
  name VARCHAR(20),
  UNIQUE KEY (id)
)
PARTITION BY KEY()
PARTITIONS 2;
```

However, if the unique key column were not defined as `NOT NULL`, then the previous statement would fail.

In both of these cases, the partitioning key is the `id` column, even though it is not shown in the output of `SHOW CREATE TABLE` or in the `PARTITION_EXPRESSION` column of the `INFORMATION_SCHEMA.PARTITIONS` table.

Unlike the case with other partitioning types, columns used for partitioning by `KEY` are not restricted to integer or `NULL` values. For example, the following `CREATE TABLE` statement is valid:

```
CREATE TABLE tml (
  s1 CHAR(32) PRIMARY KEY
)
PARTITION BY KEY(s1)
PARTITIONS 10;
```

The preceding statement would *not* be valid, were a different partitioning type to be specified. (In this case, simply using `PARTITION BY KEY()` would also be valid and have the same effect as `PARTITION BY KEY(s1)`, since `s1` is the table's primary key.)

For additional information about this issue, see [Section 21.6, “Restrictions and Limitations on Partitioning”](#).

#### Note

Tables using the `NDB` storage engine are implicitly partitioned by `KEY`, again using the table's primary key as the partitioning key. In the event that the MySQL Cluster table has no explicit primary key, the “hidden” primary key generated by the `NDB` storage engine for each MySQL Cluster table is used as the partitioning key.

If you define an explicit partitioning scheme for an `NDB` table, the table must have an explicit primary key, and any columns used in the partitioning expression must be part of this key. However, if the table uses an “empty” partitioning expression—that is, `PARTITION BY KEY()` with no column references—then no explicit primary key is required.

You can observe this partitioning using the `ndb_desc` utility (with the `-p` option).

#### Important

For a key-partitioned table, you cannot execute an `ALTER TABLE DROP PRIMARY KEY`, as doing so generates the error `ERROR 1466 (HY000): Field in list of fields for partition function not found in table`. This is not an issue for MySQL Cluster tables which are partitioned by `KEY`; in such cases, the table is reorganized using the “hidden” primary key as the table's new partitioning key. See [Chapter 20, MySQL NDB Cluster 7.5](#).

It is also possible to partition a table by linear key. Here is a simple example:

```
CREATE TABLE tk (
  col1 INT NOT NULL,
  col2 CHAR(5),
  col3 DATE
)
PARTITION BY LINEAR KEY (col1)
PARTITIONS 3;
```

Using `LINEAR` has the same effect on `KEY` partitioning as it does on `HASH` partitioning, with the partition number being derived using a powers-of-two algorithm rather than modulo arithmetic. See [Section 21.2.4.1, “LINEAR HASH Partitioning”](#), for a description of this algorithm and its implications.

## 21.2.6 Subpartitioning

Subpartitioning—also known as *composite partitioning*—is the further division of each partition in a partitioned table. Consider the following `CREATE TABLE` statement:

```
CREATE TABLE ts (id INT, purchased DATE)
  PARTITION BY RANGE( YEAR(purchased) )
  SUBPARTITION BY HASH( TO_DAYS(purchased) )
  SUBPARTITIONS 2 (
    PARTITION p0 VALUES LESS THAN (1990),
    PARTITION p1 VALUES LESS THAN (2000),
    PARTITION p2 VALUES LESS THAN MAXVALUE
  );
```

Table `ts` has 3 `RANGE` partitions. Each of these partitions—`p0`, `p1`, and `p2`—is further divided into 2 subpartitions. In effect, the entire table is divided into  $3 * 2 = 6$  partitions. However, due to the action of the `PARTITION BY RANGE` clause, the first 2 of these store only those records with a value less than 1990 in the `purchased` column.

In MySQL 5.7, it is possible to subpartition tables that are partitioned by `RANGE` or `LIST`. Subpartitions may use either `HASH` or `KEY` partitioning. This is also known as *composite partitioning*.

### Note

`SUBPARTITION BY HASH` and `SUBPARTITION BY KEY` generally follow the same syntax rules as `PARTITION BY HASH` and `PARTITION BY KEY`, respectively. An exception to this is that `SUBPARTITION BY KEY` (unlike `PARTITION BY KEY`) does not currently support a default column, so the column used for this purpose must be specified, even if the table has an explicit primary key. This is a known issue which we are working to address; see [Issues with subpartitions](#), for more information and an example.

It is also possible to define subpartitions explicitly using `SUBPARTITION` clauses to specify options for individual subpartitions. For example, a more verbose fashion of creating the same table `ts` as shown in the previous example would be:

```
CREATE TABLE ts (id INT, purchased DATE)
  PARTITION BY RANGE( YEAR(purchased) )
  SUBPARTITION BY HASH( TO_DAYS(purchased) ) (
    PARTITION p0 VALUES LESS THAN (1990) (
      SUBPARTITION s0,
      SUBPARTITION s1
    ),
    PARTITION p1 VALUES LESS THAN (2000) (
      SUBPARTITION s2,
      SUBPARTITION s3
    ),
    PARTITION p2 VALUES LESS THAN MAXVALUE (
      SUBPARTITION s4,
      SUBPARTITION s5
    )
  );
```

Some syntactical items of note are listed here:

- Each partition must have the same number of subpartitions.
- If you explicitly define any subpartitions using `SUBPARTITION` on any partition of a partitioned table, you must define them all. In other words, the following statement will fail:

```
CREATE TABLE ts (id INT, purchased DATE)
  PARTITION BY RANGE( YEAR(purchased) )
```

```
SUBPARTITION BY HASH( TO_DAYS(purchased) ) (
  PARTITION p0 VALUES LESS THAN (1990) (
    SUBPARTITION s0,
    SUBPARTITION s1
  ),
  PARTITION p1 VALUES LESS THAN (2000),
  PARTITION p2 VALUES LESS THAN MAXVALUE (
    SUBPARTITION s2,
    SUBPARTITION s3
  )
);
```

This statement would still fail even if it included a `SUBPARTITIONS 2` clause.

- Each `SUBPARTITION` clause must include (at a minimum) a name for the subpartition. Otherwise, you may set any desired option for the subpartition or allow it to assume its default setting for that option.
- Subpartition names must be unique across the entire table. For example, the following `CREATE TABLE` statement is valid in MySQL 5.7:

```
CREATE TABLE ts (id INT, purchased DATE)
PARTITION BY RANGE( YEAR(purchased) )
SUBPARTITION BY HASH( TO_DAYS(purchased) ) (
  PARTITION p0 VALUES LESS THAN (1990) (
    SUBPARTITION s0,
    SUBPARTITION s1
  ),
  PARTITION p1 VALUES LESS THAN (2000) (
    SUBPARTITION s2,
    SUBPARTITION s3
  ),
  PARTITION p2 VALUES LESS THAN MAXVALUE (
    SUBPARTITION s4,
    SUBPARTITION s5
  )
);
```

Subpartitions can be used with especially large `MyISAM` tables to distribute data and indexes across many disks. Suppose that you have 6 disks mounted as `/disk0`, `/disk1`, `/disk2`, and so on. Now consider the following example:

```
CREATE TABLE ts (id INT, purchased DATE)
ENGINE = MYISAM
PARTITION BY RANGE( YEAR(purchased) )
SUBPARTITION BY HASH( TO_DAYS(purchased) ) (
  PARTITION p0 VALUES LESS THAN (1990) (
    SUBPARTITION s0
      DATA DIRECTORY = '/disk0/data'
      INDEX DIRECTORY = '/disk0/idx',
    SUBPARTITION s1
      DATA DIRECTORY = '/disk1/data'
      INDEX DIRECTORY = '/disk1/idx'
  ),
  PARTITION p1 VALUES LESS THAN (2000) (
    SUBPARTITION s2
      DATA DIRECTORY = '/disk2/data'
      INDEX DIRECTORY = '/disk2/idx',
    SUBPARTITION s3
      DATA DIRECTORY = '/disk3/data'
      INDEX DIRECTORY = '/disk3/idx'
  ),
  PARTITION p2 VALUES LESS THAN MAXVALUE (
    SUBPARTITION s4
      DATA DIRECTORY = '/disk4/data'
      INDEX DIRECTORY = '/disk4/idx',
    SUBPARTITION s5
      DATA DIRECTORY = '/disk5/data'
  )
);
```

```

        INDEX DIRECTORY = '/disk5/idx'
    )
);

```

In this case, a separate disk is used for the data and for the indexes of each [RANGE](#). Many other variations are possible; another example might be:

```

CREATE TABLE ts (id INT, purchased DATE)
ENGINE = MYISAM
PARTITION BY RANGE(YEAR(purchased))
SUBPARTITION BY HASH( TO_DAYS(purchased) ) (
    PARTITION p0 VALUES LESS THAN (1990) (
        SUBPARTITION s0a
            DATA DIRECTORY = '/disk0'
            INDEX DIRECTORY = '/disk1',
        SUBPARTITION s0b
            DATA DIRECTORY = '/disk2'
            INDEX DIRECTORY = '/disk3'
    ),
    PARTITION p1 VALUES LESS THAN (2000) (
        SUBPARTITION s1a
            DATA DIRECTORY = '/disk4/data'
            INDEX DIRECTORY = '/disk4/idx',
        SUBPARTITION s1b
            DATA DIRECTORY = '/disk5/data'
            INDEX DIRECTORY = '/disk5/idx'
    ),
    PARTITION p2 VALUES LESS THAN MAXVALUE (
        SUBPARTITION s2a,
        SUBPARTITION s2b
    )
);

```

Here, the storage is as follows:

- Rows with [purchased](#) dates from before 1990 take up a vast amount of space, so are split up 4 ways, with a separate disk dedicated to the data and to the indexes for each of the two subpartitions ([s0a](#) and [s0b](#)) making up partition [p0](#). In other words:
  - The data for subpartition [s0a](#) is stored on [/disk0](#).
  - The indexes for subpartition [s0a](#) are stored on [/disk1](#).
  - The data for subpartition [s0b](#) is stored on [/disk2](#).
  - The indexes for subpartition [s0b](#) are stored on [/disk3](#).
- Rows containing dates ranging from 1990 to 1999 (partition [p1](#)) do not require as much room as those from before 1990. These are split between 2 disks ([/disk4](#) and [/disk5](#)) rather than 4 disks as with the legacy records stored in [p0](#):
  - Data and indexes belonging to [p1](#)'s first subpartition ([s1a](#)) are stored on [/disk4](#)—the data in [/disk4/data](#), and the indexes in [/disk4/idx](#).
  - Data and indexes belonging to [p1](#)'s second subpartition ([s1b](#)) are stored on [/disk5](#)—the data in [/disk5/data](#), and the indexes in [/disk5/idx](#).
- Rows reflecting dates from the year 2000 to the present (partition [p2](#)) do not take up as much space as required by either of the two previous ranges. Currently, it is sufficient to store all of these in the default location.

In future, when the number of purchases for the decade beginning with the year 2000 grows to a point where the default location no longer provides sufficient space, the corresponding rows can be moved using an `ALTER TABLE ... REORGANIZE PARTITION` statement. See [Section 21.3, “Partition Management”](#), for an explanation of how this can be done.

The `DATA DIRECTORY` and `INDEX DIRECTORY` options are not permitted in partition definitions when the `NO_DIR_IN_CREATE` server SQL mode is in effect. In MySQL 5.7, these options are also not permitted when defining subpartitions (Bug #42954).

## 21.2.7 How MySQL Partitioning Handles NULL

Partitioning in MySQL does nothing to disallow `NULL` as the value of a partitioning expression, whether it is a column value or the value of a user-supplied expression. Even though it is permitted to use `NULL` as the value of an expression that must otherwise yield an integer, it is important to keep in mind that `NULL` is not a number. MySQL's partitioning implementation treats `NULL` as being less than any non-`NULL` value, just as `ORDER BY` does.

This means that treatment of `NULL` varies between partitioning of different types, and may produce behavior which you do not expect if you are not prepared for it. This being the case, we discuss in this section how each MySQL partitioning type handles `NULL` values when determining the partition in which a row should be stored, and provide examples for each.

**Handling of NULL with RANGE partitioning.** If you insert a row into a table partitioned by `RANGE` such that the column value used to determine the partition is `NULL`, the row is inserted into the lowest partition. Consider these two tables in a database named `p`, created as follows:

```
mysql> CREATE TABLE t1 (
->   c1 INT,
->   c2 VARCHAR(20)
-> )
-> PARTITION BY RANGE(c1) (
->   PARTITION p0 VALUES LESS THAN (0),
->   PARTITION p1 VALUES LESS THAN (10),
->   PARTITION p2 VALUES LESS THAN MAXVALUE
-> );
Query OK, 0 rows affected (0.09 sec)

mysql> CREATE TABLE t2 (
->   c1 INT,
->   c2 VARCHAR(20)
-> )
-> PARTITION BY RANGE(c1) (
->   PARTITION p0 VALUES LESS THAN (-5),
->   PARTITION p1 VALUES LESS THAN (0),
->   PARTITION p2 VALUES LESS THAN (10),
->   PARTITION p3 VALUES LESS THAN MAXVALUE
-> );
Query OK, 0 rows affected (0.09 sec)
```

You can see the partitions created by these two `CREATE TABLE` statements using the following query against the `PARTITIONS` table in the `INFORMATION_SCHEMA` database:

```
mysql> SELECT TABLE_NAME, PARTITION_NAME, TABLE_ROWS, AVG_ROW_LENGTH, DATA_LENGTH
> FROM INFORMATION_SCHEMA.PARTITIONS
> WHERE TABLE_SCHEMA = 'p' AND TABLE_NAME LIKE 't_';
+-----+-----+-----+-----+-----+
| TABLE_NAME | PARTITION_NAME | TABLE_ROWS | AVG_ROW_LENGTH | DATA_LENGTH |
+-----+-----+-----+-----+-----+
| t1          | p0              | 0           | 0              | 0            |
| t1          | p1              | 0           | 0              | 0            |
| t1          | p2              | 0           | 0              | 0            |
| t2          | p0              | 0           | 0              | 0            |
| t2          | p1              | 0           | 0              | 0            |
| t2          | p2              | 0           | 0              | 0            |
| t2          | p3              | 0           | 0              | 0            |
+-----+-----+-----+-----+-----+
7 rows in set (0.00 sec)
```

(For more information about this table, see [Section 23.15, “The INFORMATION\\_SCHEMA PARTITIONS Table”](#).) Now let us populate each of these tables with a single row containing a `NULL` in

the column used as the partitioning key, and verify that the rows were inserted using a pair of `SELECT` statements:

```
mysql> INSERT INTO t1 VALUES (NULL, 'mothra');
Query OK, 1 row affected (0.00 sec)

mysql> INSERT INTO t2 VALUES (NULL, 'mothra');
Query OK, 1 row affected (0.00 sec)

mysql> SELECT * FROM t1;
+-----+-----+
| id    | name  |
+-----+-----+
| NULL  | mothra |
+-----+-----+
1 row in set (0.00 sec)

mysql> SELECT * FROM t2;
+-----+-----+
| id    | name  |
+-----+-----+
| NULL  | mothra |
+-----+-----+
1 row in set (0.00 sec)
```

You can see which partitions are used to store the inserted rows by rerunning the previous query against `INFORMATION_SCHEMA.PARTITIONS` and inspecting the output:

```
mysql> SELECT TABLE_NAME, PARTITION_NAME, TABLE_ROWS, AVG_ROW_LENGTH, DATA_LENGTH
> FROM INFORMATION_SCHEMA.PARTITIONS
> WHERE TABLE_SCHEMA = 'p' AND TABLE_NAME LIKE 't_';
+-----+-----+-----+-----+-----+
| TABLE_NAME | PARTITION_NAME | TABLE_ROWS | AVG_ROW_LENGTH | DATA_LENGTH |
+-----+-----+-----+-----+-----+
| t1          | p0             | 1           | 20              | 20           |
| t1          | p1             | 0           | 0               | 0            |
| t1          | p2             | 0           | 0               | 0            |
| t2          | p0             | 1           | 20              | 20           |
| t2          | p1             | 0           | 0               | 0            |
| t2          | p2             | 0           | 0               | 0            |
| t2          | p3             | 0           | 0               | 0            |
+-----+-----+-----+-----+-----+
7 rows in set (0.01 sec)
```

You can also demonstrate that these rows were stored in the lowest partition of each table by dropping these partitions, and then re-running the `SELECT` statements:

```
mysql> ALTER TABLE t1 DROP PARTITION p0;
Query OK, 0 rows affected (0.16 sec)

mysql> ALTER TABLE t2 DROP PARTITION p0;
Query OK, 0 rows affected (0.16 sec)

mysql> SELECT * FROM t1;
Empty set (0.00 sec)

mysql> SELECT * FROM t2;
Empty set (0.00 sec)
```

(For more information on `ALTER TABLE ... DROP PARTITION`, see [Section 14.1.8, “ALTER TABLE Syntax”](#).)

`NULL` is also treated in this way for partitioning expressions that use SQL functions. Suppose that we define a table using a `CREATE TABLE` statement such as this one:

```
CREATE TABLE tndate (
  id INT,
  dt DATE
)
PARTITION BY RANGE( YEAR(dt) ) (
  PARTITION p0 VALUES LESS THAN (1990),
  PARTITION p1 VALUES LESS THAN (2000),
  PARTITION p2 VALUES LESS THAN MAXVALUE
);
```

As with other MySQL functions, `YEAR(NULL)` returns `NULL`. A row with a `dt` column value of `NULL` is treated as though the partitioning expression evaluated to a value less than any other value, and so is inserted into partition `p0`.

**Handling of NULL with LIST partitioning.** A table that is partitioned by `LIST` admits `NULL` values if and only if one of its partitions is defined using that value-list that contains `NULL`. The converse of this is that a table partitioned by `LIST` which does not explicitly use `NULL` in a value list rejects rows resulting in a `NULL` value for the partitioning expression, as shown in this example:

```
mysql> CREATE TABLE ts1 (
->   c1 INT,
->   c2 VARCHAR(20)
-> )
-> PARTITION BY LIST(c1) (
->   PARTITION p0 VALUES IN (0, 3, 6),
->   PARTITION p1 VALUES IN (1, 4, 7),
->   PARTITION p2 VALUES IN (2, 5, 8)
-> );
Query OK, 0 rows affected (0.01 sec)

mysql> INSERT INTO ts1 VALUES (9, 'mothra');
ERROR 1504 (HY000): Table has no partition for value 9

mysql> INSERT INTO ts1 VALUES (NULL, 'mothra');
ERROR 1504 (HY000): Table has no partition for value NULL
```

Only rows having a `c1` value between 0 and 8 inclusive can be inserted into `ts1`. `NULL` falls outside this range, just like the number 9. We can create tables `ts2` and `ts3` having value lists containing `NULL`, as shown here:

```
mysql> CREATE TABLE ts2 (
->   c1 INT,
->   c2 VARCHAR(20)
-> )
-> PARTITION BY LIST(c1) (
->   PARTITION p0 VALUES IN (0, 3, 6),
->   PARTITION p1 VALUES IN (1, 4, 7),
->   PARTITION p2 VALUES IN (2, 5, 8),
->   PARTITION p3 VALUES IN (NULL)
-> );
Query OK, 0 rows affected (0.01 sec)

mysql> CREATE TABLE ts3 (
->   c1 INT,
->   c2 VARCHAR(20)
-> )
-> PARTITION BY LIST(c1) (
->   PARTITION p0 VALUES IN (0, 3, 6),
->   PARTITION p1 VALUES IN (1, 4, 7, NULL),
->   PARTITION p2 VALUES IN (2, 5, 8)
-> );
Query OK, 0 rows affected (0.01 sec)
```

When defining value lists for partitioning, you can (and should) treat `NULL` just as you would any other value. For example, both `VALUES IN (NULL)` and `VALUES IN (1, 4, 7, NULL)` are valid, as are `VALUES IN (1, NULL, 4, 7)`, `VALUES IN (NULL, 1, 4, 7)`, and so on. You can insert a row having `NULL` for column `c1` into each of the tables `ts2` and `ts3`:

```
mysql> INSERT INTO ts2 VALUES (NULL, 'mothra');
Query OK, 1 row affected (0.00 sec)

mysql> INSERT INTO ts3 VALUES (NULL, 'mothra');
Query OK, 1 row affected (0.00 sec)
```

By issuing the appropriate query against `INFORMATION_SCHEMA.PARTITIONS`, you can determine which partitions were used to store the rows just inserted (we assume, as in the previous examples, that the partitioned tables were created in the `p` database):

```
mysql> SELECT TABLE_NAME, PARTITION_NAME, TABLE_ROWS, AVG_ROW_LENGTH, DATA_LENGTH
> FROM INFORMATION_SCHEMA.PARTITIONS
> WHERE TABLE_SCHEMA = 'p' AND TABLE_NAME LIKE 'ts_';
```

| TABLE_NAME | PARTITION_NAME | TABLE_ROWS | AVG_ROW_LENGTH | DATA_LENGTH |
|------------|----------------|------------|----------------|-------------|
| ts2        | p0             | 0          | 0              | 0           |
| ts2        | p1             | 0          | 0              | 0           |
| ts2        | p2             | 0          | 0              | 0           |
| ts2        | p3             | 1          | 20             | 20          |
| ts3        | p0             | 0          | 0              | 0           |
| ts3        | p1             | 1          | 20             | 20          |
| ts3        | p2             | 0          | 0              | 0           |

7 rows in set (0.01 sec)

As shown earlier in this section, you can also verify which partitions were used for storing the rows by deleting these partitions and then performing a `SELECT`.

**Handling of NULL with HASH and KEY partitioning.** `NULL` is handled somewhat differently for tables partitioned by `HASH` or `KEY`. In these cases, any partition expression that yields a `NULL` value is treated as though its return value were zero. We can verify this behavior by examining the effects on the file system of creating a table partitioned by `HASH` and populating it with a record containing appropriate values. Suppose that you have a table `th` (also in the `p` database) created using the following statement:

```
mysql> CREATE TABLE th (
->   c1 INT,
->   c2 VARCHAR(20)
-> )
-> PARTITION BY HASH(c1)
-> PARTITIONS 2;
Query OK, 0 rows affected (0.00 sec)
```

The partitions belonging to this table can be viewed using the query shown here:

```
mysql> SELECT TABLE_NAME, PARTITION_NAME, TABLE_ROWS, AVG_ROW_LENGTH, DATA_LENGTH
> FROM INFORMATION_SCHEMA.PARTITIONS
> WHERE TABLE_SCHEMA = 'p' AND TABLE_NAME = 'th';
```

| TABLE_NAME | PARTITION_NAME | TABLE_ROWS | AVG_ROW_LENGTH | DATA_LENGTH |
|------------|----------------|------------|----------------|-------------|
| th         | p0             | 0          | 0              | 0           |
| th         | p1             | 0          | 0              | 0           |

2 rows in set (0.00 sec)

Note that `TABLE_ROWS` for each partition is 0. Now insert two rows into `th` whose `c1` column values are `NULL` and 0, and verify that these rows were inserted, as shown here:

```
mysql> INSERT INTO th VALUES (NULL, 'mothra'), (0, 'gigan');
Query OK, 1 row affected (0.00 sec)
```

```
mysql> SELECT * FROM th;
+-----+-----+
| c1    | c2      |
+-----+-----+
| NULL  | mothra  |
+-----+-----+
| 0     | gigan   |
+-----+-----+
2 rows in set (0.01 sec)
```

Recall that for any integer *N*, the value of `NULL MOD N` is always `NULL`. For tables that are partitioned by `HASH` or `KEY`, this result is treated for determining the correct partition as `0`. Checking the `INFORMATION_SCHEMA.PARTITIONS` table once again, we can see that both rows were inserted into partition `p0`:

```
mysql> SELECT TABLE_NAME, PARTITION_NAME, TABLE_ROWS, AVG_ROW_LENGTH, DATA_LENGTH
> FROM INFORMATION_SCHEMA.PARTITIONS
> WHERE TABLE_SCHEMA = 'p' AND TABLE_NAME = 'th';
+-----+-----+-----+-----+-----+
| TABLE_NAME | PARTITION_NAME | TABLE_ROWS | AVG_ROW_LENGTH | DATA_LENGTH |
+-----+-----+-----+-----+-----+
| th          | p0             | 2           | 20             | 20           |
| th          | p1             | 0           | 0              | 0            |
+-----+-----+-----+-----+-----+
2 rows in set (0.00 sec)
```

If you repeat this example using `PARTITION BY KEY` in place of `PARTITION BY HASH` in the definition of the table, you can verify easily that `NULL` is also treated like `0` for this type of partitioning.

## 21.3 Partition Management

MySQL 5.7 provides a number of ways to modify partitioned tables. It is possible to add, drop, redefine, merge, or split existing partitions. All of these actions can be carried out using the partitioning extensions to the `ALTER TABLE` statement. There are also ways to obtain information about partitioned tables and partitions. We discuss these topics in the sections that follow.

- For information about partition management in tables partitioned by `RANGE` or `LIST`, see [Section 21.3.1, “Management of RANGE and LIST Partitions”](#).
- For a discussion of managing `HASH` and `KEY` partitions, see [Section 21.3.2, “Management of HASH and KEY Partitions”](#).
- See [Section 21.3.5, “Obtaining Information About Partitions”](#), for a discussion of mechanisms provided in MySQL 5.7 for obtaining information about partitioned tables and partitions.
- For a discussion of performing maintenance operations on partitions, see [Section 21.3.4, “Maintenance of Partitions”](#).

### Note

In MySQL 5.7, all partitions of a partitioned table must have the same number of subpartitions, and it is not possible to change the subpartitioning once the table has been created.

To change a table's partitioning scheme, it is necessary only to use the `ALTER TABLE` statement with a `partition_options` clause. This clause has the same syntax as that as used with `CREATE TABLE` for creating a partitioned table, and always begins with the keywords `PARTITION BY`. Suppose that you have a table partitioned by range using the following `CREATE TABLE` statement:

```
CREATE TABLE trb3 (id INT, name VARCHAR(50), purchased DATE)
PARTITION BY RANGE( YEAR(purchased) ) (
PARTITION p0 VALUES LESS THAN (1990),
```

```
PARTITION p1 VALUES LESS THAN (1995),
PARTITION p2 VALUES LESS THAN (2000),
PARTITION p3 VALUES LESS THAN (2005)
);
```

To repartition this table so that it is partitioned by key into two partitions using the `id` column value as the basis for the key, you can use this statement:

```
ALTER TABLE trb3 PARTITION BY KEY(id) PARTITIONS 2;
```

This has the same effect on the structure of the table as dropping the table and re-creating it using `CREATE TABLE trb3 PARTITION BY KEY(id) PARTITIONS 2;`

`ALTER TABLE ... ENGINE = ...` changes only the storage engine used by the table, and leaves the table's partitioning scheme intact. Use `ALTER TABLE ... REMOVE PARTITIONING` to remove a table's partitioning. See [Section 14.1.8, “ALTER TABLE Syntax”](#).

### Important

Only a single `PARTITION BY`, `ADD PARTITION`, `DROP PARTITION`, `REORGANIZE PARTITION`, or `COALESCE PARTITION` clause can be used in a given `ALTER TABLE` statement. If you (for example) wish to drop a partition and reorganize a table's remaining partitions, you must do so in two separate `ALTER TABLE` statements (one using `DROP PARTITION` and then a second one using `REORGANIZE PARTITIONS`).

In MySQL 5.7, it is possible to delete all rows from one or more selected partitions using `ALTER TABLE ... TRUNCATE PARTITION`.

## 21.3.1 Management of RANGE and LIST Partitions

Range and list partitions are very similar with regard to how the adding and dropping of partitions are handled. For this reason we discuss the management of both sorts of partitioning in this section. For information about working with tables that are partitioned by hash or key, see [Section 21.3.2, “Management of HASH and KEY Partitions”](#). Dropping a `RANGE` or `LIST` partition is more straightforward than adding one, so we discuss this first.

Dropping a partition from a table that is partitioned by either `RANGE` or by `LIST` can be accomplished using the `ALTER TABLE` statement with a `DROP PARTITION` clause. Here is a very basic example, which supposes that you have already created a table which is partitioned by range and then populated with 10 records using the following `CREATE TABLE` and `INSERT` statements:

```
mysql> CREATE TABLE tr (id INT, name VARCHAR(50), purchased DATE)
-> PARTITION BY RANGE( YEAR(purchased) ) (
-> PARTITION p0 VALUES LESS THAN (1990),
-> PARTITION p1 VALUES LESS THAN (1995),
-> PARTITION p2 VALUES LESS THAN (2000),
-> PARTITION p3 VALUES LESS THAN (2005)
-> );
Query OK, 0 rows affected (0.01 sec)

mysql> INSERT INTO tr VALUES
-> (1, 'desk organiser', '2003-10-15'),
-> (2, 'CD player', '1993-11-05'),
-> (3, 'TV set', '1996-03-10'),
-> (4, 'bookcase', '1982-01-10'),
-> (5, 'exercise bike', '2004-05-09'),
-> (6, 'sofa', '1987-06-05'),
-> (7, 'popcorn maker', '2001-11-22'),
-> (8, 'aquarium', '1992-08-04'),
-> (9, 'study desk', '1984-09-16'),
-> (10, 'lava lamp', '1998-12-25');
Query OK, 10 rows affected (0.01 sec)
```

You can see which items should have been inserted into partition `p2` as shown here:

```
mysql> SELECT * FROM tr
-> WHERE purchased BETWEEN '1995-01-01' AND '1999-12-31';
+-----+-----+-----+
| id   | name   | purchased |
+-----+-----+-----+
| 3    | TV set | 1996-03-10 |
| 10   | lava lamp | 1998-12-25 |
+-----+-----+-----+
2 rows in set (0.00 sec)
```

To drop the partition named `p2`, execute the following command:

```
mysql> ALTER TABLE tr DROP PARTITION p2;
Query OK, 0 rows affected (0.03 sec)
```

#### Note

The `NDB` storage engine does not support `ALTER TABLE ... DROP PARTITION`. It does, however, support the other partitioning-related extensions to `ALTER TABLE` that are described in this chapter.

It is very important to remember that, *when you drop a partition, you also delete all the data that was stored in that partition*. You can see that this is the case by re-running the previous `SELECT` query:

```
mysql> SELECT * FROM tr WHERE purchased
-> BETWEEN '1995-01-01' AND '1999-12-31';
Empty set (0.00 sec)
```

Because of this, you must have the `DROP` privilege for a table before you can execute `ALTER TABLE ... DROP PARTITION` on that table.

If you wish to drop all data from all partitions while preserving the table definition and its partitioning scheme, use the `TRUNCATE TABLE` statement. (See [Section 14.1.34, “TRUNCATE TABLE Syntax”](#).)

If you intend to change the partitioning of a table *without* losing data, use `ALTER TABLE ... REORGANIZE PARTITION` instead. See below or in [Section 14.1.8, “ALTER TABLE Syntax”](#), for information about `REORGANIZE PARTITION`.

If you now execute a `SHOW CREATE TABLE` statement, you can see how the partitioning makeup of the table has been changed:

```
mysql> SHOW CREATE TABLE tr\G
***** 1. row *****
      Table: tr
Create Table: CREATE TABLE `tr` (
  `id` int(11) default NULL,
  `name` varchar(50) default NULL,
  `purchased` date default NULL
) ENGINE=MyISAM DEFAULT CHARSET=latin1
PARTITION BY RANGE ( YEAR(purchased) ) (
  PARTITION p0 VALUES LESS THAN (1990) ENGINE = MyISAM,
  PARTITION p1 VALUES LESS THAN (1995) ENGINE = MyISAM,
  PARTITION p3 VALUES LESS THAN (2005) ENGINE = MyISAM
)
1 row in set (0.01 sec)
```

When you insert new rows into the changed table with `purchased` column values between `'1995-01-01'` and `'2004-12-31'` inclusive, those rows will be stored in partition `p3`. You can verify this as follows:

```
mysql> INSERT INTO tr VALUES (11, 'pencil holder', '1995-07-12');
Query OK, 1 row affected (0.00 sec)

mysql> SELECT * FROM tr WHERE purchased
-> BETWEEN '1995-01-01' AND '2004-12-31';
+-----+-----+-----+
| id   | name          | purchased |
+-----+-----+-----+
| 11   | pencil holder | 1995-07-12 |
| 1    | desk organiser | 2003-10-15 |
| 5    | exercise bike | 2004-05-09 |
| 7    | popcorn maker | 2001-11-22 |
+-----+-----+-----+
4 rows in set (0.00 sec)

mysql> ALTER TABLE tr DROP PARTITION p3;
Query OK, 0 rows affected (0.03 sec)

mysql> SELECT * FROM tr WHERE purchased
-> BETWEEN '1995-01-01' AND '2004-12-31';
Empty set (0.00 sec)
```

Note that the number of rows dropped from the table as a result of `ALTER TABLE ... DROP PARTITION` is not reported by the server as it would be by the equivalent `DELETE` query.

Dropping `LIST` partitions uses exactly the same `ALTER TABLE ... DROP PARTITION` syntax as used for dropping `RANGE` partitions. However, there is one important difference in the effect this has on your use of the table afterward: You can no longer insert into the table any rows having any of the values that were included in the value list defining the deleted partition. (See [Section 21.2.2, “LIST Partitioning”](#), for an example.)

To add a new range or list partition to a previously partitioned table, use the `ALTER TABLE ... ADD PARTITION` statement. For tables which are partitioned by `RANGE`, this can be used to add a new range to the end of the list of existing partitions. Suppose that you have a partitioned table containing membership data for your organization, which is defined as follows:

```
CREATE TABLE members (
  id INT,
  fname VARCHAR(25),
  lname VARCHAR(25),
  dob DATE
)
PARTITION BY RANGE( YEAR(dob) ) (
  PARTITION p0 VALUES LESS THAN (1970),
  PARTITION p1 VALUES LESS THAN (1980),
  PARTITION p2 VALUES LESS THAN (1990)
);
```

Suppose further that the minimum age for members is 16. As the calendar approaches the end of 2005, you realize that you will soon be admitting members who were born in 1990 (and later in years to come). You can modify the `members` table to accommodate new members born in the years 1990 to 1999 as shown here:

```
ALTER TABLE members ADD PARTITION (PARTITION p3 VALUES LESS THAN (2000));
```

With tables that are partitioned by range, you can use `ADD PARTITION` to add new partitions to the high end of the partitions list only. Trying to add a new partition in this manner between or before existing partitions results in an error as shown here:

```
mysql> ALTER TABLE members
> ADD PARTITION (
> PARTITION n VALUES LESS THAN (1960));
ERROR 1463 (HY000): VALUES LESS THAN value must be strictly »
increasing for each partition
```

You can work around this problem by reorganizing the first partition into two new ones that split the range between them, like this:

```
ALTER TABLE members
  REORGANIZE PARTITION p0 INTO (
    PARTITION n0 VALUES LESS THAN (1960),
    PARTITION n1 VALUES LESS THAN (1970)
  );
```

Using `SHOW CREATE TABLE` you can see that the `ALTER TABLE` statement has had the desired effect:

```
mysql> SHOW CREATE TABLE members\G
***** 1. row *****
      Table: members
Create Table: CREATE TABLE `members` (
  `id` int(11) DEFAULT NULL,
  `fname` varchar(25) DEFAULT NULL,
  `lname` varchar(25) DEFAULT NULL,
  `dob` date DEFAULT NULL
) ENGINE=InnoDB DEFAULT CHARSET=latin1
/*:150100 PARTITION BY RANGE ( YEAR(dob))
(PARTITION n0 VALUES LESS THAN (1960) ENGINE = InnoDB,
PARTITION n1 VALUES LESS THAN (1970) ENGINE = InnoDB,
PARTITION p1 VALUES LESS THAN (1980) ENGINE = InnoDB,
PARTITION p2 VALUES LESS THAN (1990) ENGINE = InnoDB,
PARTITION p3 VALUES LESS THAN (2000) ENGINE = InnoDB) */
1 row in set (0.00 sec)
```

See also [Section 14.1.8.1, “ALTER TABLE Partition Operations”](#).

You can also use `ALTER TABLE ... ADD PARTITION` to add new partitions to a table that is partitioned by `LIST`. Suppose a table `tt` is defined using the following `CREATE TABLE` statement:

```
CREATE TABLE tt (
  id INT,
  data INT
)
PARTITION BY LIST(data) (
  PARTITION p0 VALUES IN (5, 10, 15),
  PARTITION p1 VALUES IN (6, 12, 18)
);
```

You can add a new partition in which to store rows having the `data` column values 7, 14, and 21 as shown:

```
ALTER TABLE tt ADD PARTITION (PARTITION p2 VALUES IN (7, 14, 21));
```

You *cannot* add a new `LIST` partition encompassing any values that are already included in the value list of an existing partition. If you attempt to do so, an error will result:

```
mysql> ALTER TABLE tt ADD PARTITION
> (PARTITION np VALUES IN (4, 8, 12));
ERROR 1465 (HY000): Multiple definition of same constant »
in list partitioning
```

Because any rows with the `data` column value 12 have already been assigned to partition `p1`, you cannot create a new partition on table `tt` that includes 12 in its value list. To accomplish this, you could drop `p1`, and add `np` and then a new `p1` with a modified definition. However, as discussed earlier, this would result in the loss of all data stored in `p1`—and it is often the case that this is not what you really want to do. Another solution might appear to be to make a copy of the table with the new partitioning and to copy the data into it using `CREATE TABLE ... SELECT ...`, then drop the old table and

rename the new one, but this could be very time-consuming when dealing with a large amounts of data. This also might not be feasible in situations where high availability is a requirement.

You can add multiple partitions in a single `ALTER TABLE ... ADD PARTITION` statement as shown here:

```
CREATE TABLE employees (
  id INT NOT NULL,
  fname VARCHAR(50) NOT NULL,
  lname VARCHAR(50) NOT NULL,
  hired DATE NOT NULL
)
PARTITION BY RANGE( YEAR(hired) ) (
  PARTITION p1 VALUES LESS THAN (1991),
  PARTITION p2 VALUES LESS THAN (1996),
  PARTITION p3 VALUES LESS THAN (2001),
  PARTITION p4 VALUES LESS THAN (2005)
);

ALTER TABLE employees ADD PARTITION (
  PARTITION p5 VALUES LESS THAN (2010),
  PARTITION p6 VALUES LESS THAN MAXVALUE
);
```

Fortunately, MySQL's partitioning implementation provides ways to redefine partitions without losing data. Let us look first at a couple of simple examples involving `RANGE` partitioning. Recall the `members` table which is now defined as shown here:

```
mysql> SHOW CREATE TABLE members\G
***** 1. row *****
      Table: members
Create Table: CREATE TABLE `members` (
  `id` int(11) default NULL,
  `fname` varchar(25) default NULL,
  `lname` varchar(25) default NULL,
  `dob` date default NULL
) ENGINE=MyISAM DEFAULT CHARSET=latin1
PARTITION BY RANGE ( YEAR(dob) ) (
  PARTITION p0 VALUES LESS THAN (1970) ENGINE = MyISAM,
  PARTITION p1 VALUES LESS THAN (1980) ENGINE = MyISAM,
  PARTITION p2 VALUES LESS THAN (1990) ENGINE = MyISAM,
  PARTITION p3 VALUES LESS THAN (2000) ENGINE = MyISAM
)
```

Suppose that you would like to move all rows representing members born before 1960 into a separate partition. As we have already seen, this cannot be done using `ALTER TABLE ... ADD PARTITION`. However, you can use another partition-related extension to `ALTER TABLE` to accomplish this:

```
ALTER TABLE members REORGANIZE PARTITION p0 INTO (
  PARTITION s0 VALUES LESS THAN (1960),
  PARTITION s1 VALUES LESS THAN (1970)
);
```

In effect, this command splits partition `p0` into two new partitions `s0` and `s1`. It also moves the data that was stored in `p0` into the new partitions according to the rules embodied in the two `PARTITION ... VALUES ...` clauses, so that `s0` contains only those records for which `YEAR(dob)` is less than 1960 and `s1` contains those rows in which `YEAR(dob)` is greater than or equal to 1960 but less than 1970.

A `REORGANIZE PARTITION` clause may also be used for merging adjacent partitions. You can return the `members` table to its previous partitioning as shown here:

```
ALTER TABLE members REORGANIZE PARTITION s0,s1 INTO (
  PARTITION p0 VALUES LESS THAN (1970)
);
```

No data is lost in splitting or merging partitions using `REORGANIZE PARTITION`. In executing the above statement, MySQL moves all of the records that were stored in partitions `s0` and `s1` into partition `p0`.

The general syntax for `REORGANIZE PARTITION` is shown here:

```
ALTER TABLE tbl_name
  REORGANIZE PARTITION partition_list
  INTO (partition_definitions);
```

Here, *tbl\_name* is the name of the partitioned table, and *partition\_list* is a comma-separated list of names of one or more existing partitions to be changed. *partition\_definitions* is a comma-separated list of new partition definitions, which follow the same rules as for the *partition\_definitions* list used in `CREATE TABLE` (see [Section 14.1.18, “CREATE TABLE Syntax”](#)). It should be noted that you are not limited to merging several partitions into one, or to splitting one partition into many, when using `REORGANIZE PARTITION`. For example, you can reorganize all four partitions of the `members` table into two, as follows:

```
ALTER TABLE members REORGANIZE PARTITION p0,p1,p2,p3 INTO (
  PARTITION m0 VALUES LESS THAN (1980),
  PARTITION m1 VALUES LESS THAN (2000)
);
```

You can also use `REORGANIZE PARTITION` with tables that are partitioned by `LIST`. Let us return to the problem of adding a new partition to the list-partitioned `tt` table and failing because the new partition had a value that was already present in the value-list of one of the existing partitions. We can handle this by adding a partition that contains only nonconflicting values, and then reorganizing the new partition and the existing one so that the value which was stored in the existing one is now moved to the new one:

```
ALTER TABLE tt ADD PARTITION (PARTITION np VALUES IN (4, 8));
ALTER TABLE tt REORGANIZE PARTITION p1,np INTO (
  PARTITION p1 VALUES IN (6, 18),
  PARTITION np VALUES in (4, 8, 12)
);
```

Here are some key points to keep in mind when using `ALTER TABLE ... REORGANIZE PARTITION` to repartition tables that are partitioned by `RANGE` or `LIST`:

- The `PARTITION` clauses used to determine the new partitioning scheme are subject to the same rules as those used with a `CREATE TABLE` statement.

Most importantly, you should remember that the new partitioning scheme cannot have any overlapping ranges (applies to tables partitioned by `RANGE`) or sets of values (when reorganizing tables partitioned by `LIST`).

- The combination of partitions in the *partition\_definitions* list should account for the same range or set of values overall as the combined partitions named in the *partition\_list*.

For instance, in the `members` table used as an example in this section, partitions `p1` and `p2` together cover the years 1980 through 1999. Therefore, any reorganization of these two partitions should cover the same range of years overall.

- For tables partitioned by `RANGE`, you can reorganize only adjacent partitions; you cannot skip over range partitions.

For instance, you could not reorganize the `members` table used as an example in this section using a statement beginning with `ALTER TABLE members REORGANIZE PARTITION p0,p2 INTO ...` because `p0` covers the years prior to 1970 and `p2` the years from 1990 through 1999 inclusive, and thus the two are not adjacent partitions.

- You cannot use `REORGANIZE PARTITION` to change the table's partitioning type; that is, you cannot (for example) change `RANGE` partitions to `HASH` partitions or vice versa. You also cannot use this command to change the partitioning expression or column. To accomplish either of these tasks without dropping and re-creating the table, you can use `ALTER TABLE ... PARTITION BY ...`. For example:

```
ALTER TABLE members
PARTITION BY HASH( YEAR(dob) )
PARTITIONS 8;
```

### 21.3.2 Management of HASH and KEY Partitions

Tables which are partitioned by hash or by key are very similar to one another with regard to making changes in a partitioning setup, and both differ in a number of ways from tables which have been partitioned by range or list. For that reason, this section addresses the modification of tables partitioned by hash or by key only. For a discussion of adding and dropping of partitions of tables that are partitioned by range or list, see [Section 21.3.1, “Management of RANGE and LIST Partitions”](#).

You cannot drop partitions from tables that are partitioned by `HASH` or `KEY` in the same way that you can from tables that are partitioned by `RANGE` or `LIST`. However, you can merge `HASH` or `KEY` partitions using the `ALTER TABLE ... COALESCE PARTITION` statement. Suppose that you have a table containing data about clients, which is divided into twelve partitions. The `clients` table is defined as shown here:

```
CREATE TABLE clients (
  id INT,
  fname VARCHAR(30),
  lname VARCHAR(30),
  signed DATE
)
PARTITION BY HASH( MONTH(signed) )
PARTITIONS 12;
```

To reduce the number of partitions from twelve to eight, execute the following `ALTER TABLE` command:

```
mysql> ALTER TABLE clients COALESCE PARTITION 4;
Query OK, 0 rows affected (0.02 sec)
```

`COALESCE` works equally well with tables that are partitioned by `HASH`, `KEY`, `LINEAR HASH`, or `LINEAR KEY`. Here is an example similar to the previous one, differing only in that the table is partitioned by `LINEAR KEY`:

```
mysql> CREATE TABLE clients_lk (
->   id INT,
->   fname VARCHAR(30),
->   lname VARCHAR(30),
->   signed DATE
-> )
-> PARTITION BY LINEAR KEY(signed)
-> PARTITIONS 12;
Query OK, 0 rows affected (0.03 sec)

mysql> ALTER TABLE clients_lk COALESCE PARTITION 4;
Query OK, 0 rows affected (0.06 sec)
Records: 0 Duplicates: 0 Warnings: 0
```

The number following `COALESCE PARTITION` is the number of partitions to merge into the remainder—in other words, it is the number of partitions to remove from the table.

If you attempt to remove more partitions than the table has, the result is an error like the one shown:

```
mysql> ALTER TABLE clients COALESCE PARTITION 18;
ERROR 1478 (HY000): Cannot remove all partitions, use DROP TABLE instead
```

To increase the number of partitions for the `clients` table from 12 to 18, use `ALTER TABLE ... ADD PARTITION` as shown here:

```
ALTER TABLE clients ADD PARTITION PARTITIONS 6;
```

### 21.3.3 Exchanging Partitions and Subpartitions with Tables

In MySQL 5.7, it is possible to exchange a table partition or subpartition with a table using `ALTER TABLE pt EXCHANGE PARTITION p WITH TABLE nt`, where *pt* is the partitioned table and *p* is the partition or subpartition of *pt* to be exchanged with unpartitioned table *nt*, provided that the following statements are true:

1. Table *nt* is not itself partitioned.
2. Table *nt* is not a temporary table.
3. The structures of tables *pt* and *nt* are otherwise identical.
4. Table *nt* contains no foreign key references, and no other table has any foreign keys that refer to *nt*.
5. There are no rows in *nt* that lie outside the boundaries of the partition definition for *p*. This condition does not apply if the `WITHOUT VALIDATION` option is used. The `[ {WITH|WITHOUT} VALIDATION]` option was added in MySQL 5.7.5.

In addition to the `ALTER`, `INSERT`, and `CREATE` privileges usually required for `ALTER TABLE` statements, you must have the `DROP` privilege to perform `ALTER TABLE ... EXCHANGE PARTITION`.

You should also be aware of the following effects of `ALTER TABLE ... EXCHANGE PARTITION`:

- Executing `ALTER TABLE ... EXCHANGE PARTITION` does not invoke any triggers on either the partitioned table or the table to be exchanged.
- Any `AUTO_INCREMENT` columns in the exchanged table are reset.
- The `IGNORE` keyword has no effect when used with `ALTER TABLE ... EXCHANGE PARTITION`.

The syntax of the `ALTER TABLE ... EXCHANGE PARTITION` statement is shown here, where *pt* is the partitioned table, *p* is the partition or subpartition to be exchanged, and *nt* is the nonpartitioned table to be exchanged with *p*:

```
ALTER TABLE pt
  EXCHANGE PARTITION p
  WITH TABLE nt;
```

Optionally, you can append a `WITH VALIDATION` or `WITHOUT VALIDATION` clause. When `WITHOUT VALIDATION` is specified, the `ALTER TABLE ... EXCHANGE PARTITION` operation does not perform row-by-row validation when exchanging a partition a nonpartitioned table, allowing database administrators to assume responsibility for ensuring that rows are within the boundaries of the partition definition. `WITH VALIDATION` is the default behavior and need not be specified explicitly. The `[ {WITH|WITHOUT} VALIDATION]` option was added in MySQL 5.7.5.

One and only one partition or subpartition may be exchanged with one and only one nonpartitioned table in a single `ALTER TABLE EXCHANGE PARTITION` statement. To exchange multiple partitions or subpartitions, use multiple `ALTER TABLE EXCHANGE PARTITION` statements. `EXCHANGE`

`PARTITION` may not be combined with other `ALTER TABLE` options. The partitioning and (if applicable) subpartitioning used by the partitioned table may be of any type or types supported in MySQL 5.7.

## Exchanging a Partition with a Nonpartitioned Table

Suppose that a partitioned table `e` has been created and populated using the following SQL statements:

```
CREATE TABLE e (
  id INT NOT NULL,
  fname VARCHAR(30),
  lname VARCHAR(30)
)
PARTITION BY RANGE (id) (
  PARTITION p0 VALUES LESS THAN (50),
  PARTITION p1 VALUES LESS THAN (100),
  PARTITION p2 VALUES LESS THAN (150),
  PARTITION p3 VALUES LESS THAN (MAXVALUE)
);

INSERT INTO e VALUES
  (1669, "Jim", "Smith"),
  (337, "Mary", "Jones"),
  (16, "Frank", "White"),
  (2005, "Linda", "Black");
```

Now we create a nonpartitioned copy of `e` named `e2`. This can be done using the `mysql` client as shown here:

```
mysql> CREATE TABLE e2 LIKE e;
Query OK, 0 rows affected (1.34 sec)

mysql> ALTER TABLE e2 REMOVE PARTITIONING;
Query OK, 0 rows affected (0.90 sec)
Records: 0 Duplicates: 0 Warnings: 0
```

You can see which partitions in table `e` contain rows by querying the `INFORMATION_SCHEMA.PARTITIONS` table, like this:

```
mysql> SELECT PARTITION_NAME, TABLE_ROWS
->      FROM INFORMATION_SCHEMA.PARTITIONS
->      WHERE TABLE_NAME = 'e';
+-----+-----+
| PARTITION_NAME | TABLE_ROWS |
+-----+-----+
| p0             | 1           |
| p1             | 0           |
| p2             | 0           |
| p3             | 3           |
+-----+-----+
4 rows in set (0.00 sec)
```

### Note

For partitioned `InnoDB` tables, the row count given in the `TABLE_ROWS` column of the `INFORMATION_SCHEMA.PARTITIONS` table is only an estimated value used in SQL optimization, and is not always exact.

To exchange partition `p0` in table `e` with table `e2`, you can use the `ALTER TABLE` statement shown here:

```
mysql> ALTER TABLE e EXCHANGE PARTITION p0 WITH TABLE e2;
Query OK, 0 rows affected (0.28 sec)
```

More precisely, the statement just issued causes any rows found in the partition to be swapped with those found in the table. You can observe how this has happened by querying the `INFORMATION_SCHEMA.PARTITIONS` table, as before. The table row that was previously found in partition `p0` is no longer present:

```
mysql> SELECT PARTITION_NAME, TABLE_ROWS
->      FROM INFORMATION_SCHEMA.PARTITIONS
->      WHERE TABLE_NAME = 'e';
```

| PARTITION_NAME | TABLE_ROWS |
|----------------|------------|
| p0             | 0          |
| p1             | 0          |
| p2             | 0          |
| p3             | 3          |

```
4 rows in set (0.00 sec)
```

If you query table `e2`, you can see that the “missing” row can now be found there:

```
mysql> SELECT * FROM e2;
```

| id | fname | lname |
|----|-------|-------|
| 16 | Frank | White |

```
1 row in set (0.00 sec)
```

The table to be exchanged with the partition does not necessarily have to be empty. To demonstrate this, we first insert a new row into table `e`, making sure that this row is stored in partition `p0` by choosing an `id` column value that is less than 50, and verifying this afterward by querying the `PARTITIONS` table:

```
mysql> INSERT INTO e VALUES (41, "Michael", "Green");
Query OK, 1 row affected (0.05 sec)
```

```
mysql> SELECT PARTITION_NAME, TABLE_ROWS
->      FROM INFORMATION_SCHEMA.PARTITIONS
->      WHERE TABLE_NAME = 'e';
```

| PARTITION_NAME | TABLE_ROWS |
|----------------|------------|
| p0             | 1          |
| p1             | 0          |
| p2             | 0          |
| p3             | 3          |

```
4 rows in set (0.00 sec)
```

Now we once again exchange partition `p0` with table `e2` using the same `ALTER TABLE` statement as previously:

```
mysql> ALTER TABLE e EXCHANGE PARTITION p0 WITH TABLE e2;
Query OK, 0 rows affected (0.28 sec)
```

The output of the following queries shows that the table row that was stored in partition `p0` and the table row that was stored in table `e2`, prior to issuing the `ALTER TABLE` statement, have now switched places:

```
mysql> SELECT * FROM e;
```

| id | fname | lname |
|----|-------|-------|
| 16 | Frank | White |

```

| 1669 | Jim   | Smith |
| 337  | Mary  | Jones |
| 2005 | Linda | Black |
+-----+-----+-----+
4 rows in set (0.00 sec)

mysql> SELECT PARTITION_NAME, TABLE_ROWS
->      FROM INFORMATION_SCHEMA.PARTITIONS
->      WHERE TABLE_NAME = 'e';
+-----+-----+-----+
| PARTITION_NAME | TABLE_ROWS |
+-----+-----+-----+
| p0             | 1           |
| p1             | 0           |
| p2             | 0           |
| p3             | 3           |
+-----+-----+-----+
4 rows in set (0.00 sec)

mysql> SELECT * FROM e2;
+-----+-----+-----+
| id | fname | lname |
+-----+-----+-----+
| 41 | Michael | Green |
+-----+-----+-----+
1 row in set (0.00 sec)

```

## Nonmatching Rows

You should keep in mind that any rows found in the nonpartitioned table prior to issuing the `ALTER TABLE ... EXCHANGE PARTITION` statement must meet the conditions required for them to be stored in the target partition; otherwise, the statement fails. To see how this occurs, first insert a row into `e2` that is outside the boundaries of the partition definition for partition `p0` of table `e`. For example, insert a row with an `id` column value that is too large; then, try to exchange the table with the partition again:

```

mysql> INSERT INTO e2 VALUES (51, "Ellen", "McDonald");
Query OK, 1 row affected (0.08 sec)

mysql> ALTER TABLE e EXCHANGE PARTITION p0 WITH TABLE e2;
ERROR 1707 (HY000): Found row that does not match the partition

```

The `IGNORE` keyword is accepted, but has no effect when used with `EXCHANGE PARTITION`, as shown here:

```

mysql> ALTER IGNORE TABLE e EXCHANGE PARTITION p0 WITH TABLE e2;
ERROR 1707 (HY000): Found row that does not match the partition

```

Only the `WITHOUT VALIDATION` option would permit this operation to succeed:

```

mysql> ALTER TABLE e EXCHANGE PARTITION p0 WITH TABLE e2 WITHOUT VALIDATION;
Query OK, 0 rows affected (0.02 sec)

```

When a partition is exchanged with a table that contains rows that do not match the partition definition, it is the responsibility of the database administrator to fix the non-matching rows, which can be performed using `REPAIR TABLE` or `ALTER TABLE ... REPAIR PARTITION`.

## Exchanging Partitions Without Row-By-Row Validation

To avoid time consuming validation when exchanging a partition with a table that has many rows, it is possible to skip the row-by-row validation step by appending `WITHOUT VALIDATION` to the `ALTER TABLE ... EXCHANGE PARTITION` statement.

The following example compares the difference between execution times when exchanging a partition with a nonpartitioned table, with and without validation. The partitioned table (table `e`) contains two

partitions of 1 million rows each. The rows in p0 of table e are removed and p0 is exchanged with a nonpartitioned table of 1 million rows. The `WITH VALIDATION` operation takes 0.74 seconds. By comparison, the `WITHOUT VALIDATION` operation takes 0.01 seconds.

```
# Create a partitioned table with 1 million rows in each partition

CREATE TABLE e (
    id INT NOT NULL,
    fname VARCHAR(30),
    lname VARCHAR(30)
)
    PARTITION BY RANGE (id) (
        PARTITION p0 VALUES LESS THAN (1000001),
        PARTITION p1 VALUES LESS THAN (2000001),
    );

mysql> SELECT COUNT(*) FROM e;
+-----+
| COUNT(*) |
+-----+
| 2000000 |
+-----+
1 row in set (0.27 sec)

# View the rows in each partition

SELECT PARTITION_NAME, TABLE_ROWS FROM INFORMATION_SCHEMA.PARTITIONS WHERE TABLE_NAME = 'e';
+-----+-----+
| PARTITION_NAME | TABLE_ROWS |
+-----+-----+
| p0              | 1000000     |
| p1              | 1000000     |
+-----+-----+
2 rows in set (0.00 sec)

# Create a nonpartitioned table of the same structure and populate it with 1 million rows

CREATE TABLE e2 (
    id INT NOT NULL,
    fname VARCHAR(30),
    lname VARCHAR(30)
);

mysql> SELECT COUNT(*) FROM e2;
+-----+
| COUNT(*) |
+-----+
| 1000000 |
+-----+
1 row in set (0.24 sec)

# Create another nonpartitioned table of the same structure and populate it with 1 million rows

CREATE TABLE e3 (
    id INT NOT NULL,
    fname VARCHAR(30),
    lname VARCHAR(30)
);

mysql> SELECT COUNT(*) FROM e3;
+-----+
| COUNT(*) |
+-----+
| 1000000 |
+-----+
1 row in set (0.25 sec)

# Drop the rows from p0 of table e

mysql> DELETE FROM e WHERE id < 1000001;
Query OK, 1000000 rows affected (5.55 sec)
```

```
# Confirm that there are no rows in partition p0

mysql> SELECT PARTITION_NAME, TABLE_ROWS FROM INFORMATION_SCHEMA.PARTITIONS WHERE TABLE_NAME = 'e';
+-----+-----+
| PARTITION_NAME | TABLE_ROWS |
+-----+-----+
| p0              | 0           |
| p1              | 1000000     |
+-----+-----+
2 rows in set (0.00 sec)

# Exchange partition p0 of table e with the table e2 'WITH VALIDATION'

mysql> ALTER TABLE e EXCHANGE PARTITION p0 WITH TABLE e2 WITH VALIDATION;
Query OK, 0 rows affected (0.74 sec)

# Confirm that the partition was exchanged with table e2

mysql> SELECT PARTITION_NAME, TABLE_ROWS FROM INFORMATION_SCHEMA.PARTITIONS WHERE TABLE_NAME = 'e';
+-----+-----+
| PARTITION_NAME | TABLE_ROWS |
+-----+-----+
| p0              | 1000000     |
| p1              | 1000000     |
+-----+-----+
2 rows in set (0.00 sec)

# Once again, drop the rows from p0 of table e

mysql> DELETE FROM e WHERE id < 1000001;
Query OK, 1000000 rows affected (5.55 sec)

# Confirm that there are no rows in partition p0

mysql> SELECT PARTITION_NAME, TABLE_ROWS FROM INFORMATION_SCHEMA.PARTITIONS WHERE TABLE_NAME = 'e';
+-----+-----+
| PARTITION_NAME | TABLE_ROWS |
+-----+-----+
| p0              | 0           |
| p1              | 1000000     |
+-----+-----+
2 rows in set (0.00 sec)

# Exchange partition p0 of table e with the table e3 'WITHOUT VALIDATION'

mysql> ALTER TABLE e EXCHANGE PARTITION p0 WITH TABLE e3 WITHOUT VALIDATION;
Query OK, 0 rows affected (0.01 sec)

# Confirm that the partition was exchanged with table e3

mysql> SELECT PARTITION_NAME, TABLE_ROWS FROM INFORMATION_SCHEMA.PARTITIONS WHERE TABLE_NAME = 'e';
+-----+-----+
| PARTITION_NAME | TABLE_ROWS |
+-----+-----+
| p0              | 1000000     |
| p1              | 1000000     |
+-----+-----+
2 rows in set (0.00 sec)
```

If a partition is exchanged with a table that contains rows that do not match the partition definition, it is the responsibility of the database administrator to fix the non-matching rows, which can be performed using [REPAIR TABLE](#) or [ALTER TABLE ... REPAIR PARTITION](#).

## Exchanging a Subpartition with a Nonpartitioned Table

You can also exchange a subpartition of a subpartitioned table (see [Section 21.2.6, “Subpartitioning”](#)) with a nonpartitioned table using an [ALTER TABLE ... EXCHANGE PARTITION](#) statement. In the following example, we first create a table `es` that is partitioned by [RANGE](#) and subpartitioned by [KEY](#),

populate this table as we did table `e`, and then create an empty, nonpartitioned copy `es2` of the table, as shown here:

```
mysql> CREATE TABLE es (
->     id INT NOT NULL,
->     fname VARCHAR(30),
->     lname VARCHAR(30)
-> )
->     PARTITION BY RANGE (id)
->     SUBPARTITION BY KEY (lname)
->     SUBPARTITIONS 2 (
->         PARTITION p0 VALUES LESS THAN (50),
->         PARTITION p1 VALUES LESS THAN (100),
->         PARTITION p2 VALUES LESS THAN (150),
->         PARTITION p3 VALUES LESS THAN (MAXVALUE)
-> );
Query OK, 0 rows affected (2.76 sec)

mysql> INSERT INTO es VALUES
->     (1669, "Jim", "Smith"),
->     (337, "Mary", "Jones"),
->     (16, "Frank", "White"),
->     (2005, "Linda", "Black");
Query OK, 4 rows affected (0.04 sec)
Records: 4  Duplicates: 0  Warnings: 0

mysql> CREATE TABLE es2 LIKE es;
Query OK, 0 rows affected (1.27 sec)

mysql> ALTER TABLE es2 REMOVE PARTITIONING;
Query OK, 0 rows affected (0.70 sec)
Records: 0  Duplicates: 0  Warnings: 0
```

Although we did not explicitly name any of the subpartitions when creating table `es`, we can obtain generated names for these by including the `SUBPARTITION_NAME` of the `PARTITIONS` table from `INFORMATION_SCHEMA` when selecting from that table, as shown here:

```
mysql> SELECT PARTITION_NAME, SUBPARTITION_NAME, TABLE_ROWS
->     FROM INFORMATION_SCHEMA.PARTITIONS
->     WHERE TABLE_NAME = 'es';
+-----+-----+-----+
| PARTITION_NAME | SUBPARTITION_NAME | TABLE_ROWS |
+-----+-----+-----+
| p0             | p0sp0             | 1           |
| p0             | p0sp1             | 0           |
| p1             | p1sp0             | 0           |
| p1             | p1sp1             | 0           |
| p2             | p2sp0             | 0           |
| p2             | p2sp1             | 0           |
| p3             | p3sp0             | 3           |
| p3             | p3sp1             | 0           |
+-----+-----+-----+
8 rows in set (0.00 sec)
```

The following `ALTER TABLE` statement exchanges subpartition `p3sp0` table `es` with the nonpartitioned table `es2`:

```
mysql> ALTER TABLE es EXCHANGE PARTITION p3sp0 WITH TABLE es2;
Query OK, 0 rows affected (0.29 sec)
```

You can verify that the rows were exchanged by issuing the following queries:

```
mysql> SELECT PARTITION_NAME, SUBPARTITION_NAME, TABLE_ROWS
->     FROM INFORMATION_SCHEMA.PARTITIONS
->     WHERE TABLE_NAME = 'es';
+-----+-----+-----+
```

| PARTITION_NAME | SUBPARTITION_NAME | TABLE_ROWS |
|----------------|-------------------|------------|
| p0             | p0sp0             | 1          |
| p0             | p0sp1             | 0          |
| p1             | p1sp0             | 0          |
| p1             | p1sp1             | 0          |
| p2             | p2sp0             | 0          |
| p2             | p2sp1             | 0          |
| p3             | p3sp0             | 0          |
| p3             | p3sp1             | 0          |

8 rows in set (0.00 sec)

```
mysql> SELECT * FROM es2;
```

| id   | fname | lname |
|------|-------|-------|
| 1669 | Jim   | Smith |
| 337  | Mary  | Jones |
| 2005 | Linda | Black |

3 rows in set (0.00 sec)

If a table is subpartitioned, you can exchange only a subpartition of the table—not an entire partition—with an unpartitioned table, as shown here:

```
mysql> ALTER TABLE es EXCHANGE PARTITION p3 WITH TABLE es2;
ERROR 1704 (HY000): Subpartitioned table, use subpartition instead of partition
```

The comparison of table structures used by MySQL is very strict. The number, order, names, and types of columns and indexes of the partitioned table and the nonpartitioned table must match exactly. In addition, both tables must use the same storage engine:

```
mysql> CREATE TABLE es3 LIKE e;
Query OK, 0 rows affected (1.31 sec)

mysql> ALTER TABLE es3 REMOVE PARTITIONING;
Query OK, 0 rows affected (0.53 sec)
Records: 0 Duplicates: 0 Warnings: 0

mysql> SHOW CREATE TABLE es3\G
***** 1. row *****
      Table: es3
Create Table: CREATE TABLE `es3` (
  `id` int(11) NOT NULL,
  `fname` varchar(30) DEFAULT NULL,
  `lname` varchar(30) DEFAULT NULL
) ENGINE=InnoDB DEFAULT CHARSET=latin1
1 row in set (0.00 sec)

mysql> ALTER TABLE es3 ENGINE = MyISAM;
Query OK, 0 rows affected (0.15 sec)
Records: 0 Duplicates: 0 Warnings: 0

mysql> ALTER TABLE es EXCHANGE PARTITION p3sp0 WITH TABLE es3;
ERROR 1497 (HY000): The mix of handlers in the partitions is not allowed in this version of MySQL
```

## 21.3.4 Maintenance of Partitions

A number of table and partition maintenance tasks can be carried out using SQL statements intended for such purposes on partitioned tables in MySQL 5.7.

Table maintenance of partitioned tables can be accomplished using the statements `CHECK TABLE`, `OPTIMIZE TABLE`, `ANALYZE TABLE`, and `REPAIR TABLE`, which are supported for partitioned tables.

You can use a number of extensions to `ALTER TABLE` for performing operations of this type on one or more partitions directly, as described in the following list:

- **Rebuilding partitions.** Rebuilds the partition; this has the same effect as dropping all records stored in the partition, then reinserting them. This can be useful for purposes of defragmentation.

Example:

```
ALTER TABLE t1 REBUILD PARTITION p0, p1;
```

- **Optimizing partitions.** If you have deleted a large number of rows from a partition or if you have made many changes to a partitioned table with variable-length rows (that is, having `VARCHAR`, `BLOB`, or `TEXT` columns), you can use `ALTER TABLE ... OPTIMIZE PARTITION` to reclaim any unused space and to defragment the partition data file.

Example:

```
ALTER TABLE t1 OPTIMIZE PARTITION p0, p1;
```

Using `OPTIMIZE PARTITION` on a given partition is equivalent to running `CHECK PARTITION`, `ANALYZE PARTITION`, and `REPAIR PARTITION` on that partition.

Some MySQL storage engines, including `InnoDB`, do not support per-partition optimization; in these cases, `ALTER TABLE ... OPTIMIZE PARTITION` analyzes and rebuilds the entire table, and causes an appropriate warning to be issued. (Bug #11751825, Bug #42822) Use `ALTER TABLE ... REBUILD PARTITION` and `ALTER TABLE ... ANALYZE PARTITION` instead, to avoid this issue.

- **Analyzing partitions.** This reads and stores the key distributions for partitions.

Example:

```
ALTER TABLE t1 ANALYZE PARTITION p3;
```

- **Repairing partitions.** This repairs corrupted partitions.

Example:

```
ALTER TABLE t1 REPAIR PARTITION p0,p1;
```

Normally, `REPAIR PARTITION` fails when the partition contains duplicate key errors. In MySQL 5.7.2 and later, you can use `ALTER IGNORE TABLE` with this option, in which case all rows that cannot be moved due to the presence of duplicate keys are removed from the partition (Bug #16900947).

- **Checking partitions.** You can check partitions for errors in much the same way that you can use `CHECK TABLE` with nonpartitioned tables.

Example:

```
ALTER TABLE trb3 CHECK PARTITION p1;
```

This command will tell you if the data or indexes in partition `p1` of table `t1` are corrupted. If this is the case, use `ALTER TABLE ... REPAIR PARTITION` to repair the partition.

Normally, `CHECK PARTITION` fails when the partition contains duplicate key errors. In MySQL 5.7.2 and later, you can use `ALTER IGNORE TABLE` with this option, in which case the statement returns the contents of each row in the partition where a duplicate key violation is found. Note that only the values for the columns in the partitioning expression for the table are reported. (Bug #16900947)

Each of the statements in the list just shown also supports the keyword `ALL` in place of the list of partition names. Using `ALL` causes the statement to act on all partitions in the table.

The use of `mysqlcheck` and `myisamchk` is not supported with partitioned tables.

In MySQL 5.7, you can also truncate partitions using `ALTER TABLE ... TRUNCATE PARTITION`. This statement can be used to delete all rows from one or more partitions in much the same way that `TRUNCATE TABLE` deletes all rows from a table.

`ALTER TABLE ... TRUNCATE PARTITION ALL` truncates all partitions in the table.

Prior to MySQL 5.7.2, `ANALYZE`, `CHECK`, `OPTIMIZE`, `REBUILD`, `REPAIR`, and `TRUNCATE` operations were not permitted on subpartitions (Bug #14028340, Bug #65184).

### 21.3.5 Obtaining Information About Partitions

This section discusses obtaining information about existing partitions, which can be done in a number of ways. Methods of obtaining such information include the following:

- Using the `SHOW CREATE TABLE` statement to view the partitioning clauses used in creating a partitioned table.
- Using the `SHOW TABLE STATUS` statement to determine whether a table is partitioned.
- Querying the `INFORMATION_SCHEMA.PARTITIONS` table.
- Using the statement `EXPLAIN PARTITIONS SELECT` to see which partitions are used by a given `SELECT`.

As discussed elsewhere in this chapter, `SHOW CREATE TABLE` includes in its output the `PARTITION BY` clause used to create a partitioned table. For example:

```
mysql> SHOW CREATE TABLE trb3\G
***** 1. row *****
      Table: trb3
Create Table: CREATE TABLE `trb3` (
  `id` int(11) default NULL,
  `name` varchar(50) default NULL,
  `purchased` date default NULL
) ENGINE=MyISAM DEFAULT CHARSET=latin1
PARTITION BY RANGE (YEAR(purchased)) (
  PARTITION p0 VALUES LESS THAN (1990) ENGINE = MyISAM,
  PARTITION p1 VALUES LESS THAN (1995) ENGINE = MyISAM,
  PARTITION p2 VALUES LESS THAN (2000) ENGINE = MyISAM,
  PARTITION p3 VALUES LESS THAN (2005) ENGINE = MyISAM
)
1 row in set (0.00 sec)
```

The output from `SHOW TABLE STATUS` for partitioned tables is the same as that for nonpartitioned tables, except that the `Create_options` column contains the string `partitioned`. The `Engine` column contains the name of the storage engine used by all partitions of the table. (See [Section 14.7.5.36, “SHOW TABLE STATUS Syntax”](#), for more information about this statement.)

You can also obtain information about partitions from `INFORMATION_SCHEMA`, which contains a `PARTITIONS` table. See [Section 23.15, “The INFORMATION\\_SCHEMA PARTITIONS Table”](#).

It is possible to determine which partitions of a partitioned table are involved in a given `SELECT` query using `EXPLAIN PARTITIONS`. The `PARTITIONS` keyword adds a `partitions` column to the output of `EXPLAIN` listing the partitions from which records would be matched by the query.

Suppose that you have a table `trb1` created and populated as follows:

```
CREATE TABLE trb1 (id INT, name VARCHAR(50), purchased DATE)
PARTITION BY RANGE(id)
(
  PARTITION p0 VALUES LESS THAN (3),
  PARTITION p1 VALUES LESS THAN (7),
```

```

        PARTITION p2 VALUES LESS THAN (9),
        PARTITION p3 VALUES LESS THAN (11)
    );

INSERT INTO trb1 VALUES
    (1, 'desk organiser', '2003-10-15'),
    (2, 'CD player', '1993-11-05'),
    (3, 'TV set', '1996-03-10'),
    (4, 'bookcase', '1982-01-10'),
    (5, 'exercise bike', '2004-05-09'),
    (6, 'sofa', '1987-06-05'),
    (7, 'popcorn maker', '2001-11-22'),
    (8, 'aquarium', '1992-08-04'),
    (9, 'study desk', '1984-09-16'),
    (10, 'lava lamp', '1998-12-25');

```

You can see which partitions are used in a query such as `SELECT * FROM trb1;`, as shown here:

```

mysql> EXPLAIN PARTITIONS SELECT * FROM trb1\G
***** 1. row *****
      id: 1
  select_type: SIMPLE
        table: trb1
   partitions: p0,p1,p2,p3
         type: ALL
possible_keys: NULL
          key: NULL
       key_len: NULL
         ref: NULL
        rows: 10
   Extra: Using filesort

```

In this case, all four partitions are searched. However, when a limiting condition making use of the partitioning key is added to the query, you can see that only those partitions containing matching values are scanned, as shown here:

```

mysql> EXPLAIN PARTITIONS SELECT * FROM trb1 WHERE id < 5\G
***** 1. row *****
      id: 1
  select_type: SIMPLE
        table: trb1
   partitions: p0,p1
         type: ALL
possible_keys: NULL
          key: NULL
       key_len: NULL
         ref: NULL
        rows: 10
   Extra: Using where

```

`EXPLAIN PARTITIONS` provides information about keys used and possible keys, just as with the standard `EXPLAIN SELECT` statement:

```

mysql> ALTER TABLE trb1 ADD PRIMARY KEY (id);
Query OK, 10 rows affected (0.03 sec)
Records: 10  Duplicates: 0  Warnings: 0

mysql> EXPLAIN PARTITIONS SELECT * FROM trb1 WHERE id < 5\G
***** 1. row *****
      id: 1
  select_type: SIMPLE
        table: trb1
   partitions: p0,p1
         type: range
possible_keys: PRIMARY
          key: PRIMARY
       key_len: 4
         ref: NULL

```

```
rows: 7
Extra: Using where
```

**Note**

As of MySQL 5.7.3, partition information is enabled by default and the `PARTITIONS` keyword is unnecessary.

You should take note of the following restrictions and limitations on `EXPLAIN PARTITIONS`:

- You cannot use the `PARTITIONS` and `EXTENDED` keywords together in the same `EXPLAIN ... SELECT` statement. Attempting to do so produces a syntax error.
- If `EXPLAIN PARTITIONS` is used to examine a query against a nonpartitioned table, no error is produced, but the value of the `partitions` column is always `NULL`.

The `rows` column of `EXPLAIN PARTITIONS` output displays the total number of rows in the table.

See also [Section 14.8.2, “EXPLAIN Syntax”](#).

## 21.4 Partition Pruning

This section discusses an optimization known as *partition pruning*. The core concept behind partition pruning is relatively simple, and can be described as “Do not scan partitions where there can be no matching values”. Suppose that you have a partitioned table `t1` defined by this statement:

```
CREATE TABLE t1 (
  fname VARCHAR(50) NOT NULL,
  lname VARCHAR(50) NOT NULL,
  region_code TINYINT UNSIGNED NOT NULL,
  dob DATE NOT NULL
)
PARTITION BY RANGE( region_code ) (
  PARTITION p0 VALUES LESS THAN (64),
  PARTITION p1 VALUES LESS THAN (128),
  PARTITION p2 VALUES LESS THAN (192),
  PARTITION p3 VALUES LESS THAN MAXVALUE
);
```

Consider the case where you wish to obtain results from a `SELECT` statement such as this one:

```
SELECT fname, lname, region_code, dob
FROM t1
WHERE region_code > 125 AND region_code < 130;
```

It is easy to see that none of the rows which ought to be returned will be in either of the partitions `p0` or `p3`; that is, we need to search only in partitions `p1` and `p2` to find matching rows. By doing so, it is possible to expend much less time and effort in finding matching rows than would be required to scan all partitions in the table. This “cutting away” of unneeded partitions is known as *pruning*. When the optimizer can make use of partition pruning in performing this query, execution of the query can be an order of magnitude faster than the same query against a nonpartitioned table containing the same column definitions and data.

**Note**

When pruning is performed on a partitioned `MyISAM` table, all partitions are opened, whether or not they are examined, due to the design of the `MyISAM` storage engine. This means that you must have a sufficient number of file descriptors available to cover all partitions of the table. See [MyISAM and partition file descriptor usage](#).

This limitation does not apply to partitioned tables using other MySQL storage engines such as `InnoDB`.

The optimizer can perform pruning whenever a `WHERE` condition can be reduced to either one of the following two cases:

- `partition_column = constant`
- `partition_column IN (constant1, constant2, ..., constantN)`

In the first case, the optimizer simply evaluates the partitioning expression for the value given, determines which partition contains that value, and scans only this partition. In many cases, the equal sign can be replaced with another arithmetic comparison, including `<`, `>`, `<=`, `>=`, and `<>`. Some queries using `BETWEEN` in the `WHERE` clause can also take advantage of partition pruning. See the examples later in this section.

In the second case, the optimizer evaluates the partitioning expression for each value in the list, creates a list of matching partitions, and then scans only the partitions in this partition list.

MySQL can apply partition pruning to `SELECT`, `DELETE`, and `UPDATE` statements. `INSERT` statements currently cannot be pruned.

Pruning can also be applied to short ranges, which the optimizer can convert into equivalent lists of values. For instance, in the previous example, the `WHERE` clause can be converted to `WHERE region_code IN (126, 127, 128, 129)`. Then the optimizer can determine that the first two values in the list are found in partition `p1`, the remaining two values in partition `p2`, and that the other partitions contain no relevant values and so do not need to be searched for matching rows.

The optimizer can also perform pruning for `WHERE` conditions that involve comparisons of the preceding types on multiple columns for tables that use `RANGE COLUMNS` or `LIST COLUMNS` partitioning.

This type of optimization can be applied whenever the partitioning expression consists of an equality or a range which can be reduced to a set of equalities, or when the partitioning expression represents an increasing or decreasing relationship. Pruning can also be applied for tables partitioned on a `DATE` or `DATETIME` column when the partitioning expression uses the `YEAR()` or `TO_DAYS()` function. In addition, in MySQL 5.7, pruning can be applied for such tables when the partitioning expression uses the `TO_SECONDS()` function.

Suppose that table `t2`, defined as shown here, is partitioned on a `DATE` column:

```
CREATE TABLE t2 (
  fname VARCHAR(50) NOT NULL,
  lname VARCHAR(50) NOT NULL,
  region_code TINYINT UNSIGNED NOT NULL,
  dob DATE NOT NULL
)
PARTITION BY RANGE( YEAR(dob) ) (
  PARTITION d0 VALUES LESS THAN (1970),
  PARTITION d1 VALUES LESS THAN (1975),
  PARTITION d2 VALUES LESS THAN (1980),
  PARTITION d3 VALUES LESS THAN (1985),
  PARTITION d4 VALUES LESS THAN (1990),
  PARTITION d5 VALUES LESS THAN (2000),
  PARTITION d6 VALUES LESS THAN (2005),
  PARTITION d7 VALUES LESS THAN MAXVALUE
);
```

The following statements using `t2` can make use partition pruning:

```
SELECT * FROM t2 WHERE dob = '1982-06-23';

UPDATE t2 SET region_code = 8 WHERE dob BETWEEN '1991-02-15' AND '1997-04-25';

DELETE FROM t2 WHERE dob >= '1984-06-21' AND dob <= '1999-06-21'
```

In the case of the last statement, the optimizer can also act as follows:

1. Find the partition containing the low end of the range.

`YEAR( '1984-06-21' )` yields the value `1984`, which is found in partition `d3`.

2. Find the partition containing the high end of the range.

`YEAR( '1999-06-21' )` evaluates to `1999`, which is found in partition `d5`.

3. Scan only these two partitions and any partitions that may lie between them.

In this case, this means that only partitions `d3`, `d4`, and `d5` are scanned. The remaining partitions may be safely ignored (and are ignored).

#### Important

Invalid `DATE` and `DATETIME` values referenced in the `WHERE` condition of a statement against a partitioned table are treated as `NULL`. This means that a query such as `SELECT * FROM partitioned_table WHERE date_column < '2008-12-00'` does not return any values (see Bug #40972).

So far, we have looked only at examples using `RANGE` partitioning, but pruning can be applied with other partitioning types as well.

Consider a table that is partitioned by `LIST`, where the partitioning expression is increasing or decreasing, such as the table `t3` shown here. (In this example, we assume for the sake of brevity that the `region_code` column is limited to values between 1 and 10 inclusive.)

```
CREATE TABLE t3 (
  fname VARCHAR(50) NOT NULL,
  lname VARCHAR(50) NOT NULL,
  region_code TINYINT UNSIGNED NOT NULL,
  dob DATE NOT NULL
)
PARTITION BY LIST(region_code) (
  PARTITION r0 VALUES IN (1, 3),
  PARTITION r1 VALUES IN (2, 5, 8),
  PARTITION r2 VALUES IN (4, 9),
  PARTITION r3 VALUES IN (6, 7, 10)
);
```

For a statement such as `SELECT * FROM t3 WHERE region_code BETWEEN 1 AND 3`, the optimizer determines in which partitions the values 1, 2, and 3 are found (`r0` and `r1`) and skips the remaining ones (`r2` and `r3`).

For tables that are partitioned by `HASH` or `[LINEAR] KEY`, partition pruning is also possible in cases in which the `WHERE` clause uses a simple `=` relation against a column used in the partitioning expression. Consider a table created like this:

```
CREATE TABLE t4 (
  fname VARCHAR(50) NOT NULL,
  lname VARCHAR(50) NOT NULL,
  region_code TINYINT UNSIGNED NOT NULL,
  dob DATE NOT NULL
)
PARTITION BY KEY(region_code)
PARTITIONS 8;
```

A statement that compares a column value with a constant can be pruned:

```
UPDATE t4 WHERE region_code = 7;
```

Pruning can also be employed for short ranges, because the optimizer can turn such conditions into `IN` relations. For example, using the same table `t4` as defined previously, queries such as these can be pruned:

```
SELECT * FROM t4 WHERE region_code > 2 AND region_code < 6;

SELECT * FROM t4 WHERE region_code BETWEEN 3 AND 5;
```

In both these cases, the `WHERE` clause is transformed by the optimizer into `WHERE region_code IN (3, 4, 5)`.

### Important

This optimization is used only if the range size is smaller than the number of partitions. Consider this statement:

```
DELETE FROM t4 WHERE region_code BETWEEN 4 AND 12;
```

The range in the `WHERE` clause covers 9 values (4, 5, 6, 7, 8, 9, 10, 11, 12), but `t4` has only 8 partitions. This means that the `DELETE` cannot be pruned.

When a table is partitioned by `HASH` or `[LINEAR] KEY`, pruning can be used only on integer columns. For example, this statement cannot use pruning because `dob` is a `DATE` column:

```
SELECT * FROM t4 WHERE dob >= '2001-04-14' AND dob <= '2005-10-15';
```

However, if the table stores year values in an `INT` column, then a query having `WHERE year_col >= 2001 AND year_col <= 2005` can be pruned.

Prior to MySQL 5.7.1, partition pruning was disabled for all tables using a storage engine that provides automatic partitioning, such as the `NDB` storage engine used by MySQL Cluster. (Bug #14672885) Beginning with MySQL 5.7.1, such tables can be pruned if they are explicitly partitioned. (Bug #14827952)

## 21.5 Partition Selection

MySQL 5.7 supports explicit selection of partitions and subpartitions that, when executing a statement, should be checked for rows matching a given `WHERE` condition. Partition selection is similar to partition pruning, in that only specific partitions are checked for matches, but differs in two key respects:

1. The partitions to be checked are specified by the issuer of the statement, unlike partition pruning, which is automatic.
2. Whereas partition pruning applies only to queries, explicit selection of partitions is supported for both queries and a number of DML statements.

SQL statements supporting explicit partition selection are listed here:

- `SELECT`
- `DELETE`
- `INSERT`
- `REPLACE`
- `UPDATE`
- `LOAD DATA`.
- `LOAD XML`.

The remainder of this section discusses explicit partition selection as it applies generally to the statements just listed, and provides some examples.

Explicit partition selection is implemented using a `PARTITION` option. For all supported statements, this option uses the syntax shown here:

```
PARTITION (partition_names)

partition_names:
    partition_name, ...
```

This option always follows the name of the table to which the partition or partitions belong. *partition\_names* is a comma-separated list of partitions or subpartitions to be used. Each name in this list must be the name of an existing partition or subpartition of the specified table; if any of the partitions or subpartitions are not found, the statement fails with an error (*partition 'partition\_name' doesn't exist*). Partitions and subpartitions named in *partition\_names* may be listed in any order, and may overlap.

When the `PARTITION` option is used, only the partitions and subpartitions listed are checked for matching rows. This option can be used in a `SELECT` statement to determine which rows belong to a given partition. Consider a partitioned table named `employees`, created and populated using the statements shown here:

```
SET @@SQL_MODE = '';

CREATE TABLE employees (
    id INT NOT NULL AUTO_INCREMENT PRIMARY KEY,
    fname VARCHAR(25) NOT NULL,
    lname VARCHAR(25) NOT NULL,
    store_id INT NOT NULL,
    department_id INT NOT NULL
)
PARTITION BY RANGE(id) (
    PARTITION p0 VALUES LESS THAN (5),
    PARTITION p1 VALUES LESS THAN (10),
    PARTITION p2 VALUES LESS THAN (15),
    PARTITION p3 VALUES LESS THAN MAXVALUE
);

INSERT INTO employees VALUES
    ('', 'Bob', 'Taylor', 3, 2), ('', 'Frank', 'Williams', 1, 2),
    ('', 'Ellen', 'Johnson', 3, 4), ('', 'Jim', 'Smith', 2, 4),
    ('', 'Mary', 'Jones', 1, 1), ('', 'Linda', 'Black', 2, 3),
    ('', 'Ed', 'Jones', 2, 1), ('', 'June', 'Wilson', 3, 1),
    ('', 'Andy', 'Smith', 1, 3), ('', 'Lou', 'Waters', 2, 4),
    ('', 'Jill', 'Stone', 1, 4), ('', 'Roger', 'White', 3, 2),
    ('', 'Howard', 'Andrews', 1, 2), ('', 'Fred', 'Goldberg', 3, 3),
    ('', 'Barbara', 'Brown', 2, 3), ('', 'Alice', 'Rogers', 2, 2),
    ('', 'Mark', 'Morgan', 3, 3), ('', 'Karen', 'Cole', 3, 2);
```

You can see which rows are stored in partition `p1` like this:

```
mysql> SELECT * FROM employees PARTITION (p1);
+----+-----+-----+-----+-----+
| id | fname | lname | store_id | department_id |
+----+-----+-----+-----+-----+
|  5 | Mary  | Jones |        1 |              1 |
|  6 | Linda | Black |        2 |              3 |
|  7 | Ed    | Jones |        2 |              1 |
|  8 | June  | Wilson |        3 |              1 |
|  9 | Andy  | Smith |        1 |              3 |
+----+-----+-----+-----+-----+
5 rows in set (0.00 sec)
```

The result is the same as obtained by the query `SELECT * FROM employees WHERE id BETWEEN 5 AND 9`.

To obtain rows from multiple partitions, supply their names as a comma-delimited list. For example, `SELECT * FROM employees PARTITION (p1, p2)` returns all rows from partitions `p1` and `p2` while excluding rows from the remaining partitions.

Any valid query against a partitioned table can be rewritten with a `PARTITION` option to restrict the result to one or more desired partitions. You can use `WHERE` conditions, `ORDER BY` and `LIMIT` options, and so on. You can also use aggregate functions with `HAVING` and `GROUP BY` options. Each of the following queries produces a valid result when run on the `employees` table as previously defined:

```
mysql> SELECT * FROM employees PARTITION (p0, p2)
->     WHERE lname LIKE 'S%';
+-----+-----+-----+-----+-----+
| id | fname | lname | store_id | department_id |
+-----+-----+-----+-----+-----+
| 4 | Jim   | Smith | 2        | 4             |
| 11 | Jill  | Stone | 1        | 4             |
+-----+-----+-----+-----+-----+
2 rows in set (0.00 sec)
```

```
mysql> SELECT id, CONCAT(fname, ' ', lname) AS name
->     FROM employees PARTITION (p0) ORDER BY lname;
+-----+-----+
| id | name          |
+-----+-----+
| 3 | Ellen Johnson |
| 4 | Jim Smith     |
| 1 | Bob Taylor    |
| 2 | Frank Williams |
+-----+-----+
4 rows in set (0.06 sec)
```

```
mysql> SELECT store_id, COUNT(department_id) AS c
->     FROM employees PARTITION (p1,p2,p3)
->     GROUP BY store_id HAVING c > 4;
+-----+-----+
| c | store_id |
+-----+-----+
| 5 | 2        |
| 5 | 3        |
+-----+-----+
2 rows in set (0.00 sec)
```

Statements using partition selection can be employed with tables using any of the partitioning types supported in MySQL 5.7. When a table is created using `[LINEAR] HASH` or `[LINEAR] KEY` partitioning and the names of the partitions are not specified, MySQL automatically names the partitions `p0`, `p1`, `p2`, ..., `pN-1`, where `N` is the number of partitions. For subpartitions not explicitly named, MySQL assigns automatically to the subpartitions in each partition `pX` the names `pXsp0`, `pXsp1`, `pXsp2`, ..., `pXspM-1`, where `M` is the number of subpartitions. When executing against this table a `SELECT` (or other SQL statement for which explicit partition selection is allowed), you can use these generated names in a `PARTITION` option, as shown here:

```
mysql> CREATE TABLE employees_sub (
->     id INT NOT NULL AUTO_INCREMENT,
->     fname VARCHAR(25) NOT NULL,
->     lname VARCHAR(25) NOT NULL,
->     store_id INT NOT NULL,
->     department_id INT NOT NULL,
->     PRIMARY KEY pk (id, lname)
-> )
->     PARTITION BY RANGE(id)
->     SUBPARTITION BY KEY (lname)
->     SUBPARTITIONS 2 (
->         PARTITION p0 VALUES LESS THAN (5),
->         PARTITION p1 VALUES LESS THAN (10),
->         PARTITION p2 VALUES LESS THAN (15),
->         PARTITION p3 VALUES LESS THAN MAXVALUE
-> );
Query OK, 0 rows affected (1.14 sec)
```

```
mysql> INSERT INTO employees_sub # re-use data in employees table
->     SELECT * FROM employees;
Query OK, 18 rows affected (0.09 sec)
```

```
Records: 18  Duplicates: 0  Warnings: 0

mysql> SELECT id, CONCAT(fname, ' ', lname) AS name
->      FROM employees_sub PARTITION (p2sp1);
+-----+-----+
| id | name          |
+-----+-----+
| 10 | Lou Waters    |
| 14 | Fred Goldberg |
+-----+-----+
2 rows in set (0.00 sec)
```

You may also use a `PARTITION` option in the `SELECT` portion of an `INSERT ... SELECT` statement, as shown here:

```
mysql> CREATE TABLE employees_copy LIKE employees;
Query OK, 0 rows affected (0.28 sec)

mysql> INSERT INTO employees_copy
->      SELECT * FROM employees PARTITION (p2);
Query OK, 5 rows affected (0.04 sec)
Records: 5  Duplicates: 0  Warnings: 0

mysql> SELECT * FROM employees_copy;
+-----+-----+-----+-----+-----+
| id | fname | lname | store_id | department_id |
+-----+-----+-----+-----+-----+
| 10 | Lou   | Waters | 2        | 4             |
| 11 | Jill  | Stone | 1        | 4             |
| 12 | Roger | White | 3        | 2             |
| 13 | Howard | Andrews | 1       | 2             |
| 14 | Fred  | Goldberg | 3       | 3             |
+-----+-----+-----+-----+-----+
5 rows in set (0.00 sec)
```

Partition selection can also be used with joins. Suppose we create and populate two tables using the statements shown here:

```
CREATE TABLE stores (
  id INT NOT NULL AUTO_INCREMENT PRIMARY KEY,
  city VARCHAR(30) NOT NULL
)
PARTITION BY HASH(id)
PARTITIONS 2;

INSERT INTO stores VALUES
  ('', 'Nambucca'), ('', 'Uranga'),
  ('', 'Bellinghen'), ('', 'Grafton');

CREATE TABLE departments (
  id INT NOT NULL AUTO_INCREMENT PRIMARY KEY,
  name VARCHAR(30) NOT NULL
)
PARTITION BY KEY(id)
PARTITIONS 2;

INSERT INTO departments VALUES
  ('', 'Sales'), ('', 'Customer Service'),
  ('', 'Delivery'), ('', 'Accounting');
```

You can explicitly select partitions (or subpartitions, or both) from any or all of the tables in a join. (Note that the `PARTITION` option used to select partitions from a given table immediately follows the name of the table, before all other options, including any table alias.) For example, the following query gets the name, employee ID, department, and city of all employees who work in the Sales or Delivery department (partition `p1` of the `departments` table) at the stores in either of the cities of Nambucca and Bellinghen (partition `p0` of the `stores` table):

```
mysql> SELECT
```

```
-> e.id AS 'Employee ID', CONCAT(e.fname, ' ', e.lname) AS Name,
-> s.city AS City, d.name AS department
-> FROM employees AS e
-> JOIN stores PARTITION (p1) AS s ON e.store_id=s.id
-> JOIN departments PARTITION (p0) AS d ON e.department_id=d.id
-> ORDER BY e.lname;
```

| Employee ID | Name          | City      | department |
|-------------|---------------|-----------|------------|
| 14          | Fred Goldberg | Bellingen | Delivery   |
| 5           | Mary Jones    | Nambucca  | Sales      |
| 17          | Mark Morgan   | Bellingen | Delivery   |
| 9           | Andy Smith    | Nambucca  | Delivery   |
| 8           | June Wilson   | Bellingen | Sales      |

5 rows in set (0.00 sec)

For general information about joins in MySQL, see [Section 14.2.9.2, “JOIN Syntax”](#).

When the `PARTITION` option is used with `DELETE` statements, only those partitions (and subpartitions, if any) listed with the option are checked for rows to be deleted. Any other partitions are ignored, as shown here:

```
mysql> SELECT * FROM employees WHERE fname LIKE 'j%';
```

| id | fname | lname  | store_id | department_id |
|----|-------|--------|----------|---------------|
| 4  | Jim   | Smith  | 2        | 4             |
| 8  | June  | Wilson | 3        | 1             |
| 11 | Jill  | Stone  | 1        | 4             |

3 rows in set (0.00 sec)

```
mysql> DELETE FROM employees PARTITION (p0, p1)
-> WHERE fname LIKE 'j%';
Query OK, 2 rows affected (0.09 sec)
```

```
mysql> SELECT * FROM employees WHERE fname LIKE 'j%';
```

| id | fname | lname | store_id | department_id |
|----|-------|-------|----------|---------------|
| 11 | Jill  | Stone | 1        | 4             |

1 row in set (0.00 sec)

Only the two rows in partitions `p0` and `p1` matching the `WHERE` condition were deleted. As you can see from the result when the `SELECT` is run a second time, there remains a row in the table matching the `WHERE` condition, but residing in a different partition (`p2`).

`UPDATE` statements using explicit partition selection behave in the same way; only rows in the partitions referenced by the `PARTITION` option are considered when determining the rows to be updated, as can be seen by executing the following statements:

```
mysql> UPDATE employees PARTITION (p0)
-> SET store_id = 2 WHERE fname = 'Jill';
Query OK, 0 rows affected (0.00 sec)
Rows matched: 0 Changed: 0 Warnings: 0
```

```
mysql> SELECT * FROM employees WHERE fname = 'Jill';
```

| id | fname | lname | store_id | department_id |
|----|-------|-------|----------|---------------|
| 11 | Jill  | Stone | 1        | 4             |

1 row in set (0.00 sec)

```
mysql> UPDATE employees PARTITION (p2)
-> SET store_id = 2 WHERE fname = 'Jill';
Query OK, 1 row affected (0.09 sec)
```

```

Rows matched: 1  Changed: 1  Warnings: 0

mysql> SELECT * FROM employees WHERE fname = 'Jill';
+-----+-----+-----+-----+-----+
| id | fname | lname | store_id | department_id |
+-----+-----+-----+-----+-----+
| 11 | Jill  | Stone | 2        | 4             |
+-----+-----+-----+-----+-----+
1 row in set (0.00 sec)

```

In the same way, when `PARTITION` is used with `DELETE`, only rows in the partition or partitions named in the partition list are checked for deletion.

For statements that insert rows, the behavior differs in that failure to find a suitable partition causes the statement to fail. This is true for both `INSERT` and `REPLACE` statements, as shown here:

```

mysql> INSERT INTO employees PARTITION (p2) VALUES (20, 'Jan', 'Jones', 1, 3);
ERROR 1729 (HY000): Found a row not matching the given partition set
mysql> INSERT INTO employees PARTITION (p3) VALUES (20, 'Jan', 'Jones', 1, 3);
Query OK, 1 row affected (0.07 sec)

mysql> REPLACE INTO employees PARTITION (p0) VALUES (20, 'Jan', 'Jones', 3, 2);
ERROR 1729 (HY000): Found a row not matching the given partition set

mysql> REPLACE INTO employees PARTITION (p3) VALUES (20, 'Jan', 'Jones', 3, 2);
Query OK, 2 rows affected (0.09 sec)

```

For statements that write multiple rows to a partitioned table that uses the `InnoDB` storage engine: If any row in the list following `VALUES` cannot be written to one of the partitions specified in the `partition_names` list, the entire statement fails and no rows are written. This is shown for `INSERT` statements in the following example, reusing the `employees` table created previously:

```

mysql> ALTER TABLE employees
-> REORGANIZE PARTITION p3 INTO (
-> PARTITION p3 VALUES LESS THAN (20),
-> PARTITION p4 VALUES LESS THAN (25),
-> PARTITION p5 VALUES LESS THAN MAXVALUE
-> );
Query OK, 6 rows affected (2.09 sec)
Records: 6 Duplicates: 0 Warnings: 0

mysql> SHOW CREATE TABLE employees\G
***** 1. row *****
      Table: employees
Create Table: CREATE TABLE `employees` (
  `id` int(11) NOT NULL AUTO_INCREMENT,
  `fname` varchar(25) NOT NULL,
  `lname` varchar(25) NOT NULL,
  `store_id` int(11) NOT NULL,
  `department_id` int(11) NOT NULL,
  PRIMARY KEY (`id`)
) ENGINE=InnoDB AUTO_INCREMENT=27 DEFAULT CHARSET=latin1
/*!50100 PARTITION BY RANGE (id)
(PARTITION p0 VALUES LESS THAN (5) ENGINE = InnoDB,
PARTITION p1 VALUES LESS THAN (10) ENGINE = InnoDB,
PARTITION p2 VALUES LESS THAN (15) ENGINE = InnoDB,
PARTITION p3 VALUES LESS THAN (20) ENGINE = InnoDB,
PARTITION p4 VALUES LESS THAN (25) ENGINE = InnoDB,
PARTITION p5 VALUES LESS THAN MAXVALUE ENGINE = InnoDB) */
1 row in set (0.00 sec)

mysql> INSERT INTO employees PARTITION (p3, p4) VALUES
-> (24, 'Tim', 'Greene', 3, 1), (26, 'Linda', 'Mills', 2, 1);
ERROR 1729 (HY000): Found a row not matching the given partition set

mysql> INSERT INTO employees PARTITION (p3, p4, p5) VALUES
-> (24, 'Tim', 'Greene', 3, 1), (26, 'Linda', 'Mills', 2, 1);
Query OK, 2 rows affected (0.06 sec)
Records: 2 Duplicates: 0 Warnings: 0

```

The preceding is true for both `INSERT` statements and `REPLACE` statements that write multiple rows.

In MySQL 5.7.1 and later, partition selection is disabled for tables employing a storage engine that supplies automatic partitioning, such as `NDB`. (Bug #14827952)

## 21.6 Restrictions and Limitations on Partitioning

This section discusses current restrictions and limitations on MySQL partitioning support.

**Prohibited constructs.** The following constructs are not permitted in partitioning expressions:

- Stored procedures, stored functions, UDFs, or plugins.
- Declared variables or user variables.

For a list of SQL functions which are permitted in partitioning expressions, see [Section 21.6.3, “Partitioning Limitations Relating to Functions”](#).

**Arithmetic and logical operators.** Use of the arithmetic operators `+`, `-`, and `*` is permitted in partitioning expressions. However, the result must be an integer value or `NULL` (except in the case of `[LINEAR] KEY` partitioning, as discussed elsewhere in this chapter; see [Section 21.2, “Partitioning Types”](#), for more information).

The `DIV` operator is also supported, and the `/` operator is not permitted. (Bug #30188, Bug #33182)

The bit operators `|`, `&`, `^`, `<<`, `>>`, and `~` are not permitted in partitioning expressions.

**HANDLER statements.** Previously, the `HANDLER` statement was not supported with partitioned tables. This limitation is removed beginning with MySQL 5.7.1.

**Server SQL mode.** Tables employing user-defined partitioning do not preserve the SQL mode in effect at the time that they were created. As discussed in [Section 6.1.8, “Server SQL Modes”](#), the results of many MySQL functions and operators may change according to the server SQL mode. Therefore, a change in the SQL mode at any time after the creation of partitioned tables may lead to major changes in the behavior of such tables, and could easily lead to corruption or loss of data. For these reasons, *it is strongly recommended that you never change the server SQL mode after creating partitioned tables.*

**Examples.** The following examples illustrate some changes in behavior of partitioned tables due to a change in the server SQL mode:

1. **Error handling.** Suppose that you create a partitioned table whose partitioning expression is one such as `column DIV 0` or `column MOD 0`, as shown here:

```
mysql> CREATE TABLE tn (c1 INT)
->     PARTITION BY LIST(1 DIV c1) (
->     PARTITION p0 VALUES IN (NULL),
->     PARTITION p1 VALUES IN (1)
-> );
Query OK, 0 rows affected (0.05 sec)
```

The default behavior for MySQL is to return `NULL` for the result of a division by zero, without producing any errors:

```
mysql> SELECT @@sql_mode;
+-----+
| @@sql_mode |
+-----+
|             |
+-----+
1 row in set (0.00 sec)

mysql> INSERT INTO tn VALUES (NULL), (0), (1);
```

```
Query OK, 3 rows affected (0.00 sec)
Records: 3 Duplicates: 0 Warnings: 0
```

However, changing the server SQL mode to treat division by zero as an error and to enforce strict error handling causes the same `INSERT` statement to fail, as shown here:

```
mysql> SET sql_mode='STRICT_ALL_TABLES,ERROR_FOR_DIVISION_BY_ZERO';
Query OK, 0 rows affected (0.00 sec)

mysql> INSERT INTO tn VALUES (NULL), (0), (1);
ERROR 1365 (22012): Division by 0
```

2. **Table accessibility.** Sometimes a change in the server SQL mode can make partitioned tables unusable. The following `CREATE TABLE` statement can be executed successfully only if the `NO_UNSIGNED_SUBTRACTION` mode is in effect:

```
mysql> SELECT @@sql_mode;
+-----+
| @@sql_mode |
+-----+
|             |
+-----+
1 row in set (0.00 sec)

mysql> CREATE TABLE tu (c1 BIGINT UNSIGNED)
-> PARTITION BY RANGE(c1 - 10) (
-> PARTITION p0 VALUES LESS THAN (-5),
-> PARTITION p1 VALUES LESS THAN (0),
-> PARTITION p2 VALUES LESS THAN (5),
-> PARTITION p3 VALUES LESS THAN (10),
-> PARTITION p4 VALUES LESS THAN (MAXVALUE)
-> );
ERROR 1563 (HY000): Partition constant is out of partition function domain

mysql> SET sql_mode='NO_UNSIGNED_SUBTRACTION';
Query OK, 0 rows affected (0.00 sec)

mysql> SELECT @@sql_mode;
+-----+
| @@sql_mode |
+-----+
| NO_UNSIGNED_SUBTRACTION |
+-----+
1 row in set (0.00 sec)

mysql> CREATE TABLE tu (c1 BIGINT UNSIGNED)
-> PARTITION BY RANGE(c1 - 10) (
-> PARTITION p0 VALUES LESS THAN (-5),
-> PARTITION p1 VALUES LESS THAN (0),
-> PARTITION p2 VALUES LESS THAN (5),
-> PARTITION p3 VALUES LESS THAN (10),
-> PARTITION p4 VALUES LESS THAN (MAXVALUE)
-> );
Query OK, 0 rows affected (0.05 sec)
```

If you remove the `NO_UNSIGNED_SUBTRACTION` server SQL mode after creating `tu`, you may no longer be able to access this table:

```
mysql> SET sql_mode='';
Query OK, 0 rows affected (0.00 sec)

mysql> SELECT * FROM tu;
ERROR 1563 (HY000): Partition constant is out of partition function domain
mysql> INSERT INTO tu VALUES (20);
ERROR 1563 (HY000): Partition constant is out of partition function domain
```

Server SQL modes also impact replication of partitioned tables. Differing SQL modes on master and slave can lead to partitioning expressions being evaluated differently; this can cause the distribution of data among partitions to be different in the master's and slave's copies of a given table, and may even cause inserts into partitioned tables that succeed on the master to fail on the slave. For best results, you should always use the same server SQL mode on the master and on the slave.

**Performance considerations.** Some effects of partitioning operations on performance are given in the following list:

- **File system operations.** Partitioning and repartitioning operations (such as `ALTER TABLE` with `PARTITION BY ...`, `REORGANIZE PARTITIONS`, or `REMOVE PARTITIONING`) depend on file system operations for their implementation. This means that the speed of these operations is affected by such factors as file system type and characteristics, disk speed, swap space, file handling efficiency of the operating system, and MySQL server options and variables that relate to file handling. In particular, you should make sure that `large_files_support` is enabled and that `open_files_limit` is set properly. For partitioned tables using the `MyISAM` storage engine, increasing `myisam_max_sort_file_size` may improve performance; partitioning and repartitioning operations involving `InnoDB` tables may be made more efficient by enabling `innodb_file_per_table`.

See also [Maximum number of partitions](#).

- **MyISAM and partition file descriptor usage.** For a partitioned `MyISAM` table, MySQL uses 2 file descriptors for each partition, for each such table that is open. This means that you need many more file descriptors to perform operations on a partitioned `MyISAM` table than on a table which is identical to it except that the latter table is not partitioned, particularly when performing `ALTER TABLE` operations.

Assume a `MyISAM` table `t` with 100 partitions, such as the table created by this SQL statement:

```
CREATE TABLE t (c1 VARCHAR(50))
PARTITION BY KEY (c1) PARTITIONS 100
ENGINE=MYISAM;
```

#### Note

For brevity, we use `KEY` partitioning for the table shown in this example, but file descriptor usage as described here applies to all partitioned `MyISAM` tables, regardless of the type of partitioning that is employed. Partitioned tables using other storage engines such as `InnoDB` are not affected by this issue.

Now assume that you wish to repartition `t` so that it has 101 partitions, using the statement shown here:

```
ALTER TABLE t PARTITION BY KEY (c1) PARTITIONS 101;
```

To process this `ALTER TABLE` statement, MySQL uses 402 file descriptors—that is, two for each of the 100 original partitions, plus two for each of the 101 new partitions. This is because all partitions (old and new) must be opened concurrently during the reorganization of the table data. It is recommended that, if you expect to perform such operations, you should make sure that `--open-files-limit` is not set too low to accommodate them.

- **Table locks.** The process executing a partitioning operation on a table takes a write lock on the table. Reads from such tables are relatively unaffected; pending `INSERT` and `UPDATE` operations are performed as soon as the partitioning operation has completed.
- **Storage engine.** Partitioning operations, queries, and update operations generally tend to be faster with `MyISAM` tables than with `InnoDB` or `NDB` tables.

- **Indexes; partition pruning.** As with nonpartitioned tables, proper use of indexes can speed up queries on partitioned tables significantly. In addition, designing partitioned tables and queries on these tables to take advantage of *partition pruning* can improve performance dramatically. See [Section 21.4, “Partition Pruning”](#), for more information.

Previously, index condition pushdown was not supported for partitioned tables. This limitation was removed in MySQL 5.7.3. See [Section 9.2.1.6, “Index Condition Pushdown Optimization”](#).

- **Performance with LOAD DATA.** In MySQL 5.7, `LOAD DATA` uses buffering to improve performance. You should be aware that the buffer uses 130 KB memory per partition to achieve this.

#### Maximum number of partitions.

The maximum possible number of partitions for a given table not using the `NDB` storage engine is 8192. This number includes subpartitions.

The maximum possible number of user-defined partitions for a table using the `NDB` storage engine is determined according to the version of the MySQL Cluster software being used, the number of data nodes, and other factors. See [NDB and user-defined partitioning](#), for more information.

If, when creating tables with a large number of partitions (but less than the maximum), you encounter an error message such as `Got error ... from storage engine: Out of resources when opening file`, you may be able to address the issue by increasing the value of the `open_files_limit` system variable. However, this is dependent on the operating system, and may not be possible or advisable on all platforms; see [Section B.5.2.18, “File Not Found and Similar Errors”](#), for more information. In some cases, using large numbers (hundreds) of partitions may also not be advisable due to other concerns, so using more partitions does not automatically lead to better results.

See also [File system operations](#).

#### Query cache not supported.

The query cache is not supported for partitioned tables, and is automatically disabled for queries involving partitioned tables. The query cache cannot be enabled for such queries.

#### Per-partition key caches.

In MySQL 5.7, key caches are supported for partitioned `MyISAM` tables, using the `CACHE INDEX` and `LOAD INDEX INTO CACHE` statements. Key caches may be defined for one, several, or all partitions, and indexes for one, several, or all partitions may be preloaded into key caches.

#### Foreign keys not supported for partitioned InnoDB tables.

Partitioned tables using the `InnoDB` storage engine do not support foreign keys. More specifically, this means that the following two statements are true:

1. No definition of an `InnoDB` table employing user-defined partitioning may contain foreign key references; no `InnoDB` table whose definition contains foreign key references may be partitioned.
2. No `InnoDB` table definition may contain a foreign key reference to a user-partitioned table; no `InnoDB` table with user-defined partitioning may contain columns referenced by foreign keys.

The scope of the restrictions just listed includes all tables that use the `InnoDB` storage engine. `CREATE TABLE` and `ALTER TABLE` statements that would result in tables violating these restrictions are not allowed.

**ALTER TABLE ... ORDER BY.** An `ALTER TABLE ... ORDER BY column` statement run against a partitioned table causes ordering of rows only within each partition.

**Effects on REPLACE statements by modification of primary keys.** It can be desirable in some cases (see [Section 21.6.1, “Partitioning Keys, Primary Keys, and Unique Keys”](#)) to modify a table's primary key. Be aware that, if your application uses `REPLACE` statements and you do this, the results of these statements can be drastically altered. See [Section 14.2.8, “REPLACE Syntax”](#), for more information and an example.

#### FULLTEXT indexes.

Partitioned tables do not support [FULLTEXT](#) indexes or searches, even for partitioned tables employing the [InnoDB](#) or [MyISAM](#) storage engine.

**Spatial columns.** Columns with spatial data types such as [POINT](#) or [GEOMETRY](#) cannot be used in partitioned tables.

**Temporary tables.**

Temporary tables cannot be partitioned. (Bug #17497)

**Log tables.** It is not possible to partition the log tables; an [ALTER TABLE ... PARTITION BY ...](#) statement on such a table fails with an error.

**Data type of partitioning key.**

A partitioning key must be either an integer column or an expression that resolves to an integer. Expressions employing [ENUM](#) columns cannot be used. The column or expression value may also be [NULL](#). (See [Section 21.2.7](#), “How MySQL Partitioning Handles NULL”).

There are two exceptions to this restriction:

1. When partitioning by [\[LINEAR\] KEY](#), it is possible to use columns of any valid MySQL data type other than [TEXT](#) or [BLOB](#) as partitioning keys, because MySQL's internal key-hashing functions produce the correct data type from these types. For example, the following two [CREATE TABLE](#) statements are valid:

```
CREATE TABLE tkc (c1 CHAR)
PARTITION BY KEY(c1)
PARTITIONS 4;

CREATE TABLE tke
  ( c1 ENUM('red', 'orange', 'yellow', 'green', 'blue', 'indigo', 'violet') )
PARTITION BY LINEAR KEY(c1)
PARTITIONS 6;
```

2. When partitioning by [RANGE COLUMNS](#) or [LIST COLUMNS](#), it is possible to use string, [DATE](#), and [DATETIME](#) columns. For example, each of the following [CREATE TABLE](#) statements is valid:

```
CREATE TABLE rc (c1 INT, c2 DATE)
PARTITION BY RANGE COLUMNS(c2) (
  PARTITION p0 VALUES LESS THAN('1990-01-01'),
  PARTITION p1 VALUES LESS THAN('1995-01-01'),
  PARTITION p2 VALUES LESS THAN('2000-01-01'),
  PARTITION p3 VALUES LESS THAN('2005-01-01'),
  PARTITION p4 VALUES LESS THAN(MAXVALUE)
);

CREATE TABLE lc (c1 INT, c2 CHAR(1))
PARTITION BY LIST COLUMNS(c2) (
  PARTITION p0 VALUES IN('a', 'd', 'g', 'j', 'm', 'p', 's', 'v', 'y'),
  PARTITION p1 VALUES IN('b', 'e', 'h', 'k', 'n', 'q', 't', 'w', 'z'),
  PARTITION p2 VALUES IN('c', 'f', 'i', 'l', 'o', 'r', 'u', 'x', NULL)
);
```

Neither of the preceding exceptions applies to [BLOB](#) or [TEXT](#) column types.

**Subqueries.**

A partitioning key may not be a subquery, even if that subquery resolves to an integer value or [NULL](#).

**Issues with subpartitions.**

Subpartitions must use [HASH](#) or [KEY](#) partitioning. Only [RANGE](#) and [LIST](#) partitions may be subpartitioned; [HASH](#) and [KEY](#) partitions cannot be subpartitioned.

[SUBPARTITION BY KEY](#) requires that the subpartitioning column or columns be specified explicitly, unlike the case with [PARTITION BY KEY](#), where it can be omitted (in which case the table's primary key column is used by default). Consider the table created by this statement:

```
CREATE TABLE ts (
  id INT NOT NULL AUTO_INCREMENT PRIMARY KEY,
  name VARCHAR(30)
);
```

You can create a table having the same columns, partitioned by [KEY](#), using a statement such as this one:

```
CREATE TABLE ts (
  id INT NOT NULL AUTO_INCREMENT PRIMARY KEY,
  name VARCHAR(30)
)
PARTITION BY KEY()
PARTITIONS 4;
```

The previous statement is treated as though it had been written like this, with the table's primary key column used as the partitioning column:

```
CREATE TABLE ts (
  id INT NOT NULL AUTO_INCREMENT PRIMARY KEY,
  name VARCHAR(30)
)
PARTITION BY KEY(id)
PARTITIONS 4;
```

However, the following statement that attempts to create a subpartitioned table using the default column as the subpartitioning column fails, and the column must be specified for the statement to succeed, as shown here:

```
mysql> CREATE TABLE ts (
->   id INT NOT NULL AUTO_INCREMENT PRIMARY KEY,
->   name VARCHAR(30)
-> )
-> PARTITION BY RANGE(id)
-> SUBPARTITION BY KEY()
-> SUBPARTITIONS 4
-> (
->   PARTITION p0 VALUES LESS THAN (100),
->   PARTITION p1 VALUES LESS THAN (MAXVALUE)
-> );
ERROR 1064 (42000): You have an error in your SQL syntax; check the manual that
corresponds to your MySQL server version for the right syntax to use near ')'

mysql> CREATE TABLE ts (
->   id INT NOT NULL AUTO_INCREMENT PRIMARY KEY,
->   name VARCHAR(30)
-> )
-> PARTITION BY RANGE(id)
-> SUBPARTITION BY KEY(id)
-> SUBPARTITIONS 4
-> (
->   PARTITION p0 VALUES LESS THAN (100),
->   PARTITION p1 VALUES LESS THAN (MAXVALUE)
-> );
Query OK, 0 rows affected (0.07 sec)
```

This is a known issue (see Bug #51470).

**DATA DIRECTORY and INDEX DIRECTORY options.** [DATA DIRECTORY](#) and [INDEX DIRECTORY](#) are subject to the following restrictions when used with partitioned tables:

- Table-level [DATA DIRECTORY](#) and [INDEX DIRECTORY](#) options are ignored (see Bug #32091).

- On Windows, the `DATA DIRECTORY` and `INDEX DIRECTORY` options are not supported for individual partitions or subpartitions of `MyISAM` tables. However, you can use `DATA DIRECTORY` for individual partitions or subpartitions of `InnoDB` tables.

**Repairing and rebuilding partitioned tables.** The statements `CHECK TABLE`, `OPTIMIZE TABLE`, `ANALYZE TABLE`, and `REPAIR TABLE` are supported for partitioned tables.

In addition, you can use `ALTER TABLE ... REBUILD PARTITION` to rebuild one or more partitions of a partitioned table; `ALTER TABLE ... REORGANIZE PARTITION` also causes partitions to be rebuilt. See [Section 14.1.8, “ALTER TABLE Syntax”](#), for more information about these two statements.

Starting in MySQL 5.7.2, `ANALYZE`, `CHECK`, `OPTIMIZE`, `REPAIR`, and `TRUNCATE` operations are supported with subpartitions. `REBUILD` was also accepted syntax prior to MySQL 5.7.5, although this had no effect. (Bug #19075411, Bug #73130) See also [Section 14.1.8.1, “ALTER TABLE Partition Operations”](#).

`mysqlcheck`, `myisamchk`, and `myisampack` are not supported with partitioned tables.

**FOR EXPORT option (FLUSH TABLES).** The `FLUSH TABLES` statement's `FOR EXPORT` option is not supported for partitioned `InnoDB` tables in MySQL 5.7.4 and earlier. (Bug #16943907)

## 21.6.1 Partitioning Keys, Primary Keys, and Unique Keys

This section discusses the relationship of partitioning keys with primary keys and unique keys. The rule governing this relationship can be expressed as follows: All columns used in the partitioning expression for a partitioned table must be part of every unique key that the table may have.

In other words, *every unique key on the table must use every column in the table's partitioning expression*. (This also includes the table's primary key, since it is by definition a unique key. This particular case is discussed later in this section.) For example, each of the following table creation statements is invalid:

```
CREATE TABLE t1 (
  col1 INT NOT NULL,
  col2 DATE NOT NULL,
  col3 INT NOT NULL,
  col4 INT NOT NULL,
  UNIQUE KEY (col1, col2)
)
PARTITION BY HASH(col3)
PARTITIONS 4;

CREATE TABLE t2 (
  col1 INT NOT NULL,
  col2 DATE NOT NULL,
  col3 INT NOT NULL,
  col4 INT NOT NULL,
  UNIQUE KEY (col1),
  UNIQUE KEY (col3)
)
PARTITION BY HASH(col1 + col3)
PARTITIONS 4;
```

In each case, the proposed table would have at least one unique key that does not include all columns used in the partitioning expression.

Each of the following statements is valid, and represents one way in which the corresponding invalid table creation statement could be made to work:

```
CREATE TABLE t1 (
  col1 INT NOT NULL,
  col2 DATE NOT NULL,
  col3 INT NOT NULL,
```

```

        col4 INT NOT NULL,
        UNIQUE KEY (col1, col2, col3)
    )
    PARTITION BY HASH(col3)
    PARTITIONS 4;

CREATE TABLE t2 (
    col1 INT NOT NULL,
    col2 DATE NOT NULL,
    col3 INT NOT NULL,
    col4 INT NOT NULL,
    UNIQUE KEY (col1, col3)
)
PARTITION BY HASH(col1 + col3)
PARTITIONS 4;

```

This example shows the error produced in such cases:

```

mysql> CREATE TABLE t3 (
->     col1 INT NOT NULL,
->     col2 DATE NOT NULL,
->     col3 INT NOT NULL,
->     col4 INT NOT NULL,
->     UNIQUE KEY (col1, col2),
->     UNIQUE KEY (col3)
-> )
-> PARTITION BY HASH(col1 + col3)
-> PARTITIONS 4;
ERROR 1491 (HY000): A PRIMARY KEY must include all columns in the table's partitioning function

```

The `CREATE TABLE` statement fails because both `col1` and `col3` are included in the proposed partitioning key, but neither of these columns is part of both of unique keys on the table. This shows one possible fix for the invalid table definition:

```

mysql> CREATE TABLE t3 (
->     col1 INT NOT NULL,
->     col2 DATE NOT NULL,
->     col3 INT NOT NULL,
->     col4 INT NOT NULL,
->     UNIQUE KEY (col1, col2, col3),
->     UNIQUE KEY (col3)
-> )
-> PARTITION BY HASH(col3)
-> PARTITIONS 4;
Query OK, 0 rows affected (0.05 sec)

```

In this case, the proposed partitioning key `col3` is part of both unique keys, and the table creation statement succeeds.

The following table cannot be partitioned at all, because there is no way to include in a partitioning key any columns that belong to both unique keys:

```

CREATE TABLE t4 (
    col1 INT NOT NULL,
    col2 INT NOT NULL,
    col3 INT NOT NULL,
    col4 INT NOT NULL,
    UNIQUE KEY (col1, col3),
    UNIQUE KEY (col2, col4)
);

```

Since every primary key is by definition a unique key, this restriction also includes the table's primary key, if it has one. For example, the next two statements are invalid:

```

CREATE TABLE t5 (
    col1 INT NOT NULL,

```

```

col2 DATE NOT NULL,
col3 INT NOT NULL,
col4 INT NOT NULL,
PRIMARY KEY(col1, col2)
)
PARTITION BY HASH(col3)
PARTITIONS 4;

CREATE TABLE t6 (
col1 INT NOT NULL,
col2 DATE NOT NULL,
col3 INT NOT NULL,
col4 INT NOT NULL,
PRIMARY KEY(col1, col3),
UNIQUE KEY(col2)
)
PARTITION BY HASH( YEAR(col2) )
PARTITIONS 4;

```

In both cases, the primary key does not include all columns referenced in the partitioning expression. However, both of the next two statements are valid:

```

CREATE TABLE t7 (
col1 INT NOT NULL,
col2 DATE NOT NULL,
col3 INT NOT NULL,
col4 INT NOT NULL,
PRIMARY KEY(col1, col2)
)
PARTITION BY HASH(col1 + YEAR(col2))
PARTITIONS 4;

CREATE TABLE t8 (
col1 INT NOT NULL,
col2 DATE NOT NULL,
col3 INT NOT NULL,
col4 INT NOT NULL,
PRIMARY KEY(col1, col2, col4),
UNIQUE KEY(col2, col1)
)
PARTITION BY HASH(col1 + YEAR(col2))
PARTITIONS 4;

```

If a table has no unique keys—this includes having no primary key—then this restriction does not apply, and you may use any column or columns in the partitioning expression as long as the column type is compatible with the partitioning type.

For the same reason, you cannot later add a unique key to a partitioned table unless the key includes all columns used by the table's partitioning expression. Consider the partitioned table created as shown here:

```

mysql> CREATE TABLE t_no_pk (c1 INT, c2 INT)
-> PARTITION BY RANGE(c1) (
-> PARTITION p0 VALUES LESS THAN (10),
-> PARTITION p1 VALUES LESS THAN (20),
-> PARTITION p2 VALUES LESS THAN (30),
-> PARTITION p3 VALUES LESS THAN (40)
-> );
Query OK, 0 rows affected (0.12 sec)

```

It is possible to add a primary key to `t_no_pk` using either of these `ALTER TABLE` statements:

```

# possible PK
mysql> ALTER TABLE t_no_pk ADD PRIMARY KEY(c1);
Query OK, 0 rows affected (0.13 sec)
Records: 0 Duplicates: 0 Warnings: 0

```

```
# drop this PK
mysql> ALTER TABLE t_no_pk DROP PRIMARY KEY;
Query OK, 0 rows affected (0.10 sec)
Records: 0 Duplicates: 0 Warnings: 0

# use another possible PK
mysql> ALTER TABLE t_no_pk ADD PRIMARY KEY(c1, c2);
Query OK, 0 rows affected (0.12 sec)
Records: 0 Duplicates: 0 Warnings: 0

# drop this PK
mysql> ALTER TABLE t_no_pk DROP PRIMARY KEY;
Query OK, 0 rows affected (0.09 sec)
Records: 0 Duplicates: 0 Warnings: 0
```

However, the next statement fails, because `c1` is part of the partitioning key, but is not part of the proposed primary key:

```
# fails with error 1503
mysql> ALTER TABLE t_no_pk ADD PRIMARY KEY(c2);
ERROR 1503 (HY000): A PRIMARY KEY must include all columns in the table's partitioning function
```

Since `t_no_pk` has only `c1` in its partitioning expression, attempting to adding a unique key on `c2` alone fails. However, you can add a unique key that uses both `c1` and `c2`.

These rules also apply to existing nonpartitioned tables that you wish to partition using `ALTER TABLE ... PARTITION BY`. Consider a table `np_pk` created as shown here:

```
mysql> CREATE TABLE np_pk (
->   id INT NOT NULL AUTO_INCREMENT,
->   name VARCHAR(50),
->   added DATE,
->   PRIMARY KEY (id)
-> );
Query OK, 0 rows affected (0.08 sec)
```

The following `ALTER TABLE` statement fails with an error, because the `added` column is not part of any unique key in the table:

```
mysql> ALTER TABLE np_pk
->   PARTITION BY HASH( TO_DAYS(added) )
->   PARTITIONS 4;
ERROR 1503 (HY000): A PRIMARY KEY must include all columns in the table's partitioning function
```

However, this statement using the `id` column for the partitioning column is valid, as shown here:

```
mysql> ALTER TABLE np_pk
->   PARTITION BY HASH(id)
->   PARTITIONS 4;
Query OK, 0 rows affected (0.11 sec)
Records: 0 Duplicates: 0 Warnings: 0
```

In the case of `np_pk`, the only column that may be used as part of a partitioning expression is `id`; if you wish to partition this table using any other column or columns in the partitioning expression, you must first modify the table, either by adding the desired column or columns to the primary key, or by dropping the primary key altogether.

## 21.6.2 Partitioning Limitations Relating to Storage Engines

The following limitations apply to the use of storage engines with user-defined partitioning of tables.

**MERGE storage engine.** User-defined partitioning and the `MERGE` storage engine are not compatible. Tables using the `MERGE` storage engine cannot be partitioned. Partitioned tables cannot be merged.

**FEDERATED storage engine.** Partitioning of [FEDERATED](#) tables is not supported; it is not possible to create partitioned [FEDERATED](#) tables.

**CSV storage engine.** Partitioned tables using the [CSV](#) storage engine are not supported; it is not possible to create partitioned [CSV](#) tables.

**InnoDB storage engine.** [InnoDB](#) foreign keys and MySQL partitioning are not compatible. Partitioned [InnoDB](#) tables cannot have foreign key references, nor can they have columns referenced by foreign keys. [InnoDB](#) tables which have or which are referenced by foreign keys cannot be partitioned.

[InnoDB](#) does not support the use of multiple disks for subpartitions. (This is currently supported only by [MyISAM](#).)

In addition, [ALTER TABLE ... OPTIMIZE PARTITION](#) does not work correctly with partitioned tables that use the [InnoDB](#) storage engine. Use [ALTER TABLE ... REBUILD PARTITION](#) and [ALTER TABLE ... ANALYZE PARTITION](#), instead, for such tables. For more information, see [Section 14.1.8.1, “ALTER TABLE Partition Operations”](#).

**User-defined partitioning and the NDB storage engine (MySQL Cluster).** Partitioning by [KEY](#) (including [LINEAR KEY](#)) is the only type of partitioning supported for the [NDB](#) storage engine. It is not possible under normal circumstances in MySQL Cluster to create a MySQL Cluster table using any partitioning type other than [\[LINEAR\] KEY](#), and attempting to do so fails with an error.

*Exception (not for production):* It is possible to override this restriction by setting the [new](#) system variable on MySQL Cluster SQL nodes to [ON](#). If you choose to do this, you should be aware that tables using partitioning types other than [\[LINEAR\] KEY](#) are not supported in production. *In such cases, you can create and use tables with partitioning types other than [KEY](#) or [LINEAR KEY](#), but you do this entirely at your own risk.*

The maximum number of partitions that can be defined for an [NDB](#) table depends on the number of data nodes and node groups in the cluster, the version of the MySQL Cluster software in use, and other factors. See [NDB and user-defined partitioning](#), for more information.

As of MySQL Cluster NDB 7.5.2, the maximum amount of fixed-size data that can be stored per partition in an [NDB](#) table is 128 TB. Previously, this was 16 GB.

[CREATE TABLE](#) and [ALTER TABLE](#) statements that would cause a user-partitioned [NDB](#) table not to meet either or both of the following two requirements are not permitted, and fail with an error:

1. The table must have an explicit primary key.
2. All columns listed in the table's partitioning expression must be part of the primary key.

**Exception.** If a user-partitioned [NDB](#) table is created using an empty column-list (that is, using [PARTITION BY KEY\(\)](#) or [PARTITION BY LINEAR KEY\(\)](#)), then no explicit primary key is required.

**Upgrading partitioned tables.** When performing an upgrade, tables which are partitioned by [KEY](#) and which use any storage engine other than [NDB](#) must be dumped and reloaded.

**Same storage engine for all partitions.** All partitions of a partitioned table must use the same storage engine and it must be the same storage engine used by the table as a whole. In addition, if one does not specify an engine on the table level, then one must do either of the following when creating or altering a partitioned table:

- Do *not* specify any engine for *any* partition or subpartition
- Specify the engine for *all* partitions or subpartitions

## 21.6.3 Partitioning Limitations Relating to Functions

This section discusses limitations in MySQL Partitioning relating specifically to functions used in partitioning expressions.

Only the MySQL functions shown in the following table are allowed in partitioning expressions.

|                              |  |  |
|------------------------------|--|--|
| <a href="#">ABS()</a>        | <a href="#">CEILING()</a> (see <a href="#">CEILING()</a> and <a href="#">FLOOR()</a> )                 | <a href="#">DAY()</a>  |
| <a href="#">DAYOFMONTH()</a> | <a href="#">DAYOFWEEK()</a>  | <a href="#">DAYOFYEAR()</a>  |
| <a href="#">DATEDIFF()</a>   | <a href="#">EXTRACT()</a> (see <a href="#">EXTRACT()</a> function with <a href="#">WEEK</a> specifier) | <a href="#">FLOOR()</a> (see <a href="#">CEILING()</a> and <a href="#">FLOOR()</a> ) |
| <a href="#">HOUR()</a>       | <a href="#">MICROSECOND()</a>  | <a href="#">MINUTE()</a>   |
| <a href="#">MOD()</a>        | <a href="#">MONTH()</a>  | <a href="#">QUARTER()</a>  |
| <a href="#">SECOND()</a>     | <a href="#">TIME_TO_SEC()</a>  | <a href="#">TO_DAYS()</a>  |
| <a href="#">TO_SECONDS()</a> | <a href="#">UNIX_TIMESTAMP()</a> (with <a href="#">TIMESTAMP</a> columns)                              | <a href="#">WEEKDAY()</a>  |
| <a href="#">YEAR()</a>       |  | <a href="#">YEARWEEK()</a>   |

In MySQL 5.7, partition pruning is supported for the [TO\\_DAYS\(\)](#), [TO\\_SECONDS\(\)](#), [YEAR\(\)](#), and [UNIX\\_TIMESTAMP\(\)](#) functions. See [Section 21.4, “Partition Pruning”](#), for more information.

**CEILING() and FLOOR().** Each of these functions returns an integer only if it is passed an argument of an exact numeric type, such as one of the [INT](#) types or [DECIMAL](#). This means, for example, that the following [CREATE TABLE](#) statement fails with an error, as shown here:

```
mysql> CREATE TABLE t (c FLOAT) PARTITION BY LIST( FLOOR(c) )(
->     PARTITION p0 VALUES IN (1,3,5),
->     PARTITION p1 VALUES IN (2,4,6)
-> );
ERROR 1490 (HY000): The PARTITION function returns the wrong type
```

**EXTRACT() function with WEEK specifier.** The value returned by the [EXTRACT\(\)](#) function, when used as [EXTRACT\(WEEK FROM col\)](#), depends on the value of the [default\\_week\\_format](#) system variable. For this reason, [EXTRACT\(\)](#) is not permitted as a partitioning function when it specifies the unit as [WEEK](#). (Bug #54483)

See [Section 13.6.2, “Mathematical Functions”](#), for more information about the return types of these functions, as well as [Section 12.2, “Numeric Types”](#).

## 21.6.4 Partitioning and Locking

For storage engines such as [MyISAM](#) that actually execute table-level locks when executing DML or DDL statements, such a statement in older versions of MySQL (5.6.5 and earlier) that affected a partitioned table imposed a lock on the table as a whole; that is, all partitions were locked until the statement was finished. In MySQL 5.7, *partition lock pruning* eliminates unneeded locks in many cases, and most statements reading from or updating a partitioned [MyISAM](#) table cause only the effected partitions to be locked. For example, a [SELECT](#) from a partitioned [MyISAM](#) table locks only those partitions actually containing rows that satisfy the [SELECT](#) statement's [WHERE](#) condition are locked.

For statements effecting partitioned tables using storage engines such as [InnoDB](#), that employ row-level locking and do not actually perform (or need to perform) the locks prior to partition pruning, this is not an issue.

The next few paragraphs discuss the effects of partition lock pruning for various MySQL statements on tables using storage engines that employ table-level locks.

### Effects on DML statements

[SELECT](#) statements (including those containing unions or joins) lock only those partitions that actually need to be read. This also applies to [SELECT ... PARTITION](#).

An `UPDATE` prunes locks only for tables on which no partitioning columns are updated.

`REPLACE` and `INSERT` lock only those partitions having rows to be inserted or replaced. However, if an `AUTO_INCREMENT` value is generated for any partitioning column then all partitions are locked.

`INSERT ... ON DUPLICATE KEY UPDATE` is pruned as long as no partitioning column is updated.

`INSERT ... SELECT` locks only those partitions in the source table that need to be read, although all partitions in the target table are locked.

Locks imposed by `LOAD DATA` statements on partitioned tables cannot be pruned.

The presence of `BEFORE INSERT` or `BEFORE UPDATE` triggers using any partitioning column of a partitioned table means that locks on `INSERT` and `UPDATE` statements updating this table cannot be pruned, since the trigger can alter its values: A `BEFORE INSERT` trigger on any of the table's partitioning columns means that locks set by `INSERT` or `REPLACE` cannot be pruned, since the `BEFORE INSERT` trigger may change a row's partitioning columns before the row is inserted, forcing the row into a different partition than it would be otherwise. A `BEFORE UPDATE` trigger on a partitioning column means that locks imposed by `UPDATE` or `INSERT ... ON DUPLICATE KEY UPDATE` cannot be pruned.

## Affected DDL statements

`CREATE VIEW` does not cause any locks.

`ALTER TABLE ... EXCHANGE PARTITION` prunes locks; only the exchanged table and the exchanged partition are locked.

`ALTER TABLE ... TRUNCATE PARTITION` prunes locks; only the partitions to be emptied are locked.

In addition, `ALTER TABLE` statements take metadata locks on the table level.

## Other statements

`LOCK TABLES` cannot prune partition locks.

`CALL stored_procedure(expr)` supports lock pruning, but evaluating `expr` does not.

`DO` and `SET` statements do not support partitioning lock pruning.

This chapter discusses stored programs and views, which are database objects defined in terms of SQL code that is stored on the server for later execution.

Stored programs include these objects:

- Stored routines, that is, stored procedures and functions. A stored procedure is invoked using the [CALL](#) statement. A procedure does not have a return value but can modify its parameters for later inspection by the caller. It can also generate result sets to be returned to the client program. A stored function is used much like a built-in function. you invoke it in an expression and it returns a value during expression evaluation.
- Triggers. A trigger is a named database object that is associated with a table and that is activated when a particular event occurs for the table, such as an insert or update.
- Events. An event is a task that the server runs according to schedule.

Views are stored queries that when referenced produce a result set. A view acts as a virtual table.

This chapter describes how to use stored programs and views. The following sections provide additional information about SQL syntax for statements related to these objects:

- For each object type, there are [CREATE](#), [ALTER](#), and [DROP](#) statements that control which objects exist and how they are defined. See [Section 14.1, “Data Definition Statements”](#).
- The [CALL](#) statement is used to invoke stored procedures. See [Section 14.2.1, “CALL Syntax”](#).
- Stored program definitions include a body that may use compound statements, loops, conditionals, and declared variables. See [Section 14.6, “Compound-Statement Syntax”](#).

In MySQL, metadata changes to objects referred to by stored programs are detected and cause automatic reparsing of the affected statements when the program is next executed. For more information, see [Section 9.10.4, “Caching of Prepared Statements and Stored Programs”](#).

## 22.1 Defining Stored Programs

Each stored program contains a body that consists of an SQL statement. This statement may be a compound statement made up of several statements separated by semicolon (;) characters. For example, the following stored procedure has a body made up of a `BEGIN ... END` block that contains a `SET` statement and a `REPEAT` loop that itself contains another `SET` statement:

```
CREATE PROCEDURE dorepeat(p1 INT)
BEGIN
  SET @x = 0;
  REPEAT SET @x = @x + 1; UNTIL @x > p1 END REPEAT;
END;
```

If you use the `mysql` client program to define a stored program containing semicolon characters, a problem arises. By default, `mysql` itself recognizes the semicolon as a statement delimiter, so you must redefine the delimiter temporarily to cause `mysql` to pass the entire stored program definition to the server.

To redefine the `mysql` delimiter, use the `delimiter` command. The following example shows how to do this for the `dorepeat()` procedure just shown. The delimiter is changed to `//` to enable the entire definition to be passed to the server as a single statement, and then restored to `;` before invoking the procedure. This enables the `;` delimiter used in the procedure body to be passed through to the server rather than being interpreted by `mysql` itself.

```
mysql> delimiter //

mysql> CREATE PROCEDURE dorepeat(p1 INT)
-> BEGIN
->   SET @x = 0;
->   REPEAT SET @x = @x + 1; UNTIL @x > p1 END REPEAT;
-> END
-> //
Query OK, 0 rows affected (0.00 sec)

mysql> delimiter ;

mysql> CALL dorepeat(1000);
Query OK, 0 rows affected (0.00 sec)

mysql> SELECT @x;
+-----+
| @x    |
+-----+
| 1001  |
+-----+
1 row in set (0.00 sec)
```

You can redefine the delimiter to a string other than `//`, and the delimiter can consist of a single character or multiple characters. You should avoid the use of the backslash (\) character because that is the escape character for MySQL.

The following is an example of a function that takes a parameter, performs an operation using an SQL function, and returns the result. In this case, it is unnecessary to use `delimiter` because the function definition contains no internal `;` statement delimiters:

```
mysql> CREATE FUNCTION hello (s CHAR(20))
mysql> RETURNS CHAR(50) DETERMINISTIC
-> RETURN CONCAT('Hello, ',s,'!');
Query OK, 0 rows affected (0.00 sec)
```

```
mysql> SELECT hello('world');
+-----+
| hello('world') |
+-----+
| Hello, world!  |
+-----+
1 row in set (0.00 sec)
```

## 22.2 Using Stored Routines (Procedures and Functions)

MySQL supports stored routines (procedures and functions). A stored routine is a set of SQL statements that can be stored in the server. Once this has been done, clients don't need to keep reissuing the individual statements but can refer to the stored routine instead.

Stored routines require the `proc` table in the `mysql` database. This table is created during the MySQL installation procedure. If you are upgrading to MySQL 5.7 from an earlier version, be sure to update your grant tables to make sure that the `proc` table exists. See [Section 5.4.7, “mysql\\_upgrade — Check and Upgrade MySQL Tables”](#).

Stored routines can be particularly useful in certain situations:

- When multiple client applications are written in different languages or work on different platforms, but need to perform the same database operations.
- When security is paramount. Banks, for example, use stored procedures and functions for all common operations. This provides a consistent and secure environment, and routines can ensure that each operation is properly logged. In such a setup, applications and users would have no access to the database tables directly, but can only execute specific stored routines.

Stored routines can provide improved performance because less information needs to be sent between the server and the client. The tradeoff is that this does increase the load on the database server because more of the work is done on the server side and less is done on the client (application) side. Consider this if many client machines (such as Web servers) are serviced by only one or a few database servers.

Stored routines also enable you to have libraries of functions in the database server. This is a feature shared by modern application languages that enable such design internally (for example, by using classes). Using these client application language features is beneficial for the programmer even outside the scope of database use.

MySQL follows the SQL:2003 syntax for stored routines, which is also used by IBM's DB2. All syntax described here is supported and any limitations and extensions are documented where appropriate.

### Additional Resources

- You may find the [Stored Procedures User Forum](#) of use when working with stored procedures and functions.
- For answers to some commonly asked questions regarding stored routines in MySQL, see [Section A.4, “MySQL 5.7 FAQ: Stored Procedures and Functions”](#).
- There are some restrictions on the use of stored routines. See [Section C.1, “Restrictions on Stored Programs”](#).
- Binary logging for stored routines takes place as described in [Section 22.7, “Binary Logging of Stored Programs”](#).

### 22.2.1 Stored Routine Syntax

A stored routine is either a procedure or a function. Stored routines are created with the `CREATE PROCEDURE` and `CREATE FUNCTION` statements (see [Section 14.1.16, “CREATE PROCEDURE and CREATE FUNCTION Syntax”](#)). A procedure is invoked using a `CALL` statement (see [Section 14.2.1, “CALL Syntax”](#)), and can only pass back values using output variables. A function can be called

from inside a statement just like any other function (that is, by invoking the function's name), and can return a scalar value. The body of a stored routine can use compound statements (see [Section 14.6, “Compound-Statement Syntax”](#)).

Stored routines can be dropped with the `DROP PROCEDURE` and `DROP FUNCTION` statements (see [Section 14.1.27, “DROP PROCEDURE and DROP FUNCTION Syntax”](#)), and altered with the `ALTER PROCEDURE` and `ALTER FUNCTION` statements (see [Section 14.1.6, “ALTER PROCEDURE Syntax”](#)).

A stored procedure or function is associated with a particular database. This has several implications:

- When the routine is invoked, an implicit `USE db_name` is performed (and undone when the routine terminates). `USE` statements within stored routines are not permitted.
- You can qualify routine names with the database name. This can be used to refer to a routine that is not in the current database. For example, to invoke a stored procedure `p` or function `f` that is associated with the `test` database, you can say `CALL test.p()` or `test.f()`.
- When a database is dropped, all stored routines associated with it are dropped as well.

Stored functions cannot be recursive.

Recursion in stored procedures is permitted but disabled by default. To enable recursion, set the `max_sp_recursion_depth` server system variable to a value greater than zero. Stored procedure recursion increases the demand on thread stack space. If you increase the value of `max_sp_recursion_depth`, it may be necessary to increase thread stack size by increasing the value of `thread_stack` at server startup. See [Section 6.1.5, “Server System Variables”](#), for more information.

MySQL supports a very useful extension that enables the use of regular `SELECT` statements (that is, without using cursors or local variables) inside a stored procedure. The result set of such a query is simply sent directly to the client. Multiple `SELECT` statements generate multiple result sets, so the client must use a MySQL client library that supports multiple result sets. This means the client must use a client library from a version of MySQL at least as recent as 4.1. The client should also specify the `CLIENT_MULTI_RESULTS` option when it connects. For C programs, this can be done with the `mysql_real_connect()` C API function. See [Section 26.8.7.54, “mysql\\_real\\_connect\(\)”](#), and [Section 26.8.17, “C API Support for Multiple Statement Execution”](#).

## 22.2.2 Stored Routines and MySQL Privileges

The MySQL grant system takes stored routines into account as follows:

- The `CREATE ROUTINE` privilege is needed to create stored routines.
- The `ALTER ROUTINE` privilege is needed to alter or drop stored routines. This privilege is granted automatically to the creator of a routine if necessary, and dropped from the creator when the routine is dropped.
- The `EXECUTE` privilege is required to execute stored routines. However, this privilege is granted automatically to the creator of a routine if necessary (and dropped from the creator when the routine is dropped). Also, the default `SQL SECURITY` characteristic for a routine is `DEFINER`, which enables users who have access to the database with which the routine is associated to execute the routine.
- If the `automatic_sp_privileges` system variable is 0, the `EXECUTE` and `ALTER ROUTINE` privileges are not automatically granted to and dropped from the routine creator.
- The creator of a routine is the account used to execute the `CREATE` statement for it. This might not be the same as the account named as the `DEFINER` in the routine definition.

The server manipulates the `mysql.proc` table in response to statements that create, alter, or drop stored routines. It is not supported that the server will notice manual manipulation of this table.

## 22.2.3 Stored Routine Metadata

Metadata about stored routines can be obtained as follows:

- Query the `ROUTINES` table of the `INFORMATION_SCHEMA` database. See [Section 23.20, “The INFORMATION\\_SCHEMA ROUTINES Table”](#).
- Use the `SHOW CREATE PROCEDURE` and `SHOW CREATE FUNCTION` statements to see routine definitions. See [Section 14.7.5.9, “SHOW CREATE PROCEDURE Syntax”](#).
- Use the `SHOW PROCEDURE STATUS` and `SHOW FUNCTION STATUS` statements to see routine characteristics. See [Section 14.7.5.28, “SHOW PROCEDURE STATUS Syntax”](#).

## 22.2.4 Stored Procedures, Functions, Triggers, and LAST\_INSERT\_ID()

Within the body of a stored routine (procedure or function) or a trigger, the value of `LAST_INSERT_ID()` changes the same way as for statements executed outside the body of these kinds of objects (see [Section 13.14, “Information Functions”](#)). The effect of a stored routine or trigger upon the value of `LAST_INSERT_ID()` that is seen by following statements depends on the kind of routine:

- If a stored procedure executes statements that change the value of `LAST_INSERT_ID()`, the changed value is seen by statements that follow the procedure call.
- For stored functions and triggers that change the value, the value is restored when the function or trigger ends, so following statements do not see a changed value.

## 22.3 Using Triggers

A trigger is a named database object that is associated with a table, and that activates when a particular event occurs for the table. Some uses for triggers are to perform checks of values to be inserted into a table or to perform calculations on values involved in an update.

A trigger is defined to activate when a statement inserts, updates, or deletes rows in the associated table. These row operations are trigger events. For example, rows can be inserted by `INSERT` or `LOAD DATA` statements, and an insert trigger activates for each inserted row. A trigger can be set to activate either before or after the trigger event. For example, you can have a trigger activate before each row that is inserted into a table or after each row that is updated.

### Important

MySQL triggers activate only for changes made to tables by SQL statements. They do not activate for changes in views, nor by changes to tables made by APIs that do not transmit SQL statements to the MySQL Server. This means that triggers are not activated in the following two cases:

- Triggers are not activated by changes in `INFORMATION_SCHEMA` or `performance_schema` tables, because these tables are actually views.
- Triggers are not activated by updates made using the `NDB` API.

The following sections describe the syntax for creating and dropping triggers, show some examples of how to use them, and indicate how to obtain trigger metadata.

## Additional Resources

- You may find the [Triggers User Forum](#) of use when working with triggers.
- For answers to commonly asked questions regarding triggers in MySQL, see [Section A.5, “MySQL 5.7 FAQ: Triggers”](#).
- There are some restrictions on the use of triggers; see [Section C.1, “Restrictions on Stored Programs”](#).

- Binary logging for triggers takes place as described in [Section 22.7, “Binary Logging of Stored Programs”](#).

### 22.3.1 Trigger Syntax and Examples

To create a trigger or drop a trigger, use the `CREATE TRIGGER` or `DROP TRIGGER` statement, described in [Section 14.1.20, “CREATE TRIGGER Syntax”](#), and [Section 14.1.31, “DROP TRIGGER Syntax”](#).

Here is a simple example that associates a trigger with a table, to activate for `INSERT` operations. The trigger acts as an accumulator, summing the values inserted into one of the columns of the table.

```
mysql> CREATE TABLE account (acct_num INT, amount DECIMAL(10,2));
Query OK, 0 rows affected (0.03 sec)

mysql> CREATE TRIGGER ins_sum BEFORE INSERT ON account
-> FOR EACH ROW SET @sum = @sum + NEW.amount;
Query OK, 0 rows affected (0.06 sec)
```

The `CREATE TRIGGER` statement creates a trigger named `ins_sum` that is associated with the `account` table. It also includes clauses that specify the trigger action time, the triggering event, and what to do when the trigger activates:

- The keyword `BEFORE` indicates the trigger action time. In this case, the trigger activates before each row inserted into the table. The other permitted keyword here is `AFTER`.
- The keyword `INSERT` indicates the trigger event; that is, the type of operation that activates the trigger. In the example, `INSERT` operations cause trigger activation. You can also create triggers for `DELETE` and `UPDATE` operations.
- The statement following `FOR EACH ROW` defines the trigger body; that is, the statement to execute each time the trigger activates, which occurs once for each row affected by the triggering event. In the example, the trigger body is a simple `SET` that accumulates into a user variable the values inserted into the `amount` column. The statement refers to the column as `NEW.amount` which means “the value of the `amount` column to be inserted into the new row.”

To use the trigger, set the accumulator variable to zero, execute an `INSERT` statement, and then see what value the variable has afterward:

```
mysql> SET @sum = 0;
mysql> INSERT INTO account VALUES(137,14.98),(141,1937.50),(97,-100.00);
mysql> SELECT @sum AS 'Total amount inserted';
+-----+
| Total amount inserted |
+-----+
| 1852.48                |
+-----+
```

In this case, the value of `@sum` after the `INSERT` statement has executed is `14.98 + 1937.50 - 100`, or `1852.48`.

To destroy the trigger, use a `DROP TRIGGER` statement. You must specify the schema name if the trigger is not in the default schema:

```
mysql> DROP TRIGGER test.ins_sum;
```

If you drop a table, any triggers for the table are also dropped.

Trigger names exist in the schema namespace, meaning that all triggers must have unique names within a schema. Triggers in different schemas can have the same name.

As of MySQL 5.7.2, it is possible to define multiple triggers for a given table that have the same trigger event and action time. For example, you can have two `BEFORE UPDATE` triggers for a table. By default,

triggers that have the same trigger event and action time activate in the order they were created. To affect trigger order, specify a clause after `FOR EACH ROW` that indicates `FOLLOWS` or `PRECEDES` and the name of an existing trigger that also has the same trigger event and action time. With `FOLLOWS`, the new trigger activates after the existing trigger. With `PRECEDES`, the new trigger activates before the existing trigger.

For example, the following trigger definition defines another `BEFORE INSERT` trigger for the `account` table:

```
mysql> CREATE TRIGGER ins_transaction BEFORE INSERT ON account
-> FOR EACH ROW PRECEDES ins_sum
-> SET
-> @deposits = @deposits + IF(NEW.amount>0,NEW.amount,0),
-> @withdrawals = @withdrawals + IF(NEW.amount<0,-NEW.amount,0);
Query OK, 0 rows affected (0.02 sec)
```

This trigger, `ins_transaction`, is similar to `ins_sum` but accumulates deposits and withdrawals separately. It has a `PRECEDES` clause that causes it to activate before `ins_sum`; without that clause, it would activate after `ins_sum` because it is created after `ins_sum`.

Before MySQL 5.7.2, there cannot be multiple triggers for a given table that have the same trigger event and action time. For example, you cannot have two `BEFORE UPDATE` triggers for a table. To work around this, you can define a trigger that executes multiple statements by using the `BEGIN ... END` compound statement construct after `FOR EACH ROW`. (An example appears later in this section.)

Within the trigger body, the `OLD` and `NEW` keywords enable you to access columns in the rows affected by a trigger. `OLD` and `NEW` are MySQL extensions to triggers; they are not case sensitive.

In an `INSERT` trigger, only `NEW.col_name` can be used; there is no old row. In a `DELETE` trigger, only `OLD.col_name` can be used; there is no new row. In an `UPDATE` trigger, you can use `OLD.col_name` to refer to the columns of a row before it is updated and `NEW.col_name` to refer to the columns of the row after it is updated.

A column named with `OLD` is read only. You can refer to it (if you have the `SELECT` privilege), but not modify it. You can refer to a column named with `NEW` if you have the `SELECT` privilege for it. In a `BEFORE` trigger, you can also change its value with `SET NEW.col_name = value` if you have the `UPDATE` privilege for it. This means you can use a trigger to modify the values to be inserted into a new row or used to update a row. (Such a `SET` statement has no effect in an `AFTER` trigger because the row change will have already occurred.)

In a `BEFORE` trigger, the `NEW` value for an `AUTO_INCREMENT` column is 0, not the sequence number that is generated automatically when the new row actually is inserted.

By using the `BEGIN ... END` construct, you can define a trigger that executes multiple statements. Within the `BEGIN` block, you also can use other syntax that is permitted within stored routines such as conditionals and loops. However, just as for stored routines, if you use the `mysql` program to define a trigger that executes multiple statements, it is necessary to redefine the `mysql` statement delimiter so that you can use the `;` statement delimiter within the trigger definition. The following example illustrates these points. It defines an `UPDATE` trigger that checks the new value to be used for updating each row, and modifies the value to be within the range from 0 to 100. This must be a `BEFORE` trigger because the value must be checked before it is used to update the row:

```
mysql> delimiter //
mysql> CREATE TRIGGER upd_check BEFORE UPDATE ON account
-> FOR EACH ROW
-> BEGIN
->     IF NEW.amount < 0 THEN
->         SET NEW.amount = 0;
->     ELSEIF NEW.amount > 100 THEN
->         SET NEW.amount = 100;
->     END IF;
-> END; //
mysql> delimiter ;
```

It can be easier to define a stored procedure separately and then invoke it from the trigger using a simple `CALL` statement. This is also advantageous if you want to execute the same code from within several triggers.

There are limitations on what can appear in statements that a trigger executes when activated:

- The trigger cannot use the `CALL` statement to invoke stored procedures that return data to the client or that use dynamic SQL. (Stored procedures are permitted to return data to the trigger through `OUT` or `INOUT` parameters.)
- The trigger cannot use statements that explicitly or implicitly begin or end a transaction, such as `START TRANSACTION`, `COMMIT`, or `ROLLBACK`. (`ROLLBACK to SAVEPOINT` is permitted because it does not end a transaction.).

See also [Section C.1, “Restrictions on Stored Programs”](#).

MySQL handles errors during trigger execution as follows:

- If a `BEFORE` trigger fails, the operation on the corresponding row is not performed.
- A `BEFORE` trigger is activated by the *attempt* to insert or modify the row, regardless of whether the attempt subsequently succeeds.
- An `AFTER` trigger is executed only if any `BEFORE` triggers and the row operation execute successfully.
- An error during either a `BEFORE` or `AFTER` trigger results in failure of the entire statement that caused trigger invocation.
- For transactional tables, failure of a statement should cause rollback of all changes performed by the statement. Failure of a trigger causes the statement to fail, so trigger failure also causes rollback. For nontransactional tables, such rollback cannot be done, so although the statement fails, any changes performed prior to the point of the error remain in effect.

Triggers can contain direct references to tables by name, such as the trigger named `testref` shown in this example:

```
CREATE TABLE test1(a1 INT);
CREATE TABLE test2(a2 INT);
CREATE TABLE test3(a3 INT NOT NULL AUTO_INCREMENT PRIMARY KEY);
CREATE TABLE test4(
  a4 INT NOT NULL AUTO_INCREMENT PRIMARY KEY,
  b4 INT DEFAULT 0
);

delimiter |

CREATE TRIGGER testref BEFORE INSERT ON test1
FOR EACH ROW
BEGIN
  INSERT INTO test2 SET a2 = NEW.a1;
  DELETE FROM test3 WHERE a3 = NEW.a1;
  UPDATE test4 SET b4 = b4 + 1 WHERE a4 = NEW.a1;
END;
|

delimiter ;

INSERT INTO test3 (a3) VALUES
  (NULL), (NULL), (NULL), (NULL), (NULL),
  (NULL), (NULL), (NULL), (NULL), (NULL);

INSERT INTO test4 (a4) VALUES
  (0), (0), (0), (0), (0), (0), (0), (0), (0), (0);
```

Suppose that you insert the following values into table `test1` as shown here:

```
mysql> INSERT INTO test1 VALUES
      -> (1), (3), (1), (7), (1), (8), (4), (4);
Query OK, 8 rows affected (0.01 sec)
Records: 8  Duplicates: 0  Warnings: 0
```

As a result, the four tables contain the following data:

```
mysql> SELECT * FROM test1;
+-----+
| a1 |
+-----+
| 1 |
| 3 |
| 1 |
| 7 |
| 1 |
| 8 |
| 4 |
| 4 |
+-----+
8 rows in set (0.00 sec)

mysql> SELECT * FROM test2;
+-----+
| a2 |
+-----+
| 1 |
| 3 |
| 1 |
| 7 |
| 1 |
| 8 |
| 4 |
| 4 |
+-----+
8 rows in set (0.00 sec)

mysql> SELECT * FROM test3;
+-----+
| a3 |
+-----+
| 2 |
| 5 |
| 6 |
| 9 |
| 10 |
+-----+
5 rows in set (0.00 sec)

mysql> SELECT * FROM test4;
+-----+-----+
| a4 | b4 |
+-----+-----+
| 1 | 3 |
| 2 | 0 |
| 3 | 1 |
| 4 | 2 |
| 5 | 0 |
| 6 | 0 |
| 7 | 1 |
| 8 | 1 |
| 9 | 0 |
| 10 | 0 |
+-----+-----+
10 rows in set (0.00 sec)
```

## 22.3.2 Trigger Metadata

Metadata about triggers can be obtained as follows:

- Query the `TRIGGERS` table of the `INFORMATION_SCHEMA` database. See [Section 23.28, “The INFORMATION\\_SCHEMA TRIGGERS Table”](#).
- Use the `SHOW CREATE TRIGGER` statement. See [Section 14.7.5.11, “SHOW CREATE TRIGGER Syntax”](#).
- Use the `SHOW TRIGGERS` statement. See [Section 14.7.5.38, “SHOW TRIGGERS Syntax”](#).

## 22.4 Using the Event Scheduler

The *MySQL Event Scheduler* manages the scheduling and execution of events, that is, tasks that run according to a schedule. The following discussion covers the Event Scheduler and is divided into the following sections:

- [Section 22.4.1, “Event Scheduler Overview”](#), provides an introduction to and conceptual overview of MySQL Events.
- [Section 22.4.3, “Event Syntax”](#), discusses the SQL statements for creating, altering, and dropping MySQL Events.
- [Section 22.4.4, “Event Metadata”](#), shows how to obtain information about events and how this information is stored by the MySQL Server.
- [Section 22.4.6, “The Event Scheduler and MySQL Privileges”](#), discusses the privileges required to work with events and the ramifications that events have with regard to privileges when executing.

Stored routines require the `event` table in the `mysql` database. This table is created during the MySQL 5.7 installation procedure. If you are upgrading to MySQL 5.7 from an earlier version, be sure to update your grant tables to make sure that the `event` table exists. See [Section 5.4.7, “mysql\\_upgrade — Check and Upgrade MySQL Tables”](#).

### Additional Resources

- You may find the [MySQL Event Scheduler User Forum](#) of use when working with scheduled events.
- There are some restrictions on the use of events; see [Section C.1, “Restrictions on Stored Programs”](#).
- Binary logging for events takes place as described in [Section 22.7, “Binary Logging of Stored Programs”](#).

#### 22.4.1 Event Scheduler Overview

MySQL Events are tasks that run according to a schedule. Therefore, we sometimes refer to them as *scheduled* events. When you create an event, you are creating a named database object containing one or more SQL statements to be executed at one or more regular intervals, beginning and ending at a specific date and time. Conceptually, this is similar to the idea of the Unix `crontab` (also known as a “cron job”) or the Windows Task Scheduler.

Scheduled tasks of this type are also sometimes known as “temporal triggers”, implying that these are objects that are triggered by the passage of time. While this is essentially correct, we prefer to use the term *events* to avoid confusion with triggers of the type discussed in [Section 22.3, “Using Triggers”](#). Events should more specifically not be confused with “temporary triggers”. Whereas a trigger is a database object whose statements are executed in response to a specific type of event that occurs on a given table, a (scheduled) event is an object whose statements are executed in response to the passage of a specified time interval.

While there is no provision in the SQL Standard for event scheduling, there are precedents in other database systems, and you may notice some similarities between these implementations and that found in the MySQL Server.

MySQL Events have the following major features and properties:

- In MySQL, an event is uniquely identified by its name and the schema to which it is assigned.
- An event performs a specific action according to a schedule. This action consists of an SQL statement, which can be a compound statement in a `BEGIN . . . END` block if desired (see [Section 14.6, “Compound-Statement Syntax”](#)). An event's timing can be either *one-time* or *recurrent*. A one-time event executes one time only. A recurrent event repeats its action at a regular interval, and the schedule for a recurring event can be assigned a specific start day and time, end day and time, both, or neither. (By default, a recurring event's schedule begins as soon as it is created, and continues indefinitely, until it is disabled or dropped.)

If a repeating event does not terminate within its scheduling interval, the result may be multiple instances of the event executing simultaneously. If this is undesirable, you should institute a mechanism to prevent simultaneous instances. For example, you could use the `GET_LOCK( )` function, or row or table locking.

- Users can create, modify, and drop scheduled events using SQL statements intended for these purposes. Syntactically invalid event creation and modification statements fail with an appropriate error message. *A user may include statements in an event's action which require privileges that the user does not actually have.* The event creation or modification statement succeeds but the event's action fails. See [Section 22.4.6, “The Event Scheduler and MySQL Privileges”](#) for details.
- Many of the properties of an event can be set or modified using SQL statements. These properties include the event's name, timing, persistence (that is, whether it is preserved following the expiration of its schedule), status (enabled or disabled), action to be performed, and the schema to which it is assigned. See [Section 14.1.2, “ALTER EVENT Syntax”](#).

The default definer of an event is the user who created the event, unless the event has been altered, in which case the definer is the user who issued the last `ALTER EVENT` statement affecting that event. An event can be modified by any user having the `EVENT` privilege on the database for which the event is defined. See [Section 22.4.6, “The Event Scheduler and MySQL Privileges”](#).

- An event's action statement may include most SQL statements permitted within stored routines. For restrictions, see [Section C.1, “Restrictions on Stored Programs”](#).

## 22.4.2 Event Scheduler Configuration

Events are executed by a special *event scheduler thread*; when we refer to the Event Scheduler, we actually refer to this thread. When running, the event scheduler thread and its current state can be seen by users having the `PROCESS` privilege in the output of `SHOW PROCESSLIST`, as shown in the discussion that follows.

The global `event_scheduler` system variable determines whether the Event Scheduler is enabled and running on the server. It has one of these 3 values, which affect event scheduling as described here:

- **OFF**: The Event Scheduler is stopped. The event scheduler thread does not run, is not shown in the output of `SHOW PROCESSLIST`, and no scheduled events are executed. **OFF** is the default value for `event_scheduler`.

When the Event Scheduler is stopped (`event_scheduler` is **OFF**), it can be started by setting the value of `event_scheduler` to **ON**. (See next item.)

- **ON**: The Event Scheduler is started; the event scheduler thread runs and executes all scheduled events.

When the Event Scheduler is **ON**, the event scheduler thread is listed in the output of `SHOW PROCESSLIST` as a daemon process, and its state is represented as shown here:

```
mysql> SHOW PROCESSLIST\G
***** 1. row *****
```

```

      Id: 1
      User: root
      Host: localhost
      db: NULL
Command: Query
      Time: 0
      State: NULL
      Info: show processlist
***** 2. row *****
      Id: 2
      User: event_scheduler
      Host: localhost
      db: NULL
Command: Daemon
      Time: 3
      State: Waiting for next activation
      Info: NULL
2 rows in set (0.00 sec)

```

Event scheduling can be stopped by setting the value of `event_scheduler` to `OFF`.

- **DISABLED**: This value renders the Event Scheduler nonoperational. When the Event Scheduler is **DISABLED**, the event scheduler thread does not run (and so does not appear in the output of `SHOW PROCESSLIST`). In addition, the Event Scheduler state cannot be changed at runtime.

If the Event Scheduler status has not been set to **DISABLED**, `event_scheduler` can be toggled between **ON** and **OFF** (using `SET`). It is also possible to use `0` for **OFF**, and `1` for **ON** when setting this variable. Thus, any of the following 4 statements can be used in the `mysql` client to turn on the Event Scheduler:

```

SET GLOBAL event_scheduler = ON;
SET @@global.event_scheduler = ON;
SET GLOBAL event_scheduler = 1;
SET @@global.event_scheduler = 1;

```

Similarly, any of these 4 statements can be used to turn off the Event Scheduler:

```

SET GLOBAL event_scheduler = OFF;
SET @@global.event_scheduler = OFF;
SET GLOBAL event_scheduler = 0;
SET @@global.event_scheduler = 0;

```

Although **ON** and **OFF** have numeric equivalents, the value displayed for `event_scheduler` by `SELECT` or `SHOW VARIABLES` is always one of **OFF**, **ON**, or **DISABLED**. **DISABLED** has no numeric equivalent. For this reason, **ON** and **OFF** are usually preferred over `1` and `0` when setting this variable.

Note that attempting to set `event_scheduler` without specifying it as a global variable causes an error:

```

mysql> SET @@event_scheduler = OFF;
ERROR 1229 (HY000): Variable 'event_scheduler' is a GLOBAL
variable and should be set with SET GLOBAL

```

#### Important

It is possible to set the Event Scheduler to **DISABLED** only at server startup. If `event_scheduler` is **ON** or **OFF**, you cannot set it to **DISABLED** at runtime. Also, if the Event Scheduler is set to **DISABLED** at startup, you cannot change the value of `event_scheduler` at runtime.

To disable the event scheduler, use one of the following two methods:

- As a command-line option when starting the server:

```
--event-scheduler=DISABLED
```

- In the server configuration file (`my.cnf`, or `my.ini` on Windows systems), include the line where it will be read by the server (for example, in a `[mysqld]` section):

```
event_scheduler=DISABLED
```

To enable the Event Scheduler, restart the server without the `--event-scheduler=DISABLED` command-line option, or after removing or commenting out the line containing `event_scheduler=DISABLED` in the server configuration file, as appropriate. Alternatively, you can use `ON` (or `1`) or `OFF` (or `0`) in place of the `DISABLED` value when starting the server.

#### Note

You can issue event-manipulation statements when `event_scheduler` is set to `DISABLED`. No warnings or errors are generated in such cases (provided that the statements are themselves valid). However, scheduled events cannot execute until this variable is set to `ON` (or `1`). Once this has been done, the event scheduler thread executes all events whose scheduling conditions are satisfied.

Starting the MySQL server with the `--skip-grant-tables` option causes `event_scheduler` to be set to `DISABLED`, overriding any other value set either on the command line or in the `my.cnf` or `my.ini` file (Bug #26807).

For SQL statements used to create, alter, and drop events, see [Section 22.4.3, “Event Syntax”](#).

MySQL provides an `EVENTS` table in the `INFORMATION_SCHEMA` database. This table can be queried to obtain information about scheduled events which have been defined on the server. See [Section 22.4.4, “Event Metadata”](#), and [Section 23.7, “The INFORMATION\\_SCHEMA EVENTS Table”](#), for more information.

For information regarding event scheduling and the MySQL privilege system, see [Section 22.4.6, “The Event Scheduler and MySQL Privileges”](#).

## 22.4.3 Event Syntax

MySQL provides several SQL statements for working with scheduled events:

- New events are defined using the `CREATE EVENT` statement. See [Section 14.1.12, “CREATE EVENT Syntax”](#).
- The definition of an existing event can be changed by means of the `ALTER EVENT` statement. See [Section 14.1.2, “ALTER EVENT Syntax”](#).
- When a scheduled event is no longer wanted or needed, it can be deleted from the server by its definer using the `DROP EVENT` statement. See [Section 14.1.23, “DROP EVENT Syntax”](#). Whether an event persists past the end of its schedule also depends on its `ON COMPLETION` clause, if it has one. See [Section 14.1.12, “CREATE EVENT Syntax”](#).

An event can be dropped by any user having the `EVENT` privilege for the database on which the event is defined. See [Section 22.4.6, “The Event Scheduler and MySQL Privileges”](#).

## 22.4.4 Event Metadata

Metadata about events can be obtained as follows:

- Query the `event` table of the `mysql` database.
- Query the `EVENTS` table of the `INFORMATION_SCHEMA` database. See [Section 23.7, “The INFORMATION\\_SCHEMA EVENTS Table”](#).
- Use the `SHOW CREATE EVENT` statement. See [Section 14.7.5.7, “SHOW CREATE EVENT Syntax”](#).

- Use the `SHOW EVENTS` statement. See [Section 14.7.5.18, “SHOW EVENTS Syntax”](#).

### Event Scheduler Time Representation

Each session in MySQL has a session time zone (STZ). This is the session `time_zone` value that is initialized from the server's global `time_zone` value when the session begins but may be changed during the session.

The session time zone that is current when a `CREATE EVENT` or `ALTER EVENT` statement executes is used to interpret times specified in the event definition. This becomes the event time zone (ETZ); that is, the time zone that is used for event scheduling and is in effect within the event as it executes.

For representation of event information in the `mysql.event` table, the `execute_at`, `starts`, and `ends` times are converted to UTC and stored along with the event time zone. This enables event execution to proceed as defined regardless of any subsequent changes to the server time zone or daylight saving time effects. The `last_executed` time is also stored in UTC.

If you select information from `mysql.event`, the times just mentioned are retrieved as UTC values. These times can also be obtained by selecting from the `INFORMATION_SCHEMA.EVENTS` table or from `SHOW EVENTS`, but they are reported as ETZ values. Other times available from these sources indicate when an event was created or last altered; these are displayed as STZ values. The following table summarizes representation of event times.

| Value         | <code>mysql.event</code> | <code>INFORMATION_SCHEMA.EVENTS</code> | <code>SHOW EVENTS</code> |
|---------------|--------------------------|--|--------------------------|
| Execute at    | UTC                      | ETZ                                    | ETZ                      |
| Starts        | UTC                      | ETZ                                    | ETZ                      |
| Ends          | UTC                      | ETZ                                    | ETZ                      |
| Last executed | UTC                      | ETZ                                    | n/a                      |
| Created       | STZ                      | STZ                                    | n/a                      |
| Last altered  | STZ                      | STZ                                    | n/a                      |

## 22.4.5 Event Scheduler Status

The Event Scheduler writes information about event execution that terminates with an error or warning to the MySQL Server's error log. See [Section 22.4.6, “The Event Scheduler and MySQL Privileges”](#) for an example.

To obtain information about the state of the Event Scheduler for debugging and troubleshooting purposes, run `mysqladmin debug` (see [Section 5.5.2, “mysqladmin — Client for Administering a MySQL Server”](#)); after running this command, the server's error log contains output relating to the Event Scheduler, similar to what is shown here:

```
Events status:
LLA = Last Locked At  LUA = Last Unlocked At
WOC = Waiting On Condition  DL = Data Locked

Event scheduler status:
State      : INITIALIZED
Thread id  : 0
LLA        : init_scheduler:313
LUA        : init_scheduler:318
WOC        : NO
Workers    : 0
Executed   : 0
Data locked: NO

Event queue status:
Element count : 1
Data locked   : NO
Attempting lock : NO
LLA           : init_queue:148
```

```
LUA          : init_queue:168
WOC          : NO
Next activation : 0000-00-00 00:00:00
```

In statements that occur as part of events executed by the Event Scheduler, diagnostics messages (not only errors, but also warnings) are written to the error log, and, on Windows, to the application event log. For frequently executed events, it is possible for this to result in many logged messages. For example, for `SELECT ... INTO var_list` statements, if the query returns no rows, a warning with error code 1329 occurs (*No data*), and the variable values remain unchanged. If the query returns multiple rows, error 1172 occurs (*Result consisted of more than one row*). For either condition, you can avoid having the warnings be logged by declaring a condition handler; see [Section 14.6.7.2, “DECLARE ... HANDLER Syntax”](#). For statements that may retrieve multiple rows, another strategy is to use `LIMIT 1` to limit the result set to a single row.

## 22.4.6 The Event Scheduler and MySQL Privileges

To enable or disable the execution of scheduled events, it is necessary to set the value of the global `event_scheduler` system variable. This requires the `SUPER` privilege.

The `EVENT` privilege governs the creation, modification, and deletion of events. This privilege can be bestowed using `GRANT`. For example, this `GRANT` statement confers the `EVENT` privilege for the schema named `myschema` on the user `jon@ghidora`:

```
GRANT EVENT ON myschema.* TO jon@ghidora;
```

(We assume that this user account already exists, and that we wish for it to remain unchanged otherwise.)

To grant this same user the `EVENT` privilege on all schemas, use the following statement:

```
GRANT EVENT ON *.* TO jon@ghidora;
```

The `EVENT` privilege has global or schema-level scope. Therefore, trying to grant it on a single table results in an error as shown:

```
mysql> GRANT EVENT ON myschema.mytable TO jon@ghidora;
ERROR 1144 (42000): Illegal GRANT/REVOKE command; please
consult the manual to see which privileges can be used
```

It is important to understand that an event is executed with the privileges of its definer, and that it cannot perform any actions for which its definer does not have the requisite privileges. For example, suppose that `jon@ghidora` has the `EVENT` privilege for `myschema`. Suppose also that this user has the `SELECT` privilege for `myschema`, but no other privileges for this schema. It is possible for `jon@ghidora` to create a new event such as this one:

```
CREATE EVENT e_store_ts
ON SCHEDULE
  EVERY 10 SECOND
DO
  INSERT INTO myschema.mytable VALUES (UNIX_TIMESTAMP());
```

The user waits for a minute or so, and then performs a `SELECT * FROM mytable;` query, expecting to see several new rows in the table. Instead, the table is empty. Since the user does not have the `INSERT` privilege for the table in question, the event has no effect.

If you inspect the MySQL error log (`hostname.err`), you can see that the event is executing, but the action it is attempting to perform fails:

```
2013-09-24T12:41:31.261992Z 25 [ERROR] Event Scheduler:
[jon@ghidora][cookbook.e_store_ts] INSERT command denied to user
```

```
'jon'@'ghidora' for table 'mytable'
2013-09-24T12:41:31.262022Z 25 [Note] Event Scheduler:
[jon@ghidora].[myschema.e_store_ts] event execution failed.
2013-09-24T12:41:41.271796Z 26 [ERROR] Event Scheduler:
[jon@ghidora][cookbook.e_store_ts] INSERT command denied to user
'jon'@'ghidora' for table 'mytable'
2013-09-24T12:41:41.272761Z 26 [Note] Event Scheduler:
[jon@ghidora].[myschema.e_store_ts] event execution failed.
```

Since this user very likely does not have access to the error log, it is possible to verify whether the event's action statement is valid by executing it directly:

```
mysql> INSERT INTO myschema.mytable VALUES (UNIX_TIMESTAMP());
ERROR 1142 (42000): INSERT command denied to user
'jon'@'ghidora' for table 'mytable'
```

Inspection of the `INFORMATION_SCHEMA.EVENTS` table shows that `e_store_ts` exists and is enabled, but its `LAST_EXECUTED` column is `NULL`:

```
mysql> SELECT * FROM INFORMATION_SCHEMA.EVENTS
> WHERE EVENT_NAME='e_store_ts'
> AND EVENT_SCHEMA='myschema'\G
***** 1. row *****
EVENT_CATALOG: NULL
EVENT_SCHEMA: myschema
EVENT_NAME: e_store_ts
DEFINER: jon@ghidora
EVENT_BODY: SQL
EVENT_DEFINITION: INSERT INTO myschema.mytable VALUES (UNIX_TIMESTAMP())
EVENT_TYPE: RECURRING
EXECUTE_AT: NULL
INTERVAL_VALUE: 5
INTERVAL_FIELD: SECOND
SQL_MODE: NULL
STARTS: 0000-00-00 00:00:00
ENDS: 0000-00-00 00:00:00
STATUS: ENABLED
ON_COMPLETION: NOT PRESERVE
CREATED: 2006-02-09 22:36:06
LAST_ALTERED: 2006-02-09 22:36:06
LAST_EXECUTED: NULL
EVENT_COMMENT:
1 row in set (0.00 sec)
```

To rescind the `EVENT` privilege, use the `REVOKE` statement. In this example, the `EVENT` privilege on the schema `myschema` is removed from the `jon@ghidora` user account:

```
REVOKE EVENT ON myschema.* FROM jon@ghidora;
```

### Important

Revoking the `EVENT` privilege from a user does not delete or disable any events that may have been created by that user.

An event is not migrated or dropped as a result of renaming or dropping the user who created it.

Suppose that the user `jon@ghidora` has been granted the `EVENT` and `INSERT` privileges on the `myschema` schema. This user then creates the following event:

```
CREATE EVENT e_insert
ON SCHEDULE
EVERY 7 SECOND
DO
INSERT INTO myschema.mytable;
```

After this event has been created, `root` revokes the `EVENT` privilege for `jon@ghidora`. However, `e_insert` continues to execute, inserting a new row into `mytable` each seven seconds. The same would be true if `root` had issued either of these statements:

- `DROP USER jon@ghidora;`
- `RENAME USER jon@ghidora TO someotherguy@ghidora;`

You can verify that this is true by examining the `mysql.event` table (discussed later in this section) or the `INFORMATION_SCHEMA.EVENTS` table (see [Section 23.7, “The INFORMATION\\_SCHEMA EVENTS Table”](#)) before and after issuing a `DROP USER` or `RENAME USER` statement.

Event definitions are stored in the `mysql.event` table. To drop an event created by another user account, the MySQL `root` user (or another user with the necessary privileges) can delete rows from this table. For example, to remove the event `e_insert` shown previously, `root` can use the following statement:

```
DELETE FROM mysql.event
  WHERE db = 'myschema'
        AND definer = 'jon@ghidora'
        AND name = 'e_insert';
```

It is very important to match the event name, database schema name, and user account when deleting rows from the `mysql.event` table. This is because the same user can create different events of the same name in different schemas.

Users' `EVENT` privileges are stored in the `Event_priv` columns of the `mysql.user` and `mysql.db` tables. In both cases, this column holds one of the values 'Y' or 'N'. 'N' is the default. `mysql.user.Event_priv` is set to 'Y' for a given user only if that user has the global `EVENT` privilege (that is, if the privilege was bestowed using `GRANT EVENT ON *.*`). For a schema-level `EVENT` privilege, `GRANT` creates a row in `mysql.db` and sets that row's `Db` column to the name of the schema, the `User` column to the name of the user, and the `Event_priv` column to 'Y'. There should never be any need to manipulate these tables directly, since the `GRANT EVENT` and `REVOKE EVENT` statements perform the required operations on them.

Five status variables provide counts of event-related operations (but *not* of statements executed by events; see [Section C.1, “Restrictions on Stored Programs”](#)). These are:

- `Com_create_event`: The number of `CREATE EVENT` statements executed since the last server restart.
- `Com_alter_event`: The number of `ALTER EVENT` statements executed since the last server restart.
- `Com_drop_event`: The number of `DROP EVENT` statements executed since the last server restart.
- `Com_show_create_event`: The number of `SHOW CREATE EVENT` statements executed since the last server restart.
- `Com_show_events`: The number of `SHOW EVENTS` statements executed since the last server restart.

You can view current values for all of these at one time by running the statement `SHOW STATUS LIKE '%event%';`.

## 22.5 Using Views

MySQL supports views, including updatable views. Views are stored queries that when invoked produce a result set. A view acts as a virtual table.

The following discussion describes the syntax for creating and dropping views, and shows some examples of how to use them.

## Additional Resources

- You may find the [Views User Forum](#) of use when working with views.
- For answers to some commonly asked questions regarding views in MySQL, see [Section A.6, “MySQL 5.7 FAQ: Views”](#).
- There are some restrictions on the use of views; see [Section C.5, “Restrictions on Views”](#).

### 22.5.1 View Syntax

The `CREATE VIEW` statement creates a new view (see [Section 14.1.21, “CREATE VIEW Syntax”](#)). To alter the definition of a view or drop a view, use `ALTER VIEW` (see [Section 14.1.10, “ALTER VIEW Syntax”](#)), or `DROP VIEW` (see [Section 14.1.32, “DROP VIEW Syntax”](#)).

A view can be created from many kinds of `SELECT` statements. It can refer to base tables or other views. It can use joins, `UNION`, and subqueries. The `SELECT` need not even refer to any tables. The following example defines a view that selects two columns from another table, as well as an expression calculated from those columns:

```
mysql> CREATE TABLE t (qty INT, price INT);
mysql> INSERT INTO t VALUES(3, 50), (5, 60);
mysql> CREATE VIEW v AS SELECT qty, price, qty*price AS value FROM t;
mysql> SELECT * FROM v;
+-----+-----+-----+
| qty | price | value |
+-----+-----+-----+
| 3   | 50    | 150   |
| 5   | 60    | 300   |
+-----+-----+-----+
mysql> SELECT * FROM v WHERE qty = 5;
+-----+-----+-----+
| qty | price | value |
+-----+-----+-----+
| 5   | 60    | 300   |
+-----+-----+-----+
```

### 22.5.2 View Processing Algorithms

The optional `ALGORITHM` clause for `CREATE VIEW` or `ALTER VIEW` is a MySQL extension to standard SQL. It affects how MySQL processes the view. `ALGORITHM` takes three values: `MERGE`, `TEMPTABLE`, or `UNDEFINED`.

- For `MERGE`, the text of a statement that refers to the view and the view definition are merged such that parts of the view definition replace corresponding parts of the statement.
- For `TEMPTABLE`, the results from the view are retrieved into a temporary table, which then is used to execute the statement.
- For `UNDEFINED`, MySQL chooses which algorithm to use. It prefers `MERGE` over `TEMPTABLE` if possible, because `MERGE` is usually more efficient and because a view cannot be updatable if a temporary table is used.
- If no `ALGORITHM` clause is present, `UNDEFINED` is the default algorithm prior to MySQL 5.7.6. As of 5.7.6, the default algorithm is determined by the value of the `derived_merge` flag of the `optimizer_switch` system variable. For additional discussion, see [Optimizing Derived Tables and View References](#).

A reason to specify `TEMPTABLE` explicitly is that locks can be released on underlying tables after the temporary table has been created and before it is used to finish processing the statement. This might result in quicker lock release than the `MERGE` algorithm so that other clients that use the view are not blocked as long.

A view algorithm can be `UNDEFINED` for three reasons:

- No `ALGORITHM` clause is present in the `CREATE VIEW` statement.
- The `CREATE VIEW` statement has an explicit `ALGORITHM = UNDEFINED` clause.
- `ALGORITHM = MERGE` is specified for a view that can be processed only with a temporary table. In this case, MySQL generates a warning and sets the algorithm to `UNDEFINED`.

As mentioned earlier, `MERGE` is handled by merging corresponding parts of a view definition into the statement that refers to the view. The following examples briefly illustrate how the `MERGE` algorithm works. The examples assume that there is a view `v_merge` that has this definition:

```
CREATE ALGORITHM = MERGE VIEW v_merge (vc1, vc2) AS
SELECT c1, c2 FROM t WHERE c3 > 100;
```

Example 1: Suppose that we issue this statement:

```
SELECT * FROM v_merge;
```

MySQL handles the statement as follows:

- `v_merge` becomes `t`
- `*` becomes `vc1, vc2`, which corresponds to `c1, c2`
- The view `WHERE` clause is added

The resulting statement to be executed becomes:

```
SELECT c1, c2 FROM t WHERE c3 > 100;
```

Example 2: Suppose that we issue this statement:

```
SELECT * FROM v_merge WHERE vc1 < 100;
```

This statement is handled similarly to the previous one, except that `vc1 < 100` becomes `c1 < 100` and the view `WHERE` clause is added to the statement `WHERE` clause using an `AND` connective (and parentheses are added to make sure the parts of the clause are executed with correct precedence). The resulting statement to be executed becomes:

```
SELECT c1, c2 FROM t WHERE (c3 > 100) AND (c1 < 100);
```

Effectively, the statement to be executed has a `WHERE` clause of this form:

```
WHERE (select WHERE) AND (view WHERE)
```

If the `MERGE` algorithm cannot be used, a temporary table must be used instead. `MERGE` cannot be used if the view contains any constructs in the following list. These constructs also prevent merging of derived tables (see [Optimizing Derived Tables and View References](#))

- Aggregate functions (`SUM()`, `MIN()`, `MAX()`, `COUNT()`, and so forth)
- `DISTINCT`
- `GROUP BY`
- `HAVING`
- `LIMIT`
- `UNION` or `UNION ALL`

- Subquery in the select list
- Assignment to user variables
- Refers only to literal values (in this case, there is no underlying table)

### 22.5.3 Updatable and Insertable Views

Some views are updatable and references to them can be used to specify tables to be updated in data change statements. That is, you can use them in statements such as [UPDATE](#), [DELETE](#), or [INSERT](#) to update the contents of the underlying table. Derived tables can also be specified in multiple-table [UPDATE](#) and [DELETE](#) statements, but can only be used for reading data to specify rows to be updated or deleted. Generally, the view references must be updatable, meaning that they may be merged and not materialized. Composite views have more complex rules.

For a view to be updatable, there must be a one-to-one relationship between the rows in the view and the rows in the underlying table. There are also certain other constructs that make a view nonupdatable. To be more specific, a view is not updatable if it contains any of the following:

- Aggregate functions ([SUM\(\)](#), [MIN\(\)](#), [MAX\(\)](#), [COUNT\(\)](#), and so forth)
- [DISTINCT](#)
- [GROUP BY](#)
- [HAVING](#)
- [UNION](#) or [UNION ALL](#)
- Subquery in the select list

Before MySQL 5.7.11, subqueries in the select list fail for [INSERT](#), but are okay for [UPDATE](#), [DELETE](#). As of MySQL 5.7.11, that is still true for nondependent subqueries. For dependent subqueries in the select list, no data change statements are permitted.

- Certain joins (see additional join discussion later in this section)
- Reference to nonupdatable view in the [FROM](#) clause
- Subquery in the [WHERE](#) clause that refers to a table in the [FROM](#) clause
- Refers only to literal values (in this case, there is no underlying table to update)
- [ALGORITHM = TEMPTABLE](#) (use of a temporary table always makes a view nonupdatable)
- Multiple references to any column of a base table (fails for [INSERT](#), okay for [UPDATE](#), [DELETE](#))

A generated column in a view is considered updatable because it is possible to assign to it. However, if such a column is updated explicitly, the only permitted value is [DEFAULT](#). For information about generated columns, see [Section 14.1.18.7, “CREATE TABLE and Generated Columns”](#).

It is sometimes possible for a multiple-table view to be updatable, assuming that it can be processed with the [MERGE](#) algorithm. For this to work, the view must use an inner join (not an outer join or a [UNION](#)). Also, only a single table in the view definition can be updated, so the [SET](#) clause must name only columns from one of the tables in the view. Views that use [UNION ALL](#) are not permitted even though they might be theoretically updatable.

With respect to insertability (being updatable with [INSERT](#) statements), an updatable view is insertable if it also satisfies these additional requirements for the view columns:

- There must be no duplicate view column names.
- The view must contain all columns in the base table that do not have a default value.

- The view columns must be simple column references. They must not be expressions, such as these:

```
3.14159
col1 + 3
UPPER(col2)
col3 / col4
(subquery)
```

MySQL sets a flag, called the view updatability flag, at `CREATE VIEW` time. The flag is set to `YES` (true) if `UPDATE` and `DELETE` (and similar operations) are legal for the view. Otherwise, the flag is set to `NO` (false). The `IS_UPDATABLE` column in the `INFORMATION_SCHEMA.VIEWS` table displays the status of this flag.

If a view is not updatable, statements such `UPDATE`, `DELETE`, and `INSERT` are illegal and are rejected. (Note that even if a view is updatable, it might not be possible to insert into it, as described elsewhere in this section.)

The `IS_UPDATABLE` flag may be unreliable if a view depends on one or more other views, and one of these underlying views is updated. Regardless of the `IS_UPDATABLE` value, the server keeps track of the updatability of a view and correctly rejects data change operations to views that are not updatable. If the `IS_UPDATABLE` value for a view has become inaccurate due to changes to underlying views, the value can be updated by deleting and recreating the view.

The updatability of views may be affected by the value of the `updatable_views_with_limit` system variable. See [Section 6.1.5, “Server System Variables”](#).

For the following discussion, suppose that these tables and views exist:

```
CREATE TABLE t1 (x INTEGER);
CREATE TABLE t2 (c INTEGER);
CREATE VIEW vmat AS SELECT SUM(x) AS s FROM t1;
CREATE VIEW vup AS SELECT * FROM t2;
CREATE VIEW vjoin AS SELECT * FROM vmat JOIN vup ON vmat.s=vup.c;
```

`INSERT`, `UPDATE`, and `DELETE` statements are permitted as follows:

- **INSERT:** The insert table of an `INSERT` statement may be a view reference that is merged. If the view is a join view, all components of the view must be updatable (not materialized). For a multiple-table updatable view, `INSERT` can work if it inserts into a single table.

This statement is invalid because one component of the join view is nonupdatable:

```
INSERT INTO vjoin (c) VALUES (1);
```

This statement is valid; the view contains no materialized components:

```
INSERT INTO vup (c) VALUES (1);
```

- **UPDATE:** The table or tables to be updated in an `UPDATE` statement may be view references that are merged. If a view is a join view, at least one component of the view must be updatable (this differs from `INSERT`).

In a multiple-table `UPDATE` statement, the updated table references of the statement must be base tables or updatable view references. Nonupdated table references may be materialized views or derived tables.

This statement is valid; column `c` is from the updatable part of the join view:

```
UPDATE vjoin SET c=c+1;
```

This statement is invalid; column `x` is from the nonupdatable part:

```
UPDATE vjoin SET x=x+1;
```

This statement is valid; the updated table reference of the multiple-table [UPDATE](#) is an updatable view ([vup](#)):

```
UPDATE vup JOIN (SELECT SUM(x) AS s FROM t1) AS dt ON ...
SET c=c+1;
```

This statement is invalid; it tries to update a materialized derived table:

```
UPDATE vup JOIN (SELECT SUM(x) AS s FROM t1) AS dt ON ...
SET s=s+1;
```

- [DELETE](#): The table or tables to be deleted from in a [DELETE](#) statement must be merged views. Join views are not allowed (this differs from [INSERT](#) and [UPDATE](#)).

This statement is invalid because the view is a join view:

```
DELETE vjoin WHERE ...;
```

This statement is valid because the view is a merged (updatable) view:

```
DELETE vup WHERE ...;
```

This statement is valid because it deletes from a merged (updatable) view:

```
DELETE vup FROM vup JOIN (SELECT SUM(x) AS s FROM t1) AS dt ON ...;
```

Additional discussion and examples follow.

Earlier discussion in this section pointed out that a view is not insertable if not all columns are simple column references (for example, if it contains columns that are expressions or composite expressions). Although such a view is not insertable, it can be updatable if you update only columns that are not expressions. Consider this view:

```
CREATE VIEW v AS SELECT col1, 1 AS col2 FROM t;
```

This view is not insertable because [col2](#) is an expression. But it is updatable if the update does not try to update [col2](#). This update is permissible:

```
UPDATE v SET col1 = 0;
```

This update is not permissible because it attempts to update an expression column:

```
UPDATE v SET col2 = 0;
```

If a table contains an [AUTO\\_INCREMENT](#) column, inserting into an insertable view on the table that does not include the [AUTO\\_INCREMENT](#) column does not change the value of [LAST\\_INSERT\\_ID\(\)](#), because the side effects of inserting default values into columns not part of the view should not be visible.

## 22.5.4 The View WITH CHECK OPTION Clause

The [WITH CHECK OPTION](#) clause can be given for an updatable view to prevent inserts to rows for which the [WHERE](#) clause in the [select\\_statement](#) is not true. It also prevents updates to rows for which the [WHERE](#) clause is true but the update would cause it to be not true (in other words, it prevents visible rows from being updated to nonvisible rows).

In a `WITH CHECK OPTION` clause for an updatable view, the `LOCAL` and `CASCADED` keywords determine the scope of check testing when the view is defined in terms of another view. When neither keyword is given, the default is `CASCADED`.

Before MySQL 5.7.6, `WITH CHECK OPTION` testing works like this:

- With `LOCAL`, the view `WHERE` clause is checked, but no underlying views are checked.
- With `CASCADED`, the view `WHERE` clause is checked, then checking recurses to underlying views, adds `WITH CASCADED CHECK OPTION` to them (for purposes of the check; their definitions remain unchanged), and applies the same rules.
- With no check option, the view `WHERE` clause is not checked, and no underlying views are checked.

As of MySQL 5.7.6, `WITH CHECK OPTION` testing is standard-compliant (with changed semantics from previously for `LOCAL` and no check clause):

- With `LOCAL`, the view `WHERE` clause is checked, then checking recurses to underlying views and applies the same rules.
- With `CASCADED`, the view `WHERE` clause is checked, then checking recurses to underlying views, adds `WITH CASCADED CHECK OPTION` to them (for purposes of the check; their definitions remain unchanged), and applies the same rules.
- With no check option, the view `WHERE` clause is not checked, then checking recurses to underlying views, and applies the same rules.

Consider the definitions for the following table and set of views:

```
CREATE TABLE t1 (a INT);
CREATE VIEW v1 AS SELECT * FROM t1 WHERE a < 2
WITH CHECK OPTION;
CREATE VIEW v2 AS SELECT * FROM v1 WHERE a > 0
WITH LOCAL CHECK OPTION;
CREATE VIEW v3 AS SELECT * FROM v1 WHERE a > 0
WITH CASCADED CHECK OPTION;
```

Here the `v2` and `v3` views are defined in terms of another view, `v1`. Before MySQL 5.7.6, because `v2` has a `LOCAL` check option, inserts are tested only against the `v2` check. `v3` has a `CASCADED` check option, so inserts are tested not only against the `v3` check, but against those of underlying views. The following statements illustrate these differences:

```
mysql> INSERT INTO v2 VALUES (2);
Query OK, 1 row affected (0.00 sec)
mysql> INSERT INTO v3 VALUES (2);
ERROR 1369 (HY000): CHECK OPTION failed 'test.v3'
```

As of MySQL 5.7.6, the semantics for `LOCAL` differ from previously: Inserts for `v2` are checked against its `LOCAL` check option, then (unlike before 5.7.6), the check recurses to `v1` and the rules are applied again. The rules for `v1` cause a check failure. The check for `v3` fails as before:

```
mysql> INSERT INTO v2 VALUES (2);
ERROR 1369 (HY000): CHECK OPTION failed 'test.v2'
mysql> INSERT INTO v3 VALUES (2);
ERROR 1369 (HY000): CHECK OPTION failed 'test.v3'
```

## 22.5.5 View Metadata

Metadata about views can be obtained as follows:

- Query the `VIEWS` table of the `INFORMATION_SCHEMA` database. See [Section 23.30, “The INFORMATION\\_SCHEMA VIEWS Table”](#).
- Use the `SHOW CREATE VIEW` statement. See [Section 14.7.5.13, “SHOW CREATE VIEW Syntax”](#).

## 22.6 Access Control for Stored Programs and Views

Stored programs and views are defined prior to use and, when referenced, execute within a security context that determines their privileges. These privileges are controlled by their `DEFINER` attribute, and, if there is one, their `SQL SECURITY` characteristic.

All stored programs (procedures, functions, triggers, and events) and views can have a `DEFINER` attribute that names a MySQL account. If the `DEFINER` attribute is omitted from a stored program or view definition, the default account is the user who creates the object.

In addition, stored routines (procedures and functions) and views can have a `SQL SECURITY` characteristic with a value of `DEFINER` or `INVOKER` to specify whether the object executes in definer or invoker context. If the `SQL SECURITY` characteristic is omitted, the default is definer context.

Triggers and events have no `SQL SECURITY` characteristic and always execute in definer context. The server invokes these objects automatically as necessary, so there is no invoking user.

Definer and invoker security contexts differ as follows:

- A stored program or view that executes in definer security context executes with the privileges of the account named by its `DEFINER` attribute. These privileges may be entirely different from those of the invoking user. The invoker must have appropriate privileges to reference the object (for example, `EXECUTE` to call a stored procedure or `SELECT` to select from a view), but when the object executes, the invoker's privileges are ignored and only the `DEFINER` account privileges matter. If this account has few privileges, the object is correspondingly limited in the operations it can perform. If the `DEFINER` account is highly privileged (such as a `root` account), the object can perform powerful operations *no matter who invokes it*.
- A stored routine or view that executes in invoker security context can perform only operations for which the invoker has privileges. The `DEFINER` attribute can be specified but has no effect for objects that execute in invoker context.

Consider the following stored procedure:

```
CREATE DEFINER = 'admin'@'localhost' PROCEDURE p1()
SQL SECURITY DEFINER
BEGIN
    UPDATE t1 SET counter = counter + 1;
END;
```

Any user who has the `EXECUTE` privilege for `p1` can invoke it with a `CALL` statement. However, when `p1` executes, it does so in `DEFINER` security context and thus executes with the privileges of `'admin'@'localhost'`, the account named in the `DEFINER` attribute. This account must have the `EXECUTE` privilege for `p1` as well as the `UPDATE` privilege for the table `t1`. Otherwise, the procedure fails.

Now consider this stored procedure, which is identical to `p1` except that its `SQL SECURITY` characteristic is `INVOKER`:

```
CREATE DEFINER = 'admin'@'localhost' PROCEDURE p2()
SQL SECURITY INVOKER
BEGIN
    UPDATE t1 SET counter = counter + 1;
END;
```

`p2`, unlike `p1`, executes in `INVOKER` security context. The `DEFINER` attribute is irrelevant and `p2` executes with the privileges of the invoking user. `p2` fails if the invoker lacks the `EXECUTE` privilege for `p2` or the `UPDATE` privilege for the table `t1`.

MySQL uses the following rules to control which accounts a user can specify in an object `DEFINER` attribute:

- You can specify a `DEFINER` value other than your own account only if you have the `SUPER` privilege.
- If you do not have the `SUPER` privilege, the only legal user value is your own account, either specified literally or by using `CURRENT_USER`. You cannot set the definer to some other account.

To minimize the risk potential for stored program and view creation and use, follow these guidelines:

- For a stored routine or view, use `SQL SECURITY INVOKER` in the object definition when possible so that it can be used only by users with permissions appropriate for the operations performed by the object.
- If you create definer-context stored programs or views while using an account that has the `SUPER` privilege, specify an explicit `DEFINER` attribute that names an account possessing only the privileges required for the operations performed by the object. Specify a highly privileged `DEFINER` account only when absolutely necessary.
- Administrators can prevent users from specifying highly privileged `DEFINER` accounts by not granting them the `SUPER` privilege.
- Definer-context objects should be written keeping in mind that they may be able to access data for which the invoking user has no privileges. In some cases, you can prevent reference to these objects by not granting unauthorized users particular privileges:
  - A stored procedure or function cannot be referenced by a user who does not have the `EXECUTE` privilege for it.
  - A view cannot be referenced by a user who does not have the appropriate privilege for it (`SELECT` to select from it, `INSERT` to insert into it, and so forth).

However, no such control exists for triggers because users do not reference them directly. A trigger always executes in `DEFINER` context and is activated by access to the table with which it is associated, even ordinary table accesses by users with no special privileges. If the `DEFINER` account is highly privileged, the trigger can perform sensitive or dangerous operations. This remains true if the `SUPER` and `TRIGGER` privileges needed to create the trigger are revoked from the account of the user who created it. Administrators should be especially careful about granting users that combination of privileges.

## 22.7 Binary Logging of Stored Programs

The binary log contains information about SQL statements that modify database contents. This information is stored in the form of “events” that describe the modifications. The binary log has two important purposes:

- For replication, the binary log is used on master replication servers as a record of the statements to be sent to slave servers. The master server sends the events contained in its binary log to its slaves, which execute those events to make the same data changes that were made on the master. See [Section 18.2, “Replication Implementation”](#).
- Certain data recovery operations require use of the binary log. After a backup file has been restored, the events in the binary log that were recorded after the backup was made are re-executed. These events bring databases up to date from the point of the backup. See [Section 8.3.2, “Using Backups for Recovery”](#).

However, there are certain binary logging issues that apply with respect to stored programs (stored procedures and functions, triggers, and events), if logging occurs at the statement level:

- In some cases, it is possible that a statement will affect different sets of rows on a master and a slave.
- Replicated statements executed on a slave are processed by the slave SQL thread, which has full privileges. It is possible for a procedure to follow different execution paths on master and slave

servers, so a user can write a routine containing a dangerous statement that will execute only on the slave where it is processed by a thread that has full privileges.

- If a stored program that modifies data is nondeterministic, it is not repeatable. This can result in different data on a master and slave, or cause restored data to differ from the original data.

This section describes how MySQL handles binary logging for stored programs. It states the current conditions that the implementation places on the use of stored programs, and what you can do to avoid problems. It also provides additional information about the reasons for these conditions.

In general, the issues described here result when binary logging occurs at the SQL statement level. If you use row-based binary logging, the log contains changes made to individual rows as a result of executing SQL statements. When routines or triggers execute, row changes are logged, not the statements that make the changes. For stored procedures, this means that the `CALL` statement is not logged. For stored functions, row changes made within the function are logged, not the function invocation. For triggers, row changes made by the trigger are logged. On the slave side, only the row changes are seen, not the stored program invocation. For general information about row-based logging, see [Section 18.2.1, “Replication Formats”](#).

Unless noted otherwise, the remarks here assume that you have enabled binary logging by starting the server with the `--log-bin` option. (See [Section 6.4.4, “The Binary Log”](#).) If the binary log is not enabled, replication is not possible, nor is the binary log available for data recovery.

The conditions on the use of stored functions in MySQL can be summarized as follows. These conditions do not apply to stored procedures or Event Scheduler events and they do not apply unless binary logging is enabled.

- To create or alter a stored function, you must have the `SUPER` privilege, in addition to the `CREATE ROUTINE` or `ALTER ROUTINE` privilege that is normally required. (Depending on the `DEFINER` value in the function definition, `SUPER` might be required regardless of whether binary logging is enabled. See [Section 14.1.16, “CREATE PROCEDURE and CREATE FUNCTION Syntax”](#).)
- When you create a stored function, you must declare either that it is deterministic or that it does not modify data. Otherwise, it may be unsafe for data recovery or replication.

By default, for a `CREATE FUNCTION` statement to be accepted, at least one of `DETERMINISTIC`, `NO SQL`, or `READS SQL DATA` must be specified explicitly. Otherwise an error occurs:

```
ERROR 1418 (HY000): This function has none of DETERMINISTIC, NO SQL,
or READS SQL DATA in its declaration and binary logging is enabled
(you *might* want to use the less safe log_bin_trust_function_creators
variable)
```

This function is deterministic (and does not modify data), so it is safe:

```
CREATE FUNCTION f1(i INT)
RETURNS INT
DETERMINISTIC
READS SQL DATA
BEGIN
    RETURN i;
END;
```

This function uses `UUID()`, which is not deterministic, so the function also is not deterministic and is not safe:

```
CREATE FUNCTION f2()
RETURNS CHAR(36) CHARACTER SET utf8
BEGIN
    RETURN UUID();
END;
```

This function modifies data, so it may not be safe:

```
CREATE FUNCTION f3(p_id INT)
RETURNS INT
BEGIN
    UPDATE t SET modtime = NOW() WHERE id = p_id;
    RETURN ROW_COUNT();
END;
```

Assessment of the nature of a function is based on the “honesty” of the creator: MySQL does not check that a function declared `DETERMINISTIC` is free of statements that produce nondeterministic results.

- Although it is possible to create a deterministic stored function without specifying `DETERMINISTIC`, you cannot execute this function using statement-based binary logging. To execute such a function, you must use row-based or mixed binary logging. Alternatively, if you explicitly specify `DETERMINISTIC` in the function definition, you can use any kind of logging, including statement-based logging.
- To relax the preceding conditions on function creation (that you must have the `SUPER` privilege and that a function must be declared deterministic or to not modify data), set the global `log_bin_trust_function_creators` system variable to 1. By default, this variable has a value of 0, but you can change it like this:

```
mysql> SET GLOBAL log_bin_trust_function_creators = 1;
```

You can also set this variable by using the `--log-bin-trust-function-creators=1` option when starting the server.

If binary logging is not enabled, `log_bin_trust_function_creators` does not apply. `SUPER` is not required for function creation unless, as described previously, the `DEFINER` value in the function definition requires it.

- For information about built-in functions that may be unsafe for replication (and thus cause stored functions that use them to be unsafe as well), see [Section 18.4.1, “Replication Features and Issues”](#).

Triggers are similar to stored functions, so the preceding remarks regarding functions also apply to triggers with the following exception: `CREATE TRIGGER` does not have an optional `DETERMINISTIC` characteristic, so triggers are assumed to be always deterministic. However, this assumption might in some cases be invalid. For example, the `UUID()` function is nondeterministic (and does not replicate). You should be careful about using such functions in triggers.

Triggers can update tables, so error messages similar to those for stored functions occur with `CREATE TRIGGER` if you do not have the required privileges. On the slave side, the slave uses the trigger `DEFINER` attribute to determine which user is considered to be the creator of the trigger.

The rest of this section provides additional detail about the logging implementation and its implications. You need not read it unless you are interested in the background on the rationale for the current logging-related conditions on stored routine use. This discussion applies only for statement-based logging, and not for row-based logging, with the exception of the first item: `CREATE` and `DROP` statements are logged as statements regardless of the logging mode.

- The server writes `CREATE EVENT`, `CREATE PROCEDURE`, `CREATE FUNCTION`, `ALTER EVENT`, `ALTER PROCEDURE`, `ALTER FUNCTION`, `DROP EVENT`, `DROP PROCEDURE`, and `DROP FUNCTION` statements to the binary log.
- A stored function invocation is logged as a `SELECT` statement if the function changes data and occurs within a statement that would not otherwise be logged. This prevents nonreplication of data changes that result from use of stored functions in nonlogged statements. For example, `SELECT` statements are not written to the binary log, but a `SELECT` might invoke a stored function that makes

changes. To handle this, a `SELECT func_name()` statement is written to the binary log when the given function makes a change. Suppose that the following statements are executed on the master:

```
CREATE FUNCTION f1(a INT) RETURNS INT
BEGIN
  IF (a < 3) THEN
    INSERT INTO t2 VALUES (a);
  END IF;
  RETURN 0;
END;

CREATE TABLE t1 (a INT);
INSERT INTO t1 VALUES (1),(2),(3);

SELECT f1(a) FROM t1;
```

When the `SELECT` statement executes, the function `f1()` is invoked three times. Two of those invocations insert a row, and MySQL logs a `SELECT` statement for each of them. That is, MySQL writes the following statements to the binary log:

```
SELECT f1(1);
SELECT f1(2);
```

The server also logs a `SELECT` statement for a stored function invocation when the function invokes a stored procedure that causes an error. In this case, the server writes the `SELECT` statement to the log along with the expected error code. On the slave, if the same error occurs, that is the expected result and replication continues. Otherwise, replication stops.

- Logging stored function invocations rather than the statements executed by a function has a security implication for replication, which arises from two factors:
  - It is possible for a function to follow different execution paths on master and slave servers.
  - Statements executed on a slave are processed by the slave SQL thread which has full privileges.

The implication is that although a user must have the `CREATE ROUTINE` privilege to create a function, the user can write a function containing a dangerous statement that will execute only on the slave where it is processed by a thread that has full privileges. For example, if the master and slave servers have server ID values of 1 and 2, respectively, a user on the master server could create and invoke an unsafe function `unsafe_func()` as follows:

```
mysql> delimiter //
mysql> CREATE FUNCTION unsafe_func () RETURNS INT
-> BEGIN
->   IF @@server_id=2 THEN dangerous_statement; END IF;
->   RETURN 1;
-> END;
-> //
mysql> delimiter ;
mysql> INSERT INTO t VALUES(unsafe_func());
```

The `CREATE FUNCTION` and `INSERT` statements are written to the binary log, so the slave will execute them. Because the slave SQL thread has full privileges, it will execute the dangerous statement. Thus, the function invocation has different effects on the master and slave and is not replication-safe.

To guard against this danger for servers that have binary logging enabled, stored function creators must have the `SUPER` privilege, in addition to the usual `CREATE ROUTINE` privilege that is required. Similarly, to use `ALTER FUNCTION`, you must have the `SUPER` privilege in addition to the `ALTER ROUTINE` privilege. Without the `SUPER` privilege, an error will occur:

```
ERROR 1419 (HY000): You do not have the SUPER privilege and
```

```
binary logging is enabled (you *might* want to use the less safe
log_bin_trust_function_creators variable)
```

If you do not want to require function creators to have the `SUPER` privilege (for example, if all users with the `CREATE ROUTINE` privilege on your system are experienced application developers), set the global `log_bin_trust_function_creators` system variable to 1. You can also set this variable by using the `--log-bin-trust-function-creators=1` option when starting the server. If binary logging is not enabled, `log_bin_trust_function_creators` does not apply. `SUPER` is not required for function creation unless, as described previously, the `DEFINER` value in the function definition requires it.

- If a function that performs updates is nondeterministic, it is not repeatable. This can have two undesirable effects:
  - It will make a slave different from the master.
  - Restored data will be different from the original data.

To deal with these problems, MySQL enforces the following requirement: On a master server, creation and alteration of a function is refused unless you declare the function to be deterministic or to not modify data. Two sets of function characteristics apply here:

- The `DETERMINISTIC` and `NOT DETERMINISTIC` characteristics indicate whether a function always produces the same result for given inputs. The default is `NOT DETERMINISTIC` if neither characteristic is given. To declare that a function is deterministic, you must specify `DETERMINISTIC` explicitly.
- The `CONTAINS SQL`, `NO SQL`, `READS SQL DATA`, and `MODIFIES SQL DATA` characteristics provide information about whether the function reads or writes data. Either `NO SQL` or `READS SQL DATA` indicates that a function does not change data, but you must specify one of these explicitly because the default is `CONTAINS SQL` if no characteristic is given.

By default, for a `CREATE FUNCTION` statement to be accepted, at least one of `DETERMINISTIC`, `NO SQL`, or `READS SQL DATA` must be specified explicitly. Otherwise an error occurs:

```
ERROR 1418 (HY000): This function has none of DETERMINISTIC, NO SQL,
or READS SQL DATA in its declaration and binary logging is enabled
(you *might* want to use the less safe log_bin_trust_function_creators
variable)
```

If you set `log_bin_trust_function_creators` to 1, the requirement that functions be deterministic or not modify data is dropped.

- Stored procedure calls are logged at the statement level rather than at the `CALL` level. That is, the server does not log the `CALL` statement, it logs those statements within the procedure that actually execute. As a result, the same changes that occur on the master will be observed on slave servers. This prevents problems that could result from a procedure having different execution paths on different machines.

In general, statements executed within a stored procedure are written to the binary log using the same rules that would apply were the statements to be executed in standalone fashion. Some special care is taken when logging procedure statements because statement execution within procedures is not quite the same as in nonprocedure context:

- A statement to be logged might contain references to local procedure variables. These variables do not exist outside of stored procedure context, so a statement that refers to such a variable cannot be logged literally. Instead, each reference to a local variable is replaced by this construct for logging purposes:

```
NAME_CONST(var_name, var_value)
```

`var_name` is the local variable name, and `var_value` is a constant indicating the value that the variable has at the time the statement is logged. `NAME_CONST()` has a value of `var_value`, and a “name” of `var_name`. Thus, if you invoke this function directly, you get a result like this:

```
mysql> SELECT NAME_CONST('myname', 14);
+-----+
| myname |
+-----+
|      14 |
+-----+
```

`NAME_CONST()` enables a logged standalone statement to be executed on a slave with the same effect as the original statement that was executed on the master within a stored procedure.

The use of `NAME_CONST()` can result in a problem for `CREATE TABLE ... SELECT` statements when the source column expressions refer to local variables. Converting these references to `NAME_CONST()` expressions can result in column names that are different on the master and slave servers, or names that are too long to be legal column identifiers. A workaround is to supply aliases for columns that refer to local variables. Consider this statement when `myvar` has a value of 1:

```
CREATE TABLE t1 SELECT myvar;
```

That will be rewritten as follows:

```
CREATE TABLE t1 SELECT NAME_CONST(myvar, 1);
```

To ensure that the master and slave tables have the same column names, write the statement like this:

```
CREATE TABLE t1 SELECT myvar AS myvar;
```

The rewritten statement becomes:

```
CREATE TABLE t1 SELECT NAME_CONST(myvar, 1) AS myvar;
```

- A statement to be logged might contain references to user-defined variables. To handle this, MySQL writes a `SET` statement to the binary log to make sure that the variable exists on the slave with the same value as on the master. For example, if a statement refers to a variable `@my_var`, that statement will be preceded in the binary log by the following statement, where `value` is the value of `@my_var` on the master:

```
SET @my_var = value;
```

- Procedure calls can occur within a committed or rolled-back transaction. Transactional context is accounted for so that the transactional aspects of procedure execution are replicated correctly. That is, the server logs those statements within the procedure that actually execute and modify data, and also logs `BEGIN`, `COMMIT`, and `ROLLBACK` statements as necessary. For example, if a procedure updates only transactional tables and is executed within a transaction that is rolled back, those updates are not logged. If the procedure occurs within a committed transaction, `BEGIN` and `COMMIT` statements are logged with the updates. For a procedure that executes within a rolled-back transaction, its statements are logged using the same rules that would apply if the statements were executed in standalone fashion:
  - Updates to transactional tables are not logged.
  - Updates to nontransactional tables are logged because rollback does not cancel them.

- Updates to a mix of transactional and nontransactional tables are logged surrounded by `BEGIN` and `ROLLBACK` so that slaves will make the same changes and rollbacks as on the master.
- A stored procedure call is *not* written to the binary log at the statement level if the procedure is invoked from within a stored function. In that case, the only thing logged is the statement that invokes the function (if it occurs within a statement that is logged) or a `DO` statement (if it occurs within a statement that is not logged). For this reason, care should be exercised in the use of stored functions that invoke a procedure, even if the procedure is otherwise safe in itself.

---

## Chapter 23 INFORMATION\_SCHEMA Tables

### Table of Contents

[INFORMATION\\_SCHEMA](#) provides access to database *metadata*, information about the MySQL server such as the name of a database or table, the data type of a column, or access privileges. Other terms that are sometimes used for this information are *data dictionary* and *system catalog*.

## INFORMATION\_SCHEMA Usage Notes

[INFORMATION\\_SCHEMA](#) is a database within each MySQL instance, the place that stores information about all the other databases that the MySQL server maintains. The [INFORMATION\\_SCHEMA](#) database contains several read-only tables. They are actually views, not base tables, so there are no files associated with them, and you cannot set triggers on them. Also, there is no database directory with that name.

Although you can select [INFORMATION\\_SCHEMA](#) as the default database with a [USE](#) statement, you can only read the contents of tables, not perform [INSERT](#), [UPDATE](#), or [DELETE](#) operations on them.

## Example

Here is an example of a statement that retrieves information from [INFORMATION\\_SCHEMA](#):

```
mysql> SELECT table_name, table_type, engine
      FROM information_schema.tables
      WHERE table_schema = 'db5'
      ORDER BY table_name;
```

| table_name | table_type | engine |
|------------|------------|--------|
| fk         | BASE TABLE | InnoDB |
| fk2        | BASE TABLE | InnoDB |
| goto       | BASE TABLE | MyISAM |
| into       | BASE TABLE | MyISAM |
| k          | BASE TABLE | MyISAM |
| kurs       | BASE TABLE | MyISAM |
| loop       | BASE TABLE | MyISAM |
| pk         | BASE TABLE | InnoDB |
| t          | BASE TABLE | MyISAM |
| t2         | BASE TABLE | MyISAM |
| t3         | BASE TABLE | MyISAM |
| t7         | BASE TABLE | MyISAM |
| tables     | BASE TABLE | MyISAM |
| v          | VIEW       | NULL   |
| v2         | VIEW       | NULL   |
| v3         | VIEW       | NULL   |
| v56        | VIEW       | NULL   |

```
17 rows in set (0.01 sec)
```

Explanation: The statement requests a list of all the tables in database `db5`, showing just three pieces of information: the name of the table, its type, and its storage engine.

## Character Set Considerations

The definition for character columns (for example, `TABLES.TABLE_NAME`) is generally `VARCHAR(N) CHARACTER SET utf8` where `N` is at least 64. MySQL uses the default collation for this character set (`utf8_general_ci`) for all searches, sorts, comparisons, and other string operations on such columns.

Because some MySQL objects are represented as files, searches in `INFORMATION_SCHEMA` string columns can be affected by file system case sensitivity. For more information, see [Section 11.1.8.7, “Using Collation in INFORMATION\\_SCHEMA Searches”](#).

## INFORMATION\_SCHEMA as Alternative to SHOW Statements

The `SELECT ... FROM INFORMATION_SCHEMA` statement is intended as a more consistent way to provide access to the information provided by the various `SHOW` statements that MySQL supports (`SHOW DATABASES`, `SHOW TABLES`, and so forth). Using `SELECT` has these advantages, compared to `SHOW`:

- It conforms to Codd's rules, because all access is done on tables.
- You can use the familiar syntax of the `SELECT` statement, and only need to learn some table and column names.
- The implementor need not worry about adding keywords.
- You can filter, sort, concatenate, and transform the results from `INFORMATION_SCHEMA` queries into whatever format your application needs, such as a data structure or a text representation to parse.
- This technique is more interoperable with other database systems. For example, Oracle Database users are familiar with querying tables in the Oracle data dictionary.

Because `SHOW` is familiar and widely used, the `SHOW` statements remain as an alternative. In fact, along with the implementation of `INFORMATION_SCHEMA`, there are enhancements to `SHOW` as described in [Section 23.34, “Extensions to SHOW Statements”](#).

## Privileges

Each MySQL user has the right to access these tables, but can see only the rows in the tables that correspond to objects for which the user has the proper access privileges. In some cases (for example, the `ROUTINE_DEFINITION` column in the `INFORMATION_SCHEMA.ROUTINES` table), users who have insufficient privileges see `NULL`. These restrictions do not apply for `InnoDB` tables; you can see them with only the `PROCESS` privilege.

The same privileges apply to selecting information from `INFORMATION_SCHEMA` and viewing the same information through `SHOW` statements. In either case, you must have some privilege on an object to see information about it.

## Performance Considerations

`INFORMATION_SCHEMA` queries that search for information from more than one database might take a long time and impact performance. To check the efficiency of a query, you can use `EXPLAIN`. For information about using `EXPLAIN` output to tune `INFORMATION_SCHEMA` queries, see [Section 9.2.4, “Optimizing INFORMATION\\_SCHEMA Queries”](#).

## Standards Considerations

The implementation for the `INFORMATION_SCHEMA` table structures in MySQL follows the ANSI/ISO SQL:2003 standard Part 11 *Schemata*. Our intent is approximate compliance with SQL:2003 core feature F021 *Basic information schema*.

Users of SQL Server 2000 (which also follows the standard) may notice a strong similarity. However, MySQL has omitted many columns that are not relevant for our implementation, and added columns that are MySQL-specific. One such column is the `ENGINE` column in the `INFORMATION_SCHEMA.TABLES` table.

Although other DBMSs use a variety of names, like `syscat` or `system`, the standard name is `INFORMATION_SCHEMA`.

To avoid using any name that is reserved in the standard or in DB2, SQL Server, or Oracle, we changed the names of some columns marked “MySQL extension”. (For example, we changed `COLLATION` to `TABLE_COLLATION` in the `TABLES` table.) See the list of reserved words near the end of this article: <https://web.archive.org/web/20070428032454/http://www.dbazine.com/db2/db2-disarticles/gulutzan5>.

## Conventions in the INFORMATION\_SCHEMA Reference Sections

The following sections describe each of the tables and columns in `INFORMATION_SCHEMA`. For each column, there are three pieces of information:

- “`INFORMATION_SCHEMA` Name” indicates the name for the column in the `INFORMATION_SCHEMA` table. This corresponds to the standard SQL name unless the “Remarks” field says “MySQL extension.”
- “`SHOW` Name” indicates the equivalent field name in the closest `SHOW` statement, if there is one.
- “Remarks” provides additional information where applicable. If this field is `NULL`, it means that the value of the column is always `NULL`. If this field says “MySQL extension,” the column is a MySQL extension to standard SQL.

Many sections indicate what `SHOW` statement is equivalent to a `SELECT` that retrieves information from `INFORMATION_SCHEMA`. For `SHOW` statements that display information for the default database if you omit a `FROM db_name` clause, you can often select information for the default database by adding an `AND TABLE_SCHEMA = SCHEMA( )` condition to the `WHERE` clause of a query that retrieves information from an `INFORMATION_SCHEMA` table.

## Related Information

These sections discuss additional `INFORMATION_SCHEMA`-related topics:

- information about `INFORMATION_SCHEMA` tables specific to the `InnoDB` storage engine: [Section 23.31, “InnoDB INFORMATION\\_SCHEMA Tables”](#)
- information about `INFORMATION_SCHEMA` tables specific to the thread pool plugin: [Section 23.32, “Thread Pool INFORMATION\\_SCHEMA Tables”](#)
- Answers to questions that are often asked concerning the `INFORMATION_SCHEMA` database: [Section A.7, “MySQL 5.7 FAQ: INFORMATION\\_SCHEMA”](#)
- `INFORMATION_SCHEMA` queries and the optimizer: [Section 9.2.4, “Optimizing INFORMATION\\_SCHEMA Queries”](#)
- The effect of collation on `INFORMATION_SCHEMA` comparisons: [Section 11.1.8.7, “Using Collation in INFORMATION\\_SCHEMA Searches”](#)

## 23.1 The INFORMATION\_SCHEMA CHARACTER\_SETS Table

The `CHARACTER_SETS` table provides information about available character sets.

| <code>INFORMATION_SCHEMA</code> Name | <code>SHOW</code> Name | Remarks |
|--------------------------------------|------------------------|---------|
| <code>CHARACTER_SET_NAME</code>      | <code>Charset</code>   |         |

| INFORMATION_SCHEMA Name | SHOW Name         | Remarks         |
|-------------------------|-------------------|-----------------|
| DEFAULT_COLLATE_NAME    | Default collation |                 |
| DESCRIPTION             | Description       | MySQL extension |
| MAXLEN                  | Maxlen            | MySQL extension |

The following statements are equivalent:

```
SELECT * FROM INFORMATION_SCHEMA.CHARACTER_SETS
  [WHERE CHARACTER_SET_NAME LIKE 'wild']

SHOW CHARACTER SET
  [LIKE 'wild']
```

## 23.2 The INFORMATION\_SCHEMA COLLATIONS Table

The [COLLATIONS](#) table provides information about collations for each character set.

| INFORMATION_SCHEMA Name | SHOW Name | Remarks         |
|-------------------------|-----------|-----------------|
| COLLATION_NAME          | Collation |                 |
| CHARACTER_SET_NAME      | Charset   | MySQL extension |
| ID                      | Id        | MySQL extension |
| IS_DEFAULT              | Default   | MySQL extension |
| IS_COMPILED             | Compiled  | MySQL extension |
| SORTLEN                 | Sortlen   | MySQL extension |

- [COLLATION\\_NAME](#) is the collation name.
- [CHARACTER\\_SET\\_NAME](#) is the name of the character set with which the collation is associated.
- [ID](#) is the collation ID.
- [IS\\_DEFAULT](#) indicates whether the collation is the default for its character set.
- [IS\\_COMPILED](#) indicates whether the character set is compiled into the server.
- [SORTLEN](#) is related to the amount of memory required to sort strings expressed in the character set.

Collation information is also available from the [SHOW COLLATION](#) statement. The following statements are equivalent:

```
SELECT COLLATION_NAME FROM INFORMATION_SCHEMA.COLLATIONS
  [WHERE COLLATION_NAME LIKE 'wild']

SHOW COLLATION
  [LIKE 'wild']
```

## 23.3 The INFORMATION\_SCHEMA COLLATION\_CHARACTER\_SET\_APPLICABILITY Table

The [COLLATION\\_CHARACTER\\_SET\\_APPLICABILITY](#) table indicates what character set is applicable for what collation. The columns are equivalent to the first two display fields that we get from [SHOW COLLATION](#).

| INFORMATION_SCHEMA Name | SHOW Name | Remarks |
|-------------------------|-----------|---------|
| COLLATION_NAME          | Collation |         |
| CHARACTER_SET_NAME      | Charset   |         |

## 23.4 The INFORMATION\_SCHEMA COLUMNS Table

The `COLUMNS` table provides information about columns in tables.

| INFORMATION_SCHEMA Name  | SHOW Name  | Remarks         |
|--------------------------|------------|-----------------|
| TABLE_CATALOG            |            | def             |
| TABLE_SCHEMA             |            |                 |
| TABLE_NAME               |            |                 |
| COLUMN_NAME              | Field      |                 |
| ORDINAL_POSITION         |            | see notes       |
| COLUMN_DEFAULT           | Default    |                 |
| IS_NULLABLE              | Null       |                 |
| DATA_TYPE                | Type       |                 |
| CHARACTER_MAXIMUM_LENGTH | Type       |                 |
| CHARACTER_OCTET_LENGTH   |            |                 |
| NUMERIC_PRECISION        | Type       |                 |
| NUMERIC_SCALE            | Type       |                 |
| DATETIME_PRECISION       | Type       |                 |
| CHARACTER_SET_NAME       |            |                 |
| COLLATION_NAME           | Collation  |                 |
| COLUMN_TYPE              | Type       | MySQL extension |
| COLUMN_KEY               | Key        | MySQL extension |
| EXTRA                    | Extra      | MySQL extension |
| PRIVILEGES               | Privileges | MySQL extension |
| COLUMN_COMMENT           | Comment    | MySQL extension |
| GENERATION_EXPRESSION    |            | MySQL extension |

### Notes:

- In `SHOW`, the `Type` display includes values from several different `COLUMNS` columns.
- `ORDINAL_POSITION` is necessary because you might want to say `ORDER BY ORDINAL_POSITION`. Unlike `SHOW`, `SELECT` does not have automatic ordering.
- `CHARACTER_OCTET_LENGTH` should be the same as `CHARACTER_MAXIMUM_LENGTH`, except for multibyte character sets.
- `CHARACTER_SET_NAME` can be derived from `Collation`. For example, if you say `SHOW FULL COLUMNS FROM t`, and you see in the `Collation` column a value of `latin1_swedish_ci`, the character set is what is before the first underscore: `latin1`.
- `GENERATION_EXPRESSION` is nonempty for generated columns and displays the expression used to compute column values. For information about generated columns, see [Section 14.1.18.7, “CREATE TABLE and Generated Columns”](#). This column was added in MySQL 5.7.6.
- As of MySQL 5.7.6, the `EXTRA` column contains `VIRTUAL GENERATED` or `VIRTUAL STORED` for generated columns.

The following statements are nearly equivalent:

```
SELECT COLUMN_NAME, DATA_TYPE, IS_NULLABLE, COLUMN_DEFAULT
```

```

FROM INFORMATION_SCHEMA.COLUMNS
WHERE table_name = 'tbl_name'
[AND table_schema = 'db_name']
[AND column_name LIKE 'wild']

SHOW COLUMNS
FROM tbl_name
[FROM db_name]
[LIKE 'wild']

```

## 23.5 The INFORMATION\_SCHEMA COLUMN\_PRIVILEGES Table

The `COLUMN_PRIVILEGES` table provides information about column privileges. This information comes from the `mysql.columns_priv` grant table.

| INFORMATION_SCHEMA Name | SHOW Name | Remarks                       |
|-------------------------|-----------|-------------------------------|
| GRANTEE                 |           | 'user_name'@'host_name' value |
| TABLE_CATALOG           |           | def                           |
| TABLE_SCHEMA            |           |                               |
| TABLE_NAME              |           |                               |
| COLUMN_NAME             |           |                               |
| PRIVILEGE_TYPE          |           |                               |
| IS_GRANTABLE            |           |                               |

### Notes:

- In the output from `SHOW FULL COLUMNS`, the privileges are all in one field and in lowercase, for example, `select,insert,update,references`. In `COLUMN_PRIVILEGES`, there is one privilege per row, in uppercase.
- `PRIVILEGE_TYPE` can contain one (and only one) of these values: `SELECT`, `INSERT`, `UPDATE`, `REFERENCES`.
- If the user has `GRANT OPTION` privilege, `IS_GRANTABLE` should be `YES`. Otherwise, `IS_GRANTABLE` should be `NO`. The output does not list `GRANT OPTION` as a separate privilege.

The following statements are *not* equivalent:

```

SELECT ... FROM INFORMATION_SCHEMA.COLUMN_PRIVILEGES

SHOW GRANTS ...

```

## 23.6 The INFORMATION\_SCHEMA ENGINES Table

The `ENGINES` table provides information about storage engines.

| INFORMATION_SCHEMA Name | SHOW Name    | Remarks         |
|-------------------------|--------------|-----------------|
| ENGINE                  | Engine       | MySQL extension |
| SUPPORT                 | Support      | MySQL extension |
| COMMENT                 | Comment      | MySQL extension |
| TRANSACTIONS            | Transactions | MySQL extension |
| XA                      | XA           | MySQL extension |
| SAVEPOINTS              | Savepoints   | MySQL extension |

### Notes:

- The `ENGINES` table is a nonstandard table. Its contents correspond to the columns of the `SHOW ENGINES` statement. For descriptions of its columns, see [Section 14.7.5.16, “SHOW ENGINES Syntax”](#).

See also [Section 14.7.5.16, “SHOW ENGINES Syntax”](#).

## 23.7 The INFORMATION\_SCHEMA EVENTS Table

The `EVENTS` table provides information about scheduled events, which are discussed in [Section 22.4, “Using the Event Scheduler”](#). The `SHOW Name` values correspond to column names of the `SHOW EVENTS` statement.

| INFORMATION_SCHEMA Name | SHOW Name                         | Remarks                            |
|-------------------------|-----------------------------------|------------------------------------|
| EVENT_CATALOG           |                                   | <code>def</code> , MySQL extension |
| EVENT_SCHEMA            | <code>Db</code>                   | MySQL extension                    |
| EVENT_NAME              | <code>Name</code>                 | MySQL extension                    |
| DEFINER                 | <code>Definer</code>              | MySQL extension                    |
| TIME_ZONE               | <code>Time zone</code>            | MySQL extension                    |
| EVENT_BODY              |                                   | MySQL extension                    |
| EVENT_DEFINITION        |                                   | MySQL extension                    |
| EVENT_TYPE              | <code>Type</code>                 | MySQL extension                    |
| EXECUTE_AT              | <code>Execute at</code>           | MySQL extension                    |
| INTERVAL_VALUE          | <code>Interval value</code>       | MySQL extension                    |
| INTERVAL_FIELD          | <code>Interval field</code>       | MySQL extension                    |
| SQL_MODE                |                                   | MySQL extension                    |
| STARTS                  | <code>Starts</code>               | MySQL extension                    |
| ENDS                    | <code>Ends</code>                 | MySQL extension                    |
| STATUS                  | <code>Status</code>               | MySQL extension                    |
| ON_COMPLETION           |                                   | MySQL extension                    |
| CREATED                 |                                   | MySQL extension                    |
| LAST_ALTERED            |                                   | MySQL extension                    |
| LAST_EXECUTED           |                                   | MySQL extension                    |
| EVENT_COMMENT           |                                   | MySQL extension                    |
| ORIGINATOR              | <code>Originator</code>           | MySQL extension                    |
| CHARACTER_SET_CLIENT    | <code>character_set_client</code> | MySQL extension                    |
| COLLATION_CONNECTION    | <code>collation_connection</code> | MySQL extension                    |
| DATABASE_COLLATION      | <code>Database Collation</code>   | MySQL extension                    |

### Notes:

- The `EVENTS` table is a nonstandard table.
- `EVENT_CATALOG`: The value of this column is always `def`.
- `EVENT_SCHEMA`: The name of the schema (database) to which this event belongs.
- `EVENT_NAME`: The name of the event.
- `DEFINER`: The account of the user who created the event, in `'user_name'@'host_name'` format.
- `TIME_ZONE`: The event time zone, which is the time zone used for scheduling the event and that is in effect within the event as it executes. The default value is `SYSTEM`.

- **EVENT\_BODY**: The language used for the statements in the event's **DO** clause; in MySQL 5.7, this is always **SQL**.

This column is not to be confused with the column of the same name (now named **EVENT\_DEFINITION**) that existed in earlier MySQL versions.

- **EVENT\_DEFINITION**: The text of the SQL statement making up the event's **DO** clause; in other words, the statement executed by this event.
- **EVENT\_TYPE**: The event repetition type, either **ONE TIME** (transient) or **RECURRING** (repeating).
- **EXECUTE\_AT**: For a one-time event, this is the **DATETIME** value specified in the **AT** clause of the **CREATE EVENT** statement used to create the event, or of the last **ALTER EVENT** statement that modified the event. The value shown in this column reflects the addition or subtraction of any **INTERVAL** value included in the event's **AT** clause. For example, if an event is created using **ON SCHEDULE AT CURRENT\_TIMESTAMP + '1:6' DAY\_HOUR**, and the event was created at 2006-02-09 14:05:30, the value shown in this column would be **'2006-02-10 20:05:30'**.

If the event's timing is determined by an **EVERY** clause instead of an **AT** clause (that is, if the event is recurring), the value of this column is **NULL**.

- **INTERVAL\_VALUE**: For recurring events, this column contains the numeric portion of the event's **EVERY** clause.

For a one-time event (that is, an event whose timing is determined by an **AT** clause), this column is **NULL**.

- **INTERVAL\_FIELD**: For recurring events, this column contains the units portion of the **EVERY** clause governing the timing of the event. Thus, this column contains a value such as **'YEAR'**, **'QUARTER'**, **'DAY'**, and so on.

For a one-time event (that is, an event whose timing is determined by an **AT** clause), this column is **NULL**.

- **SQL\_MODE**: The SQL mode in effect when the event was created or altered, and under which the event executes. For the permitted values, see [Section 6.1.8, "Server SQL Modes"](#).
- **STARTS**: For a recurring event whose definition includes a **STARTS** clause, this column contains the corresponding **DATETIME** value. As with the **EXECUTE\_AT** column, this value resolves any expressions used.

If there is no **STARTS** clause affecting the timing of the event, this column is **NULL**.

- **ENDS**: For a recurring event whose definition includes a **ENDS** clause, this column contains the corresponding **DATETIME** value. As with the **EXECUTE\_AT** column, this value resolves any expressions used.

If there is no **ENDS** clause affecting the timing of the event, this column is **NULL**.

- **STATUS**: One of the three values **ENABLED**, **DISABLED**, or **SLAVESIDE\_DISABLED**.

**SLAVESIDE\_DISABLED** indicates that the creation of the event occurred on another MySQL server acting as a replication master and was replicated to the current MySQL server which is acting as a slave, but the event is not presently being executed on the slave. See [Section 18.4.1.12, "Replication of Invoked Features"](#), for more information.

- **ON\_COMPLETION**: One of the two values **PRESERVE** or **NOT PRESERVE**.
- **CREATED**: The date and time when the event was created. This is a **TIMESTAMP** value.
- **LAST\_ALTERED**: The date and time when the event was last modified. This is a **TIMESTAMP** value. If the event has not been modified since its creation, this column holds the same value as the **CREATED** column.

- **LAST\_EXECUTED**: The date and time when the event last executed. A **DATETIME** value. If the event has never executed, this column is **NULL**.

**LAST\_EXECUTED** indicates when the event started. As a result, the **ENDS** column is never less than **LAST\_EXECUTED**.

- **EVENT\_COMMENT**: The text of a comment, if the event has one. If not, the value of this column is an empty string.
- **ORIGINATOR**: The server ID of the MySQL server on which the event was created; used in replication. The default value is 0.
- **CHARACTER\_SET\_CLIENT**: The session value of the **character\_set\_client** system variable when the event was created.
- **COLLATION\_CONNECTION**: The session value of the **collation\_connection** system variable when the event was created.
- **DATABASE\_COLLATION**: The collation of the database with which the event is associated.

**Example:** Suppose that the user **jon@ghidora** creates an event named **e\_daily**, and then modifies it a few minutes later using an **ALTER EVENT** statement, as shown here:

```
DELIMITER |

CREATE EVENT e_daily
ON SCHEDULE
  EVERY 1 DAY
COMMENT 'Saves total number of sessions then clears the table each day'
DO
  BEGIN
    INSERT INTO site_activity.totals (time, total)
      SELECT CURRENT_TIMESTAMP, COUNT(*)
        FROM site_activity.sessions;
    DELETE FROM site_activity.sessions;
  END |

DELIMITER ;

ALTER EVENT e_daily
  ENABLE;
```

(Note that comments can span multiple lines.)

This user can then run the following **SELECT** statement, and obtain the output shown:

```
mysql> SELECT * FROM INFORMATION_SCHEMA.EVENTS
> WHERE EVENT_NAME = 'e_daily'
> AND EVENT_SCHEMA = 'myschema'\G
***** 1. row *****
EVENT_CATALOG: def
EVENT_SCHEMA: test
EVENT_NAME: e_daily
DEFINER: me@localhost
TIME_ZONE: SYSTEM
EVENT_BODY: SQL
EVENT_DEFINITION: BEGIN
  INSERT INTO site_activity.totals (time, total)
    SELECT CURRENT_TIMESTAMP, COUNT(*)
      FROM site_activity.sessions;
  DELETE FROM site_activity.sessions;
END
EVENT_TYPE: RECURRING
EXECUTE_AT: NULL
INTERVAL_VALUE: 1
INTERVAL_FIELD: DAY
SQL_MODE:
```

```

STARTS: 2008-09-03 12:13:39
ENDS: NULL
STATUS: ENABLED
ON_COMPLETION: NOT PRESERVE
CREATED: 2008-09-03 12:13:39
LAST_ALTERED: 2008-09-03 12:13:39
LAST_EXECUTED: NULL
EVENT_COMMENT: Saves total number of sessions then clears the
                 table each day
ORIGINATOR: 1
CHARACTER_SET_CLIENT: latin1
COLLATION_CONNECTION: latin1_swedish_ci
DATABASE_COLLATION: latin1_swedish_ci

```

Times in the [EVENTS](#) table are displayed using the event time zone or the current session time zone, as described in [Section 22.4.4, “Event Metadata”](#).

See also [Section 14.7.5.18, “SHOW EVENTS Syntax”](#).

## 23.8 The INFORMATION\_SCHEMA FILES Table

The [FILES](#) table provides information about the files in which MySQL tablespace data is stored.

[INFORMATION\\_SCHEMA.FILES](#) provides information about [InnoDB](#) data files (MySQL 5.7.8 and later). In MySQL Cluster this table also provides information about the files in which MySQL Cluster Disk Data tables are stored. For information specific to [InnoDB](#), see [InnoDB Notes](#), later in this section; for information specific to MySQL Cluster, see [NDB Notes](#).

| INFORMATION_SCHEMA Name | SHOW Name | Remarks         |
|-------------------------|-----------|-----------------|
| FILE_ID                 |           | MySQL extension |
| FILE_NAME               |           | MySQL extension |
| FILE_TYPE               |           | MySQL extension |
| TABLESPACE_NAME         |           | MySQL extension |
| TABLE_CATALOG           |           | MySQL extension |
| TABLE_SCHEMA            |           | MySQL extension |
| TABLE_NAME              |           | MySQL extension |
| LOGFILE_GROUP_NAME      |           | MySQL extension |
| LOGFILE_GROUP_NUMBER    |           | MySQL extension |
| ENGINE                  |           | MySQL extension |
| FULLTEXT_KEYS           |           | MySQL extension |
| DELETED_ROWS            |           | MySQL extension |
| UPDATE_COUNT            |           | MySQL extension |
| FREE_EXTENTS            |           | MySQL extension |
| TOTAL_EXTENTS           |           | MySQL extension |
| EXTENT_SIZE             |           | MySQL extension |
| INITIAL_SIZE            |           | MySQL extension |
| MAXIMUM_SIZE            |           | MySQL extension |
| AUTOEXTEND_SIZE         |           | MySQL extension |
| CREATION_TIME           |           | MySQL extension |
| LAST_UPDATE_TIME        |           | MySQL extension |
| LAST_ACCESS_TIME        |           | MySQL extension |
| RECOVER_TIME            |           | MySQL extension |

| INFORMATION_SCHEMA Name | SHOW Name | Remarks         |
|-------------------------|-----------|-----------------|
| TRANSACTION_COUNTER     |           | MySQL extension |
| VERSION                 |           | MySQL extension |
| ROW_FORMAT              |           | MySQL extension |
| TABLE_ROWS              |           | MySQL extension |
| AVG_ROW_LENGTH          |           | MySQL extension |
| DATA_LENGTH             |           | MySQL extension |
| MAX_DATA_LENGTH         |           | MySQL extension |
| INDEX_LENGTH            |           | MySQL extension |
| DATA_FREE               |           | MySQL extension |
| CREATE_TIME             |           | MySQL extension |
| UPDATE_TIME             |           | MySQL extension |
| CHECK_TIME              |           | MySQL extension |
| CHECKSUM                |           | MySQL extension |
| STATUS                  |           | MySQL extension |
| EXTRA                   |           | MySQL extension |

## InnoDB Notes

The following notes apply to InnoDB data files. `INFORMATION_SCHEMA.FILES` fields that are not described below are not applicable to InnoDB and report a `NULL` value.

- Data reported by `INFORMATION_SCHEMA.FILES` is reported from the InnoDB in-memory cache for open files. By comparison, `INFORMATION_SCHEMA.INNODB_SYS_DATAFILES` reports data from the InnoDB `SYS_DATAFILES` internal data dictionary table.
- The data reported by `INFORMATION_SCHEMA.FILES` includes temporary tablespace data. This data is not available in the internal `SYS_DATAFILES` data dictionary table, and is therefore not reported by `INNODB_SYS_DATAFILES`.
- Undo tablespace data is reported by `INFORMATION_SCHEMA.FILES` when separate undo tablespaces are configured using the `innodb_undo_tablespaces` configuration option.
- `FILE_ID` is the tablespace ID, also referred to as the `space_id` or `fil_space_t::id`.
- `FILE_NAME` is the name of the data file. File-per-table and general tablespaces have a `.ibd` file name extension. Undo tablespaces are prefixed by `undo`. The system tablespace is prefixed by `ibdata`. Temporary tablespaces are prefixed by `ibtmp`. The file name includes the file path, which may be relative to the MySQL data directory (`datadir`).
- `FILE_TYPE` is the tablespace file type. There are three possible file types for InnoDB files. `TABLESPACE` is the file type for any system, general, or file-per-table tablespace file that holds tables, indexes, or other forms of user data. `TEMPORARY` is the file type for temporary tablespaces. `UNDO LOG` is the file type for undo log tablespaces, which hold undo records. By default, undo records are stored in the system tablespace. Separate undo log tablespaces can be added using the `innodb_undo_tablespaces` option.
- `TABLESPACE_NAME` is the SQL name for the tablespace. A general tablespace name is the `SYS_TABLESPACES.NAME` value. For other tablespace files, names start with `innodb_`, such as `innodb_system`, `innodb_undo`, and `innodb_file_per_table`. The file-per-table tablespace name format is `innodb_file_per_table_##`, where `##` is the tablespace ID.
- `ENGINE` is the storage engine. For InnoDB files, the value is always `InnoDB`.
- `FREE_EXTENTS` is the number of fully free extents in the current data file.

- `TOTAL_EXTENTS` is the number of full extents used in the current data file. Any partial extent at the end of the file is not counted.
- `EXTENT_SIZE` is 1048576 (1MB) for files with a 4k, 8k, or 16k page size. Extent size is 2097152 bytes (2MB) for files with a 32k page size, and 4194304 (4MB) for files with a 64k page size. `INFORMATION_SCHEMA.FILES` does not report InnoDB page size. Page size is defined by the `innodb_page_size` option. Extent size information can also be retrieved from `INNODB_SYS_TABLESPACES` where `FILES.FILE_ID = INNODB_SYS_TABLESPACES.SPACE_ID`.
- `INITIAL_SIZE` is the initial size of the file, in bytes.
- `MAXIMUM_SIZE` is the maximum number of bytes allowed in the file. The value is `NULL` for all data files except for predefined system tablespace data files. Maximum system tablespace file size is defined by `innodb_data_file_path`. Maximum temporary tablespace file size is defined by `innodb_temp_data_file_path`. A `NULL` value for a predefined system tablespace data file indicates that a file size limit was not defined explicitly.
- `AUTOEXTEND_SIZE` is the auto-extend size defined by `innodb_data_file_path` for the system tablespace, or defined by `innodb_temp_data_file_path` for temporary tablespaces.
- `DATA_FREE` is the total amount of free space (in bytes) for the entire tablespace. Predefined system tablespaces, which include the system tablespace and temporary table tablespaces, may have one or more data files.
- `STATUS` is `NORMAL` by default. InnoDB file-per-table tablespaces may report `IMPORTING`, which indicates that the tablespace is not yet available.
- The following query returns all data pertinent to InnoDB tablespaces.

```
mysql> SELECT FILE_ID, FILE_NAME, FILE_TYPE, TABLESPACE_NAME, FREE_EXTENTS, TOTAL_EXTENTS,
EXTENT_SIZE, INITIAL_SIZE, MAXIMUM_SIZE, AUTOEXTEND_SIZE, DATA_FREE, STATUS ENGINE
FROM INFORMATION_SCHEMA.FILES \G
```

## NDB Notes

- The `FILES` table provides information about Disk Data *files* only; you cannot use it for determining disk space allocation or availability for individual NDB tables. However, it is possible to see how much space is allocated for each NDB table having data stored on disk—as well as how much remains available for storage of data on disk for that table—using `ndb_desc`. For more information, see [Section 20.4.10, “ndb\\_desc — Describe NDB Tables”](#).
- `FILE_ID` column values are auto-generated.
- `FILE_NAME` is the name of an `UNDO` log file created by `CREATE LOGFILE GROUP` or `ALTER LOGFILE GROUP`, or of a data file created by `CREATE TABLESPACE` or `ALTER TABLESPACE`.
- `FILE_TYPE` is one of the values `UNDOFILE`, `DATAFILE`, or `TABLESPACE`.
- `TABLESPACE_NAME` is the name of the tablespace with which the file is associated.
- Currently, the value of the `TABLESPACE_CATALOG` column is always `NULL`.
- `TABLE_NAME` is the name of the Disk Data table with which the file is associated, if any.
- The `LOGFILE_GROUP_NAME` column gives the name of the log file group to which the log file or data file belongs.
- For an `UNDO` log file, the `LOGFILE_GROUP_NUMBER` contains the auto-generated ID number of the log file group to which the log file belongs.
- For a MySQL Cluster Disk Data log file or data file, the value of the `ENGINE` column is always `NDB` or `NDBCLUSTER`.

- For a MySQL Cluster Disk Data log file or data file, the value of the `FULLTEXT_KEYS` column is always empty.
- The `FREE_EXTENTS` column displays the number of extents which have not yet been used by the file. The `TOTAL_EXTENTS` column show the total number of extents allocated to the file.

The difference between these two columns is the number of extents currently in use by the file:

```
SELECT TOTAL_EXTENTS - FREE_EXTENTS AS extents_used
FROM INFORMATION_SCHEMA.FILES
WHERE FILE_NAME = 'myfile.dat';
```

You can approximate the amount of disk space in use by the file by multiplying this difference by the value of the `EXTENT_SIZE` column, which gives the size of an extent for the file in bytes:

```
SELECT (TOTAL_EXTENTS - FREE_EXTENTS) * EXTENT_SIZE AS bytes_used
FROM INFORMATION_SCHEMA.FILES
WHERE FILE_NAME = 'myfile.dat';
```

Similarly, you can estimate the amount of space that remains available in a given file by multiplying `FREE_EXTENTS` by `EXTENT_SIZE`:

```
SELECT FREE_EXTENTS * EXTENT_SIZE AS bytes_free
FROM INFORMATION_SCHEMA.FILES
WHERE FILE_NAME = 'myfile.dat';
```

#### Important

The byte values produced by the preceding queries are approximations only, and their precision is inversely proportional to the value of `EXTENT_SIZE`. That is, the larger `EXTENT_SIZE` becomes, the less accurate the approximations are.

It is also important to remember that once an extent is used, it cannot be freed again without dropping the data file of which it is a part. This means that deletes from a Disk Data table do *not* release disk space.

The extent size can be set in a `CREATE TABLESPACE` statement. See [Section 14.1.19, “CREATE TABLESPACE Syntax”](#), for more information.

- The `INITIAL_SIZE` column shows the size in bytes of the file. This is the same value that was used in the `INITIAL_SIZE` clause of the `CREATE LOGFILE GROUP`, `ALTER LOGFILE GROUP`, `CREATE TABLESPACE`, or `ALTER TABLESPACE` statement used to create the file.

For MySQL Cluster Disk Data files, the value of the `MAXIMUM_SIZE` column is always the same as `INITIAL_SIZE`, and the `AUTOEXTEND_SIZE` column is always empty.

- The `CREATION_TIME` column shows the date and time when the file was created. The `LAST_UPDATE_TIME` column displays the date and time when the file was last modified. The `LAST_ACCESSED` column provides the date and time when the file was last accessed by the server.

Currently, the values of these columns are as reported by the operating system, and are not supplied by the NDB storage engine. Where no value is provided by the operating system, these columns display `0000-00-00 00:00:00`.

- For MySQL Cluster Disk Data files, the value of the `RECOVER_TIME` and `TRANSACTION_COUNTER` columns is always 0.
- For MySQL Cluster Disk Data files, the following columns are always `NULL`:
  - `VERSION`

- `ROW_FORMAT`
- `TABLE_ROWS`
- `AVG_ROW_LENGTH`
- `DATA_LENGTH`
- `MAX_DATA_LENGTH`
- `INDEX_LENGTH`
- `DATA_FREE`
- `CREATE_TIME`
- `UPDATE_TIME`
- `CHECK_TIME`
- `CHECKSUM`
- For MySQL Cluster Disk Data files, the value of the `STATUS` column is always `NORMAL`.
- For MySQL Cluster Disk Data files, the `EXTRA` column shows which data node the file belongs to, as each data node has its own copy of the file. Suppose that you use this statement on a MySQL Cluster with four data nodes:

```
CREATE LOGFILE GROUP mygroup
  ADD UNDOFILE 'new_undo.dat'
  INITIAL_SIZE 2G
  ENGINE NDB;
```

After running the `CREATE LOGFILE GROUP` statement successfully, you should see a result similar to the one shown here for this query against the `FILES` table:

```
mysql> SELECT LOGFILE_GROUP_NAME, FILE_TYPE, EXTRA
->      FROM INFORMATION_SCHEMA.FILES
->      WHERE FILE_NAME = 'new_undo.dat';
```

| LOGFILE_GROUP_NAME | FILE_TYPE | EXTRA          |
|--------------------|-----------|----------------|
| mygroup            | UNDO FILE | CLUSTER_NODE=3 |
| mygroup            | UNDO FILE | CLUSTER_NODE=4 |
| mygroup            | UNDO FILE | CLUSTER_NODE=5 |
| mygroup            | UNDO FILE | CLUSTER_NODE=6 |

4 rows in set (0.01 sec)

- The `FILES` table is a nonstandard table.
- An additional row is present in the `FILES` table following the creation of a logfile group. This row has `NULL` for the value of the `FILE_NAME` column. For this row, the value of the `FILE_ID` column is always 0, that of the `FILE_TYPE` column is always `UNDO FILE`, and that of the `STATUS` column is always `NORMAL`. Currently, the value of the `ENGINE` column is always `NDBCLUSTER`.

The `FREE_EXTENTS` column in this row shows the total number of free extents available to all undo files belonging to a given log file group whose name and number are shown in the `LOGFILE_GROUP_NAME` and `LOGFILE_GROUP_NUMBER` columns, respectively.

Suppose there are no existing log file groups on your MySQL Cluster, and you create one using the following statement:

```
mysql> CREATE LOGFILE GROUP lg1
-> ADD UNDOFILE 'undofile.dat'
-> INITIAL_SIZE = 16M
-> UNDO_BUFFER_SIZE = 1M
-> ENGINE = NDB;
Query OK, 0 rows affected (3.81 sec)
```

You can now see this `NULL` row when you query the `FILES` table:

```
mysql> SELECT DISTINCT
-> FILE_NAME AS File,
-> FREE_EXTENTS AS Free,
-> TOTAL_EXTENTS AS Total,
-> EXTENT_SIZE AS Size,
-> INITIAL_SIZE AS Initial
-> FROM INFORMATION_SCHEMA.FILES;
+-----+-----+-----+-----+-----+
| File          | Free   | Total  | Size  | Initial |
+-----+-----+-----+-----+-----+
| undofile.dat  | NULL   | 4194304 | 4     | 16777216 |
| NULL          | 4184068 | NULL    | 4     | NULL    |
+-----+-----+-----+-----+-----+
2 rows in set (0.01 sec)
```

The total number of free extents available for undo logging is always somewhat less than the sum of the `TOTAL_EXTENTS` column values for all undo files in the log file group due to overhead required for maintaining the undo files. This can be seen by adding a second undo file to the log file group, then repeating the previous query against the `FILES` table:

```
mysql> ALTER LOGFILE GROUP lg1
-> ADD UNDOFILE 'undofile02.dat'
-> INITIAL_SIZE = 4M
-> ENGINE = NDB;
Query OK, 0 rows affected (1.02 sec)

mysql> SELECT DISTINCT
-> FILE_NAME AS File,
-> FREE_EXTENTS AS Free,
-> TOTAL_EXTENTS AS Total,
-> EXTENT_SIZE AS Size,
-> INITIAL_SIZE AS Initial
-> FROM INFORMATION_SCHEMA.FILES;
+-----+-----+-----+-----+-----+
| File          | Free   | Total  | Size  | Initial |
+-----+-----+-----+-----+-----+
| undofile.dat  | NULL   | 4194304 | 4     | 16777216 |
| undofile02.dat | NULL   | 1048576 | 4     | 4194304  |
| NULL          | 5223944 | NULL    | 4     | NULL    |
+-----+-----+-----+-----+-----+
3 rows in set (0.01 sec)
```

The amount of free space in bytes which is available for undo logging by Disk Data tables using this log file group can be approximated by multiplying the number of free extents by the initial size:

```
mysql> SELECT
-> FREE_EXTENTS AS 'Free Extents',
-> FREE_EXTENTS * EXTENT_SIZE AS 'Free Bytes'
-> FROM INFORMATION_SCHEMA.FILES
-> WHERE LOGFILE_GROUP_NAME = 'lg1'
-> AND FILE_NAME IS NULL;
+-----+-----+
| Free Extents | Free Bytes |
+-----+-----+
| 5223944     | 20895776  |
+-----+-----+
```

```
1 row in set (0.02 sec)
```

If you create a MySQL Cluster Disk Data table and then insert some rows into it, you can see approximately how much space remains for undo logging afterward, for example:

```
mysql> CREATE TABLESPACE ts1
-> ADD DATAFILE 'data1.dat'
-> USE LOGFILE GROUP lg1
-> INITIAL_SIZE 512M
-> ENGINE = NDB;
Query OK, 0 rows affected (8.71 sec)

mysql> CREATE TABLE dd (
-> c1 INT NOT NULL PRIMARY KEY,
-> c2 INT,
-> c3 DATE
-> )
-> TABLESPACE ts1 STORAGE DISK
-> ENGINE = NDB;
Query OK, 0 rows affected (2.11 sec)

mysql> INSERT INTO dd VALUES
-> (NULL, 1234567890, '2007-02-02'),
-> (NULL, 1126789005, '2007-02-03'),
-> (NULL, 1357924680, '2007-02-04'),
-> (NULL, 1642097531, '2007-02-05');
Query OK, 4 rows affected (0.01 sec)

mysql> SELECT
-> FREE_EXTENTS AS 'Free Extents',
-> FREE_EXTENTS * EXTENT_SIZE AS 'Free Bytes'
-> FROM INFORMATION_SCHEMA.FILES
-> WHERE LOGFILE_GROUP_NAME = 'lg1'
-> AND FILE_NAME IS NULL;
+-----+-----+
| Free Extents | Free Bytes |
+-----+-----+
|          5207565 |      20830260 |
+-----+-----+
1 row in set (0.01 sec)
```

- An additional row is present in the `FILES` table for any MySQL Cluster tablespace, whether or not any data files are associated with the tablespace. This row has `NULL` for the value of the `FILE_NAME` column. For this row, the value of the `FILE_ID` column is always `0`, that of the `FILE_TYPE` column is always `TABLESPACE`, and that of the `STATUS` column is always `NORMAL`. Currently, the value of the `ENGINE` column is always `NDBCLUSTER`.
- There are no `SHOW` statements associated with the `FILES` table.
- For additional information, and examples of creating and dropping MySQL Cluster Disk Data objects, see [Section 20.5.13, “NDB Cluster Disk Data Tables”](#).

## 23.9 The INFORMATION\_SCHEMA GLOBAL\_STATUS and SESSION\_STATUS Tables

### Note

As of MySQL 5.7.6, the value of the `show_compatibility_56` system variable affects the information available from the tables described here. For details, see the description of that variable in [Section 6.1.5, “Server System Variables”](#).

**Note**

As of MySQL 5.7.6, information available from the tables described here is also available from the Performance Schema. The [INFORMATION\\_SCHEMA](#) tables are deprecated in preference to the Performance Schema tables and will be removed in a future MySQL release. For advice on migrating away from the [INFORMATION\\_SCHEMA](#) tables to the Performance Schema tables, see [Section 24.18, “Migrating to Performance Schema System and Status Variable Tables”](#).

The [GLOBAL\\_STATUS](#) and [SESSION\\_STATUS](#) tables provide information about server status variables. Their contents correspond to the information produced by the [SHOW GLOBAL STATUS](#) and [SHOW SESSION STATUS](#) statements (see [Section 14.7.5.35, “SHOW STATUS Syntax”](#)).

| <a href="#">INFORMATION_SCHEMA</a> Name | <a href="#">SHOW</a> Name | Remarks |
|---|---------------------------|---------|
| VARIABLE_NAME                           | Variable_name             |         |
| VARIABLE_VALUE                          | Value                     |         |

**Notes:**

- The [VARIABLE\\_VALUE](#) column for each of these tables is defined as [VARCHAR\(1024\)](#).

## 23.10 The INFORMATION\_SCHEMA GLOBAL\_VARIABLES and SESSION\_VARIABLES Tables

**Note**

As of MySQL 5.7.6, the value of the [show\\_compatibility\\_56](#) system variable affects the information available from the tables described here. For details, see the description of that variable in [Section 6.1.5, “Server System Variables”](#).

**Note**

As of MySQL 5.7.6, information available from the tables described here is also available from the Performance Schema. The [INFORMATION\\_SCHEMA](#) tables are deprecated in preference to the Performance Schema tables and will be removed in a future MySQL release. For advice on migrating away from the [INFORMATION\\_SCHEMA](#) tables to the Performance Schema tables, see [Section 24.18, “Migrating to Performance Schema System and Status Variable Tables”](#).

The [GLOBAL\\_VARIABLES](#) and [SESSION\\_VARIABLES](#) tables provide information about server status variables. Their contents correspond to the information produced by the [SHOW GLOBAL VARIABLES](#) and [SHOW SESSION VARIABLES](#) statements (see [Section 14.7.5.39, “SHOW VARIABLES Syntax”](#)).

| <a href="#">INFORMATION_SCHEMA</a> Name | <a href="#">SHOW</a> Name | Remarks |
|---|---------------------------|---------|
| VARIABLE_NAME                           | Variable_name             |         |
| VARIABLE_VALUE                          | Value                     |         |

**Notes:**

- The [VARIABLE\\_VALUE](#) column for each of these tables is defined as [VARCHAR\(1024\)](#). For variables with very long values that are not completely displayed, use [SELECT](#) as a workaround. For example:

```
SELECT VARIABLE_NAME, VARIABLE_VALUE FROM INFORMATION_SCHEMA.GLOBAL_VARIABLES
```

```
SELECT @@GLOBAL.innodb_data_file_path;
```

## 23.11 The INFORMATION\_SCHEMA KEY\_COLUMN\_USAGE Table

The `KEY_COLUMN_USAGE` table describes which key columns have constraints.

| INFORMATION_SCHEMA Name       | SHOW Name | Remarks |
|-------------------------------|-----------|---------|
| CONSTRAINT_CATALOG            |           | def     |
| CONSTRAINT_SCHEMA             |           |         |
| CONSTRAINT_NAME               |           |         |
| TABLE_CATALOG                 |           | def     |
| TABLE_SCHEMA                  |           |         |
| TABLE_NAME                    |           |         |
| COLUMN_NAME                   |           |         |
| ORDINAL_POSITION              |           |         |
| POSITION_IN_UNIQUE_CONSTRAINT |           |         |
| REFERENCED_TABLE_SCHEMA       |           |         |
| REFERENCED_TABLE_NAME         |           |         |
| REFERENCED_COLUMN_NAME        |           |         |

### Notes:

- If the constraint is a foreign key, then this is the column of the foreign key, not the column that the foreign key references.
- The value of `ORDINAL_POSITION` is the column's position within the constraint, not the column's position within the table. Column positions are numbered beginning with 1.
- The value of `POSITION_IN_UNIQUE_CONSTRAINT` is `NULL` for unique and primary-key constraints. For foreign-key constraints, it is the ordinal position in key of the table that is being referenced.

Suppose that there are two tables name `t1` and `t3` that have the following definitions:

```
CREATE TABLE t1
(
  s1 INT,
  s2 INT,
  s3 INT,
  PRIMARY KEY(s3)
) ENGINE=InnoDB;

CREATE TABLE t3
(
  s1 INT,
  s2 INT,
  s3 INT,
  KEY(s1),
  CONSTRAINT CO FOREIGN KEY (s2) REFERENCES t1(s3)
) ENGINE=InnoDB;
```

For those two tables, the `KEY_COLUMN_USAGE` table has two rows:

- One row with `CONSTRAINT_NAME = 'PRIMARY'`, `TABLE_NAME = 't1'`, `COLUMN_NAME = 's3'`, `ORDINAL_POSITION = 1`, `POSITION_IN_UNIQUE_CONSTRAINT = NULL`.
- One row with `CONSTRAINT_NAME = 'CO'`, `TABLE_NAME = 't3'`, `COLUMN_NAME = 's2'`, `ORDINAL_POSITION = 1`, `POSITION_IN_UNIQUE_CONSTRAINT = 1`.

## 23.12 The INFORMATION\_SCHEMA ndb\_transid\_mysql\_connection\_map Table

The `ndb_transid_mysql_connection_map` table provides a mapping between NDB transactions, NDB transaction coordinators, and MySQL Servers attached to a MySQL Cluster as API nodes. This information is used when populating the `server_operations` and `server_transactions` tables of the `ndbinfo` MySQL Cluster information database.

| INFORMATION_SCHEMA Name          | SHOW Name | Remarks                         |
|----------------------------------|-----------|---------------------------------|
| <code>mysql_connection_id</code> |           | MySQL Server connection ID      |
| <code>node_id</code>             |           | Transaction coordinator node ID |
| <code>ndb_transid</code>         |           | NDB transaction ID              |

The `mysql_connection_id` is the same as the connection or session ID shown in the output of `SHOW PROCESSLIST`.

There are no `SHOW` statements associated with this table.

This is a nonstandard table, specific to MySQL Cluster. It is implemented as an `INFORMATION_SCHEMA` plugin; you can verify that it is supported by checking the output of `SHOW PLUGINS`. If `ndb_transid_mysql_connection_map` support is enabled, the output from this statement includes a plugin having this name, of type `INFORMATION_SCHEMA`, and having status `ACTIVE`, as shown here (using emphasized text):

```
mysql> SHOW PLUGINS;
```

| Name                                    | Status        | Type                      | Library     | License    |
|---|---------------|---------------------------|-------------|------------|
| binlog                                  | ACTIVE        | STORAGE ENGINE            | NULL        | GPL        |
| mysql_native_password                   | ACTIVE        | AUTHENTICATION            | NULL        | GPL        |
| mysql_old_password                      | ACTIVE        | AUTHENTICATION            | NULL        | GPL        |
| CSV                                     | ACTIVE        | STORAGE ENGINE            | NULL        | GPL        |
| MEMORY                                  | ACTIVE        | STORAGE ENGINE            | NULL        | GPL        |
| MRG_MYISAM                              | ACTIVE        | STORAGE ENGINE            | NULL        | GPL        |
| MyISAM                                  | ACTIVE        | STORAGE ENGINE            | NULL        | GPL        |
| PERFORMANCE_SCHEMA                      | ACTIVE        | STORAGE ENGINE            | NULL        | GPL        |
| BLACKHOLE                               | ACTIVE        | STORAGE ENGINE            | NULL        | GPL        |
| ARCHIVE                                 | ACTIVE        | STORAGE ENGINE            | NULL        | GPL        |
| ndbcluster                              | ACTIVE        | STORAGE ENGINE            | NULL        | GPL        |
| ndbinfo                                 | ACTIVE        | STORAGE ENGINE            | NULL        | GPL        |
| <b>ndb_transid_mysql_connection_map</b> | <b>ACTIVE</b> | <b>INFORMATION_SCHEMA</b> | <b>NULL</b> | <b>GPL</b> |
| InnoDB                                  | ACTIVE        | STORAGE ENGINE            | NULL        | GPL        |
| INNODB_TRX                              | ACTIVE        | INFORMATION_SCHEMA        | NULL        | GPL        |
| INNODB_LOCKS                            | ACTIVE        | INFORMATION_SCHEMA        | NULL        | GPL        |
| INNODB_LOCK_WAITS                       | ACTIVE        | INFORMATION_SCHEMA        | NULL        | GPL        |
| INNODB_CMP                              | ACTIVE        | INFORMATION_SCHEMA        | NULL        | GPL        |
| INNODB_CMP_RESET                        | ACTIVE        | INFORMATION_SCHEMA        | NULL        | GPL        |
| INNODB_CMPMEM                           | ACTIVE        | INFORMATION_SCHEMA        | NULL        | GPL        |
| INNODB_CMPMEM_RESET                     | ACTIVE        | INFORMATION_SCHEMA        | NULL        | GPL        |
| partition                               | ACTIVE        | STORAGE ENGINE            | NULL        | GPL        |

22 rows in set (0.00 sec)

The plugin is enabled by default. You can disable it (or force the server not to run unless the plugin starts) by starting the server with the `--ndb-transid-mysql-connection-map` option. If the plugin is disabled, the status is shown by `SHOW PLUGINS` as `DISABLED`. The plugin cannot be enabled or disabled at runtime.

Although the names of this table and its columns are displayed using lowercase, you can use uppercase or lowercase when referring to them in SQL statements.

For this table to be created, the MySQL Server must be a binary supplied with the MySQL Cluster distribution, or one built from the MySQL Cluster sources with [NDB](#) storage engine support enabled. It is not available in the standard MySQL 5.7 Server.

## 23.13 The INFORMATION\_SCHEMA OPTIMIZER\_TRACE Table

The [OPTIMIZER\\_TRACE](#) table provides information produced by the optimizer tracing capability. To enable tracking, use the [optimizer\\_trace](#) system variable. For details, see [MySQL Internals: Tracing the Optimizer](#).

## 23.14 The INFORMATION\_SCHEMA PARAMETERS Table

The [PARAMETERS](#) table provides information about stored procedure and function parameters, and about return values for stored functions. Parameter information is similar to the contents of the [param\\_list](#) column in the [mysql.proc](#) table.

| INFORMATION_SCHEMA Name  | mysql.proc Name | Remarks  |
|--------------------------|-----------------|--|
| SPECIFIC_CATALOG         |                 | def  |
| SPECIFIC_SCHEMA          | db              | routine database   |
| SPECIFIC_NAME            | name            | routine name   |
| ORDINAL_POSITION         |                 | 1, 2, 3, ... for parameters, 0 for function <a href="#">RETURNS</a> clause |
| PARAMETER_MODE           |                 | IN, OUT, INOUT (NULL for <a href="#">RETURNS</a> )                         |
| PARAMETER_NAME           |                 | parameter name (NULL for <a href="#">RETURNS</a> )                         |
| DATA_TYPE                |                 | same as for <a href="#">COLUMNS</a> table                                  |
| CHARACTER_MAXIMUM_LENGTH |                 | same as for <a href="#">COLUMNS</a> table                                  |
| CHARACTER_OCTET_LENGTH   |                 | same as for <a href="#">COLUMNS</a> table                                  |
| NUMERIC_PRECISION        |                 | same as for <a href="#">COLUMNS</a> table                                  |
| NUMERIC_SCALE            |                 | same as for <a href="#">COLUMNS</a> table                                  |
| DATETIME_PRECISION       |                 | same as for <a href="#">COLUMNS</a> table                                  |
| CHARACTER_SET_NAME       |                 | same as for <a href="#">COLUMNS</a> table                                  |
| COLLATION_NAME           |                 | same as for <a href="#">COLUMNS</a> table                                  |
| DTD_IDENTIFIER           |                 | same as for <a href="#">COLUMNS</a> table                                  |
| ROUTINE_TYPE             | type            | same as for <a href="#">ROUTINES</a> table                                 |

### Notes:

- For successive parameters of a stored procedure or function, the [ORDINAL\\_POSITION](#) values are 1, 2, 3, and so forth. For a stored function, there is also a row that describes the data type for the [RETURNS](#) clause. The return value is not a true parameter, so the row that describes it has these unique characteristics:
  - The [ORDINAL\\_POSITION](#) value is 0.
  - The [PARAMETER\\_NAME](#) and [PARAMETER\\_MODE](#) values are NULL because the return value has no name and the mode does not apply.

## 23.15 The INFORMATION\_SCHEMA PARTITIONS Table

The [PARTITIONS](#) table provides information about table partitions. See [Chapter 21, Partitioning](#), for more information about partitioning tables.

| INFORMATION_SCHEMA Name       | SHOW Name | Remarks         |
|-------------------------------|-----------|-----------------|
| TABLE_CATALOG                 |           | MySQL extension |
| TABLE_SCHEMA                  |           | MySQL extension |
| TABLE_NAME                    |           | MySQL extension |
| PARTITION_NAME                |           | MySQL extension |
| SUBPARTITION_NAME             |           | MySQL extension |
| PARTITION_ORDINAL_POSITION    |           | MySQL extension |
| SUBPARTITION_ORDINAL_POSITION |           | MySQL extension |
| PARTITION_METHOD              |           | MySQL extension |
| SUBPARTITION_METHOD           |           | MySQL extension |
| PARTITION_EXPRESSION          |           | MySQL extension |
| SUBPARTITION_EXPRESSION       |           | MySQL extension |
| PARTITION_DESCRIPTION         |           | MySQL extension |
| TABLE_ROWS                    |           | MySQL extension |
| AVG_ROW_LENGTH                |           | MySQL extension |
| DATA_LENGTH                   |           | MySQL extension |
| MAX_DATA_LENGTH               |           | MySQL extension |
| INDEX_LENGTH                  |           | MySQL extension |
| DATA_FREE                     |           | MySQL extension |
| CREATE_TIME                   |           | MySQL extension |
| UPDATE_TIME                   |           | MySQL extension |
| CHECK_TIME                    |           | MySQL extension |
| CHECKSUM                      |           | MySQL extension |
| PARTITION_COMMENT             |           | MySQL extension |
| NODEGROUP                     |           | MySQL extension |
| TABLESPACE_NAME               |           | MySQL extension |

**Notes:**

- The `PARTITIONS` table is a nonstandard table.  
Each record in this table corresponds to an individual partition or subpartition of a partitioned table.
- `TABLE_CATALOG`: This column is always `def`.
- `TABLE_SCHEMA`: This column contains the name of the database to which the table belongs.
- `TABLE_NAME`: This column contains the name of the table containing the partition.
- `PARTITION_NAME`: The name of the partition.
- `SUBPARTITION_NAME`: If the `PARTITIONS` table record represents a subpartition, then this column contains the name of subpartition; otherwise it is `NULL`.
- `PARTITION_ORDINAL_POSITION`: All partitions are indexed in the same order as they are defined, with `1` being the number assigned to the first partition. The indexing can change as partitions are added, dropped, and reorganized; the number shown in this column reflects the current order, taking into account any indexing changes.
- `SUBPARTITION_ORDINAL_POSITION`: Subpartitions within a given partition are also indexed and reindexed in the same manner as partitions are indexed within a table.

- **PARTITION\_METHOD**: One of the values [RANGE](#), [LIST](#), [HASH](#), [LINEAR HASH](#), [KEY](#), or [LINEAR KEY](#); that is, one of the available partitioning types as discussed in [Section 21.2, “Partitioning Types”](#).
- **SUBPARTITION\_METHOD**: One of the values [HASH](#), [LINEAR HASH](#), [KEY](#), or [LINEAR KEY](#); that is, one of the available subpartitioning types as discussed in [Section 21.2.6, “Subpartitioning”](#).
- **PARTITION\_EXPRESSION**: This is the expression for the partitioning function used in the [CREATE TABLE](#) or [ALTER TABLE](#) statement that created the table's current partitioning scheme.

For example, consider a partitioned table created in the `test` database using this statement:

```
CREATE TABLE tp (
  c1 INT,
  c2 INT,
  c3 VARCHAR(25)
)
PARTITION BY HASH(c1 + c2)
PARTITIONS 4;
```

The **PARTITION\_EXPRESSION** column in a **PARTITIONS** table record for a partition from this table displays `c1 + c2`, as shown here:

```
mysql> SELECT DISTINCT PARTITION_EXPRESSION
> FROM INFORMATION_SCHEMA.PARTITIONS
> WHERE TABLE_NAME='tp' AND TABLE_SCHEMA='test';
+-----+
| PARTITION_EXPRESSION |
+-----+
| c1 + c2              |
+-----+
1 row in set (0.09 sec)
```

- **SUBPARTITION\_EXPRESSION**: This works in the same fashion for the subpartitioning expression that defines the subpartitioning for a table as **PARTITION\_EXPRESSION** does for the partitioning expression used to define a table's partitioning.

If the table has no subpartitions, then this column is `NULL`.

- **PARTITION\_DESCRIPTION**: This column is used for [RANGE](#) and [LIST](#) partitions. For a [RANGE](#) partition, it contains the value set in the partition's [VALUES LESS THAN](#) clause, which can be either an integer or [MAXVALUE](#). For a [LIST](#) partition, this column contains the values defined in the partition's [VALUES IN](#) clause, which is a comma-separated list of integer values.

For partitions whose **PARTITION\_METHOD** is other than [RANGE](#) or [LIST](#), this column is always `NULL`.

- **TABLE\_ROWS**: The number of table rows in the partition.

For partitioned [InnoDB](#) tables, the row count given in the **TABLE\_ROWS** column is only an estimated value used in SQL optimization, and may not always be exact.

- **AVG\_ROW\_LENGTH**: The average length of the rows stored in this partition or subpartition, in bytes.

This is the same as **DATA\_LENGTH** divided by **TABLE\_ROWS**.

- **DATA\_LENGTH**: The total length of all rows stored in this partition or subpartition, in bytes—that is, the total number of bytes stored in the partition or subpartition.
- **MAX\_DATA\_LENGTH**: The maximum number of bytes that can be stored in this partition or subpartition.
- **INDEX\_LENGTH**: The length of the index file for this partition or subpartition, in bytes.
- **DATA\_FREE**: The number of bytes allocated to the partition or subpartition but not used.

- **CREATE\_TIME**: The time of the partition's or subpartition's creation.

Prior to MySQL 5.7.8, for partitioned **InnoDB** tables, this column was always **NULL**. The correct creation time is shown in MySQL 5.7.8 and later. (Bug #17299181, Bug #69990)

- **UPDATE\_TIME**: The time that the partition or subpartition was last modified.

Prior to MySQL 5.7.8, for partitioned **InnoDB** tables, this column was always **NULL**. The correct modification time is shown in MySQL 5.7.8 and later. (Bug #17299181, Bug #69990)

- **CHECK\_TIME**: The last time that the table to which this partition or subpartition belongs was checked.

For partitioned **InnoDB** tables, this column is always **NULL**.

- **CHECKSUM**: The checksum value, if any; otherwise, this column is **NULL**.

- **PARTITION\_COMMENT**: This column contains the text of any comment made for the partition.

In MySQL 5.7, the maximum length for a partition comment is defined as 1024 characters, and the display width of the **PARTITION\_COMMENT** column is also 1024, characters to match this limit (Bug #11748924, Bug #37728).

The default value for this column is an empty string.

- **NODEGROUP**: This is the nodegroup to which the partition belongs. This is relevant only to MySQL Cluster tables; otherwise the value of this column is always 0.

- **TABLESPACE\_NAME**: This column contains the name of the tablespace to which the partition belongs. The value of this column is always **DEFAULT**.

- A nonpartitioned table has one record in **INFORMATION\_SCHEMA.PARTITIONS**; however, the values of the **PARTITION\_NAME**, **SUBPARTITION\_NAME**, **PARTITION\_ORDINAL\_POSITION**, **SUBPARTITION\_ORDINAL\_POSITION**, **PARTITION\_METHOD**, **SUBPARTITION\_METHOD**, **PARTITION\_EXPRESSION**, **SUBPARTITION\_EXPRESSION**, and **PARTITION\_DESCRIPTION** columns are all **NULL**. (The **PARTITION\_COMMENT** column in this case is blank.)

## 23.16 The INFORMATION\_SCHEMA PLUGINS Table

The **PLUGINS** table provides information about server plugins.

| <b>INFORMATION_SCHEMA</b> Name | <b>SHOW</b> Name | Remarks         |
|--------------------------------|------------------|-----------------|
| <b>PLUGIN_NAME</b>             | Name             | MySQL extension |
| <b>PLUGIN_VERSION</b>          |                  | MySQL extension |
| <b>PLUGIN_STATUS</b>           | Status           | MySQL extension |
| <b>PLUGIN_TYPE</b>             | Type             | MySQL extension |
| <b>PLUGIN_TYPE_VERSION</b>     |                  | MySQL extension |
| <b>PLUGIN_LIBRARY</b>          | Library          | MySQL extension |
| <b>PLUGIN_LIBRARY_VERSION</b>  |                  | MySQL extension |
| <b>PLUGIN_AUTHOR</b>           |                  | MySQL extension |
| <b>PLUGIN_DESCRIPTION</b>      |                  | MySQL extension |
| <b>PLUGIN_LICENSE</b>          | License          | MySQL extension |
| <b>LOAD_OPTION</b>             |                  | MySQL extension |

### Notes:

- The **PLUGINS** table is a nonstandard table.

- `PLUGIN_NAME` is the name used to refer to the plugin in statements such as `INSTALL PLUGIN` and `UNINSTALL PLUGIN`.
- `PLUGIN_VERSION` is the version from the plugin's general type descriptor.
- `PLUGIN_STATUS` indicates the plugin status, one of `ACTIVE`, `INACTIVE`, `DISABLED`, or `DELETED`.
- `PLUGIN_TYPE` indicates the type of plugin, such as `STORAGE ENGINE`, `INFORMATION_SCHEMA`, or `AUTHENTICATION`.
- `PLUGIN_TYPE_VERSION` is the version from the plugin's type-specific descriptor.
- `PLUGIN_LIBRARY` is the name of the plugin shared library file. This is the name used to refer to the plugin file in statements such as `INSTALL PLUGIN` and `UNINSTALL PLUGIN`. This file is located in the directory named by the `plugin_dir` system variable. If the library name is `NULL`, the plugin is compiled in and cannot be uninstalled with `UNINSTALL PLUGIN`.
- `PLUGIN_LIBRARY_VERSION` indicates the plugin API interface version.
- `PLUGIN_AUTHOR` names the plugin author.
- `PLUGIN_DESCRIPTION` provides a short description of the plugin.
- `PLUGIN_LICENSE` indicates how the plugin is licensed; for example, `GPL`.
- `LOAD_OPTION` indicates how the plugin was loaded. The value is `OFF`, `ON`, `FORCE`, or `FORCE_PLUS_PERMANENT`. See [Section 6.5.2, “Installing and Uninstalling Plugins”](#).

For plugins installed with `INSTALL PLUGIN`, the `PLUGIN_NAME` and `PLUGIN_LIBRARY` values are also registered in the `mysql.plugin` table.

These statements are equivalent:

```
SELECT
  PLUGIN_NAME, PLUGIN_STATUS, PLUGIN_TYPE,
  PLUGIN_LIBRARY, PLUGIN_LICENSE
FROM INFORMATION_SCHEMA.PLUGINS;

SHOW PLUGINS;
```

For information about plugin data structures that form the basis of the information in the `PLUGINS` table, see [Section 27.2, “The MySQL Plugin API”](#).

Plugin information is also available using the `SHOW PLUGINS` statement. See [Section 14.7.5.25, “SHOW PLUGINS Syntax”](#).

## 23.17 The INFORMATION\_SCHEMA PROCESSLIST Table

The `PROCESSLIST` table provides information about which threads are running.

| INFORMATION_SCHEMA Name | SHOW Name | Remarks         |
|-------------------------|-----------|-----------------|
| ID                      | Id        | MySQL extension |
| USER                    | User      | MySQL extension |
| HOST                    | Host      | MySQL extension |
| DB                      | db        | MySQL extension |
| COMMAND                 | Command   | MySQL extension |
| TIME                    | Time      | MySQL extension |
| STATE                   | State     | MySQL extension |
| INFO                    | Info      | MySQL extension |

For an extensive description of the table columns, see [Section 14.7.5.29, “SHOW PROCESSLIST Syntax”](#).

#### Notes:

- The `PROCESSLIST` table is a nonstandard table.
- Like the output from the corresponding `SHOW` statement, the `PROCESSLIST` table will only show information about your own threads, unless you have the `PROCESS` privilege, in which case you will see information about other threads, too. As an anonymous user, you cannot see any rows at all.
- If an SQL statement refers to `INFORMATION_SCHEMA.PROCESSLIST`, MySQL populates the entire table once, when statement execution begins, so there is read consistency during the statement. There is no read consistency for a multi-statement transaction, though.
- Process information is also available from the `performance_schema.threads` table. However, access to `threads` does not require a mutex and has minimal impact on server performance. `INFORMATION_SCHEMA.PROCESSLIST` and `SHOW PROCESSLIST` have negative performance consequences because they require a mutex. `threads` also shows information about background threads, which `INFORMATION_SCHEMA.PROCESSLIST` and `SHOW PROCESSLIST` do not. This means that `threads` can be used to monitor activity the other thread information sources cannot.

The following statements are equivalent:

```
SELECT * FROM INFORMATION_SCHEMA.PROCESSLIST
SHOW FULL PROCESSLIST
```

## 23.18 The INFORMATION\_SCHEMA PROFILING Table

The `PROFILING` table provides statement profiling information. Its contents correspond to the information produced by the `SHOW PROFILES` and `SHOW PROFILE` statements (see [Section 14.7.5.31, “SHOW PROFILES Syntax”](#)). The table is empty unless the `profiling` session variable is set to 1.

#### Note

This table is deprecated as of MySQL 5.7.2 and will be removed in a future MySQL release. Use the Performance Schema instead; see [Chapter 24, MySQL Performance Schema](#).

| INFORMATION_SCHEMA Name | SHOW Name           | Remarks |
|-------------------------|---------------------|---------|
| QUERY_ID                | Query_ID            |         |
| SEQ                     |                     |         |
| STATE                   | Status              |         |
| DURATION                | Duration            |         |
| CPU_USER                | CPU_user            |         |
| CPU_SYSTEM              | CPU_system          |         |
| CONTEXT_VOLUNTARY       | Context_voluntary   |         |
| CONTEXT_INVOLUNTARY     | Context_involuntary |         |
| BLOCK_OPS_IN            | Block_ops_in        |         |
| BLOCK_OPS_OUT           | Block_ops_out       |         |
| MESSAGES_SENT           | Messages_sent       |         |
| MESSAGES_RECEIVED       | Messages_received   |         |
| PAGE_FAULTS_MAJOR       | Page_faults_major   |         |

| INFORMATION_SCHEMA Name | SHOW Name         | Remarks |
|-------------------------|-------------------|---------|
| PAGE_FAULTS_MINOR       | Page_faults_minor |         |
| SWAPS                   | Swaps             |         |
| SOURCE_FUNCTION         | Source_function   |         |
| SOURCE_FILE             | Source_file       |         |
| SOURCE_LINE             | Source_line       |         |

**Notes:**

- [QUERY\\_ID](#) is a numeric statement identifier.
- [SEQ](#) is a sequence number indicating the display order for rows with the same [QUERY\\_ID](#) value.
- [STATE](#) is the profiling state to which the row measurements apply.
- [DURATION](#) indicates how long statement execution remained in the given state, in seconds.
- [CPU\\_USER](#) and [CPU\\_SYSTEM](#) indicate user and system CPU use, in seconds.
- [CONTEXT\\_VOLUNTARY](#) and [CONTEXT\\_INVOLUNTARY](#) indicate how many voluntary and involuntary context switches occurred.
- [BLOCK\\_OPS\\_IN](#) and [BLOCK\\_OPS\\_OUT](#) indicate the number of block input and output operations.
- [MESSAGES\\_SENT](#) and [MESSAGES\\_RECEIVED](#) indicate the number of communication messages sent and received.
- [PAGE\\_FAULTS\\_MAJOR](#) and [PAGE\\_FAULTS\\_MINOR](#) indicate the number of major and minor page faults.
- [SWAPS](#) indicates how many swaps occurred.
- [SOURCE\\_FUNCTION](#), [SOURCE\\_FILE](#), and [SOURCE\\_LINE](#) provide information indicating where in the source code the profiled state executes.

## 23.19 The INFORMATION\_SCHEMA REFERENTIAL\_CONSTRAINTS Table

The [REFERENTIAL\\_CONSTRAINTS](#) table provides information about foreign keys.

| INFORMATION_SCHEMA Name   | SHOW Name | Remarks |
|---------------------------|-----------|---------|
| CONSTRAINT_CATALOG        |           | def     |
| CONSTRAINT_SCHEMA         |           |         |
| CONSTRAINT_NAME           |           |         |
| UNIQUE_CONSTRAINT_CATALOG |           | def     |
| UNIQUE_CONSTRAINT_SCHEMA  |           |         |
| UNIQUE_CONSTRAINT_NAME    |           |         |
| MATCH_OPTION              |           |         |
| UPDATE_RULE               |           |         |
| DELETE_RULE               |           |         |
| TABLE_NAME                |           |         |
| REFERENCED_TABLE_NAME     |           |         |

**Notes:**

- `TABLE_NAME` has the same value as `TABLE_NAME` in `INFORMATION_SCHEMA.TABLE_CONSTRAINTS`.
- `CONSTRAINT_SCHEMA` and `CONSTRAINT_NAME` identify the foreign key.
- `UNIQUE_CONSTRAINT_SCHEMA`, `UNIQUE_CONSTRAINT_NAME`, and `REFERENCED_TABLE_NAME` identify the referenced key.
- The only valid value at this time for `MATCH_OPTION` is `NONE`.
- The possible values for `UPDATE_RULE` or `DELETE_RULE` are `CASCADE`, `SET NULL`, `SET DEFAULT`, `RESTRICT`, `NO ACTION`.

## 23.20 The INFORMATION\_SCHEMA ROUTINES Table

The `ROUTINES` table provides information about stored routines (both procedures and functions). The `ROUTINES` table does not include user-defined functions (UDFs).

The column named “`mysql.proc Name`” indicates the `mysql.proc` table column that corresponds to the `INFORMATION_SCHEMA.ROUTINES` table column, if any.

| INFORMATION_SCHEMA Name               | mysql.proc Name               | Remarks  |
|---------------------------------------|-------------------------------|--|
| <code>SPECIFIC_NAME</code>            | <code>specific_name</code>    |  |
| <code>ROUTINE_CATALOG</code>          |                               | <code>def</code>                                   |
| <code>ROUTINE_SCHEMA</code>           | <code>db</code>               |  |
| <code>ROUTINE_NAME</code>             | <code>name</code>             |  |
| <code>ROUTINE_TYPE</code>             | <code>type</code>             | { <code>PROCEDURE</code>   <code>FUNCTION</code> } |
| <code>DATA_TYPE</code>                |                               | same as for <code>COLUMNS</code> table             |
| <code>CHARACTER_MAXIMUM_LENGTH</code> |                               | same as for <code>COLUMNS</code> table             |
| <code>CHARACTER_OCTET_LENGTH</code>   |                               | same as for <code>COLUMNS</code> table             |
| <code>NUMERIC_PRECISION</code>        |                               | same as for <code>COLUMNS</code> table             |
| <code>NUMERIC_SCALE</code>            |                               | same as for <code>COLUMNS</code> table             |
| <code>DATETIME_PRECISION</code>       |                               | same as for <code>COLUMNS</code> table             |
| <code>CHARACTER_SET_NAME</code>       |                               | same as for <code>COLUMNS</code> table             |
| <code>COLLATION_NAME</code>           |                               | same as for <code>COLUMNS</code> table             |
| <code>DTD_IDENTIFIER</code>           |                               | data type descriptor                               |
| <code>ROUTINE_BODY</code>             |                               | <code>SQL</code>                                   |
| <code>ROUTINE_DEFINITION</code>       | <code>body_utf8</code>        |  |
| <code>EXTERNAL_NAME</code>            |                               | <code>NULL</code>                                  |
| <code>EXTERNAL_LANGUAGE</code>        | <code>language</code>         | <code>NULL</code>                                  |
| <code>PARAMETER_STYLE</code>          |                               | <code>SQL</code>                                   |
| <code>IS_DETERMINISTIC</code>         | <code>is_deterministic</code> |  |
| <code>SQL_DATA_ACCESS</code>          | <code>sql_data_access</code>  |  |
| <code>SQL_PATH</code>                 |                               | <code>NULL</code>                                  |
| <code>SECURITY_TYPE</code>            | <code>security_type</code>    |  |
| <code>CREATED</code>                  | <code>created</code>          |  |
| <code>LAST_ALTERED</code>             | <code>modified</code>         |  |
| <code>SQL_MODE</code>                 | <code>sql_mode</code>         | MySQL extension                                    |
| <code>ROUTINE_COMMENT</code>          | <code>comment</code>          | MySQL extension                                    |

| INFORMATION_SCHEMA Name | mysql.proc Name | Remarks         |
|-------------------------|-----------------|-----------------|
| DEFINER                 | definer         | MySQL extension |
| CHARACTER_SET_CLIENT    |                 | MySQL extension |
| COLLATION_CONNECTION    |                 | MySQL extension |
| DATABASE_COLLATION      |                 | MySQL extension |

**Notes:**

- MySQL calculates `EXTERNAL_LANGUAGE` thus:
  - If `mysql.proc.language = 'SQL'`, `EXTERNAL_LANGUAGE` is `NULL`
  - Otherwise, `EXTERNAL_LANGUAGE` is what is in `mysql.proc.language`. However, we do not have external languages yet, so it is always `NULL`.
- `CREATED`: The date and time when the routine was created. This is a `TIMESTAMP` value.
- `LAST_ALTERED`: The date and time when the routine was last modified. This is a `TIMESTAMP` value. If the routine has not been modified since its creation, this column holds the same value as the `CREATED` column.
- `SQL_MODE`: The SQL mode in effect when the routine was created or altered, and under which the routine executes. For the permitted values, see [Section 6.1.8, "Server SQL Modes"](#).
- `CHARACTER_SET_CLIENT`: The session value of the `character_set_client` system variable when the routine was created.
- `COLLATION_CONNECTION`: The session value of the `collation_connection` system variable when the routine was created.
- `DATABASE_COLLATION`: The collation of the database with which the routine is associated.
- The `DATA_TYPE`, `CHARACTER_MAXIMUM_LENGTH`, `CHARACTER_OCTET_LENGTH`, `NUMERIC_PRECISION`, `NUMERIC_SCALE`, `DATETIME_PRECISION`, `CHARACTER_SET_NAME`, and `COLLATION_NAME` columns provide information about the data type for the `RETURNS` clause of stored functions. If a stored routine is a stored procedure, these columns all are `NULL`.
- Information about stored function `RETURNS` data types is also available in the `PARAMETERS` table. The return value data type row for a function can be identified as the row that has an `ORDINAL_POSITION` value of 0.

## 23.21 The INFORMATION\_SCHEMA SCHEMATA Table

A schema is a database, so the `SCHEMATA` table provides information about databases.

| INFORMATION_SCHEMA Name    | SHOW Name | Remarks |
|----------------------------|-----------|---------|
| CATALOG_NAME               |           | def     |
| SCHEMA_NAME                | Database  |         |
| DEFAULT_CHARACTER_SET_NAME |           |         |
| DEFAULT_COLLATION_NAME     |           |         |
| SQL_PATH                   |           | NULL    |

The following statements are equivalent:

```
SELECT SCHEMA_NAME AS `Database`
FROM INFORMATION_SCHEMA.SCHEMATA
[WHERE SCHEMA_NAME LIKE 'wild']
```

```
SHOW DATABASES
[LIKE 'wild']
```

## 23.22 The INFORMATION\_SCHEMA SCHEMA\_PRIVILEGES Table

The `SCHEMA_PRIVILEGES` table provides information about schema (database) privileges. This information comes from the `mysql.db` grant table.

| INFORMATION_SCHEMA Name | SHOW Name | Remarks  |
|-------------------------|-----------|--|
| GRANTEE                 |           | ' <i>user_name</i> '@' <i>host_name</i> ' value, MySQL extension |
| TABLE_CATALOG           |           | <i>def</i> , MySQL extension                                     |
| TABLE_SCHEMA            |           | MySQL extension  |
| PRIVILEGE_TYPE          |           | MySQL extension  |
| IS_GRANTABLE            |           | MySQL extension  |

### Notes:

- This is a nonstandard table. It takes its values from the `mysql.db` table.

## 23.23 The INFORMATION\_SCHEMA STATISTICS Table

The `STATISTICS` table provides information about table indexes.

| INFORMATION_SCHEMA Name | SHOW Name            | Remarks         |
|-------------------------|----------------------|-----------------|
| TABLE_CATALOG           |                      | <i>def</i>      |
| TABLE_SCHEMA            |                      | = Database      |
| TABLE_NAME              | <i>Table</i>         |                 |
| NON_UNIQUE              | <i>Non_unique</i>    |                 |
| INDEX_SCHEMA            |                      | = Database      |
| INDEX_NAME              | <i>Key_name</i>      |                 |
| SEQ_IN_INDEX            | <i>Seq_in_index</i>  |                 |
| COLUMN_NAME             | <i>Column_name</i>   |                 |
| COLLATION               | <i>Collation</i>     |                 |
| CARDINALITY             | <i>Cardinality</i>   |                 |
| SUB_PART                | <i>Sub_part</i>      | MySQL extension |
| PACKED                  | <i>Packed</i>        | MySQL extension |
| NULLABLE                | <i>Null</i>          | MySQL extension |
| INDEX_TYPE              | <i>Index_type</i>    | MySQL extension |
| COMMENT                 | <i>Comment</i>       | MySQL extension |
| INDEX_COMMENT           | <i>Index_comment</i> | MySQL extension |

### Notes:

- There is no standard table for indexes. The preceding list is similar to what SQL Server 2000 returns for `sp_statistics`, except that we replaced the name `QUALIFIER` with `CATALOG` and we replaced the name `OWNER` with `SCHEMA`.

Clearly, the preceding table and the output from `SHOW INDEX` are derived from the same parent. So the correlation is already close.

The following statements are equivalent:

```

SELECT * FROM INFORMATION_SCHEMA.STATISTICS
  WHERE table_name = 'tbl_name'
     AND table_schema = 'db_name'

SHOW INDEX
  FROM tbl_name
  FROM db_name

```

## 23.24 The INFORMATION\_SCHEMA TABLES Table

The `TABLES` table provides information about tables in databases.

| INFORMATION_SCHEMA Name | SHOW Name       | Remarks   |
|-------------------------|-----------------|---|
| TABLE_CATALOG           |                 | def   |
| TABLE_SCHEMA            | Table_...       |   |
| TABLE_NAME              | Table_...       |   |
| TABLE_TYPE              |                 |   |
| ENGINE                  | Engine          | MySQL extension   |
| VERSION                 | Version         | The version number of the table's <code>.frm</code> file, MySQL extension |
| ROW_FORMAT              | Row_format      | MySQL extension   |
| TABLE_ROWS              | Rows            | MySQL extension   |
| AVG_ROW_LENGTH          | Avg_row_length  | MySQL extension   |
| DATA_LENGTH             | Data_length     | MySQL extension   |
| MAX_DATA_LENGTH         | Max_data_length | MySQL extension   |
| INDEX_LENGTH            | Index_length    | MySQL extension   |
| DATA_FREE               | Data_free       | MySQL extension   |
| AUTO_INCREMENT          | Auto_increment  | MySQL extension   |
| CREATE_TIME             | Create_time     | MySQL extension   |
| UPDATE_TIME             | Update_time     | MySQL extension   |
| CHECK_TIME              | Check_time      | MySQL extension   |
| TABLE_COLLATION         | Collation       | MySQL extension   |
| CHECKSUM                | Checksum        | MySQL extension   |
| CREATE_OPTIONS          | Create_options  | MySQL extension   |
| TABLE_COMMENT           | Comment         | MySQL extension   |

### Notes:

- Refer to `SHOW TABLE STATUS` for field descriptions.
- `TABLE_SCHEMA` and `TABLE_NAME` are a single field in a `SHOW` display, for example `Table_in_db1`.
- `TABLE_TYPE` should be `BASE TABLE` or `VIEW`. The `TABLES` table does not list `TEMPORARY` tables.
- For partitioned tables, the `ENGINE` column shows the name of the storage engine used by all partitions. (Previously, this column showed `PARTITION` for such tables.)
- The `TABLE_ROWS` column is `NULL` if the table is in the `INFORMATION_SCHEMA` database.

For `InnoDB` tables, the row count is only a rough estimate used in SQL optimization. (This is also true if the `InnoDB` table is partitioned.)

- The `DATA_FREE` column shows the free space in bytes for `InnoDB` tables.
- Prior to MySQL 5.7.8, for partitioned `InnoDB` tables, the `CREATE_TIME` column always showed `NULL`. This column shows the correct table creation time for such tables in MySQL 5.7.8 and later. (Bug #17299181, Bug #69990)
- Beginning with MySQL 5.7.2, `UPDATE_TIME` displays a timestamp value for the last `UPDATE`, `INSERT`, or `DELETE` performed on `InnoDB` tables that are not partitioned. Previously, `UPDATE_TIME` displayed a `NULL` value for `InnoDB` tables. For MVCC, the timestamp value reflects the `COMMIT` time, which is considered the last update time. Timestamps are not persisted when the server is restarted or when the table is evicted from the `InnoDB` data dictionary cache.

The `UPDATE_TIME` column also shows this information for partitioned `InnoDB` tables in MySQL 5.7.8 and later. Previously this column was always `NULL` for such tables. (Bug #17299181, Bug #69990)

- For partitioned `InnoDB` tables, the `CHECK_TIME` column is always `NULL`.
- We have nothing for the table's default character set. `TABLE_COLLATION` is close, because collation names begin with a character set name.
- The `CREATE_OPTIONS` column shows `partitioned` if the table is partitioned.

The following statements are equivalent:

```
SELECT table_name FROM INFORMATION_SCHEMA.TABLES
  WHERE table_schema = 'db_name'
 [AND table_name LIKE 'wild']

SHOW TABLES
  FROM db_name
 [LIKE 'wild']
```

## 23.25 The INFORMATION\_SCHEMA TABLESPACES Table

The `TABLESPACES` table provides information about active tablespaces.

| INFORMATION_SCHEMA Name         | SHOW Name | Remarks         |
|---------------------------------|-----------|-----------------|
| <code>TABLESPACE_NAME</code>    |           | MySQL extension |
| <code>ENGINE</code>             |           | MySQL extension |
| <code>TABLESPACE_TYPE</code>    |           | MySQL extension |
| <code>LOGFILE_GROUP_NAME</code> |           | MySQL extension |
| <code>EXTENT_SIZE</code>        |           | MySQL extension |
| <code>AUTOEXTEND_SIZE</code>    |           | MySQL extension |
| <code>MAXIMUM_SIZE</code>       |           | MySQL extension |
| <code>NODEGROUP_ID</code>       |           | MySQL extension |
| <code>TABLESPACE_COMMENT</code> |           | MySQL extension |

### Notes:

The `INFORMATION_SCHEMA.TABLESPACES` table does not provide information about `InnoDB` tablespaces. For `InnoDB` tablespace metadata, see `INNODB_SYS_TABLESPACES` and `INNODB_SYS_DATAFILES`. As of MySQL 5.7.8, the `INFORMATION_SCHEMA.FILES` table also provides metadata for `InnoDB` tablespaces.

## 23.26 The INFORMATION\_SCHEMA TABLE\_CONSTRAINTS Table

The `TABLE_CONSTRAINTS` table describes which tables have constraints.

| INFORMATION_SCHEMA Name | SHOW Name | Remarks |
|-------------------------|-----------|---------|
| CONSTRAINT_CATALOG      |           | def     |
| CONSTRAINT_SCHEMA       |           |         |
| CONSTRAINT_NAME         |           |         |
| TABLE_SCHEMA            |           |         |
| TABLE_NAME              |           |         |
| CONSTRAINT_TYPE         |           |         |

**Notes:**

- The `CONSTRAINT_TYPE` value can be `UNIQUE`, `PRIMARY KEY`, or `FOREIGN KEY`.
- The `UNIQUE` and `PRIMARY KEY` information is about the same as what you get from the `Key_name` field in the output from `SHOW INDEX` when the `Non_unique` field is 0.
- The `CONSTRAINT_TYPE` column can contain one of these values: `UNIQUE`, `PRIMARY KEY`, `FOREIGN KEY`, `CHECK`. This is a `CHAR` (not `ENUM`) column. The `CHECK` value is not available until we support `CHECK`.

## 23.27 The INFORMATION\_SCHEMA TABLE\_PRIVILEGES Table

The `TABLE_PRIVILEGES` table provides information about table privileges. This information comes from the `mysql.tables_priv` grant table.

| INFORMATION_SCHEMA Name | SHOW Name | Remarks                       |
|-------------------------|-----------|-------------------------------|
| GRANTEE                 |           | 'user_name'@'host_name' value |
| TABLE_CATALOG           |           | def                           |
| TABLE_SCHEMA            |           |                               |
| TABLE_NAME              |           |                               |
| PRIVILEGE_TYPE          |           |                               |
| IS_GRANTABLE            |           |                               |

**Notes:**

- `PRIVILEGE_TYPE` can contain one (and only one) of these values: `SELECT`, `INSERT`, `UPDATE`, `REFERENCES`, `ALTER`, `INDEX`, `DROP`, `CREATE VIEW`.

The following statements are *not* equivalent:

```
SELECT ... FROM INFORMATION_SCHEMA.TABLE_PRIVILEGES

SHOW GRANTS ...
```

## 23.28 The INFORMATION\_SCHEMA TRIGGERS Table

The `TRIGGERS` table provides information about triggers. To see information about a table's triggers, you must have the `TRIGGER` privilege for the table.

| INFORMATION_SCHEMA Name | SHOW Name | Remarks |
|-------------------------|-----------|---------|
| TRIGGER_CATALOG         |           | def     |
| TRIGGER_SCHEMA          |           |         |
| TRIGGER_NAME            | Trigger   |         |

| INFORMATION_SCHEMA Name    | SHOW Name            | Remarks         |
|----------------------------|----------------------|-----------------|
| EVENT_MANIPULATION         | Event                |                 |
| EVENT_OBJECT_CATALOG       |                      | def             |
| EVENT_OBJECT_SCHEMA        |                      |                 |
| EVENT_OBJECT_TABLE         | Table                |                 |
| ACTION_ORDER               |                      |                 |
| ACTION_CONDITION           |                      | NULL            |
| ACTION_STATEMENT           | Statement            |                 |
| ACTION_ORIENTATION         |                      | ROW             |
| ACTION_TIMING              | Timing               |                 |
| ACTION_REFERENCE_OLD_TABLE |                      | NULL            |
| ACTION_REFERENCE_NEW_TABLE |                      | NULL            |
| ACTION_REFERENCE_OLD_ROW   |                      | OLD             |
| ACTION_REFERENCE_NEW_ROW   |                      | NEW             |
| CREATED                    | Created              |                 |
| SQL_MODE                   | sql_mode             | MySQL extension |
| DEFINER                    | Definer              | MySQL extension |
| CHARACTER_SET_CLIENT       | character_set_client | MySQL extension |
| COLLATION_CONNECTION       | collation_connection | MySQL extension |
| DATABASE_COLLATION         | Database Collation   | MySQL extension |

**Notes:**

- The names in the “SHOW Name” column refer to the `SHOW TRIGGERS` statement, not `SHOW CREATE TRIGGER`. See [Section 14.7.5.38, “SHOW TRIGGERS Syntax”](#).
- `TRIGGER_SCHEMA` and `TRIGGER_NAME`: The name of the database in which the trigger occurs and the trigger name, respectively.
- `EVENT_MANIPULATION`: The trigger event. This is the type of operation on the associated table for which the trigger activates. The value is `'INSERT'` (a row was inserted), `'DELETE'` (a row was deleted), or `'UPDATE'` (a row was modified).
- `EVENT_OBJECT_SCHEMA` and `EVENT_OBJECT_TABLE`: As noted in [Section 22.3, “Using Triggers”](#), every trigger is associated with exactly one table. These columns indicate the database in which this table occurs, and the table name, respectively.
- `ACTION_ORDER`: The ordinal position of the trigger's action within the list of triggers on the same table with the same `EVENT_MANIPULATION` and `ACTION_TIMING` values. Before MySQL 5.7.2, this value is always 0 because it is not possible for a table to have more than one trigger with the same `EVENT_MANIPULATION` and `ACTION_TIMING` values.
- `ACTION_STATEMENT`: The trigger body; that is, the statement executed when the trigger activates. This text uses UTF-8 encoding.
- `ACTION_ORIENTATION`: Always contains the value `'ROW'`.
- `ACTION_TIMING`: Whether the trigger activates before or after the triggering event. The value is `'BEFORE'` or `'AFTER'`.
- `ACTION_REFERENCE_OLD_ROW` and `ACTION_REFERENCE_NEW_ROW`: The old and new column identifiers, respectively. This means that `ACTION_REFERENCE_OLD_ROW` always contains the value `'OLD'` and `ACTION_REFERENCE_NEW_ROW` always contains the value `'NEW'`.

- **CREATED**: The date and time when the trigger was created. This is a `TIMESTAMP(2)` value (with a fractional part in hundredths of seconds) for triggers created in MySQL 5.7.2 or later, `NULL` for triggers created prior to 5.7.2.
- **SQL\_MODE**: The SQL mode in effect when the trigger was created, and under which the trigger executes. For the permitted values, see [Section 6.1.8, “Server SQL Modes”](#).
- **DEFINER**: The account of the user who created the trigger, in `'user_name'@'host_name'` format.
- **CHARACTER\_SET\_CLIENT**: The session value of the `character_set_client` system variable when the trigger was created.
- **COLLATION\_CONNECTION**: The session value of the `collation_connection` system variable when the trigger was created.
- **DATABASE\_COLLATION**: The collation of the database with which the trigger is associated.
- The following columns currently always contain `NULL`: `ACTION_CONDITION`, `ACTION_REFERENCE_OLD_TABLE`, and `ACTION_REFERENCE_NEW_TABLE`.

Example, using the `ins_sum` trigger defined in [Section 22.3, “Using Triggers”](#):

```
mysql> SELECT * FROM INFORMATION_SCHEMA.TRIGGERS
      WHERE TRIGGER_SCHEMA='test' AND TRIGGER_NAME='ins_sum'\G
***** 1. row *****
      TRIGGER_CATALOG: def
      TRIGGER_SCHEMA: test
      TRIGGER_NAME: ins_sum
      EVENT_MANIPULATION: INSERT
      EVENT_OBJECT_CATALOG: def
      EVENT_OBJECT_SCHEMA: test
      EVENT_OBJECT_TABLE: account
      ACTION_ORDER: 1
      ACTION_CONDITION: NULL
      ACTION_STATEMENT: SET @sum = @sum + NEW.amount
      ACTION_ORIENTATION: ROW
      ACTION_TIMING: BEFORE
      ACTION_REFERENCE_OLD_TABLE: NULL
      ACTION_REFERENCE_NEW_TABLE: NULL
      ACTION_REFERENCE_OLD_ROW: OLD
      ACTION_REFERENCE_NEW_ROW: NEW
      CREATED: 2013-07-05 07:41:21.26
      SQL_MODE: NO_ENGINE_SUBSTITUTION
      DEFINER: me@localhost
      CHARACTER_SET_CLIENT: utf8
      COLLATION_CONNECTION: utf8_general_ci
      DATABASE_COLLATION: latin1_swedish_ci
```

## 23.29 The INFORMATION\_SCHEMA USER\_PRIVILEGES Table

The `USER_PRIVILEGES` table provides information about global privileges. This information comes from the `mysql.user` grant table.

| INFORMATION_SCHEMA Name | SHOW Name | Remarks   |
|-------------------------|-----------|---|
| GRANTEE                 |           | <code>'user_name'@'host_name'</code> value, MySQL extension |
| TABLE_CATALOG           |           | <code>def</code> , MySQL extension                          |
| PRIVILEGE_TYPE          |           | MySQL extension   |
| IS_GRANTABLE            |           | MySQL extension   |

### Notes:

- This is a nonstandard table. It takes its values from the `mysql.user` table.

## 23.30 The INFORMATION\_SCHEMA VIEWS Table

The **VIEWS** table provides information about views in databases. You must have the **SHOW VIEW** privilege to access this table.

| INFORMATION_SCHEMA Name | SHOW Name | Remarks         |
|-------------------------|-----------|-----------------|
| TABLE_CATALOG           |           | def             |
| TABLE_SCHEMA            |           |                 |
| TABLE_NAME              |           |                 |
| VIEW_DEFINITION         |           |                 |
| CHECK_OPTION            |           |                 |
| IS_UPDATABLE            |           |                 |
| DEFINER                 |           |                 |
| SECURITY_TYPE           |           |                 |
| CHARACTER_SET_CLIENT    |           | MySQL extension |
| COLLATION_CONNECTION    |           | MySQL extension |

### Notes:

- The **VIEW\_DEFINITION** column has most of what you see in the **Create Table** field that **SHOW CREATE VIEW** produces. Skip the words before **SELECT** and skip the words **WITH CHECK OPTION**. Suppose that the original statement was:

```
CREATE VIEW v AS
  SELECT s2,s1 FROM t
  WHERE s1 > 5
  ORDER BY s1
  WITH CHECK OPTION;
```

Then the view definition looks like this:

```
SELECT s2,s1 FROM t WHERE s1 > 5 ORDER BY s1
```

- The **CHECK\_OPTION** column has a value of **NONE**, **CASCADE**, or **LOCAL**.
- MySQL sets a flag, called the view updatability flag, at **CREATE VIEW** time. The flag is set to **YES** (true) if **UPDATE** and **DELETE** (and similar operations) are legal for the view. Otherwise, the flag is set to **NO** (false). The **IS\_UPDATABLE** column in the **VIEWS** table displays the status of this flag.

If a view is not updatable, statements such **UPDATE**, **DELETE**, and **INSERT** are illegal and will be rejected. (Note that even if a view is updatable, it might not be possible to insert into it; for details, refer to [Section 22.5.3, “Updatable and Insertable Views”](#).)

The **IS\_UPDATABLE** flag may be unreliable if a view depends on one or more other views, and one of these underlying views is updated. Regardless of the **IS\_UPDATABLE** value, the server keeps track of the updatability of a view and correctly rejects data change operations to views that are not updatable. If the **IS\_UPDATABLE** value for a view has become inaccurate due to changes to underlying views, the value can be updated by deleting and recreating the view.

- DEFINER**: The account of the user who created the view, in '*user\_name*'@'*host\_name*' format. **SECURITY\_TYPE** has a value of **DEFINER** or **INVOKER**.
- CHARACTER\_SET\_CLIENT**: The session value of the **character\_set\_client** system variable when the view was created.
- COLLATION\_CONNECTION**: The session value of the **collation\_connection** system variable when the view was created.

MySQL lets you use different `sql_mode` settings to tell the server the type of SQL syntax to support. For example, you might use the `ANSI` SQL mode to ensure MySQL correctly interprets the standard SQL concatenation operator, the double bar (`||`), in your queries. If you then create a view that concatenates items, you might worry that changing the `sql_mode` setting to a value different from `ANSI` could cause the view to become invalid. But this is not the case. No matter how you write out a view definition, MySQL always stores it the same way, in a canonical form. Here is an example that shows how the server changes a double bar concatenation operator to a `CONCAT()` function:

```
mysql> SET sql_mode = 'ANSI';
Query OK, 0 rows affected (0.00 sec)

mysql> CREATE VIEW test.v AS SELECT 'a' || 'b' as coll;
Query OK, 0 rows affected (0.00 sec)

mysql> SELECT VIEW_DEFINITION FROM INFORMATION_SCHEMA.VIEWS
       WHERE TABLE_SCHEMA = 'test' AND TABLE_NAME = 'v';
+-----+
| VIEW_DEFINITION |
+-----+
| select concat('a','b') AS `coll` |
+-----+
1 row in set (0.00 sec)
```

The advantage of storing a view definition in canonical form is that changes made later to the value of `sql_mode` will not affect the results from the view. However an additional consequence is that comments prior to `SELECT` are stripped from the definition by the server.

## 23.31 InnoDB INFORMATION\_SCHEMA Tables

This section provides table definitions for InnoDB INFORMATION\_SCHEMA tables. For related information and examples, see [Section 15.15, “InnoDB INFORMATION\\_SCHEMA Tables”](#).

InnoDB INFORMATION\_SCHEMA tables can be used to monitor ongoing InnoDB activity, to detect inefficiencies before they turn into issues, or to troubleshoot performance and capacity issues. As your database becomes bigger and busier, running up against the limits of your hardware capacity, you monitor and tune these aspects to keep the database running smoothly.

### 23.31.1 The INFORMATION\_SCHEMA INNODB\_BUFFER\_PAGE Table

The `INNODB_BUFFER_PAGE` table holds information about each [page](#) in the [InnoDB buffer pool](#).

For related usage information and examples, see [Section 15.15.5, “InnoDB INFORMATION\\_SCHEMA Buffer Pool Tables”](#).

#### Warning

Querying the `INNODB_BUFFER_PAGE` table can introduce significant performance overhead. Do not query this table on a production system unless you are aware of the performance impact that your query may have, and have determined it to be acceptable. To avoid impacting performance, reproduce the issue you want to investigate on a test instance and query the `INNODB_BUFFER_PAGE` table on the test instance.

**Table 23.1 INNODB\_BUFFER\_PAGE Columns**

| Column name           | Description  |
|-----------------------|--|
| <code>POOL_ID</code>  | Buffer Pool ID. An identifier to distinguish between multiple buffer pool instances. |
| <code>BLOCK_ID</code> | Buffer Pool Block ID.  |
| <code>SPACE</code>    | Tablespace ID. Uses the same value as in <code>INNODB_SYS_TABLES.SPACE</code> .      |

| Column name         | Description  |
|---------------------|--|
| PAGE_NUMBER         | Page number.   |
| PAGE_TYPE           | Page type. Permitted values are <code>ALLOCATED</code> (Freshly allocated page), <code>INDEX</code> (B-tree node), <code>UNDO_LOG</code> (Undo log page), <code>INODE</code> (Index node), <code>IBUF_FREE_LIST</code> (Insert buffer free list), <code>IBUF_BITMAP</code> (Insert buffer bitmap), <code>SYSTEM</code> (System page), <code>TRX_SYSTEM</code> (Transaction system data), <code>FILE_SPACE_HEADER</code> (File space header), <code>EXTENT_DESCRIPTOR</code> (Extent descriptor page), <code>BLOB</code> (Uncompressed BLOB page), <code>COMPRESSED_BLOB</code> (First compressed BLOB page), <code>COMPRESSED_BLOB2</code> (Subsequent comp BLOB page), <code>IBUF_INDEX</code> (Insert buffer index), <code>RTREE_INDEX</code> (spatial index), <code>UNKNOWN</code> (unknown). |
| FLUSH_TYPE          | Flush type.  |
| FIX_COUNT           | Number of threads using this block within the buffer pool. When zero, the block is eligible to be evicted.   |
| IS_HASHED           | Whether hash index has been built on this page.  |
| NEWEST_MODIFICATION | Log Sequence Number of the youngest modification.  |
| OLDEST_MODIFICATION | Log Sequence Number of the oldest modification.  |
| ACCESS_TIME         | An abstract number used to judge the first access time of the page.  |
| TABLE_NAME          | Name of the table the page belongs to. This column is only applicable to pages of type <code>INDEX</code> .  |
| INDEX_NAME          | Name of the index the page belongs to. It can be the name of a clustered index or a secondary index. This column is only applicable to pages of type <code>INDEX</code> .  |
| NUMBER_RECORDS      | Number of records within the page.   |
| DATA_SIZE           | Sum of the sizes of the records. This column is only applicable to pages of type <code>INDEX</code> .  |
| COMPRESSED_SIZE     | Compressed page size. Null for pages that are not compressed.  |
| PAGE_STATE          | Page state. A page with valid data has one of the following states: <code>FILE_PAGE</code> (buffers a page of data from a file), <code>MEMORY</code> (buffers a page from an in-memory object), <code>COMPRESSED</code> . Other possible states (managed by InnoDB) are: <code>NULL</code> , <code>READY_FOR_USE</code> , <code>NOT_USED</code> , <code>REMOVE_HASH</code> .   |
| IO_FIX              | Specifies whether any I/O is pending for this page: <code>IO_NONE</code> = no pending I/O, <code>IO_READ</code> = read pending, <code>IO_WRITE</code> = write pending.   |
| IS_OLD              | Specifies whether or not the block is in the sublist of old blocks in the LRU list.  |
| FREE_PAGE_CLOCK     | The value of the <code>freed_page_clock</code> counter when the block was the last placed at the head of the LRU list. The <code>freed_page_clock</code> counter tracks the number of blocks removed from the end of the LRU list.   |

**Example:**

```
mysql> SELECT * FROM INFORMATION_SCHEMA.INNODB_BUFFER_PAGE LIMIT 1\G
***** 1. row *****
      POOL_ID: 0
      BLOCK_ID: 0
        SPACE: 97
    PAGE_NUMBER: 2473
      PAGE_TYPE: INDEX
      FLUSH_TYPE: 1
        FIX_COUNT: 0
        IS_HASHED: YES
NEWEST_MODIFICATION: 733855581
```

```

OLDEST_MODIFICATION: 0
ACCESS_TIME: 3378385672
TABLE_NAME: `employees`.`salaries`
INDEX_NAME: PRIMARY
NUMBER_RECORDS: 468
DATA_SIZE: 14976
COMPRESSED_SIZE: 0
PAGE_STATE: FILE_PAGE
IO_FIX: IO_NONE
IS_OLD: YES
FREE_PAGE_CLOCK: 66
1 row in set (0.03 sec)

```

**Notes:**

- This table is primarily useful for expert-level performance monitoring, or when developing performance-related extensions for MySQL.
- Use [DESCRIBE](#) or [SHOW COLUMNS](#) to view additional information about the columns of this table including data types and default values.
- You must have the [PROCESS](#) privilege to query this table.
- When tables, table rows, partitions, or indexes are deleted, associated pages remain in the buffer pool until space is required for other data. The [INNODB\\_BUFFER\\_PAGE](#) table reports information about these pages until they are evicted from the buffer pool. For more information about how the [InnoDB](#) manages buffer pool data, see [Section 15.6.3.1, “The InnoDB Buffer Pool”](#).

## 23.31.2 The INFORMATION\_SCHEMA INNODB\_BUFFER\_PAGE\_LRU Table

The [INNODB\\_BUFFER\\_PAGE\\_LRU](#) table holds information about the pages in the [InnoDB buffer pool](#), in particular how they are ordered in the LRU list that determines which pages to [evict](#) from the buffer pool when it becomes full.

The [INNODB\\_BUFFER\\_PAGE\\_LRU](#) table has the same columns as the [INNODB\\_BUFFER\\_PAGE](#) table, except that the [INNODB\\_BUFFER\\_PAGE\\_LRU](#) table has an [LRU\\_POSITION](#) column instead of a [BLOCK\\_ID](#) column.

For related usage information and examples, see [Section 15.15.5, “InnoDB INFORMATION\\_SCHEMA Buffer Pool Tables”](#).

**Warning**

Querying the [INNODB\\_BUFFER\\_PAGE\\_LRU](#) table can introduce significant performance overhead. Do not query this table on a production system unless you are aware of the performance impact that your query may have, and have determined it to be acceptable. To avoid impacting performance, reproduce the issue you want to investigate on a test instance and query the [INNODB\\_BUFFER\\_PAGE\\_LRU](#) table on the test instance.

**Table 23.2 INNODB\_BUFFER\_PAGE\_LRU Columns**

| Column name                  | Description  |
|------------------------------|--|
| <a href="#">POOL_ID</a>      | Buffer Pool ID. An identifier to distinguish between multiple buffer pool instances.   |
| <a href="#">LRU_POSITION</a> | The position of the page in the LRU list.  |
| <a href="#">SPACE</a>        | Tablespace ID. Uses the same value as in <a href="#">INNODB_SYS_TABLES.SPACE</a> .   |
| <a href="#">PAGE_NUMBER</a>  | Page number.   |
| <a href="#">PAGE_TYPE</a>    | Page type. Permitted values are <a href="#">ALLOCATED</a> (Freshly allocated page), <a href="#">INDEX</a> (B-tree node), <a href="#">UNDO_LOG</a> (Undo log page), <a href="#">INODE</a> (Index node), <a href="#">IBUF_FREE_LIST</a> (Insert buffer free list), <a href="#">IBUF_BITMAP</a> |

| Column name                         | Description   |
|-------------------------------------|---|
|                                     | (Insert buffer bitmap), <a href="#">SYSTEM</a> (System page), <a href="#">TRX_SYSTEM</a> (Transaction system data), <a href="#">FILE_SPACE_HEADER</a> (File space header), <a href="#">EXTENT_DESCRIPTOR</a> (Extent descriptor page), <a href="#">BLOB</a> (Uncompressed BLOB page), <a href="#">COMPRESSED_BLOB</a> (First compressed BLOB page), <a href="#">COMPRESSED_BLOB2</a> (Subsequent comp BLOB page), <a href="#">IBUF_INDEX</a> (Insert buffer index), <a href="#">RTREE_INDEX</a> (spatial index), <a href="#">UNKNOWN</a> (unknown). |
| <a href="#">FLUSH_TYPE</a>          | Flush type.   |
| <a href="#">FIX_COUNT</a>           | Number of threads using this block within the buffer pool. When zero, the block is eligible to be evicted.  |
| <a href="#">IS_HASHED</a>           | Whether hash index has been built on this page.   |
| <a href="#">NEWEST_MODIFICATION</a> | Log Sequence Number of the youngest modification.   |
| <a href="#">OLDEST_MODIFICATION</a> | Log Sequence Number of the oldest modification.   |
| <a href="#">ACCESS_TIME</a>         | An abstract number used to judge the first access time of the page.   |
| <a href="#">TABLE_NAME</a>          | Name of the table the page belongs to. This column is only applicable to pages of type <a href="#">INDEX</a> .  |
| <a href="#">INDEX_NAME</a>          | Name of the index the page belongs to. It can be the name of a clustered index or a secondary index. This column is only applicable to pages of type <a href="#">INDEX</a> .  |
| <a href="#">NUMBER_RECORDS</a>      | Number of records within the page.  |
| <a href="#">DATA_SIZE</a>           | Sum of the sizes of the records. This column is only applicable to pages of type <a href="#">INDEX</a> .  |
| <a href="#">COMPRESSED_SIZE</a>     | Compressed page size. Null for pages that are not compressed.   |
| <a href="#">PAGE_STATE</a>          | Page state. A page with valid data has one of the following states: <a href="#">FILE_PAGE</a> (buffers a page of data from a file), <a href="#">MEMORY</a> (buffers a page from an in-memory object), <a href="#">COMPRESSED</a> . Other possible states (managed by InnoDB) are: <a href="#">NULL</a> , <a href="#">READY_FOR_USE</a> , <a href="#">NOT_USED</a> , <a href="#">REMOVE_HASH</a> .   |
| <a href="#">IO_FIX</a>              | Specifies whether any I/O is pending for this page: <a href="#">IO_NONE</a> = no pending I/O, <a href="#">IO_READ</a> = read pending, <a href="#">IO_WRITE</a> = write pending.   |
| <a href="#">IS_OLD</a>              | Specifies whether or not the block is in the sublist of old blocks in the LRU list.   |
| <a href="#">FREE_PAGE_CLOCK</a>     | The value of the <a href="#">freed_page_clock</a> counter when the block was the last placed at the head of the LRU list. The <a href="#">freed_page_clock</a> counter tracks the number of blocks removed from the end of the LRU list.  |

## Example

```
mysql> SELECT * FROM INFORMATION_SCHEMA.INNODB_BUFFER_PAGE_LRU LIMIT 1\G
***** 1. row *****
      POOL_ID: 0
    LRU_POSITION: 0
        SPACE: 97
    PAGE_NUMBER: 1984
    PAGE_TYPE: INDEX
    FLUSH_TYPE: 1
    FIX_COUNT: 0
    IS_HASHED: YES
NEWEST_MODIFICATION: 719490396
OLDEST_MODIFICATION: 0
    ACCESS_TIME: 3378383796
    TABLE_NAME: `employees`.`salaries`
    INDEX_NAME: PRIMARY
    NUMBER_RECORDS: 468
    DATA_SIZE: 14976
```

```

COMPRESSED_SIZE: 0
COMPRESSED: NO
IO_FIX: IO_NONE
IS_OLD: YES
FREE_PAGE_CLOCK: 0

```

## Notes

- This table is primarily useful for expert-level performance monitoring, or when developing performance-related extensions for MySQL.
- You must have the [PROCESS](#) privilege to query this table.
- Use [DESCRIBE](#) or [SHOW COLUMNS](#) to view additional information about the columns of this table including data types and default values.
- Querying this table can require MySQL to allocate a large block of contiguous memory, more than 64 bytes time the number of active pages in the buffer pool. This allocation could potentially cause an out-of-memory error, especially for systems with multi-gigabyte buffer pools.
- Querying this table requires MySQL to lock the data structure representing the buffer pool while traversing the LRU list, which can reduce concurrency, especially for systems with multi-gigabyte buffer pools.
- When tables, table rows, partitions, or indexes are deleted, associated pages remain in the buffer pool until space is required for other data. The [INNODB\\_BUFFER\\_PAGE\\_LRU](#) table reports information about these pages until they are evicted from the buffer pool. For more information about how the [InnoDB](#) manages buffer pool data, see [Section 15.6.3.1, “The InnoDB Buffer Pool”](#).

## 23.31.3 The INFORMATION\_SCHEMA INNODB\_BUFFER\_POOL\_STATS Table

The [INNODB\\_BUFFER\\_POOL\\_STATS](#) table provides much of the same buffer pool information provided in [SHOW ENGINE INNODB STATUS](#) output. Much of the same information may also be obtained using [InnoDB](#) buffer pool [server status variables](#).

The idea of making pages in the buffer pool “young” or “not young” refers to transferring them between the [sublists](#) at the head and tail of the buffer pool data structure. Pages made “young” take longer to age out of the buffer pool, while pages made “not young” are moved much closer to the point of [eviction](#).

For related usage information and examples, see [Section 15.15.5, “InnoDB INFORMATION\\_SCHEMA Buffer Pool Tables”](#).

**Table 23.3 INNODB\_BUFFER\_POOL\_STATS Columns**

| Column name                             | Description  |
|---|--|
| <a href="#">POOL_ID</a>                 | Buffer Pool ID. A unique identifier to distinguish between multiple buffer pool instances.                                     |
| <a href="#">POOL_SIZE</a>               | The <a href="#">InnoDB</a> buffer pool size in pages.  |
| <a href="#">FREE_BUFFERS</a>            | The number of free pages in the <a href="#">InnoDB</a> buffer pool   |
| <a href="#">DATABASE_PAGES</a>          | The number of pages in the <a href="#">InnoDB</a> buffer pool containing data. The number includes both dirty and clean pages. |
| <a href="#">OLD_DATABASE_PAGES</a>      | The number of pages in the <a href="#">old</a> buffer pool sublist.  |
| <a href="#">MODIFIED_DATABASE_PAGES</a> | The number of modified (dirty) database pages  |
| <a href="#">PENDING_DECOMPRESS</a>      | The number of pages pending decompression  |
| <a href="#">PENDING_READS</a>           | The number of pending reads  |
| <a href="#">PENDING_FLUSH_LRU</a>       | The number of pages pending flush in the LRU   |

| Column name                      | Description  |
|----------------------------------|--|
| PENDING_FLUSH_LIST               | The number of pages pending flush in the flush list  |
| PAGES_MADE_YOUNG                 | The number of pages made young   |
| PAGES_NOT_MADE_YOUNG             | The number of pages not made young   |
| PAGES_MADE_YOUNG_RATE            | The number of pages made young per second (pages made young since the last printout / time elapsed)  |
| PAGES_MADE_NOT_YOUNG_RATE        | The number of pages not made per second (pages not made young since the last printout / time elapsed)  |
| NUMBER_PAGES_READ                | The number of pages read   |
| NUMBER_PAGES_CREATED             | The number of pages created  |
| NUMBER_PAGES_WRITTEN             | The number of pages written  |
| PAGES_READ_RATE                  | The number of pages read per second (pages read since the last printout / time elapsed)  |
| PAGES_CREATE_RATE                | The number of pages created per second (pages created since the last printout / time elapsed)  |
| PAGES_WRITTEN_RATE               | The number of pages written per second (pages written since the last printout / time elapsed)  |
| NUMBER_PAGES_GET                 | The number of logical read requests.   |
| HIT_RATE                         | The buffer pool hit rate   |
| YOUNG_MAKE_PER_THOUSAND_GETS     | The number of pages made young per thousand gets   |
| NOT_YOUNG_MAKE_PER_THOUSAND_GETS | The number of pages not made young per thousand gets   |
| NUMBER_PAGES_READ_AHEAD          | The number of pages read ahead   |
| NUMBER_READ_AHEAD_EVICTED        | The number of pages read into the InnoDB buffer pool by the read-ahead background thread that were subsequently evicted without having been accessed by queries. |
| READ_AHEAD_RATE                  | The read ahead rate per second (pages read ahead since the last printout / time elapsed)   |
| READ_AHEAD_EVICTED_RATE          | The number of read ahead pages evicted without access per second (read ahead pages not accessed since the last printout / time elapsed)                          |
| LRU_IO_TOTAL                     | LRU IO total   |
| LRU_IO_CURRENT                   | LRU IO for the current interval  |
| UNCOMPRESS_TOTAL                 | Total number of pages decompressed   |
| UNCOMPRESS_CURRENT               | The number of pages decompressed in the current interval   |

**Example:**

```
mysql> SELECT * FROM INFORMATION_SCHEMA.INNODB_BUFFER_POOL_STATS\G
***** 1. row *****
      POOL_ID: 0
      POOL_SIZE: 8192
      FREE_BUFFERS: 1
      DATABASE_PAGES: 8085
      OLD_DATABASE_PAGES: 2964
      MODIFIED_DATABASE_PAGES: 0
      PENDING_DECOMPRESS: 0
      PENDING_READS: 0
      PENDING_FLUSH_LRU: 0
      PENDING_FLUSH_LIST: 0
      PAGES_MADE_YOUNG: 22821
      PAGES_NOT_MADE_YOUNG: 3544303
      PAGES_MADE_YOUNG_RATE: 357.62602199870594
      PAGES_MADE_NOT_YOUNG_RATE: 0
```

```

        NUMBER_PAGES_READ: 2389
        NUMBER_PAGES_CREATED: 12385
        NUMBER_PAGES_WRITTEN: 13111
        PAGES_READ_RATE: 0
        PAGES_CREATE_RATE: 0
        PAGES_WRITTEN_RATE: 0
        NUMBER_PAGES_GET: 33322210
        HIT_RATE: 1000
        YOUNG_MAKE_PER_THOUSAND_GETS: 18
        NOT_YOUNG_MAKE_PER_THOUSAND_GETS: 0
        NUMBER_PAGES_READ_AHEAD: 2024
        NUMBER_READ_AHEAD_EVICTED: 0
        READ_AHEAD_RATE: 0
        READ_AHEAD_EVICTED_RATE: 0
        LRU_IO_TOTAL: 0
        LRU_IO_CURRENT: 0
        UNCOMPRESS_TOTAL: 0
        UNCOMPRESS_CURRENT: 0

```

**Notes:**

- This table is primarily useful for expert-level performance monitoring, or when developing performance-related extensions for MySQL.
- Use [DESCRIBE](#) or [SHOW COLUMNS](#) to view additional information about the columns of this table including data types and default values.
- You must have the [PROCESS](#) privilege to query this table.

## 23.31.4 The INFORMATION\_SCHEMA INNODB\_CMP and INNODB\_CMP\_RESET Tables

The [INNODB\\_CMP](#) and [INNODB\\_CMP\\_RESET](#) tables contain status information on operations related to [compressed](#) InnoDB tables.

**Table 23.4 Columns of INNODB\_CMP and INNODB\_CMP\_RESET**

| Column name                     | Description  |
|---------------------------------|--|
| <a href="#">PAGE_SIZE</a>       | Compressed page size in bytes.   |
| <a href="#">COMPRESS_OPS</a>    | Number of times a B-tree page of the size <a href="#">PAGE_SIZE</a> has been compressed. Pages are compressed whenever an empty page is created or the space for the uncompressed modification log runs out.                         |
| <a href="#">COMPRESS_OPS_OK</a> | Number of times a B-tree page of the size <a href="#">PAGE_SIZE</a> has been successfully compressed. This count should never exceed <a href="#">COMPRESS_OPS</a> .  |
| <a href="#">COMPRESS_TIME</a>   | Total time in seconds spent in attempts to compress B-tree pages of the size <a href="#">PAGE_SIZE</a> .   |
| <a href="#">UNCOMPRESS_OPS</a>  | Number of times a B-tree page of the size <a href="#">PAGE_SIZE</a> has been uncompressed. B-tree pages are uncompressed whenever compression fails or at first access when the uncompressed page does not exist in the buffer pool. |
| <a href="#">UNCOMPRESS_TIME</a> | Total time in seconds spent in uncompressing B-tree pages of the size <a href="#">PAGE_SIZE</a> .  |

**Example:**

```

mysql> SELECT * FROM INFORMATION_SCHEMA.INNODB_CMP\G
***** 1. row *****
        page_size: 1024
        compress_ops: 0

```

```

compress_ops_ok: 0
compress_time: 0
uncompress_ops: 0
uncompress_time: 0
***** 2. row *****
    page_size: 2048
    compress_ops: 0
compress_ops_ok: 0
compress_time: 0
uncompress_ops: 0
uncompress_time: 0
***** 3. row *****
    page_size: 4096
    compress_ops: 0
compress_ops_ok: 0
compress_time: 0
uncompress_ops: 0
uncompress_time: 0
***** 4. row *****
    page_size: 8192
    compress_ops: 86955
compress_ops_ok: 81182
compress_time: 27
uncompress_ops: 26828
uncompress_time: 5
***** 5. row *****
    page_size: 16384
    compress_ops: 0
compress_ops_ok: 0
compress_time: 0
uncompress_ops: 0
uncompress_time: 0

```

**Notes:**

- Use these tables to measure the effectiveness of [InnoDB table compression](#) in your database.
- Use [DESCRIBE](#) or [SHOW COLUMNS](#) to view additional information about the columns of these tables including data types and default values.
- You must have the [PROCESS](#) privilege to query this table.
- For usage information, see [Section 15.9.1.4, “Monitoring Compression at Runtime”](#) and [Section 15.15.1.3, “Using the Compression Information Schema Tables”](#). For general information about [InnoDB table compression](#), see [Section 15.9, “InnoDB Table and Page Compression”](#).

### 23.31.5 The INFORMATION\_SCHEMA INNODB\_CMPMEM and INNODB\_CMPMEM\_RESET Tables

The [INNODB\\_CMPMEM](#) and [INNODB\\_CMPMEM\\_RESET](#) tables contain status information on compressed [pages](#) within the [InnoDB buffer pool](#).

**Table 23.5 Columns of INNODB\_CMPMEM and INNODB\_CMPMEM\_RESET**

| Column name                          | Description  |
|--------------------------------------|--|
| <a href="#">PAGE_SIZE</a>            | Block size in bytes. Each record of this table describes blocks of this size.  |
| <a href="#">BUFFER_POOL_INSTANCE</a> | A unique identifier for the buffer pool instance.  |
| <a href="#">PAGES_USED</a>           | Number of blocks of the size <a href="#">PAGE_SIZE</a> that are currently in use.  |
| <a href="#">PAGES_FREE</a>           | Number of blocks of the size <a href="#">PAGE_SIZE</a> that are currently available for allocation. This column shows the external fragmentation in the memory pool. Ideally, these numbers should be at most 1. |
| <a href="#">RELOCATION_OPS</a>       | Number of times a block of the size <a href="#">PAGE_SIZE</a> has been relocated. The buddy system can relocate the allocated “buddy neighbor” of a freed  |

| Column name                     | Description   |
|---------------------------------|---|
|                                 | block when it tries to form a bigger freed block. Reading from the table <a href="#">INNODB_CMPMEM_RESET</a> resets this count.   |
| <a href="#">RELOCATION_TIME</a> | Total time in microseconds spent in relocating blocks of the size <a href="#">PAGE_SIZE</a> . Reading from the table <a href="#">INNODB_CMPMEM_RESET</a> resets this count. |

**Example:**

```
mysql> SELECT * FROM INFORMATION_SCHEMA.INNODB_CMPMEM\G
***** 1. row *****
      page_size: 1024
buffer_pool_instance: 0
      pages_used: 0
      pages_free: 0
      relocation_ops: 0
      relocation_time: 0
***** 2. row *****
      page_size: 2048
buffer_pool_instance: 0
      pages_used: 0
      pages_free: 0
      relocation_ops: 0
      relocation_time: 0
***** 3. row *****
      page_size: 4096
buffer_pool_instance: 0
      pages_used: 0
      pages_free: 0
      relocation_ops: 0
      relocation_time: 0
***** 4. row *****
      page_size: 8192
buffer_pool_instance: 0
      pages_used: 7673
      pages_free: 15
      relocation_ops: 4638
      relocation_time: 0
***** 5. row *****
      page_size: 16384
buffer_pool_instance: 0
      pages_used: 0
      pages_free: 0
      relocation_ops: 0
      relocation_time: 0
```

**Notes:**

- Use these tables to measure the effectiveness of [InnoDB](#) table [compression](#) in your database.
- Use [DESCRIBE](#) or [SHOW COLUMNS](#) to view additional information about the columns of these tables including data types and default values.
- You must have the [PROCESS](#) privilege to query this table.
- For usage information, see [Section 15.9.1.4, “Monitoring Compression at Runtime”](#) and [Section 15.15.1.3, “Using the Compression Information Schema Tables”](#). For general information about [InnoDB](#) table compression, see [Section 15.9, “InnoDB Table and Page Compression”](#).

## 23.31.6 The INFORMATION\_SCHEMA INNODB\_CMP\_PER\_INDEX and INNODB\_CMP\_PER\_INDEX\_RESET Tables

The [INNODB\\_CMP\\_PER\\_INDEX](#) and [INNODB\\_CMP\\_PER\\_INDEX\\_RESET](#) tables contain status information on operations related to [compressed](#) [InnoDB](#) tables and indexes, with separate statistics

for each combination of database, table, and index, to help you evaluate the performance and usefulness of compression for specific tables.

For a compressed [InnoDB](#) table, both the table data and all the [secondary indexes](#) are compressed. In this context, the table data is treated as just another index, one that happens to contain all the columns: the [clustered index](#).

**Table 23.6 Columns of INNODB\_CMP\_PER\_INDEX and INNODB\_CMP\_PER\_INDEX\_RESET**

| Column name                     | Description  |
|---------------------------------|--|
| <a href="#">DATABASE_NAME</a>   | Database containing the applicable table.  |
| <a href="#">TABLE_NAME</a>      | Table to monitor for compression statistics.   |
| <a href="#">INDEX_NAME</a>      | Index to monitor for compression statistics.   |
| <a href="#">COMPRESS_OPS</a>    | Number of compression operations attempted. <a href="#">Pages</a> are compressed whenever an empty page is created or the space for the uncompressed modification log runs out.  |
| <a href="#">COMPRESS_OPS_OK</a> | Number of successful compression operations. Subtract from the <a href="#">COMPRESS_OPS</a> value to get the number of <a href="#">compression failures</a> . Divide by the <a href="#">COMPRESS_OPS</a> value to get the percentage of compression failures.                    |
| <a href="#">COMPRESS_TIME</a>   | Total amount of CPU time, in seconds, used for compressing data in this index.   |
| <a href="#">UNCOMPRESS_OPS</a>  | Number of uncompression operations performed. Compressed <a href="#">InnoDB</a> pages are uncompressed whenever compression <a href="#">fails</a> , or the first time a compressed page is accessed in the <a href="#">buffer pool</a> and the uncompressed page does not exist. |
| <a href="#">UNCOMPRESS_TIME</a> | Total amount of CPU time, in seconds, used for uncompressing data in this index.   |

**Example:**

```
mysql> SELECT * FROM INFORMATION_SCHEMA.INNODB_CMP_PER_INDEX\G
***** 1. row *****
  database_name: employees
    table_name: salaries
    index_name: PRIMARY
   compress_ops: 0
compress_ops_ok: 0
   compress_time: 0
  uncompress_ops: 23451
 uncompress_time: 4
***** 2. row *****
  database_name: employees
    table_name: salaries
    index_name: emp_no
   compress_ops: 0
compress_ops_ok: 0
   compress_time: 0
  uncompress_ops: 1597
 uncompress_time: 0
```

**Notes:**

- Use these tables to measure the effectiveness of [InnoDB](#) table [compression](#) for specific tables, indexes, or both.
- Use [DESCRIBE](#) or [SHOW COLUMNS](#) to view additional information about the columns of these tables including data types and default values.

- You must have the [PROCESS](#) privilege to query these tables.
- Because collecting separate measurements for every index imposes substantial performance overhead, [INNODB\\_CMP\\_PER\\_INDEX](#) and [INNODB\\_CMP\\_PER\\_INDEX\\_RESET](#) statistics are not gathered by default. You must enable the [innodb\\_cmp\\_per\\_index\\_enabled](#) configuration option before performing the operations on compressed tables that you want to monitor.
- For usage information, see [Section 15.9.1.4, “Monitoring Compression at Runtime”](#) and [Section 15.15.1.3, “Using the Compression Information Schema Tables”](#). For general information about [InnoDB](#) table compression, see [Section 15.9, “InnoDB Table and Page Compression”](#).

### 23.31.7 The INFORMATION\_SCHEMA INNODB\_FT\_BEING\_DELETED Table

The [INNODB\\_FT\\_BEING\\_DELETED](#) table is a snapshot of the [INNODB\\_FT\\_DELETED](#) table that is only used during an [OPTIMIZE TABLE](#) maintenance operation. When [OPTIMIZE TABLE](#) is run, the [INNODB\\_FT\\_BEING\\_DELETED](#) table is emptied, and DOC\_IDs are removed from the [INNODB\\_FT\\_DELETED](#) table. Because the contents of [INNODB\\_FT\\_BEING\\_DELETED](#) typically have a short lifetime, this table has limited utility for monitoring or debugging. For information about running [OPTIMIZE TABLE](#) on tables with [FULLTEXT](#) indexes, see [Section 13.9.6, “Fine-Tuning MySQL Full-Text Search”](#).

This table initially appears empty, until you set the value of the configuration variable [innodb\\_ft\\_aux\\_table](#). The output appears similar to the example provided for the [INNODB\\_FT\\_DELETED](#) table.

For related usage information and examples, see [Section 15.15.4, “InnoDB INFORMATION\\_SCHEMA FULLTEXT Index Tables”](#).

**Table 23.7 INNODB\_FT\_BEING\_DELETED Columns**

| Column name            | Description   |
|------------------------|---|
| <a href="#">DOC_ID</a> | The document ID of the row that is in the process of being deleted. This value might reflect the value of an ID column that you defined for the underlying table, or it can be a sequence value generated by <a href="#">InnoDB</a> when the table does not contain a suitable column. This value is used to skip rows in the <a href="#">innodb_ft_index_table</a> table, when you do text searches before data for deleted rows is physically removed from the <a href="#">FULLTEXT</a> index by an <a href="#">OPTIMIZE TABLE</a> statement. See <a href="#">Optimizing InnoDB Full-Text Indexes</a> for more information. |

**Notes:**

- Use [DESCRIBE](#) or [SHOW COLUMNS](#) to view additional information about the columns of this table including data types and default values.
- You must have the [PROCESS](#) privilege to query this table.
- For more information about [InnoDB FULLTEXT](#) search, see [Section 15.8.10, “InnoDB FULLTEXT Indexes”](#), and [Section 13.9, “Full-Text Search Functions”](#).

### 23.31.8 The INFORMATION\_SCHEMA INNODB\_FT\_CONFIG Table

The [INNODB\\_FT\\_CONFIG](#) table displays metadata about the [FULLTEXT](#) index and associated processing for an [InnoDB](#) table.

Before you query this table, set the configuration variable [innodb\\_ft\\_aux\\_table](#) to the name (including the database name) of the table that contains the [FULLTEXT](#) index, for example [test/articles](#).

For related usage information and examples, see [Section 15.15.4, “InnoDB INFORMATION\\_SCHEMA FULLTEXT Index Tables”](#).

**Table 23.8 INNODB\_FT\_CONFIG Columns**

| Column name | Description   |
|-------------|---|
| KEY         | The name designating an item of metadata for an <a href="#">InnoDB</a> table containing a <a href="#">FULLTEXT</a> index.   |
| VALUE       | The value associated with the corresponding <a href="#">KEY</a> column, reflecting some limit or current value for an aspect of a <a href="#">FULLTEXT</a> index for an <a href="#">InnoDB</a> table. |

**Example:**

```
mysql> SELECT * FROM INFORMATION_SCHEMA.INNODB_FT_CONFIG;
+-----+-----+
| KEY | VALUE |
+-----+-----+
| optimize_checkpoint_limit | 180 |
| synced_doc_id | 0 |
| stopwords_table_name | test/my_stopwords |
| use_stopword | 1 |
+-----+-----+
```

**Notes:**

- This table is only intended for internal configuration. It is not intended for statistical information purposes.
- Use [DESCRIBE](#) or [SHOW COLUMNS](#) to view additional information about the columns of this table including data types and default values.
- You must have the [PROCESS](#) privilege to query this table.
- The values for the [KEY](#) column might evolve depending on the needs for performance tuning and debugging for [InnoDB](#) full-text processing. The key values include:
  - [optimize\\_checkpoint\\_limit](#): The number of seconds after which an [OPTIMIZE TABLE](#) run will stop.
  - [synced\\_doc\\_id](#): The next [DOC\\_ID](#) to be issued.
  - [stopword\\_table\\_name](#): The *database/table* name for a user defined stopwords table. This field appears empty if there is no user-defined stopwords table.
  - [use\\_stopword](#): Indicates whether or not a stopwords table is used, which is defined when the [FULLTEXT](#) index is created.
- For more information about [InnoDB FULLTEXT](#) search, see [Section 15.8.10, “InnoDB FULLTEXT Indexes”](#), and [Section 13.9, “Full-Text Search Functions”](#).

## 23.31.9 The INFORMATION\_SCHEMA INNODB\_FT\_DEFAULT\_STOPWORD Table

The [INNODB\\_FT\\_DEFAULT\\_STOPWORD](#) table holds a list of [stopwords](#) that are used by default when creating a [FULLTEXT](#) index on an [InnoDB](#) table. For information about the default [InnoDB](#) stopwords list and how to define your own stopwords lists, see [Section 13.9.4, “Full-Text Stopwords”](#).

For related usage information and examples, see [Section 15.15.4, “InnoDB INFORMATION\\_SCHEMA FULLTEXT Index Tables”](#).

**Table 23.9 INNODB\_FT\_DEFAULT\_STOPWORD Columns**

| Column name           | Description   |
|-----------------------|---|
| <a href="#">value</a> | A word that is used by default as a stopwords for <a href="#">FULLTEXT</a> indexes on <a href="#">InnoDB</a> tables. Not used if you override the default stopwords processing with either the <a href="#">innodb_ft_server_stopword_table</a> or the <a href="#">innodb_ft_user_stopword_table</a> option. |

**Example:**

```
mysql> SELECT * FROM INFORMATION_SCHEMA.INNODB_FT_DEFAULT_STOPWORD;
+-----+
| value |
+-----+
| a      |
| about  |
| an     |
| are    |
| as     |
| at     |
| be     |
| by     |
| com    |

| the    |
| www    |
+-----+
36 rows in set (0.00 sec)
```

**Notes:**

- Use [DESCRIBE](#) or [SHOW COLUMNS](#) to view additional information about the columns of this table including data types and default values.
- You must have the [PROCESS](#) privilege to query this table.
- For more information about [InnoDB FULLTEXT](#) search, see [Section 15.8.10, “InnoDB FULLTEXT Indexes”](#), and [Section 13.9, “Full-Text Search Functions”](#).

### 23.31.10 The INFORMATION\_SCHEMA INNODB\_FT\_DELETED Table

The [INNODB\\_FT\\_DELETED](#) table records rows that are deleted from the [FULLTEXT](#) index for an [InnoDB](#) table. To avoid expensive index reorganization during DML operations for an [InnoDB](#)

`FULLTEXT` index, the information about newly deleted words is stored separately, filtered out of search results when you do a text search, and removed from the main search index only when you issue the `OPTIMIZE TABLE` statement for the `InnoDB` table. See [Optimizing InnoDB Full-Text Indexes](#) for more information.

This table initially appears empty, until you set the value of the configuration variable `innodb_ft_aux_table` to the name (including the database name) of the table that contains the `FULLTEXT` index, for example `test/articles`.

For related usage information and examples, see [Section 15.15.4, “InnoDB INFORMATION\\_SCHEMA FULLTEXT Index Tables”](#).

**Table 23.10 INNODB\_FT\_DELETED Columns**

| Column name         | Description   |
|---------------------|---|
| <code>DOC_ID</code> | The document ID of the newly deleted row. This value might reflect the value of an ID column that you defined for the underlying table, or it can be a sequence value generated by <code>InnoDB</code> when the table does not contain a suitable column. This value is used to skip rows in the <code>innodb_ft_index_table</code> table, when you do text searches before data for deleted rows is physically removed from the <code>FULLTEXT</code> index by an <code>OPTIMIZE TABLE</code> statement. See <a href="#">Optimizing InnoDB Full-Text Indexes</a> for more information. |

**Example:**

```
mysql> SELECT * FROM INFORMATION_SCHEMA.INNODB_FT_DELETED;
+-----+
| DOC_ID |
+-----+
|      6 |
|      7 |
|      8 |
+-----+
```

**Notes:**

- Use `DESCRIBE` or `SHOW COLUMNS` to view additional information about the columns of this table including data types and default values.
- You must have the `PROCESS` privilege to query this table.
- For more information about `InnoDB FULLTEXT` search, see [Section 15.8.10, “InnoDB FULLTEXT Indexes”](#), and [Section 13.9, “Full-Text Search Functions”](#).

## 23.31.11 The INFORMATION\_SCHEMA INNODB\_FT\_INDEX\_CACHE Table

`INNODB_FT_INDEX_CACHE`: Contains token information about newly inserted rows in a `FULLTEXT` index. To avoid expensive index reorganization during DML operations, the information about newly indexed words is stored separately, and combined with the main search index only when `OPTIMIZE TABLE` is run, when the server is shut down, or when the cache size exceeds a limit defined by `innodb_ft_cache_size` or `innodb_ft_total_cache_size`.

Before you query this table, set the configuration variable `innodb_ft_aux_table` to the name (including the database name) of the table that contains the `FULLTEXT` index, for example `test/articles`.

For related usage information and examples, see [Section 15.15.4, “InnoDB INFORMATION\\_SCHEMA FULLTEXT Index Tables”](#).

**Table 23.11 INNODB\_FT\_INDEX\_CACHE Columns**

| Column name               | Description   |
|---------------------------|---|
| <code>WORD</code>         | A word extracted from the text of a newly inserted row.   |
| <code>FIRST_DOC_ID</code> | The first document ID that this word appears in the <code>FULLTEXT</code> index.  |
| <code>LAST_DOC_ID</code>  | The last document ID that this word appears in the <code>FULLTEXT</code> index.   |
| <code>DOC_COUNT</code>    | The number of rows this word appears in the <code>FULLTEXT</code> index. The same word can occur several times within the cache table, once for each combination of <code>DOC_ID</code> and <code>POSITION</code> values.   |
| <code>DOC_ID</code>       | The document ID of the newly inserted row. This value might reflect the value of an ID column that you defined for the underlying table, or it can be a sequence value generated by <code>InnoDB</code> when the table does not contain a suitable column.                  |
| <code>POSITION</code>     | The position of this particular instance of the word within the relevant document identified by the <code>DOC_ID</code> value. The value does not represent an absolute position; it is an offset added to the <code>POSITION</code> of the previous instance of that word. |

**Notes:**

- This table initially appears empty, until you set the value of the configuration variable `innodb_ft_aux_table`. The following example demonstrates how to use the `innodb_ft_aux_table` option to show information about a `FULLTEXT` index for a specified table.

```
mysql> USE test;

mysql> CREATE TABLE articles (
    id INT UNSIGNED AUTO_INCREMENT NOT NULL PRIMARY KEY,
    title VARCHAR(200),
    body TEXT,
    FULLTEXT (title,body)
) ENGINE=InnoDB;

mysql> INSERT INTO articles (title,body) VALUES
('MySQL Tutorial','DBMS stands for DataBase ...'),
('How To Use MySQL Well','After you went through a ...'),
('Optimizing MySQL','In this tutorial we will show ...'),
('1001 MySQL Tricks','1. Never run mysqld as root. 2. ...'),
('MySQL vs. YourSQL','In the following database comparison ...'),
('MySQL Security','When configured properly, MySQL ...');

mysql> SET GLOBAL innodb_ft_aux_table = 'test/articles';
Query OK, 0 rows affected (0.00 sec)

mysql> USE INFORMATION_SCHEMA;

mysql> SELECT word, doc_count, doc_id, position FROM INNODB_FT_INDEX_CACHE LIMIT 5;
+-----+-----+-----+-----+
| word      | doc_count | doc_id | position |
+-----+-----+-----+-----+
| 1001      | 1         | 4      | 0         |
| after     | 1         | 2      | 22        |
| comparison | 1         | 5      | 44        |
| configured | 1         | 6      | 20        |
| database  | 2         | 1      | 31        |
+-----+-----+-----+-----+
```

- Use `DESCRIBE` or `SHOW COLUMNS` to view additional information about the columns of this table including data types and default values.
- You must have the `PROCESS` privilege to query this table.

- For more information about [InnoDB FULLTEXT](#) search, see [Section 15.8.10, “InnoDB FULLTEXT Indexes”](#), and [Section 13.9, “Full-Text Search Functions”](#).

### 23.31.12 The INFORMATION\_SCHEMA INNODB\_FT\_INDEX\_TABLE Table

The `INNODB_FT_INDEX_TABLE` table displays information about the inverted index used to process text searches against the `FULLTEXT` index of an `InnoDB` table.

For related usage information and examples, see [Section 15.15.4, “InnoDB INFORMATION\\_SCHEMA FULLTEXT Index Tables”](#).

Before you query this table, set the configuration variable `innodb_ft_aux_table` to the name (including the database name) of the table that contains the `FULLTEXT` index, for example `test/articles`.

**Table 23.12 INNODB\_FT\_INDEX\_TABLE Columns**

| Column name               | Description   |
|---------------------------|---|
| <code>WORD</code>         | A word extracted from the text of the columns that are part of a <code>FULLTEXT</code> .  |
| <code>FIRST_DOC_ID</code> | The first document ID that this word appears in the <code>FULLTEXT</code> index.  |
| <code>LAST_DOC_ID</code>  | The last document ID that this word appears in the <code>FULLTEXT</code> index.   |
| <code>DOC_COUNT</code>    | The number of rows this word appears in the <code>FULLTEXT</code> index. The same word can occur several times within the cache table, once for each combination of <code>DOC_ID</code> and <code>POSITION</code> values.                                       |
| <code>DOC_ID</code>       | The document ID of the row containing the word. This value might reflect the value of an ID column that you defined for the underlying table, or it can be a sequence value generated by <code>InnoDB</code> when the table does not contain a suitable column. |
| <code>POSITION</code>     | The position of this particular instance of the word within the relevant document identified by the <code>DOC_ID</code> value.  |

#### Notes:

- This table initially appears empty, until you set the value of the configuration variable `innodb_ft_aux_table`. The following example demonstrates how to use the `innodb_ft_aux_table` option to show information about a `FULLTEXT` index for a specified table. Before information for newly inserted rows appears in `INNODB_FT_INDEX_TABLE`, the `FULLTEXT` index cache must be flushed to disk. This is accomplished by running an `OPTIMIZE TABLE` operation on the indexed table with `innodb_optimize_fulltext_only=ON`.

```
mysql> use test;

mysql> CREATE TABLE articles (
  id INT UNSIGNED AUTO_INCREMENT NOT NULL PRIMARY KEY,
  title VARCHAR(200),
  body TEXT,
  FULLTEXT (title,body)
) ENGINE=InnoDB;

mysql> INSERT INTO articles (title,body) VALUES
('MySQL Tutorial','DBMS stands for DataBase ...'),
('How To Use MySQL Well','After you went through a ...'),
('Optimizing MySQL','In this tutorial we will show ...'),
('1001 MySQL Tricks','1. Never run mysqld as root. 2. ...'),
('MySQL vs. YourSQL','In the following database comparison ...'),
('MySQL Security','When configured properly, MySQL ...');

mysql> SET GLOBAL innodb_optimize_fulltext_only=ON;
Query OK, 0 rows affected (0.00 sec)
```

```
mysql> OPTIMIZE TABLE articles;
+-----+-----+-----+-----+
| Table          | Op       | Msg_type | Msg_text |
+-----+-----+-----+-----+
| test.articles | optimize | status   | OK        |
+-----+-----+-----+-----+
1 row in set (0.00 sec)

mysql> SET GLOBAL innodb_ft_aux_table = 'test/articles';
Query OK, 0 rows affected (0.00 sec)

mysql> USE INFORMATION_SCHEMA;

mysql> SELECT word, doc_count, doc_id, position FROM INNODB_FT_INDEX_TABLE LIMIT 5;
+-----+-----+-----+-----+
| word      | doc_count | doc_id | position |
+-----+-----+-----+-----+
| 1001      |          1 |      4 |          0 |
| after     |          1 |      2 |          22 |
| comparison |          1 |      5 |          44 |
| configured |          1 |      6 |          20 |
| database  |          2 |      1 |          31 |
+-----+-----+-----+-----+
```

- Use [DESCRIBE](#) or [SHOW COLUMNS](#) to view additional information about the columns of this table including data types and default values.
- You must have the [PROCESS](#) privilege to query this table.
- For more information about [InnoDB FULLTEXT](#) search, see [Section 15.8.10, “InnoDB FULLTEXT Indexes”](#), and [Section 13.9, “Full-Text Search Functions”](#).

### 23.31.13 The INFORMATION\_SCHEMA INNODB\_LOCKS Table

The [INNODB\\_LOCKS](#) table contains information about each lock that an [InnoDB](#) transaction has requested but not yet acquired, and each lock that a transaction holds that is blocking another transaction.

#### Note

This table is deprecated as of MySQL 5.7.14 and is removed in MySQL 8.0.

**Table 23.13 INNODB\_LOCKS Columns**

| Column name                 | Description  |
|-----------------------------|--|
| <a href="#">LOCK_ID</a>     | Unique lock ID number, internal to <a href="#">InnoDB</a> . Treat it as an opaque string. Although <a href="#">LOCK_ID</a> currently contains <a href="#">TRX_ID</a> , the format of the data in <a href="#">LOCK_ID</a> is subject to change at any time. Do not write applications that parse the <a href="#">LOCK_ID</a> value.   |
| <a href="#">LOCK_TRX_ID</a> | ID of the transaction holding the lock. To obtain details about the transaction, join this column with the <a href="#">TRX_ID</a> column of the <a href="#">INNODB_TRX</a> table.  |
| <a href="#">LOCK_MODE</a>   | How the lock is requested. Permitted values are <a href="#">S[ ,GAP]</a> , <a href="#">X[ ,GAP]</a> , <a href="#">IS[ ,GAP]</a> , <a href="#">IX[ ,GAP]</a> , <a href="#">AUTO_INC</a> , and <a href="#">UNKNOWN</a> . Lock modes other than <a href="#">AUTO_INC</a> and <a href="#">UNKNOWN</a> indicate gap locks, if present. For information about <a href="#">S</a> , <a href="#">X</a> , <a href="#">IS</a> , <a href="#">IX</a> , and gap locks, refer to <a href="#">Section 15.5.1, “InnoDB Locking”</a> . |
| <a href="#">LOCK_TYPE</a>   | The type of lock. Permitted values are <a href="#">RECORD</a> for a row-level lock, <a href="#">TABLE</a> for a table-level lock.  |
| <a href="#">LOCK_TABLE</a>  | Name of the table that has been locked or contains locked records.   |
| <a href="#">LOCK_INDEX</a>  | Name of the index, if <a href="#">LOCK_TYPE</a> is <a href="#">RECORD</a> ; otherwise <a href="#">NULL</a> .   |
| <a href="#">LOCK_SPACE</a>  | Tablespace ID of the locked record, if <a href="#">LOCK_TYPE</a> is <a href="#">RECORD</a> ; otherwise <a href="#">NULL</a> .  |

| Column name | Description   |
|-------------|---|
| LOCK_PAGE   | Page number of the locked record, if <a href="#">LOCK_TYPE</a> is <a href="#">RECORD</a> ; otherwise <a href="#">NULL</a> .   |
| LOCK_REC    | Heap number of the locked record within the page, if <a href="#">LOCK_TYPE</a> is <a href="#">RECORD</a> ; otherwise <a href="#">NULL</a> .   |
| LOCK_DATA   | The data associated with the lock, if any. Values are primary key values of the locked record if <a href="#">LOCK_TYPE</a> is <a href="#">RECORD</a> , otherwise <a href="#">NULL</a> . This column contains the values of the primary key columns in the locked row, formatted as a valid SQL string (ready to be copied to SQL statements). If there is no primary key, <a href="#">LOCK_DATA</a> is the unique <a href="#">InnoDB</a> internal row ID number. If a gap lock is taken for key values or ranges above the largest value in the index, <a href="#">LOCK_DATA</a> reports <a href="#">supremum pseudo-record</a> . When the page containing the locked record is not in the buffer pool (in the case that it was paged out to disk while the lock was held), <a href="#">InnoDB</a> does not fetch the page from disk, to avoid unnecessary disk operations. Instead, <a href="#">LOCK_DATA</a> is set to <a href="#">NULL</a> . |

**Example:**

```
mysql> SELECT * FROM INFORMATION_SCHEMA.INNODB_LOCKS\G
***** 1. row *****
    lock_id: 3723:72:3:2
lock_trx_id: 3723
    lock_mode: X
    lock_type: RECORD
lock_table: `mysql`.`t`
lock_index: PRIMARY
lock_space: 72
    lock_page: 3
    lock_rec: 2
    lock_data: 1, 9
***** 2. row *****
    lock_id: 3722:72:3:2
lock_trx_id: 3722
    lock_mode: S
    lock_type: RECORD
lock_table: `mysql`.`t`
lock_index: PRIMARY
lock_space: 72
    lock_page: 3
    lock_rec: 2
    lock_data: 1, 9
```

**Notes:**

- Use this table to help diagnose performance problems that occur during times of heavy concurrent load. Its contents are updated as described in [Section 15.15.2.3, “Persistence and Consistency of InnoDB Transaction and Locking Information”](#).
- Use [DESCRIBE](#) or [SHOW COLUMNS](#) to view additional information about the columns of this table including data types and default values.
- You must have the [PROCESS](#) privilege to query this table.
- For usage information, see [Section 15.15.2.1, “Using InnoDB Transaction and Locking Information”](#).

## 23.31.14 The INFORMATION\_SCHEMA INNODB\_LOCK\_WAITS Table

The [INNODB\\_LOCK\\_WAITS](#) table contains one or more rows for each blocked [InnoDB](#) transaction, indicating the lock it has requested and any locks that are blocking that request.

**Note**

This table is deprecated as of MySQL 5.7.14 and is removed in MySQL 8.0.

**Table 23.14 INNODB\_LOCK\_WAITS Columns**

| Column name                       | Description  |
|-----------------------------------|--|
| <a href="#">REQUESTING_TRX_ID</a> | ID of the requesting (blocked) transaction.  |
| <a href="#">REQUESTED_LOCK_ID</a> | ID of the lock for which a transaction is waiting. To obtain details about the lock, join this column with the <a href="#">LOCK_ID</a> column of the <a href="#">INNODB_LOCKS</a> table.                               |
| <a href="#">BLOCKING_TRX_ID</a>   | ID of the blocking transaction.  |
| <a href="#">BLOCKING_LOCK_ID</a>  | ID of a lock held by a transaction blocking another transaction from proceeding. To obtain details about the lock, join this column with the <a href="#">LOCK_ID</a> column of the <a href="#">INNODB_LOCKS</a> table. |

**Example:**

```
mysql> SELECT * FROM INFORMATION_SCHEMA.INNODB_LOCK_WAITS\G
***** 1. row *****
requesting_trx_id: 3396
requested_lock_id: 3396:91:3:2
  blocking_trx_id: 3395
  blocking_lock_id: 3395:91:3:2
```

**Notes:**

- Use this table to help diagnose performance problems that occur during times of heavy concurrent load. Its contents are updated as described in [Section 15.15.2.3, “Persistence and Consistency of InnoDB Transaction and Locking Information”](#).
- Use [DESCRIBE](#) or [SHOW COLUMNS](#) to view additional information about the columns of this table including data types and default values.
- You must have the [PROCESS](#) privilege to query this table.
- For usage information, see [Section 15.15.2.1, “Using InnoDB Transaction and Locking Information”](#).

## 23.31.15 The INFORMATION\_SCHEMA INNODB\_METRICS Table

This [INFORMATION\\_SCHEMA](#) table presents a wide variety of [InnoDB](#) performance information, complementing the specific focus areas of the [PERFORMANCE\\_SCHEMA](#) tables for [InnoDB](#). With simple queries, you can check the overall health of the system. With more detailed queries, you can diagnose issues such as performance bottlenecks, resource shortages, and application issues.

Each monitor represents a point within the [InnoDB](#) source code that is instrumented to gather counter information. Each counter can be started, stopped, and reset. You can also perform these actions for a group of counters using their common module name.

By default, relatively little data is collected. To start, stop, and reset counters, you set one of the configuration options [innodb\\_monitor\\_enable](#), [innodb\\_monitor\\_disable](#), [innodb\\_monitor\\_reset](#), or [innodb\\_monitor\\_reset\\_all](#), using the name of the counter, the name of the module, a wildcard match for such a name using the “%” character, or the special keyword [all](#).

For usage information, see [Section 15.15.6, “InnoDB INFORMATION\\_SCHEMA Metrics Table”](#).

**Table 23.15 INNODB\_METRICS Columns**

| Column name               | Description   |
|---------------------------|---|
| <a href="#">NAME</a>      | Unique name for the counter.  |
| <a href="#">SUBSYSTEM</a> | The aspect of <a href="#">InnoDB</a> that the metric applies to. See the list following the table for the corresponding module names to use with the <a href="#">SET GLOBAL</a> syntax. |

| Column name     | Description  |
|-----------------|--|
| COUNT           | Value since the counter is enabled.  |
| MAX_COUNT       | Maximum value since the counter is enabled.  |
| MIN_COUNT       | Minimum value since the counter is enabled.  |
| AVG_COUNT       | Average value since the counter is enabled.  |
| COUNT_RESET     | Counter value since it was last reset. (The <code>_RESET</code> fields act like the lap counter on a stopwatch: you can measure the activity during some time interval, while the cumulative figures are still available in the <code>COUNT</code> , <code>MAX_COUNT</code> , and so on fields.) |
| MAX_COUNT_RESET | Maximum counter value since it was last reset.   |
| MIN_COUNT_RESET | Minimum counter value since it was last reset.   |
| AVG_COUNT_RESET | Average counter value since it was last reset.   |
| TIME_ENABLED    | Timestamp of last start.   |
| TIME_DISABLED   | Timestamp of last stop.  |
| TIME_ELAPSED    | Elapsed time in seconds since the counter started.   |
| TIME_RESET      | Timestamp of last stop.  |
| STATUS          | Whether the counter is still running ( <code>enabled</code> ) or stopped ( <code>disabled</code> ).  |
| TYPE            | Whether the item is a cumulative counter, or measures the current value of some resource.  |
| COMMENT         | Counter description.   |

**Example:**

```
mysql> SELECT * FROM INFORMATION_SCHEMA.INNODB_METRICS WHERE NAME="dml_inserts"\G
***** 1. row *****
      NAME: dml_inserts
    SUBSYSTEM: dml
      COUNT: 3
    MAX_COUNT: 3
    MIN_COUNT: NULL
    AVG_COUNT: 0.046153846153846156
    COUNT_RESET: 3
MAX_COUNT_RESET: 3
MIN_COUNT_RESET: NULL
AVG_COUNT_RESET: NULL
    TIME_ENABLED: 2014-12-04 14:18:28
    TIME_DISABLED: NULL
    TIME_ELAPSED: 65
    TIME_RESET: NULL
      STATUS: enabled
      TYPE: status_counter
    COMMENT: Number of rows inserted
```

**Notes:**

- You must have the `PROCESS` privilege to query this table.
- Use `DESCRIBE` or `SHOW COLUMNS` to view additional information about the columns of this table including data types and default values.

## 23.31.16 The INFORMATION\_SCHEMA INNODB\_SYS\_COLUMNS Table

The `INNODB_SYS_COLUMNS` table provides metadata about `InnoDB` table columns, equivalent to the information from the `SYS_COLUMNS` table in the `InnoDB` data dictionary.

For related usage information and examples, see [Section 15.15.3, “InnoDB INFORMATION\\_SCHEMA System Tables”](#).

**Table 23.16 INNODB\_SYS\_COLUMNS Columns**

| Column name              | Description   |
|--------------------------|---|
| <a href="#">TABLE_ID</a> | An identifier representing the table associated with the column; the same value from <a href="#">INNODB_SYS_TABLES.TABLE_ID</a> .   |
| <a href="#">NAME</a>     | The name of each column in each table. These names can be uppercase or lowercase depending on the <a href="#">lower_case_table_names</a> setting. There are no special system-reserved names for columns.   |
| <a href="#">POS</a>      | The ordinal position of the column within the table, starting from 0 and incrementing sequentially. When a column is dropped, the remaining columns are reordered so that the sequence has no gaps. The <a href="#">POS</a> value for a virtual generated column encodes the column sequence number and ordinal position of the column. For more information, see the <a href="#">POS</a> column description in <a href="#">Section 23.31.25, “The INFORMATION_SCHEMA INNODB_SYS_VIRTUAL Table”</a> . |
| <a href="#">MTYPE</a>    | Stands for “main type”. A numeric identifier for the column type. 1 = <a href="#">VARCHAR</a> , 2 = <a href="#">CHAR</a> , 3 = <a href="#">FIXBINARY</a> , 4 = <a href="#">BINARY</a> , 5 = <a href="#">BLOB</a> , 6 = <a href="#">INT</a> , 7 = <a href="#">SYS_CHILD</a> , 8 = <a href="#">SYS</a> , 9 = <a href="#">FLOAT</a> , 10 = <a href="#">DOUBLE</a> , 11 = <a href="#">DECIMAL</a> , 12 = <a href="#">VARMYSQL</a> , 13 = <a href="#">MYSQL</a> , 14 = <a href="#">GEOMETRY</a> .          |
| <a href="#">PRTYPE</a>   | The InnoDB “precise type”, a binary value with bits representing MySQL data type, character set code, and nullability.  |
| <a href="#">LEN</a>      | The column length, for example 4 for <a href="#">INT</a> and 8 for <a href="#">BIGINT</a> . For character columns in multibyte character sets, this length value is the maximum length in bytes needed to represent a definition such as <a href="#">VARCHAR(N)</a> ; that is, it might be $2*N$ , $3*N$ , and so on depending on the character encoding.   |

**Example:**

```
mysql> SELECT * FROM INFORMATION_SCHEMA.INNODB_SYS_COLUMNS where TABLE_ID = 71\G
***** 1. row *****
TABLE_ID: 71
  NAME: col1
   POS: 0
  MTYPE: 6
 PRTYPE: 1027
   LEN: 4
***** 2. row *****
TABLE_ID: 71
  NAME: col2
   POS: 1
  MTYPE: 2
 PRTYPE: 524542
   LEN: 10
***** 3. row *****
TABLE_ID: 71
  NAME: col3
   POS: 2
  MTYPE: 1
 PRTYPE: 524303
   LEN: 10
```

**Notes:**

- Use [DESCRIBE](#) or [SHOW COLUMNS](#) to view additional information about the columns of this table including data types and default values.
- You must have the [PROCESS](#) privilege to query this table.

**23.31.17 The INFORMATION\_SCHEMA INNODB\_SYS\_DATAFILES Table**

The `INNODB_SYS_DATAFILES` table provides data file path information for InnoDB file-per-table and general tablespaces, equivalent to the information in the `SYS_DATAFILES` table in the InnoDB data dictionary.

For related usage information and examples, see [Section 15.15.3, “InnoDB INFORMATION\\_SCHEMA System Tables”](#).

#### Note

As of MySQL 5.7.8, the `INFORMATION_SCHEMA.FILES` table provides data file path information and other metadata about all InnoDB tablespace types including file-per-table tablespaces, general tablespaces, the system tablespace, temporary tablespaces, and undo tablespaces (if present).

**Table 23.17 INNODB\_SYS\_DATAFILES Columns**

| Column name        | Description  |
|--------------------|--|
| <code>SPACE</code> | The tablespace Space ID.   |
| <code>PATH</code>  | The tablespace data file path (for example, <code>.\world\innodb\city.ibd</code> ). If a file-per-table tablespace is created in a location outside the MySQL data directory using the <code>DATA DIRECTORY</code> clause of the <code>CREATE TABLE</code> statement, the tablespace <code>PATH</code> field shows the fully qualified directory path. |

#### Example:

```
mysql> SELECT * FROM INFORMATION_SCHEMA.INNODB_SYS_DATAFILES WHERE SPACE = 57\G
***** 1. row *****
SPACE: 57
PATH: ./test/t1.ibd
```

#### Notes:

- Use `DESCRIBE` or `SHOW COLUMNS` to view additional information about the columns of this table including data types and default values.
- You must have the `PROCESS` privilege to query this table.

## 23.31.18 The INFORMATION\_SCHEMA INNODB\_SYS\_FIELDS Table

The `INNODB_SYS_FIELDS` table provides metadata about the key columns (fields) of InnoDB indexes, equivalent to the information from the `SYS_FIELDS` table in the InnoDB data dictionary.

For related usage information and examples, see [Section 15.15.3, “InnoDB INFORMATION\\_SCHEMA System Tables”](#).

**Table 23.18 INNODB\_SYS\_FIELDS Columns**

| Column name           | Description  |
|-----------------------|--|
| <code>INDEX_ID</code> | An identifier for the index associated with this key field, using the same value as in <code>INNODB_SYS_INDEXES.INDEX_ID</code> .  |
| <code>NAME</code>     | The name of the original column from the table, using the same value as in <code>INNODB_SYS_COLUMNS.NAME</code> .  |
| <code>POS</code>      | The ordinal position of the key field within the index, starting from 0 and incrementing sequentially. When a column is dropped, the remaining columns are reordered so that the sequence has no gaps. |

#### Example:

```
mysql> SELECT * FROM INFORMATION_SCHEMA.INNODB_SYS_FIELDS WHERE INDEX_ID = 117\G
***** 1. row *****
INDEX_ID: 117
NAME: coll
POS: 0
```

**Notes:**

- Use [DESCRIBE](#) or [SHOW COLUMNS](#) to view additional information about the columns of this table including data types and default values.
- You must have the [PROCESS](#) privilege to query this table.

### 23.31.19 The INFORMATION\_SCHEMA INNODB\_SYS\_FOREIGN Table

The [INNODB\\_SYS\\_FOREIGN](#) table provides metadata about [InnoDB foreign keys](#), equivalent to the information from the [SYS\\_FOREIGN](#) table in the [InnoDB](#) data dictionary.

For related usage information and examples, see [Section 15.15.3, “InnoDB INFORMATION\\_SCHEMA System Tables”](#).

**Table 23.19 INNODB\_SYS\_FOREIGN Columns**

| Column name              | Description   |
|--------------------------|---|
| <a href="#">ID</a>       | The name (not a numeric value) of the foreign key index. Preceded by the database name, for example, <a href="#">test/products_fk</a> .   |
| <a href="#">FOR_NAME</a> | The name of the <a href="#">child table</a> in this foreign key relationship.   |
| <a href="#">REF_NAME</a> | The name of the <a href="#">parent table</a> in this foreign key relationship.  |
| <a href="#">N_COLS</a>   | The number of columns in the foreign key index.   |
| <a href="#">TYPE</a>     | A collection of bit flags with information about the foreign key column, Ored together. 1 = <a href="#">ON DELETE CASCADE</a> , 2 = <a href="#">ON UPDATE SET NULL</a> , 4 = <a href="#">ON UPDATE CASCADE</a> , 8 = <a href="#">ON UPDATE SET NULL</a> , 16 = <a href="#">ON DELETE NO ACTION</a> , 32 = <a href="#">ON UPDATE NO ACTION</a> . |

**Example:**

```
mysql> SELECT * FROM INFORMATION_SCHEMA.INNODB_SYS_FOREIGN\G
***** 1. row *****
ID: test/fk1
FOR_NAME: test/child
REF_NAME: test/parent
N_COLS: 1
TYPE: 1
```

**Notes:**

- Use [DESCRIBE](#) or [SHOW COLUMNS](#) to view additional information about the columns of this table including data types and default values.
- You must have the [PROCESS](#) privilege to query this table.

### 23.31.20 The INFORMATION\_SCHEMA INNODB\_SYS\_FOREIGN\_COLS Table

The [INNODB\\_SYS\\_FOREIGN\\_COLS](#) table provides status information about the columns of [InnoDB](#) foreign keys, equivalent to the information from the [SYS\\_FOREIGN\\_COLS](#) table in the [InnoDB](#) data dictionary.

For related usage information and examples, see [Section 15.15.3, “InnoDB INFORMATION\\_SCHEMA System Tables”](#).

**Table 23.20 INNODB\_SYS\_FOREIGN\_COLS Columns**

| Column name  | Description  |
|--------------|--|
| ID           | The foreign key index associated with this index key field, using the same value as <code>INNODB_SYS_FOREIGN.ID</code> . |
| FOR_COL_NAME | The name of the associated column in the child table.  |
| REF_COL_NAME | The name of the associated column in the parent table.   |
| POS          | The ordinal position of this key field within the foreign key index, starting from 0.                                    |

**Example:**

```
mysql> SELECT * FROM INFORMATION_SCHEMA.INNODB_SYS_FOREIGN_COLS WHERE ID = 'test/fk1'\G
***** 1. row *****
      ID: test/fk1
FOR_COL_NAME: parent_id
REF_COL_NAME: id
      POS: 0
```

**Notes:**

- Use `DESCRIBE` or `SHOW COLUMNS` to view additional information about the columns of this table including data types and default values.
- You must have the `PROCESS` privilege to query this table.

## 23.31.21 The INFORMATION\_SCHEMA INNODB\_SYS\_INDEXES Table

The `INNODB_SYS_INDEXES` table provides metadata about `InnoDB` indexes, equivalent to the information in the internal `SYS_INDEXES` table in the `InnoDB` data dictionary.

For related usage information and examples, see [Section 15.15.3, “InnoDB INFORMATION\\_SCHEMA System Tables”](#).

**Table 23.21 INNODB\_SYS\_INDEXES Columns**

| Column name | Description  |
|-------------|--|
| INDEX_ID    | An identifier for each index that is unique across all the databases in an instance.   |
| NAME        | The name of the index. Most indexes created implicitly by <code>InnoDB</code> have consistent names but the index names are not necessarily unique. For example, <code>PRIMARY</code> for a primary key index, <code>GEN_CLUST_INDEX</code> for the index representing a primary key when one is not specified, and <code>ID_IND</code> , <code>FOR_IND</code> , and <code>REF_IND</code> for foreign key constraints. |
| TABLE_ID    | An identifier representing the table associated with the index; the same value from <code>INNODB_SYS_TABLES.TABLE_ID</code> .  |
| TYPE        | A numeric identifier signifying the kind of index. 0 = Secondary Index, 1 = Clustered Index, 2 = Unique Index, 3 = Primary Index, 32 = Full-text Index, 64 = Spatial Index, 128 = A secondary index that includes a <a href="#">generated virtual column</a> .   |
| N_FIELDS    | The number of columns in the index key. For the <code>GEN_CLUST_INDEX</code> indexes, this value is 0 because the index is created using an artificial value rather than a real table column.  |
| PAGE_NO     | The root page number of the index B-tree. For full-text indexes, the <code>PAGE_NO</code> field is unused and set to -1 ( <code>FIL_NULL</code> ) because the full-text index is laid out in several B-trees (auxiliary tables).   |
| SPACE       | An identifier for the tablespace where the index resides. 0 means the <code>InnoDB system tablespace</code> . Any other number represents a table created  |

| Column name                     | Description   |
|---------------------------------|---|
|                                 | in <a href="#">file-per-table</a> mode with a separate <a href="#">.ibd</a> file. This identifier stays the same after a <a href="#">TRUNCATE TABLE</a> statement. Because all indexes for a table reside in the same tablespace as the table, this value is not necessarily unique.  |
| <a href="#">MERGE_THRESHOLD</a> | The merge threshold value for index pages. If the amount of data in an index page falls below the <a href="#">MERGE_THRESHOLD</a> value when a row is deleted or when a row is shortened by an update operation, <a href="#">InnoDB</a> attempts to merge the index page with the neighboring index page. The default threshold value is 50%. The <a href="#">MERGE_THRESHOLD</a> column was added to <a href="#">INNODB_SYS_INDEXES</a> in MySQL 5.7.6. For more information, see <a href="#">Section 15.6.12, “Configuring the Merge Threshold for Index Pages”</a> . |

**Example:**

```
mysql> SELECT * FROM INFORMATION_SCHEMA.INNODB_SYS_INDEXES WHERE TABLE_ID = 34\G
***** 1. row *****
      INDEX_ID: 39
        NAME: GEN_CLUST_INDEX
      TABLE_ID: 34
        TYPE: 1
      N_FIELDS: 0
        PAGE_NO: 3
        SPACE: 23
MERGE_THRESHOLD: 50
***** 2. row *****
      INDEX_ID: 40
        NAME: i1
      TABLE_ID: 34
        TYPE: 0
      N_FIELDS: 1
        PAGE_NO: 4
        SPACE: 23
MERGE_THRESHOLD: 50
```

**Notes:**

- Use [DESCRIBE](#) or [SHOW COLUMNS](#) to view additional information about the columns of this table including data types and default values.
- You must have the [PROCESS](#) privilege to query this table.

## 23.31.22 The INFORMATION\_SCHEMA INNODB\_SYS\_TABLES Table

The [INNODB\\_SYS\\_TABLES](#) table provides metadata about [InnoDB](#) tables, equivalent to the information from the [SYS\\_TABLES](#) table in the [InnoDB](#) data dictionary.

For related usage information and examples, see [Section 15.15.3, “InnoDB INFORMATION\\_SCHEMA System Tables”](#).

**Table 23.22 INNODB\_SYS\_TABLES Columns**

| Column name              | Description   |
|--------------------------|---|
| <a href="#">TABLE_ID</a> | An identifier for each <a href="#">InnoDB</a> table that is unique across all databases in the instance.  |
| <a href="#">NAME</a>     | The name of the table. Preceded by the database name where appropriate, for example <a href="#">test/t1</a> . <a href="#">InnoDB</a> system table names are in all uppercase. Names of databases and user tables are in the same case as they were originally defined, possibly influenced by the <a href="#">lower_case_table_names</a> setting. |
| <a href="#">FLAG</a>     | This value provides bit level information about table format and storage characteristics including row format, compressed page size (if applicable),  |

| Column name                | Description  |
|----------------------------|--|
|                            | and whether or not the <code>DATA DIRECTORY</code> clause was used with <code>CREATE TABLE</code> or <code>ALTER TABLE</code> .  |
| <code>N_COLS</code>        | The number of columns in the table. The number reported includes three hidden columns that are created by InnoDB ( <code>DB_ROW_ID</code> , <code>DB_TRX_ID</code> , and <code>DB_ROLL_PTR</code> ). The number reported also includes <a href="#">generated virtual columns</a> , if present.   |
| <code>SPACE</code>         | An identifier for the tablespace where the table resides. 0 means the InnoDB system tablespace. Any other number represents either a <a href="#">file-per-table</a> tablespace or a general tablespace. This identifier stays the same after a <code>TRUNCATE TABLE</code> statement. For file-per-table tablespaces, this identifier is unique for tables across all databases in the instance.   |
| <code>FILE_FORMAT</code>   | The table's file format (Antelope or Barracuda).   |
| <code>ROW_FORMAT</code>    | The table's row format (Compact, Redundant, Dynamic, or Compressed).   |
| <code>ZIP_PAGE_SIZE</code> | The zip page size. Only applies to tables that use the Compressed row format.  |
| <code>SPACE_TYPE</code>    | The type of tablespace to which the table belongs. Possible values include <a href="#">System</a> (for the InnoDB system tablespace), <a href="#">General</a> (for InnoDB general tablespaces created using <code>CREATE TABLESPACE</code> , and <a href="#">Single</a> (for InnoDB file-per-table tablespaces). Tables assigned to the system tablespace using the <code>CREATE TABLE</code> or <code>ALTER TABLE TABLESPACE=innodb_system</code> clause have a <a href="#">General</a> <code>SPACE_TYPE</code> . The <code>SPACE_TYPE</code> column was added in MySQL 5.7.6 with the introduction of InnoDB general tablespaces. For more information, see <code>CREATE TABLESPACE</code> . |

**Example:**

```
mysql> SELECT * FROM INFORMATION_SCHEMA.INNODB_SYS_TABLES WHERE TABLE_ID = 214\G
***** 1. row *****
TABLE_ID: 214
NAME: test/t1
FLAG: 129
N_COLS: 4
SPACE: 233
FILE_FORMAT: Antelope
ROW_FORMAT: Compact
ZIP_PAGE_SIZE: 0
SPACE_TYPE: General
```

**Notes:**

- Use `DESCRIBE` or `SHOW COLUMNS` to view additional information about the columns of this table including data types and default values.
- You must have the `PROCESS` privilege to query this table.

**Interpreting the INNODB\_SYS\_TABLES.FLAG Column Value:**

The `INNODB_SYS_TABLES.FLAG` column provides bit-level information about the table's format and storage characteristics. You can interpret the `FLAG` column value by adding together the applicable decimal numeric values that are provided in the following table.

**Table 23.23 Bit Position Values for Interpreting INNODB\_SYS\_TABLES FLAG Column Data**

| Bit Position | Description   | Decimal Numeric Value   |
|--------------|---|---|
| 0            | This bit is set if the row format is not <a href="#">REDUNDANT</a> . In other words, it is set if | <ul style="list-style-type: none"> <li>• 0 - <a href="#">REDUNDANT</a></li> </ul> |

| Bit Position | Description  | Decimal Numeric Value  |
|--------------|--|--|
|              | the row format is <code>COMPACT</code> , <code>DYNAMIC</code> or <code>COMPRESSED</code> .   | <ul style="list-style-type: none"> <li>1 - <code>COMPACT</code>, <code>DYNAMIC</code> or <code>COMPRESSED</code></li> </ul>  |
| 1-4          | These four bits contain a small number that represents the compressed page size of the table. The <code>INNODB_SYS_TABLES.ZIP_PAGE_SIZE</code> field also reports the compressed page size, if applicable.   | <ul style="list-style-type: none"> <li>0 - Not Compressed</li> <li>2 - 1024 Byte Compressed Page Size</li> <li>4 - 2048 Byte Compressed Page Size</li> <li>6 - 4096 Byte Compressed Page Size</li> <li>8 - 8192 Byte Compressed Page Size</li> <li>10 - 16384 Byte Compressed Page Size</li> </ul> |
| 5            | This bit is set if the row format is <code>DYNAMIC</code> or <code>COMPRESSED</code> .   | <ul style="list-style-type: none"> <li>0 - <code>REDUNDANT</code> or <code>COMPACT</code></li> <li>32 - <code>DYNAMIC</code> or <code>COMPRESSED</code></li> </ul>   |
| 6            | This bit is set if the <code>DATA DIRECTORY</code> option is used with <code>CREATE TABLE</code> or <code>ALTER TABLE</code> . This bit is set for file-per-table tablespaces that are located in directories other than the default data directory ( <code>datadir</code> ). For these tables, a <code>tablename.isl</code> file is present in the same location as the <code>tablename.frm</code> file. The <code>tablename.isl</code> file stores the actual directory path to the <code>tablename.ibd</code> file-per-table tablespace file. | <ul style="list-style-type: none"> <li>0 - Not a remote file-per-table tablespace</li> <li>64 - A remote file-per-table tablespace</li> </ul>  |
| 7            | This bit is set if the table is assigned to a shared tablespace (either a general tablespace or a system tablespace) using the <code>CREATE TABLE</code> or <code>ALTER TABLE TABLESPACE=tablespace_name</code> option.  | <ul style="list-style-type: none"> <li>0 - Table is located in a default location depending on the value of the <code>innodb_file_per_table</code>.</li> <li>128 - The table is explicitly assigned to a shared tablespace.</li> </ul>   |

In the following, table `t1` uses `ROW_FORMAT=DYNAMIC` and has a `FLAG` value of 33. Based on the information in the preceding table, we can see that bit position 0 would be set to 1, and bit position 5 would be set to 32 for a table with a `DYNAMIC` row format. These values add up to a `FLAG` value of 33.

```
mysql> use test;
Database changed

mysql> SET GLOBAL innodb_file_format=Barracuda;
Query OK, 0 rows affected (0.00 sec)

mysql> CREATE TABLE t1 (c1 int) ROW_FORMAT=DYNAMIC;
Query OK, 0 rows affected (0.02 sec)

mysql> SELECT * FROM INFORMATION_SCHEMA.INNODB_SYS_TABLES WHERE NAME LIKE 'test/t1'\G
***** 1. row *****
TABLE_ID: 89
NAME: test/t1
FLAG: 33
N_COLS: 4
SPACE: 75
FILE_FORMAT: Barracuda
ROW_FORMAT: Dynamic
```

```
ZIP_PAGE_SIZE: 0
1 row in set (0.00 sec)
```

## 23.31.23 The INFORMATION\_SCHEMA INNODB\_SYS\_TABLESPACES Table

The `INNODB_SYS_TABLESPACES` table provides metadata about InnoDB file-per-table and general tablespaces, equivalent to the information in the `SYS_TABLESPACES` table in the InnoDB data dictionary.

For related usage information and examples, see [Section 15.15.3, “InnoDB INFORMATION\\_SCHEMA System Tables”](#).

### Note

As of MySQL 5.7.8, the `INFORMATION_SCHEMA.FILES` table provides metadata about all InnoDB tablespace types including file-per-table tablespaces, general tablespaces, the system tablespace, temporary tablespaces, and undo tablespaces (if present).

**Table 23.24 INNODB\_SYS\_TABLESPACES Columns**

| Column name                 | Description  |
|-----------------------------|--|
| <code>SPACE</code>          | Tablespace Space ID.   |
| <code>NAME</code>           | The database and table name (for example, <code>world_innodb\city</code> )   |
| <code>FLAG</code>           | This value provides bit level information about tablespace format and storage characteristics.   |
| <code>FILE_FORMAT</code>    | The tablespace file format. For example, <a href="#">Antelope</a> , <a href="#">Barracuda</a> , or <a href="#">Any</a> ( <a href="#">general tablespaces</a> support any row format). The data in this field is interpreted from the tablespace flags information that resides in the <code>.ibd</code> file. For more information about InnoDB file formats, see <a href="#">Section 15.10, “InnoDB File-Format Management”</a> . |
| <code>ROW_FORMAT</code>     | The tablespace row format (Compact or Redundant, Dynamic, or Compressed). The data in this field is interpreted from the tablespace flags information that resides in the <code>.ibd</code> file.  |
| <code>PAGE_SIZE</code>      | The tablespace page size. The data in this field is interpreted from the tablespace flags information that resides in the <code>.ibd</code> file.  |
| <code>ZIP_PAGE_SIZE</code>  | The tablespace zip page size. The data in this field is interpreted from the tablespace flags information that resides in the <code>.ibd</code> file.  |
| <code>SPACE_TYPE</code>     | The type of tablespace. Possible values include <a href="#">General</a> (for InnoDB general tablespaces created using <code>CREATE TABLESPACE</code> and <code>Single</code> (for InnoDB file-per-table tablespaces). The <code>SPACE_TYPE</code> column was added in MySQL 5.7.6 with the introduction of InnoDB general tablespaces. For more information, see <code>CREATE TABLESPACE</code> .                                  |
| <code>FS_BLOCK_SIZE</code>  | The file system block size, which is the unit size used for hole punching. This column was added in MySQL 5.7.8 with the introduction of the <a href="#">InnoDB transparent page compression</a> feature.  |
| <code>FILE_SIZE</code>      | The apparent size of the file, which represents the maximum size of the file, uncompressed. This column was added in MySQL 5.7.8 with the introduction of the <a href="#">InnoDB transparent page compression</a> feature.   |
| <code>ALLOCATED_SIZE</code> | The actual size of the file, which is the amount of space allocated on disk. This column was added in MySQL 5.7.8 with the introduction of the <a href="#">InnoDB transparent page compression</a> feature.  |

**Example:**

```
mysql> SELECT * FROM INFORMATION_SCHEMA.INNODB_SYS_TABLESPACES WHERE SPACE = 26\G
***** 1. row *****
      SPACE: 26
      NAME: test/t1
      FLAG: 0
      FILE_FORMAT: Antelope
      ROW_FORMAT: Compact or Redundant
      PAGE_SIZE: 16384
      ZIP_PAGE_SIZE: 0
      SPACE_TYPE: Single
      FS_BLOCK_SIZE: 4096
      FILE_SIZE: 98304
      ALLOCATED_SIZE: 65536
```

**Notes:**

- Use [DESCRIBE](#) or [SHOW COLUMNS](#) to view additional information about the columns of this table including data types and default values.
- You must have the [PROCESS](#) privilege to query this table.
- Because tablespace flags are always zero for all Antelope file formats (unlike table flags), there is no way to determine from this flag integer if the tablespace row format is Redundant or Compact. As a result, the possible values for the [ROW\\_FORMAT](#) field are “Compact or Redundant”, “Compressed”, or “Dynamic.”
- With the introduction of general tablespaces in MySQL 5.7.6, [InnoDB](#) system tablespace data (for SPACE 0) is exposed in [INNODB\\_SYS\\_TABLESPACES](#).

**Interpreting the INNODB\_SYS\_TABLESPACES.FLAG Column Value:**

The [INNODB\\_SYS\\_TABLESPACES.FLAG](#) column provides bit-level information about tablespace format and storage characteristics.

Until MySQL 5.6, table and tablespace flags were the same except for the bit position 0 settings. In MySQL 5.6, support was added for 4K and 8K pages, which required an additional 4 bits to hold the logical page size. Also in MySQL 5.6, support was added for the [CREATE TABLE](#) and [ALTER TABLE DATA DIRECTORY](#) clause, which allows file-per-table tablespaces to be stored in a location outside of the MySQL data directory. This feature required an additional bit for both table and tablespace flags, but not at the same position.

You can interpret the tablespace [FLAG](#) column value by adding together the applicable decimal numeric values that are provided in the following table.

**Table 23.25 Bit Position Values for Interpreting INNODB\_SYS\_TABLESPACES FLAG Column Data**

| Bit Position | Description  | Decimal Numeric Value  |
|--------------|--|--|
| 0            | This bit is set if the row format of tables in the tablespace is <a href="#">DYNAMIC</a> or <a href="#">COMPRESSED</a> . This information can help you distinguish between Antelope and Barracuda file formats but not between <a href="#">REDUNDANT</a> and <a href="#">COMPACT</a> file formats ( <a href="#">DYNAMIC</a> and <a href="#">COMPRESSED</a> row formats require the Barracuda file format). If it is a file-per-table tablespace, you must query <a href="#">INNODB_SYS_TABLES</a> to determine which of the two Antelope row formats is used ( <a href="#">REDUNDANT</a> or <a href="#">COMPACT</a> ). | <ul style="list-style-type: none"> <li>• 0 - <a href="#">REDUNDANT</a> or <a href="#">COMPACT</a> (<a href="#">FILE_FORMAT=Antelope</a>)</li> <li>• 1 - <a href="#">DYNAMIC</a> or <a href="#">COMPRESSED</a> (<a href="#">FILE_FORMAT=Barracuda</a>)</li> </ul> |
| 1-4          | These four bits contain a small number that represents the compressed page size (the <a href="#">KEY_BLOCK_SIZE</a> or “physical block size”) of the tablespace.   | <ul style="list-style-type: none"> <li>• 0 - Not Compressed</li> <li>• 2 - 1024 Byte Compressed Page Size</li> </ul>   |

| Bit Position | Description  | Decimal Numeric Value   |
|--------------|--|---|
|              |  | <ul style="list-style-type: none"> <li>• 4 - 2048 Byte Compressed Page Size</li> <li>• 6 - 4096 Byte Compressed Page Size</li> <li>• 8 - 8192 Byte Compressed Page Size</li> <li>• 10 - 16384 Byte Compressed Page Size</li> <li>• 12 - 32768 Byte Compressed Page Size</li> <li>• 14 - 65536 Byte Compressed Page Size</li> </ul>          |
| 5            | This bit is set for file-per-table tablespaces if the row format of the table is <a href="#">DYNAMIC</a> or <a href="#">COMPRESSED</a> . General tablespaces that do not contain compressed tables will have the first 6 bits set to zero, including this bit, making it appear to be the Antelope file format. But actually, general tablespaces may contain any combination of <a href="#">REDUNDANT</a> , <a href="#">COMPACT</a> and <a href="#">DYNAMIC</a> tables. For more information about general tablespaces, see <a href="#">CREATE TABLESPACE</a> .         | <ul style="list-style-type: none"> <li>• 0 - <a href="#">REDUNDANT</a> or <a href="#">COMPACT</a></li> <li>• 32 - <a href="#">DYNAMIC</a> or <a href="#">COMPRESSED</a></li> </ul>  |
| 6-9          | These four bits contain a small number that represents the uncompressed page size (logical page size) of the tablespace. The setting is zero if the logical page size is the original <a href="#">InnoDB</a> default page size of 16K.   | <ul style="list-style-type: none"> <li>• 192 - 4096 Byte Logical/Uncompressed Page Size</li> <li>• 256 - 8192 Byte Logical/Uncompressed Page Size</li> <li>• 0 - 16384 Byte Logical/Uncompressed Page size</li> <li>• 384 - 32768 Byte Logical/Uncompressed Page Size</li> <li>• 448 - 65536 Byte Logical/Uncompressed Page Size</li> </ul> |
| 10           | This bit is set if the <a href="#">DATA DIRECTORY</a> option is used with <a href="#">CREATE TABLE</a> or <a href="#">ALTER TABLE</a> . This bit is set for file-per-table tablespaces that are located in directories other than the default data directory ( <a href="#">datadir</a> ). For these tables, a <a href="#">tablename.isl</a> file is present in the same location as the <a href="#">tablename.frm</a> file. The <a href="#">tablename.isl</a> file stores the actual directory path to the <a href="#">tablename.ibd</a> file-per-table tablespace file. | <ul style="list-style-type: none"> <li>• 0 - Not a remote file-per-table tablespace</li> <li>• 1024 - A remote file-per-table tablespace</li> </ul>   |
| 11           | This bit is set if the tablespace is a shared general tablespace created using <a href="#">CREATE TABLESPACE</a> .   | <ul style="list-style-type: none"> <li>• 0 - Table is located in a default location depending on the value of the <a href="#">innodb_file_per_table</a> setting.</li> </ul>   |

| Bit Position | Description  | Decimal Numeric Value  |
|--------------|--|--|
|              |  | <ul style="list-style-type: none"> <li>2048 - The table was explicitly assigned to a shared tablespace.</li> </ul>   |
| 12           | This bit is set if the tablespace is dedicated to temporary tables. In MySQL 5.7, only the predefined <code>ibtmp1</code> tablespace uses this flag. | <ul style="list-style-type: none"> <li>0 - The tablespace does not contain temporary tables, so it is not recreated upon startup.</li> <li>4096 - The tablespace contains temporary tables and is recreated on startup.</li> </ul> |

In the following example, table `t1` is created with `innodb_file_per_table=ON`, which creates table `t1` in its own tablespace. When querying `INNODB_SYS_TABLESPACES`, we see that the tablespace has a `FLAG` value of 33. To determine how this value is arrived at, review the bit values described in the preceding table. Bit 0 has a value of 1 because table `t1` uses the `DYNAMIC` row format. Bit 5 has a value of 32 because the tablespace is a file-per-table tablespace that uses a `DYNAMIC` row format. Bit position 6-9 is 0 because `innodb_page_size` is set to the default 16K value. The other bit values are not applicable and are therefore set to 0. The values for bit position 0 and bit position 5 add up to a `FLAG` value of 33.

```
mysql> use test;
Database changed

mysql> SHOW VARIABLES LIKE 'innodb_file_per_table';
+-----+-----+
| Variable_name | Value |
+-----+-----+
| innodb_file_per_table | ON    |
+-----+-----+
1 row in set (0.00 sec)

mysql> SHOW VARIABLES LIKE 'innodb_page_size';
+-----+-----+
| Variable_name | Value |
+-----+-----+
| innodb_page_size | 16384 |
+-----+-----+
1 row in set (0.00 sec)

mysql> SET GLOBAL innodb_file_format=Barracuda;
Query OK, 0 rows affected (0.00 sec)

mysql> CREATE TABLE t1 (c1 int) ROW_FORMAT=DYNAMIC;
Query OK, 0 rows affected (0.02 sec)

mysql> SELECT * FROM INFORMATION_SCHEMA.INNODB_SYS_TABLESPACES WHERE NAME LIKE 'test/t1'\G
***** 1. row *****
      SPACE: 75
      NAME: test/t1
      FLAG: 33
  FILE_FORMAT: Barracuda
  ROW_FORMAT: Dynamic
    PAGE_SIZE: 16384
  ZIP_PAGE_SIZE: 0
1 row in set (0.00 sec)
```

## 23.31.24 The INFORMATION\_SCHEMA INNODB\_SYS\_TABLESTATS View

The `INNODB_SYS_TABLESTATS` provides a view of low-level status information about `InnoDB` tables. This data is used by the MySQL optimizer to calculate which index to use when querying an `InnoDB` table. This information is derived from in-memory data structures rather than corresponding to data stored on disk. There is no corresponding internal `InnoDB` system table.

[InnoDB](#) tables are represented in this view if they have been opened since the last server restart, and not aged out of the table cache. Tables for which persistent stats are available are always represented in this view.

Table statistics are only updated for [DELETE](#) or [UPDATE](#) operations that modify indexed columns. Statistics are not updated by operations that only modify non-indexed columns.

For related usage information and examples, see [Section 15.15.3, “InnoDB INFORMATION\\_SCHEMA System Tables”](#).

**Table 23.26 INNODB\_SYS\_TABLESTATS Columns**

| Column name                       | Description   |
|-----------------------------------|---|
| <a href="#">TABLE_ID</a>          | An identifier representing the table for which statistics are available, using the same value as <a href="#">INNODB_SYS_TABLES.TABLE_ID</a> .   |
| <a href="#">NAME</a>              | The name of the table, using the same value as <a href="#">INNODB_SYS_TABLES.NAME</a> .   |
| <a href="#">STATS_INITIALIZED</a> | The value is <a href="#">Initialized</a> if the statistics are already collected, <a href="#">Uninitialized</a> if not.   |
| <a href="#">NUM_ROWS</a>          | The current estimated number of rows in the table. Updated after each DML operation. Could be imprecise if uncommitted transactions are inserting into or deleting from the table.  |
| <a href="#">CLUST_INDEX_SIZE</a>  | Number of pages on disk that store the clustered index, which holds the <a href="#">InnoDB</a> table data in primary key order. This value might be null if no statistics are collected yet for the table.  |
| <a href="#">OTHER_INDEX_SIZE</a>  | Number of pages on disk that store all secondary indexes for the table. This value might be null if no statistics are collected yet for the table.  |
| <a href="#">MODIFIED_COUNTER</a>  | The number of rows modified by DML operations, such as <a href="#">INSERT</a> , <a href="#">UPDATE</a> , <a href="#">DELETE</a> , and also cascade operations from foreign keys. This column is reset each time table statistics are recalculated   |
| <a href="#">AUTOINC</a>           | The next number to be issued for any auto-increment-based operation. The rate at which the <a href="#">AUTOINC</a> value changes depends on how many times auto-increment numbers have been requested and how many numbers are granted per request. |
| <a href="#">REF_COUNT</a>         | When this counter reaches zero, the table metadata can be evicted from the table cache.   |

**Example:**

```
mysql> SELECT * FROM INFORMATION_SCHEMA.INNODB_SYS_TABLESTATS where TABLE_ID = 71\G
***** 1. row *****
      TABLE_ID: 71
        NAME: test/t1
STATS_INITIALIZED: Initialized
        NUM_ROWS: 1
      CLUST_INDEX_SIZE: 1
      OTHER_INDEX_SIZE: 0
    MODIFIED_COUNTER: 1
        AUTOINC: 0
        REF_COUNT: 1
```

**Notes:**

- This table is primarily useful for expert-level performance monitoring, or when developing performance-related extensions for MySQL.
- Use [DESCRIBE](#) or [SHOW COLUMNS](#) to view additional information about the columns of this table including data types and default values.

- You must have the `PROCESS` privilege to query this table.

### 23.31.25 The INFORMATION\_SCHEMA INNODB\_SYS\_VIRTUAL Table

The `INNODB_SYS_VIRTUAL` table provides metadata about [InnoDB generated virtual columns](#) and columns upon which generated virtual columns are based, equivalent to information in the `SYS_VIRTUAL` table in the `InnoDB` data dictionary.

A row appears in the `INNODB_SYS_VIRTUAL` table for each column upon which a generated virtual column is based.

**Table 23.27 INNODB\_SYS\_VIRTUAL Columns**

| Column name           | Description   |
|-----------------------|---|
| <code>TABLE_ID</code> | An identifier representing the table associated with the virtual column; the same value as <code>INNODB_SYS_TABLES.TABLE_ID</code> .  |
| <code>POS</code>      | The position value of the <a href="#">generated virtual column</a> . The value is large because it encodes the column sequence number and ordinal position. The formula used to calculate the value uses a bitwise operation. The formula is <code>((nth virtual generated column for the InnoDB instance + 1) &lt;&lt; 16) + the ordinal position of the generated virtual column</code> . For example, if the first virtual generated column in the <code>InnoDB</code> instance is the third column of the table, the formula is <code>(0 + 1) &lt;&lt; 16) + 2</code> . The first generated virtual column in the <code>InnoDB</code> instance is always number 0. As the third column in the table, the ordinal position of the generated virtual column is 2. Ordinal positions are counted from 0. |
| <code>BASE_POS</code> | The ordinal position of the columns upon which a generated virtual column is based.   |

#### Example:

```
mysql> CREATE TABLE `t1` (
  `a` int(11) DEFAULT NULL,
  `b` int(11) DEFAULT NULL,
  `c` int(11) GENERATED ALWAYS AS (a+b) VIRTUAL,
  `h` varchar(10) DEFAULT NULL
) ENGINE=InnoDB DEFAULT CHARSET=latin1;

mysql> SELECT * FROM INFORMATION_SCHEMA.INNODB_SYS_VIRTUAL
WHERE TABLE_ID IN (SELECT TABLE_ID FROM INFORMATION_SCHEMA.INNODB_SYS_TABLES WHERE NAME LIKE "t1");
+-----+-----+-----+
| TABLE_ID | POS   | BASE_POS |
+-----+-----+-----+
| 45        | 65538 | 0        |
| 45        | 65538 | 1        |
+-----+-----+-----+
```

#### Notes:

- If a constant value is assigned to a [generated virtual column](#), as in the following example, an entry for the column does not appear in the `INNODB_SYS_VIRTUAL` table. For an entry to appear, a generated virtual column must have a base column.

```
mysql> CREATE TABLE `t1` (
  `a` int(11) DEFAULT NULL,
  `b` int(11) DEFAULT NULL,
  `c` int(11) GENERATED ALWAYS AS (5) VIRTUAL
) ENGINE=InnoDB DEFAULT CHARSET=latin1;
```

However, metadata for such a column appears in the `INNODB_SYS_COLUMNS` table.

- Use [DESCRIBE](#) or [SHOW COLUMNS](#) to view additional information about the columns of this table including data types and default values.
- You must have the [PROCESS](#) privilege to query this table.

## 23.31.26 The INFORMATION\_SCHEMA INNODB\_TEMP\_TABLE\_INFO Table

[INNODB\\_TEMP\\_TABLE\\_INFO](#) contains metadata about active [InnoDB](#) temporary tables. With the exception of optimized internal temporary tables used by [InnoDB](#), [INNODB\\_TEMP\\_TABLE\\_INFO](#) reports on all user and system-created temporary tables that are active within a given [InnoDB](#) instance. The table is maintained in memory and not persisted to disk.

Prior to the introduction of the [INNODB\\_TEMP\\_TABLE\\_INFO](#) table in MySQL 5.7.1, [InnoDB](#) temporary table metadata was stored in [InnoDB](#) system tables.

For usage information and examples, see [Section 15.15.7, “InnoDB INFORMATION\\_SCHEMA Temporary Table Information Table”](#).

**Table 23.28 INNODB\_TEMP\_TABLE\_INFO Columns**

| Column name                     | Description   |
|---------------------------------|---|
| <a href="#">TABLE_ID</a>        | The table ID of the active temporary table.   |
| <a href="#">NAME</a>            | The name of the active temporary table.   |
| <a href="#">N_COLS</a>          | The number of columns in the temporary table. The number always includes three hidden columns created by <a href="#">InnoDB</a> (DB_ROW_ID, DB_TRX_ID, and DB_ROLL_PTR).  |
| <a href="#">SPACE</a>           | The tablespace identifier (a numerical value) for the tablespace in which the temporary table resides. As of MySQL 5.7.1, all non-compressed <a href="#">InnoDB</a> temporary tables reside in a shared temporary tablespace, as defined by <a href="#">innodb_temp_data_file_path</a> . By default the shared temporary tablespace is named <a href="#">ibtmp1</a> and located in the <a href="#">data</a> directory. Compressed temporary tables reside in separate per-table tablespaces located in the temporary file directory, as defined by <a href="#">tmpdir</a> . The <a href="#">SPACE</a> ID is always a non-zero value and is dynamically generated on server restart. |
| <a href="#">PER_TABLE_SPACE</a> | A value of <a href="#">TRUE</a> indicates that the temporary table resides in a separate per-table tablespace. A value of <a href="#">FALSE</a> indicates that the temporary table resides in the shared temporary tablespace.  |
| <a href="#">IS_COMPRESSED</a>   | A value of <a href="#">TRUE</a> indicates that the temporary table is compressed.   |

### Example:

```
mysql> CREATE TEMPORARY TABLE t1 (c1 INT PRIMARY KEY) ENGINE=INNODB;
Query OK, 0 rows affected (0.00 sec)

mysql> SELECT * FROM INFORMATION_SCHEMA.INNODB_TEMP_TABLE_INFO\G
***** 1. row *****
      TABLE_ID: 32
        NAME: #sqlaf56_2_0
       N_COLS: 4
        SPACE: 19
PER_TABLE_SPACE: FALSE
   IS_COMPRESSED: FALSE
1 row in set (0.00 sec)
```

### Notes:

- This table is primarily useful for expert level monitoring.

- Use [DESCRIBE](#) or [SHOW COLUMNS](#) to view additional information about the columns of this table including data types and default values.
- You must have the [PROCESS](#) privilege to query this table.

### 23.31.27 The INFORMATION\_SCHEMA INNODB\_TRX Table

The [INNODB\\_TRX](#) table contains information about every transaction (excluding read-only transactions) currently executing inside [InnoDB](#), including whether the transaction is waiting for a lock, when the transaction started, and the SQL statement the transaction is executing, if any.

**Table 23.29 INNODB\_TRX Columns**

| Column name                           | Description   |
|---------------------------------------|---|
| <a href="#">TRX_ID</a>                | Unique transaction ID number, internal to <a href="#">InnoDB</a> . These IDs are not created for transactions that are read only and nonlocking. See <a href="#">Section 9.5.3, “Optimizing InnoDB Read-Only Transactions”</a> for details.   |
| <a href="#">TRX_WEIGHT</a>            | The weight of a transaction, reflecting (but not necessarily the exact count of) the number of rows altered and the number of rows locked by the transaction. To resolve a deadlock, <a href="#">InnoDB</a> selects the transaction with the smallest weight as the “victim” to roll back. Transactions that have changed non-transactional tables are considered heavier than others, regardless of the number of altered and locked rows. |
| <a href="#">TRX_STATE</a>             | Transaction execution state. Permitted values are <a href="#">RUNNING</a> , <a href="#">LOCK WAIT</a> , <a href="#">ROLLING BACK</a> , and <a href="#">COMMITTING</a> .   |
| <a href="#">TRX_STARTED</a>           | Transaction start time.   |
| <a href="#">TRX_REQUESTED_LOCK_ID</a> | ID of the lock the transaction is currently waiting for, if <a href="#">TRX_STATE</a> is <a href="#">LOCK WAIT</a> ; otherwise <a href="#">NULL</a> . To obtain details about the lock, join this column with the <a href="#">LOCK_ID</a> column of the <a href="#">INNODB_LOCKS</a> table.   |
| <a href="#">TRX_WAIT_STARTED</a>      | Time when the transaction started waiting on the lock, if <a href="#">TRX_STATE</a> is <a href="#">LOCK WAIT</a> ; otherwise <a href="#">NULL</a> .   |
| <a href="#">TRX_MYSQL_THREAD_ID</a>   | MySQL thread ID. To obtain details about the thread, join this column with the <a href="#">ID</a> column of the <a href="#">INFORMATION_SCHEMA PROCESSLIST</a> table, but see <a href="#">Section 15.15.2.3, “Persistence and Consistency of InnoDB Transaction and Locking Information”</a> .  |
| <a href="#">TRX_QUERY</a>             | The SQL statement that is being executed by the transaction.  |
| <a href="#">TRX_OPERATION_STATE</a>   | The transaction's current operation, if any; otherwise <a href="#">NULL</a> .   |
| <a href="#">TRX_TABLES_IN_USE</a>     | The number of <a href="#">InnoDB</a> tables used while processing the current SQL statement of this transaction.  |
| <a href="#">TRX_TABLES_LOCKED</a>     | Number of <a href="#">InnoDB</a> tables that the current SQL statement has row locks on. (Because these are row locks, not table locks, the tables can usually still be read from and written to by multiple transactions, despite some rows being locked.)   |
| <a href="#">TRX_LOCK_STRUCTS</a>      | The number of locks reserved by the transaction.  |
| <a href="#">TRX_LOCK_MEMORY_BYTES</a> | Total size taken up by the lock structures of this transaction in memory.   |
| <a href="#">TRX_ROWS_LOCKED</a>       | Approximate number of rows locked by this transaction. The value might include delete-marked rows that are physically present but not visible to the transaction.   |
| <a href="#">TRX_ROWS_MODIFIED</a>     | The number of modified and inserted rows in this transaction.   |

| Column name                                | Description   |
|--|---|
| <a href="#">TRX_CONCURRENCY_TICKETS</a>    | A value indicating how much work the current transaction can do before being swapped out, as specified by the <a href="#">innodb_concurrency_tickets</a> system variable.   |
| <a href="#">TRX_ISOLATION_LEVEL</a>        | The isolation level of the current transaction.   |
| <a href="#">TRX_UNIQUE_CHECKS</a>          | Whether unique checks are turned on or off for the current transaction. For example, they might be turned off during a bulk data load.  |
| <a href="#">TRX_FOREIGN_KEY_CHECKS</a>     | Whether foreign key checks are turned on or off for the current transaction. For example, they might be turned off during a bulk data load.   |
| <a href="#">TRX_LAST_FOREIGN_KEY_ERROR</a> | Detailed error message for the last foreign key error, if any; otherwise <a href="#">NULL</a> .   |
| <a href="#">TRX_ADAPTIVE_HASH_LATCHED</a>  | Whether the adaptive hash index is locked by the current transaction. When the adaptive hash index search system is partitioned, a single transaction does not lock the entire adaptive hash index. Adaptive hash index partitioning is controlled by <a href="#">innodb_adaptive_hash_index_parts</a> , which is set to 8 by default.  |
| <a href="#">TRX_ADAPTIVE_HASH_TIMEOUT</a>  | Whether to relinquish the search latch immediately for the adaptive hash index, or reserve it across calls from MySQL. When there is no adaptive hash index contention, this value remains zero and statements reserve the latch until they finish. During times of contention, it counts down to zero, and statements release the latch immediately after each row lookup. When the adaptive hash index search system is partitioned (controlled by <a href="#">innodb_adaptive_hash_index_parts</a> ), the value remains 0. |
| <a href="#">TRX_IS_READ_ONLY</a>           | A value of 1 indicates the transaction is read only.  |
| <a href="#">TRX_AUTOCOMMIT_NON_LOCKING</a> | A value of 1 indicates the transaction is a <a href="#">SELECT</a> statement that does not use the <a href="#">FOR UPDATE</a> or <a href="#">LOCK IN SHARED MODE</a> clauses, and is executing with <a href="#">autocommit</a> enabled so that the transaction will only contain this one statement. When this column and <a href="#">TRX_IS_READ_ONLY</a> are both 1, <a href="#">InnoDB</a> optimizes the transaction to reduce the overhead associated with transactions that change table data.                           |

**Example:**

```
mysql> SELECT * FROM INFORMATION_SCHEMA.INNODB_TRX\G
***** 1. row *****
      trx_id: 1510
      trx_state: RUNNING
      trx_started: 2014-11-19 13:24:40
      trx_requested_lock_id: NULL
      trx_wait_started: NULL
      trx_weight: 586739
      trx_mysql_thread_id: 2
      trx_query: DELETE FROM employees.salaries WHERE salary > 65000
      trx_operation_state: updating or deleting
      trx_tables_in_use: 1
      trx_tables_locked: 1
      trx_lock_structs: 3003
      trx_lock_memory_bytes: 450768
      trx_rows_locked: 1407513
      trx_rows_modified: 583736
      trx_concurrency_tickets: 0
      trx_isolation_level: REPEATABLE READ
      trx_unique_checks: 1
```

```
    trx_foreign_key_checks: 1
trx_last_foreign_key_error: NULL
    trx_adaptive_hash_latched: 0
    trx_adaptive_hash_timeout: 10000
        trx_is_read_only: 0
trx_autocommit_non_locking: 0
```

**Notes:**

- Use this table to help diagnose performance problems that occur during times of heavy concurrent load. Its contents are updated as described in [Section 15.15.2.3, “Persistence and Consistency of InnoDB Transaction and Locking Information”](#).
- Use `DESCRIBE` or `SHOW COLUMNS` to view additional information about the columns of this table including data types and default values.
- You must have the `PROCESS` privilege to query this table.
- For usage information, see [Section 15.15.2.1, “Using InnoDB Transaction and Locking Information”](#).

## 23.32 Thread Pool INFORMATION\_SCHEMA Tables

The following sections describe the `INFORMATION_SCHEMA` tables associated with the thread pool plugin. They provide information about thread pool operation:

- `TP_THREAD_GROUP_STATE`: Information about thread pool thread group states
- `TP_THREAD_GROUP_STATS`: Thread group statistics
- `TP_THREAD_STATE`: Information about thread pool thread states

Rows in these tables represent snapshots in time. In the case of `TP_THREAD_STATE`, all rows for a thread group comprise a snapshot in time. Thus, the MySQL server holds the mutex of the thread group while producing the snapshot. But it does not hold mutexes on all thread groups at the same time, to prevent a statement against `TP_THREAD_STATE` from blocking the entire MySQL server.

The thread pool `INFORMATION_SCHEMA` tables are implemented by individual plugins and the decision whether to load one can be made independently of the others (see [Section 6.5.4.2, “Thread Pool Installation”](#)). However, the content of all the tables depends on the thread pool plugin being enabled. If a table plugin is enabled but the thread pool plugin is not, the table becomes visible and can be accessed but will be empty.

### 23.32.1 The INFORMATION\_SCHEMA TP\_THREAD\_GROUP\_STATE Table

This table has one row per thread group in the thread pool. Each row provides information about the current state of a group. The table has these columns:

- `TP_GROUP_ID`

The thread group ID. This is a unique key within the table.

- `CONSUMER_THREADS`

The number of consumer threads. There is at most one thread ready to start executing if the active threads become stalled or blocked.

- `RESERVE_THREADS`

The number of threads in the reserved state. This means that they will not be started until there is a need to wake a new thread and there is no consumer thread. This is where most threads end up when the thread group has created more threads than needed for normal operation. Often a thread group needs additional threads for a short while and then does not need them again for a while. In

this case, they go into the reserved state and remain until needed again. They take up some extra memory resources, but no extra computing resources.

- [CONNECTION\\_COUNT](#)

The number of connections using this thread group.

- [QUEUED\\_QUERIES](#)

The number of statements waiting in the high-priority queue.

- [QUEUED\\_TRANSACTIONS](#)

The number of statements waiting in the low-priority queue. These are the initial statements for transactions that have not started, so they also represent queued transactions.

- [STALL\\_LIMIT](#)

The value of the `thread_pool_stall_limit` variable on the thread group. This is the same value for all thread groups.

- [PRIO\\_KICKUP\\_TIMER](#)

The value of the `thread_pool_prio_kickup_timer` on the thread group. This is the same value for all thread groups.

- [ALGORITHM](#)

The value of the `thread_pool_algorithm` on the thread group. This is the same value for all thread groups.

- [THREAD\\_COUNT](#)

The number of threads started in the thread pool as part of this thread group.

- [ACTIVE\\_THREAD\\_COUNT](#)

The number of threads active executing statements.

- [MAX\\_THREAD\\_IDS\\_IN\\_GROUP](#)

The maximum thread ID of the threads in the group. This is the same as `MAX(TP_THREAD_NUMBER)` for the threads when selected from the `TP_THREAD_GROUP_STATE` table. That is, these two queries are equivalent:

```
SELECT TP_GROUP_ID, MAX_THREAD_IDS_IN_GROUP
FROM TP_THREAD_GROUP_STATE;

SELECT TP_GROUP_ID, MAX(TP_THREAD_NUMBER)
FROM TP_THREAD_STATE GROUP BY TP_GROUP_ID;
```

- [STALLED\\_THREAD\\_COUNT](#)

The number of stalled statements in the thread group. A stalled statement could be executing, but from a thread pool perspective it is stalled and making no progress. A long-running statement quickly ends up in this category.

- [WAITING\\_THREAD\\_NUMBER](#)

If there is a thread handling the polling of statements in the thread group, this specifies the thread number within this thread group. It is possible that this thread could be executing a statement.

- [OLDEST\\_QUEUED](#)

How long in milliseconds the oldest queued statement has been waiting for execution.

## 23.32.2 The INFORMATION\_SCHEMA TP\_THREAD\_GROUP\_STATS Table

This table reports statistics per thread group. There is one row per group. The table has these columns:

- [TP\\_GROUP\\_ID](#)

The thread group ID. This is a unique key within the table.

- [CONNECTIONS\\_STARTED](#)

The number of connections started.

- [CONNECTIONS\\_CLOSED](#)

The number of connections closed.

- [QUERIES\\_EXECUTED](#)

The number of statements executed. This number is incremented when a statement starts executing, not when it finishes.

- [QUERIES\\_QUEUED](#)

The number of statements received that were queued for execution. This does not count statements that the thread group was able to begin executing immediately without queuing, which can happen under the conditions described in [Section 6.5.4.3, “Thread Pool Operation”](#).

- [THREADS\\_STARTED](#)

The number of threads started.

- [PRIO\\_KICKUPS](#)

The number of statements that have been moved from low-priority queue to high-priority queue based on the value of the [thread\\_pool\\_prio\\_kickup\\_timer](#) system variable. If this number increases quickly, consider increasing the value of that variable. A quickly increasing counter means that the priority system is not keeping transactions from starting too early. For [InnoDB](#), this most likely means deteriorating performance due to too many concurrent transactions..

- [STALLED\\_QUERIES\\_EXECUTED](#)

The number of statements that have become defined as stalled due to executing for a time longer than the value of the [thread\\_pool\\_stall\\_limit](#) system variable.

- [BECOME\\_CONSUMER\\_THREAD](#)

The number of times thread have been assigned the consumer thread role.

- [BECOME\\_RESERVE\\_THREAD](#)

The number of times threads have been assigned the reserve thread role.

- [BECOME\\_WAITING\\_THREAD](#)

The number of times threads have been assigned the waiter thread role. When statements are queued, this happens very often, even in normal operation, so rapid increases in this value are normal in the case of a highly loaded system where statements are queued up.

- [WAKE\\_THREAD\\_STALL\\_CHECKER](#)

The number of times the stall check thread decided to wake or create a thread to possibly handle some statements or take care of the waiter thread role.

- `SLEEP_WAITS`

The number of `THD_WAIT_SLEEP` waits. These occur when threads go to sleep; for example, by calling the `SLEEP( )` function.

- `DISK_IO_WAITS`

The number of `THD_WAIT_DISKIO` waits. These occur when threads perform disk I/O that is likely to not hit the file system cache. Such waits occur when the buffer pool reads and writes data to disk, not for normal reads from and writes to files.

- `ROW_LOCK_WAITS`

The number of `THD_WAIT_ROW_LOCK` waits for release of a row lock by another transaction.

- `GLOBAL_LOCK_WAITS`

The number of `THD_WAIT_GLOBAL_LOCK` waits for a global lock to be released.

- `META_DATA_LOCK_WAITS`

The number of `THD_WAIT_META_DATA_LOCK` waits for a metadata lock to be released.

- `TABLE_LOCK_WAITS`

The number of `THD_WAIT_TABLE_LOCK` waits for a table to be unlocked that the statement needs to access.

- `USER_LOCK_WAITS`

The number of `THD_WAIT_USER_LOCK` waits for a special lock constructed by the user thread.

- `BINLOG_WAITS`

The number of `THD_WAIT_BINLOG_WAITS` waits for the binary log to become free.

- `GROUP_COMMIT_WAITS`

The number of `THD_WAIT_GROUP_COMMIT` waits. These occur when a group commit must wait for the other parties to complete their part of a transaction.

- `FSYNC_WAITS`

The number of `THD_WAIT_SYNC` waits for a file sync operation.

### 23.32.3 The INFORMATION\_SCHEMA TP\_THREAD\_STATE Table

This table has one row per thread created by the thread pool to handle connections. The table has these columns:

- `TP_GROUP_ID`

The thread group ID.

- `TP_THREAD_NUMBER`

The ID of the thread within its thread group. `TP_GROUP_ID` and `TP_THREAD_NUMBER` together provide a unique key within the table.

- `PROCESS_COUNT`

The 10ms interval in which the statement that uses this thread is currently executing. 0 means no statement is executing, 1 means it is in the first 10ms, and so forth.

- `WAIT_TYPE`

The type of wait for the thread. `NULL` means the thread is not blocked. Otherwise, the thread is blocked by a call to `thd_wait_begin()` and the value specifies the type of wait. The `xxx_WAIT` columns of the `TP_THREAD_GROUP_STATS` table accumulate counts for each wait type.

The `WAIT_TYPE` value is a string that describes the type of wait, as shown in the following table.

**Table 23.30** `WAIT_TYPE` Values

| Wait Type                            | Meaning                   |
|--------------------------------------|---------------------------|
| <code>THD_WAIT_SLEEP</code>          | Waiting for sleep         |
| <code>THD_WAIT_DISKIO</code>         | Waiting for Disk IO       |
| <code>THD_WAIT_ROW_LOCK</code>       | Waiting for row lock      |
| <code>THD_WAIT_GLOBAL_LOCK</code>    | Waiting for global lock   |
| <code>THD_WAIT_META_DATA_LOCK</code> | Waiting for metadata lock |
| <code>THD_WAIT_TABLE_LOCK</code>     | Waiting for table lock    |
| <code>THD_WAIT_USER_LOCK</code>      | Waiting for user lock     |
| <code>THD_WAIT_BINLOG</code>         | Waiting for binlog        |
| <code>THD_WAIT_GROUP_COMMIT</code>   | Waiting for group commit  |
| <code>THD_WAIT_SYNC</code>           | Waiting for fsync         |

## 23.33 Connection-Control INFORMATION\_SCHEMA Tables

The following sections describe the `INFORMATION_SCHEMA` tables associated with the `connection_control` plugin.

### 23.33.1 The INFORMATION\_SCHEMA CONNECTION\_CONTROL\_FAILED\_LOGIN\_ATTEMPTS Table

This table provides information about the current number of consecutive failed connection attempts per client user/host combination. The table was added in MySQL 5.7.17.

`CONNECTION_CONTROL_FAILED_LOGIN_ATTEMPTS` has these columns:

- `USERHOST`

The user/host combination of a client that has failed connection attempts, in `'user_name'@'host_name'` format.

- `FAILED_ATTEMPTS`

The current number of consecutive failed connection attempts for the `USERHOST` value. This counts all failed attempts, regardless of whether they were delayed. The number of attempts for which the server added a delay to its response is the difference between the `FAILED_ATTEMPTS` value and the `connection_control_failed_connections_threshold` system variable value.

**Notes:**

- The `CONNECTION_CONTROL_FAILED_LOGIN_ATTEMPTS` plugin must be activated for this table to be available, and the `connection_control` plugin must be activated or the table contents will always be empty. See [Section 7.5.2, “The Connection-Control Plugin”](#).

- The table contains rows only for clients that have had one or more consecutive failed connection attempts without a subsequent successful attempt. When a client connects successfully, its failed-connection count is reset to zero and the server removes any row corresponding to the client.
- Assigning a value to the `connection_control_failed_connections_threshold` system variable at runtime resets all accumulated failed-connection counters to zero, which causes the table to become empty.

## 23.34 Extensions to SHOW Statements

Some extensions to `SHOW` statements accompany the implementation of `INFORMATION_SCHEMA`:

- `SHOW` can be used to get information about the structure of `INFORMATION_SCHEMA` itself.
- Several `SHOW` statements accept a `WHERE` clause that provides more flexibility in specifying which rows to display.

`INFORMATION_SCHEMA` is an information database, so its name is included in the output from `SHOW DATABASES`. Similarly, `SHOW TABLES` can be used with `INFORMATION_SCHEMA` to obtain a list of its tables:

```
mysql> SHOW TABLES FROM INFORMATION_SCHEMA;
+-----+
| Tables_in_INFORMATION_SCHEMA |
+-----+
| CHARACTER_SETS                |
| COLLATIONS                    |
| COLLATION_CHARACTER_SET_APPLICABILITY |
| COLUMNS                      |
| COLUMN_PRIVILEGES             |
| ENGINES                       |
| EVENTS                        |
| FILES                          |
| GLOBAL_STATUS                 |
| GLOBAL_VARIABLES              |
| KEY_COLUMN_USAGE              |
| PARTITIONS                    |
| PLUGINS                       |
| PROCESSLIST                   |
| REFERENTIAL_CONSTRAINTS       |
| ROUTINES                      |
| SCHEMATA                      |
| SCHEMA_PRIVILEGES             |
| SESSION_STATUS                |
| SESSION_VARIABLES             |
| STATISTICS                    |
| TABLES                       |
| TABLE_CONSTRAINTS            |
| TABLE_PRIVILEGES             |
| TRIGGERS                      |
| USER_PRIVILEGES               |
| VIEWS                         |
+-----+
```

`SHOW COLUMNS` and `DESCRIBE` can display information about the columns in individual `INFORMATION_SCHEMA` tables.

`SHOW` statements that accept a `LIKE` clause to limit the rows displayed also permit a `WHERE` clause that specifies more general conditions that selected rows must satisfy:

```
SHOW CHARACTER SET
SHOW COLLATION
SHOW COLUMNS
SHOW DATABASES
SHOW FUNCTION STATUS
```

```

SHOW INDEX
SHOW OPEN TABLES
SHOW PROCEDURE STATUS
SHOW STATUS
SHOW TABLE STATUS
SHOW TABLES
SHOW TRIGGERS
SHOW VARIABLES

```

The [WHERE](#) clause, if present, is evaluated against the column names displayed by the [SHOW](#) statement. For example, the [SHOW CHARACTER SET](#) statement produces these output columns:

```

mysql> SHOW CHARACTER SET;
+-----+-----+-----+-----+
| Charset | Description | Default collation | Maxlen |
+-----+-----+-----+-----+
| big5    | Big5 Traditional Chinese | big5_chinese_ci | 2 |
| dec8    | DEC West European | dec8_swedish_ci | 1 |
| cp850   | DOS West European | cp850_general_ci | 1 |
| hp8     | HP West European | hp8_english_ci | 1 |
| koi8r   | KOI8-R Relcom Russian | koi8r_general_ci | 1 |
| latin1  | cp1252 West European | latin1_swedish_ci | 1 |
| latin2  | ISO 8859-2 Central European | latin2_general_ci | 1 |
| ...

```

To use a [WHERE](#) clause with [SHOW CHARACTER SET](#), you would refer to those column names. As an example, the following statement displays information about character sets for which the default collation contains the string 'japanese':

```

mysql> SHOW CHARACTER SET WHERE `Default collation` LIKE '%japanese%';
+-----+-----+-----+-----+
| Charset | Description | Default collation | Maxlen |
+-----+-----+-----+-----+
| ujis    | EUC-JP Japanese | ujis_japanese_ci | 3 |
| sjis    | Shift-JIS Japanese | sjis_japanese_ci | 2 |
| cp932   | SJIS for Windows Japanese | cp932_japanese_ci | 2 |
| eucjpms | UJIS for Windows Japanese | eucjpms_japanese_ci | 3 |

```

This statement displays the multibyte character sets:

```

mysql> SHOW CHARACTER SET WHERE Maxlen > 1;
+-----+-----+-----+-----+
| Charset | Description | Default collation | Maxlen |
+-----+-----+-----+-----+
| big5    | Big5 Traditional Chinese | big5_chinese_ci | 2 |
| ujis    | EUC-JP Japanese | ujis_japanese_ci | 3 |
| sjis    | Shift-JIS Japanese | sjis_japanese_ci | 2 |
| euckr   | EUC-KR Korean | euckr_korean_ci | 2 |
| gb2312  | GB2312 Simplified Chinese | gb2312_chinese_ci | 2 |
| gbk     | GBK Simplified Chinese | gbk_chinese_ci | 2 |
| utf8    | UTF-8 Unicode | utf8_general_ci | 3 |
| ucs2    | UCS-2 Unicode | ucs2_general_ci | 2 |
| cp932   | SJIS for Windows Japanese | cp932_japanese_ci | 2 |
| eucjpms | UJIS for Windows Japanese | eucjpms_japanese_ci | 3 |

```

---

## Chapter 24 MySQL Performance Schema

### Table of Contents

|   |      |

The MySQL Performance Schema is a feature for monitoring MySQL Server execution at a low level.  
The Performance Schema has these characteristics:

- 
- The Performance Schema provides a way to inspect internal execution of the server at runtime. It is implemented using the [PERFORMANCE\\_SCHEMA](#) storage engine and the [performance\\_schema](#) database. The Performance Schema focuses primarily on performance data. This differs from [INFORMATION\\_SCHEMA](#), which serves for inspection of metadata.
  - The Performance Schema monitors server events. An “event” is anything the server does that takes time and has been instrumented so that timing information can be collected. In general, an event could be a function call, a wait for the operating system, a stage of an SQL statement execution such as parsing or sorting, or an entire statement or group of statements. Event collection provides access to information about synchronization calls (such as for mutexes) file and table I/O, table locks, and so forth for the server and for several storage engines.
  - Performance Schema events are distinct from events written to the server's binary log (which describe data modifications) and Event Scheduler events (which are a type of stored program).
  - Performance Schema events are specific to a given instance of the MySQL Server. Performance Schema tables are considered local to the server, and changes to them are not replicated or written to the binary log.
  - Current events are available, as well as event histories and summaries. This enables you to determine how many times instrumented activities were performed and how much time they took. Event information is available to show the activities of specific threads, or activity associated with particular objects such as a mutex or file.
  - The [PERFORMANCE\\_SCHEMA](#) storage engine collects event data using “instrumentation points” in server source code.
  - Collected events are stored in tables in the [performance\\_schema](#) database. These tables can be queried using [SELECT](#) statements like other tables.
  - Performance Schema configuration can be modified dynamically by updating tables in the [performance\\_schema](#) database through SQL statements. Configuration changes affect data collection immediately.
  - Tables in the [performance\\_schema](#) database are views or temporary tables that use no persistent on-disk storage.
  - Monitoring is available on all platforms supported by MySQL.

Some limitations might apply: The types of timers might vary per platform. Instruments that apply to storage engines might not be implemented for all storage engines. Instrumentation of each third-party engine is the responsibility of the engine maintainer. See also [Section C.8, “Restrictions on Performance Schema”](#).

- Data collection is implemented by modifying the server source code to add instrumentation. There are no separate threads associated with the Performance Schema, unlike other features such as replication or the Event Scheduler.

The Performance Schema is intended to provide access to useful information about server execution while having minimal impact on server performance. The implementation follows these design goals:

- Activating the Performance Schema causes no changes in server behavior. For example, it does not cause thread scheduling to change, and it does not cause query execution plans (as shown by [EXPLAIN](#)) to change.
- Server monitoring occurs continuously and unobtrusively with very little overhead. Activating the Performance Schema does not make the server unusable.
- The parser is unchanged. There are no new keywords or statements.
- Execution of server code proceeds normally even if the Performance Schema fails internally.

- When there is a choice between performing processing during event collection initially or during event retrieval later, priority is given to making collection faster. This is because collection is ongoing whereas retrieval is on demand and might never happen at all.
- It is easy to add new instrumentation points.
- Instrumentation is versioned. If the instrumentation implementation changes, previously instrumented code will continue to work. This benefits developers of third-party plugins because it is not necessary to upgrade each plugin to stay synchronized with the latest Performance Schema changes.

#### Note

The MySQL `sys` schema is a set of objects that provides convenient access to data collected by the Performance Schema. The `sys` schema is installed by default as of MySQL 5.7.7. For usage instructions, see [Chapter 25, MySQL sys Schema](#).

## 24.1 Performance Schema Quick Start

This section briefly introduces the Performance Schema with examples that show how to use it. For additional examples, see [Section 24.17, “Using the Performance Schema to Diagnose Problems”](#).

For the Performance Schema to be available, support for it must have been configured when MySQL was built. You can verify whether this is the case by checking the server's help output. If the Performance Schema is available, the output will mention several variables with names that begin with `performance_schema`:

```
shell> mysql --verbose --help
...
--performance_schema
           Enable the performance schema.
--performance_schema_events_waits_history_long_size=#
           Number of rows in events_waits_history_long.
...
```

If such variables do not appear in the output, your server has not been built to support the Performance Schema. In this case, see [Section 24.2, “Performance Schema Build and Startup Configuration”](#).

Assuming that the Performance Schema is available, it is enabled by default. To enable or disable it explicitly, start the server with the `performance_schema` variable set to an appropriate value. For example, use these lines in your `my.cnf` file:

```
[mysqld]
performance_schema=ON
```

When the server starts, it sees `performance_schema` and attempts to initialize the Performance Schema. To verify successful initialization, use this statement:

```
mysql> SHOW VARIABLES LIKE 'performance_schema';
+-----+-----+
| Variable_name | Value |
+-----+-----+
| performance_schema | ON    |
+-----+-----+
```

A value of `ON` means that the Performance Schema initialized successfully and is ready for use. A value of `OFF` means that some error occurred. Check the server error log for information about what went wrong.

The Performance Schema is implemented as a storage engine. If this engine is available (which you should already have checked earlier), you should see it listed with a `SUPPORT` value of `YES` in the output from the `INFORMATION_SCHEMA.ENGINES` table or the `SHOW ENGINES` statement:

```
mysql> SELECT * FROM INFORMATION_SCHEMA.ENGINES
      WHERE ENGINE='PERFORMANCE_SCHEMA'\G
***** 1. row *****
ENGINE: PERFORMANCE_SCHEMA
SUPPORT: YES
COMMENT: Performance Schema
TRANSACTIONS: NO
XA: NO
SAVEPOINTS: NO

mysql> SHOW ENGINES\G
...
Engine: PERFORMANCE_SCHEMA
Support: YES
Comment: Performance Schema
Transactions: NO
XA: NO
Savepoints: NO
...
```

The `PERFORMANCE_SCHEMA` storage engine operates on tables in the `performance_schema` database. You can make `performance_schema` the default database so that references to its tables need not be qualified with the database name:

```
mysql> USE performance_schema;
```

Many examples in this chapter assume `performance_schema` as the default database.

Performance Schema tables are stored in the `performance_schema` database. Information about the structure of this database and its tables can be obtained, as for any other database, by selecting from the `INFORMATION_SCHEMA` database or by using `SHOW` statements. For example, use either of these statements to see what Performance Schema tables exist:

```
mysql> SELECT TABLE_NAME FROM INFORMATION_SCHEMA.TABLES
      WHERE TABLE_SCHEMA = 'performance_schema';
+-----+
| TABLE_NAME |
+-----+
| accounts    |
| cond_instances |
...
| events_stages_current
| events_stages_history
| events_stages_history_long

The number of Performance Schema tables increases over time as implementation of additional instrumentation proceeds.

The name of the `performance_schema` database is lowercase, as are the names of tables within it. Queries should specify the names in lowercase.

To see the structure of individual tables, use `SHOW CREATE TABLE`:

```

mysql> SHOW CREATE TABLE setup_timers\G
***** 1. row *****
      Table: setup_timers
Create Table: CREATE TABLE `setup_timers` (
  `NAME` varchar(64) NOT NULL,
  `TIMER_NAME` enum('CYCLE','NANOSECOND','MICROSECOND','MILLISECOND','TICK')
    NOT NULL
) ENGINE=PERFORMANCE_SCHEMA DEFAULT CHARSET=utf8

```

Table structure is also available by selecting from tables such as `INFORMATION_SCHEMA.COLUMNS` or by using statements such as `SHOW COLUMNS`.

Tables in the `performance_schema` database can be grouped according to the type of information in them: Current events, event histories and summaries, object instances, and setup (configuration) information. The following examples illustrate a few uses for these tables. For detailed information about the tables in each group, see [Section 24.10, “Performance Schema Table Descriptions”](#).

Initially, not all instruments and consumers are enabled, so the performance schema does not collect all events. To turn all of these on and enable event timing, execute two statements (the row counts may differ depending on MySQL version):

```

mysql> UPDATE setup_instruments SET ENABLED = 'YES', TIMED = 'YES';
Query OK, 560 rows affected (0.04 sec)

```

```
mysql> UPDATE setup_consumers SET ENABLED = 'YES';
Query OK, 10 rows affected (0.00 sec)
```

To see what the server is doing at the moment, examine the `events_waits_current` table. It contains one row per thread showing each thread's most recent monitored event:

```
mysql> SELECT * FROM events_waits_current\G
***** 1. row *****
      THREAD_ID: 0
      EVENT_ID: 5523
    END_EVENT_ID: 5523
      EVENT_NAME: wait/synch/mutex/mysys/THR_LOCK::mutex
        SOURCE: thr_lock.c:525
      TIMER_START: 201660494489586
      TIMER_END: 201660494576112
      TIMER_WAIT: 86526
        SPINS: NULL
    OBJECT_SCHEMA: NULL
      OBJECT_NAME: NULL
      INDEX_NAME: NULL
      OBJECT_TYPE: NULL
OBJECT_INSTANCE_BEGIN: 142270668
    NESTING_EVENT_ID: NULL
    NESTING_EVENT_TYPE: NULL
      OPERATION: lock
    NUMBER_OF_BYTES: NULL
        FLAGS: 0
...

```

This event indicates that thread 0 was waiting for 86,526 picoseconds to acquire a lock on `THR_LOCK::mutex`, a mutex in the `mysys` subsystem. The first few columns provide the following information:

- The ID columns indicate which thread the event comes from and the event number.
- `EVENT_NAME` indicates what was instrumented and `SOURCE` indicates which source file contains the instrumented code.
- The timer columns show when the event started and stopped and how long it took. If an event is still in progress, the `TIMER_END` and `TIMER_WAIT` values are `NULL`. Timer values are approximate and expressed in picoseconds. For information about timers and event time collection, see [Section 24.3.1, “Performance Schema Event Timing”](#).

The history tables contain the same kind of rows as the current-events table but have more rows and show what the server has been doing “recently” rather than “currently.” The `events_waits_history` and `events_waits_history_long` tables contain the most recent 10 events per thread and most recent 10,000 events, respectively. For example, to see information for recent events produced by thread 13, do this:

```
mysql> SELECT EVENT_ID, EVENT_NAME, TIMER_WAIT
FROM events_waits_history WHERE THREAD_ID = 13
ORDER BY EVENT_ID;
```

| EVENT_ID | EVENT_NAME                              | TIMER_WAIT |
|----------|---|------------|
| 86       | wait/synch/mutex/mysys/THR_LOCK::mutex  | 686322     |
| 87       | wait/synch/mutex/mysys/THR_LOCK_malloc  | 320535     |
| 88       | wait/synch/mutex/mysys/THR_LOCK_malloc  | 339390     |
| 89       | wait/synch/mutex/mysys/THR_LOCK_malloc  | 377100     |
| 90       | wait/synch/mutex/sql/LOCK_plugin        | 614673     |
| 91       | wait/synch/mutex/sql/LOCK_open          | 659925     |
| 92       | wait/synch/mutex/sql/THD::LOCK_thd_data | 494001     |
| 93       | wait/synch/mutex/mysys/THR_LOCK_malloc  | 222489     |
| 94       | wait/synch/mutex/mysys/THR_LOCK_malloc  | 214947     |
| 95       | wait/synch/mutex/mysys/LOCK_alarm       | 312993     |

As new events are added to a history table, older events are discarded if the table is full.

Summary tables provide aggregated information for all events over time. The tables in this group summarize event data in different ways. To see which instruments have been executed the most times or have taken the most wait time, sort the `events_waits_summary_global_by_event_name` table on the `COUNT_STAR` or `SUM_TIMER_WAIT` column, which correspond to a `COUNT(*)` or `SUM(TIMER_WAIT)` value, respectively, calculated over all events:

```
mysql> SELECT EVENT_NAME, COUNT_STAR
        FROM events_waits_summary_global_by_event_name
        ORDER BY COUNT_STAR DESC LIMIT 10;
```

| EVENT_NAME  | COUNT_STAR |
|---|------------|
| wait/synch/mutex/mysys/THR_LOCK_malloc            | 6419       |
| wait/io/file/sql/FRM                              | 452        |
| wait/synch/mutex/sql/LOCK_plugin                  | 337        |
| wait/synch/mutex/mysys/THR_LOCK_open              | 187        |
| wait/synch/mutex/mysys/LOCK_alarm                 | 147        |
| wait/synch/mutex/sql/THD::LOCK_thd_data           | 115        |
| wait/io/file/myisam/kfile                         | 102        |
| wait/synch/mutex/sql/LOCK_global_system_variables | 89         |
| wait/synch/mutex/mysys/THR_LOCK::mutex            | 89         |
| wait/synch/mutex/sql/LOCK_open                    | 88         |

```
mysql> SELECT EVENT_NAME, SUM_TIMER_WAIT
        FROM events_waits_summary_global_by_event_name
        ORDER BY SUM_TIMER_WAIT DESC LIMIT 10;
```

| EVENT_NAME                             | SUM_TIMER_WAIT |
|--|----------------|
| wait/io/file/sql/MYSQL_LOG             | 1599816582     |
| wait/synch/mutex/mysys/THR_LOCK_malloc | 1530083250     |
| wait/io/file/sql/binlog_index          | 1385291934     |
| wait/io/file/sql/FRM                   | 1292823243     |
| wait/io/file/myisam/kfile              | 411193611      |
| wait/io/file/myisam/dfile              | 322401645      |
| wait/synch/mutex/mysys/LOCK_alarm      | 145126935      |
| wait/io/file/sql/casetest              | 104324715      |
| wait/synch/mutex/sql/LOCK_plugin       | 86027823       |
| wait/io/file/sql/pid                   | 72591750       |

These results show that the `THR_LOCK_malloc` mutex is “hot,” both in terms of how often it is used and amount of time that threads wait attempting to acquire it.

#### Note

The `THR_LOCK_malloc` mutex is used only in debug builds. In production builds it is not hot because it is nonexistent.

Instance tables document what types of objects are instrumented. An instrumented object, when used by the server, produces an event. These tables provide event names and explanatory notes or status information. For example, the `file_instances` table lists instances of instruments for file I/O operations and their associated files:

```
mysql> SELECT * FROM file_instances\G
***** 1. row *****
FILE_NAME: /opt/mysql-log/60500/binlog.000007
EVENT_NAME: wait/io/file/sql/binlog
OPEN_COUNT: 0
***** 2. row *****
FILE_NAME: /opt/mysql/60500/data/mysql/tables_priv.MYI
EVENT_NAME: wait/io/file/myisam/kfile
OPEN_COUNT: 1
***** 3. row *****
```

```
FILE_NAME: /opt/mysql/60500/data/mysql/columns_priv.MYI
EVENT_NAME: wait/io/file/myisam/kfile
OPEN_COUNT: 1
...
```

Setup tables are used to configure and display monitoring characteristics. For example, to see which event timers are selected, query the `setup_timers` tables:

```
mysql> SELECT * FROM setup_timers;
+-----+-----+
| NAME          | TIMER_NAME |
+-----+-----+
| idle          | MICROSECOND |
| wait          | CYCLE      |
| stage         | NANOSECOND |
| statement     | NANOSECOND |
| transaction   | NANOSECOND |
+-----+-----+
```

`setup_instruments` lists the set of instruments for which events can be collected and shows which of them are enabled:

```
mysql> SELECT * FROM setup_instruments;
+-----+-----+-----+-----+
| NAME                                     | ENABLED | TIMED |
+-----+-----+-----+-----+
...
| wait/synch/mutex/sql/LOCK_global_read_lock | YES     | YES   |
| wait/synch/mutex/sql/LOCK_global_system_variables | YES     | YES   |
| wait/synch/mutex/sql/LOCK_lock_db | YES     | YES   |
| wait/synch/mutex/sql/LOCK_manager | YES     | YES   |
...
| wait/synch/rwlock/sql/LOCK_grant | YES     | YES   |
| wait/synch/rwlock/sql/LOGGER::LOCK_logger | YES     | YES   |
| wait/synch/rwlock/sql/LOCK_sys_init_connect | YES     | YES   |
| wait/synch/rwlock/sql/LOCK_sys_init_slave | YES     | YES   |
...
| wait/io/file/sql/binlog | YES     | YES   |
| wait/io/file/sql/binlog_index | YES     | YES   |
| wait/io/file/sql/casetest | YES     | YES   |
| wait/io/file/sql/dbopt | YES     | YES   |
...
```

To understand how to interpret instrument names, see [Section 24.5, “Performance Schema Instrument Naming Conventions”](#).

To control whether events are collected for an instrument, set its `ENABLED` value to `YES` or `NO`. For example:

```
mysql> UPDATE setup_instruments SET ENABLED = 'NO'
      WHERE NAME = 'wait/synch/mutex/sql/LOCK_mysql_create_db';
```

The Performance Schema uses collected events to update tables in the `performance_schema` database, which act as “consumers” of event information. The `setup_consumers` table lists the available consumers and which are enabled:

```
mysql> SELECT * FROM setup_consumers;
+-----+-----+
| NAME                                     | ENABLED |
+-----+-----+
| events_stages_current | NO      |
| events_stages_history | NO      |
| events_stages_history_long | NO      |
| events_statements_current | YES     |
| events_statements_history | YES     |
| events_statements_history_long | NO      |
+-----+-----+
```

|                                  |     |  |
|----------------------------------|-----|--|
| events_transactions_current      | NO  |  |
| events_transactions_history      | NO  |  |
| events_transactions_history_long | NO  |  |
| events_waits_current             | NO  |  |
| events_waits_history             | NO  |  |
| events_waits_history_long        | NO  |  |
| global_instrumentation           | YES |  |
| thread_instrumentation           | YES |  |
| statements_digest                | YES |  |
| +-----+-----+                    |     |  |

To control whether the Performance Schema maintains a consumer as a destination for event information, set its `ENABLED` value.

For more information about the setup tables and how to use them to control event collection, see [Section 24.3.2, “Performance Schema Event Filtering”](#).

There are some miscellaneous tables that do not fall into any of the previous groups. For example, `performance_timers` lists the available event timers and their characteristics. For information about timers, see [Section 24.3.1, “Performance Schema Event Timing”](#).

## 24.2 Performance Schema Build and Startup Configuration

To use the MySQL Performance Schema, these configuration considerations apply:

- The Performance Schema must be configured into MySQL Server at build time to make it available. Performance Schema support is included in binary MySQL distributions. If you are building from source, you must ensure that it is configured into the build as described in [Section 24.2.1, “Performance Schema Build Configuration”](#).
- The Performance Schema must be enabled at server startup to enable event collection to occur. Specific Performance Schema features can be enabled at server startup or at runtime to control which types of event collection occur. See [Section 24.2.2, “Performance Schema Startup Configuration”](#), [Section 24.3, “Performance Schema Runtime Configuration”](#), and [Section 24.3.2, “Performance Schema Event Filtering”](#).

### 24.2.1 Performance Schema Build Configuration

For the Performance Schema to be available, it must be configured into the MySQL server at build time. Binary MySQL distributions provided by Oracle Corporation are configured to support the Performance Schema. If you use a binary MySQL distribution from another provider, check with the provider whether the distribution has been appropriately configured.

As of MySQL 5.7.9, the Performance Schema is mandatory and always compiled in. Before 5.7.9, if you build MySQL from a source distribution, enable the Performance Schema by running `CMake` with the `WITH_PERFSCHEMA_STORAGE_ENGINE=1` option enabled:

```
shell> cmake . -DWITH_PERFSCHEMA_STORAGE_ENGINE=1
```

Configuring MySQL with the `-DWITHOUT_PERFSCHEMA_STORAGE_ENGINE=1` option prevents inclusion of the Performance Schema, so if you want it included, do not use this option.

As of MySQL 5.7.3, it is possible to enable the Performance Schema but exclude certain parts of the instrumentation. For example, to enable the Performance Schema but exclude stage and statement instrumentation, do this:

```
shell> cmake . -DWITH_PERFSCHEMA_STORAGE_ENGINE=1 \
-DDISABLE_PSI_STAGE=1 \
-DDISABLE_PSI_STATEMENT=1
```

For more information, see the descriptions of the `DISABLE_PSI_XXX` `CMake` options in [Section 2.9.4, “MySQL Source-Configuration Options”](#).

If you install MySQL over a previous installation that was configured without the Performance Schema (or with an older version of the Performance Schema that may not have all the current tables), run `mysql_upgrade` after starting the server to ensure that the `performance_schema` database exists with all current tables. Then restart the server. One indication that you need to do this is the presence of messages such as the following in the error log:

```
[ERROR] Native table 'performance_schema'.'events_waits_history'
has the wrong structure
[ERROR] Native table 'performance_schema'.'events_waits_history_long'
has the wrong structure
...
```

To verify whether a server was built with Performance Schema support, check its help output. If the Performance Schema is available, the output will mention several variables with names that begin with `performance_schema`:

```
shell> mysqld --verbose --help
...
--performance_schema
        Enable the performance schema.
--performance_schema_events_waits_history_long_size=#
        Number of rows in events_waits_history_long.
...
```

You can also connect to the server and look for a line that names the `PERFORMANCE_SCHEMA` storage engine in the output from `SHOW ENGINES`:

```
mysql> SHOW ENGINES\G
...
  Engine: PERFORMANCE_SCHEMA
  Support: YES
  Comment: Performance Schema
  Transactions: NO
            XA: NO
  Savepoints: NO
...
```

If the Performance Schema was not configured into the server at build time, no row for `PERFORMANCE_SCHEMA` will appear in the output from `SHOW ENGINES`. You might see `performance_schema` listed in the output from `SHOW DATABASES`, but it will have no tables and you will not be able to use it.

A line for `PERFORMANCE_SCHEMA` in the `SHOW ENGINES` output means that the Performance Schema is available, not that it is enabled. To enable it, you must do so at server startup, as described in the next section.

## 24.2.2 Performance Schema Startup Configuration

Assuming that the Performance Schema is available, it is enabled by default. To enable or disable it explicitly, start the server with the `performance_schema` variable set to an appropriate value. For example, use these lines in your `my.cnf` file:

```
[mysqld]
performance_schema=ON
```

If the server is unable to allocate any internal buffer during Performance Schema initialization, the Performance Schema disables itself and sets `performance_schema` to `OFF`, and the server runs without instrumentation.

The Performance Schema also permits instrument and consumer configuration at server startup.

To control an instrument at server startup, use an option of this form:

```
--performance-schema-instrument='instrument_name=value'
```

Here, *instrument\_name* is an instrument name such as `wait/synch/mutex/sql/LOCK_open`, and *value* is one of these values:

- `OFF`, `FALSE`, or `0`: Disable the instrument
- `ON`, `TRUE`, or `1`: Enable and time the instrument
- `COUNTED`: Enable and count (rather than time) the instrument

Each `--performance-schema-instrument` option can specify only one instrument name, but multiple instances of the option can be given to configure multiple instruments. In addition, patterns are permitted in instrument names to configure instruments that match the pattern. To configure all condition synchronization instruments as enabled and counted, use this option:

```
--performance-schema-instrument='wait/synch/cond/%=COUNTED'
```

To disable all instruments, use this option:

```
--performance-schema-instrument='%=OFF'
```

Exception: The `memory/performance_schema/%` instruments are built in and cannot be disabled at startup.

Longer instrument name strings take precedence over shorter pattern names, regardless of order. For information about specifying patterns to select instruments, see [Section 24.3.9, “Naming Instruments or Consumers for Filtering Operations”](#).

An unrecognized instrument name is ignored. It is possible that a plugin installed later may create the instrument, at which time the name is recognized and configured.

To control a consumer at server startup, use an option of this form:

```
--performance-schema-consumer-consumer_name=value
```

Here, *consumer\_name* is a consumer name such as `events_waits_history`, and *value* is one of these values:

- `OFF`, `FALSE`, or `0`: Do not collect events for the consumer
- `ON`, `TRUE`, or `1`: Collect events for the consumer

For example, to enable the `events_waits_history` consumer, use this option:

```
--performance-schema-consumer-events-waits-history=ON
```

The permitted consumer names can be found by examining the `setup_consumers` table. Patterns are not permitted. Consumer names in the `setup_consumers` table use underscores, but for consumers set at startup, dashes and underscores within the name are equivalent.

The Performance Schema includes several system variables that provide configuration information:

```
mysql> SHOW VARIABLES LIKE 'perf%';
```

| Variable_name                                      | Value |
|--|-------|
| performance_schema                                 | ON    |
| performance_schema_accounts_size                   | 100   |
| performance_schema_digests_size                    | 200   |
| performance_schema_events_stages_history_long_size | 10000 |
| performance_schema_events_stages_history_size      | 10    |

|  |       |  |
|--|-------|--|
| performance_schema_events_statements_history_long_size | 10000 |  |
| performance_schema_events_statements_history_size      | 10    |  |
| performance_schema_events_waits_history_long_size      | 10000 |  |
| performance_schema_events_waits_history_size           | 10    |  |
| performance_schema_hosts_size                          | 100   |  |
| performance_schema_max_cond_classes                    | 80    |  |
| performance_schema_max_cond_instances                  | 1000  |  |
| ...  |       |  |

The `performance_schema` variable is `ON` or `OFF` to indicate whether the Performance Schema is enabled or disabled. The other variables indicate table sizes (number of rows) or memory allocation values.

#### Note

With the Performance Schema enabled, the number of Performance Schema instances affects the server memory footprint, perhaps to a large extent. Before MySQL 5.7.6, it may be necessary to tune the values of Performance Schema system variables to find the number of instances that balances insufficient instrumentation against excessive memory consumption. As of MySQL 5.7.6, the Performance Schema autoscales many parameters to use memory only as required; see [Section 24.15, “The Performance Schema Memory-Allocation Model”](#).

To change the value of Performance Schema system variables, set them at server startup. For example, put the following lines in a `my.cnf` file to change the sizes of the history tables for wait events:

```
[mysqld]
performance_schema
performance_schema_events_waits_history_size=20
performance_schema_events_waits_history_long_size=15000
```

The Performance Schema automatically sizes the values of several of its parameters at server startup if they are not set explicitly. For example, it sizes the parameters that control the sizes of the events waits tables this way. As of MySQL 5.7.6, the Performance Schema allocates memory incrementally, scaling its memory use to actual server load, instead of allocating all the memory it needs during server startup. Consequently, many sizing parameters need not be set at all. To see which parameters are autosized or autoscaled, use `mysqld --verbose --help` and examine the option descriptions, or see [Section 24.13, “Performance Schema System Variables”](#).

For each autosized parameter that is not set at server startup (or is set to `-1`), the Performance Schema determines how to set its value based on the value of the following system values, which are considered as “hints” about how you have configured your MySQL server:

```
max_connections
open_files_limit
table_definition_cache
table_open_cache
```

To override autosizing or autoscaling for a given parameter, set it to a value other than `-1` at startup. In this case, the Performance Schema assigns it the specified value.

At runtime, `SHOW VARIABLES` displays the actual values that autosized parameters were set to. Autoscaled parameters display with a value of `-1`.

If the Performance Schema is disabled, its autosized and autoscaled parameters remain set to `-1` and `SHOW VARIABLES` displays `-1`.

## 24.3 Performance Schema Runtime Configuration

Performance Schema setup tables contain information about monitoring configuration:

```
mysql> SELECT TABLE_NAME FROM INFORMATION_SCHEMA.TABLES
       WHERE TABLE_SCHEMA = 'performance_schema'
       AND TABLE_NAME LIKE 'setup%';
```

| TABLE_NAME        |
|-------------------|
| setup_actors      |
| setup_consumers   |
| setup_instruments |
| setup_objects     |
| setup_timers      |

You can examine the contents of these tables to obtain information about Performance Schema monitoring characteristics. If you have the `UPDATE` privilege, you can change Performance Schema operation by modifying setup tables to affect how monitoring occurs. For additional details about these tables, see [Section 24.10.2, “Performance Schema Setup Tables”](#).

To see which event timers are selected, query the `setup_timers` tables:

```
mysql> SELECT * FROM setup_timers;
```

| NAME        | TIMER_NAME  |
|-------------|-------------|
| idle        | MICROSECOND |
| wait        | CYCLE       |
| stage       | NANOSECOND  |
| statement   | NANOSECOND  |
| transaction | NANOSECOND  |

The `NAME` value indicates the type of instrument to which the timer applies, and `TIMER_NAME` indicates which timer applies to those instruments. The timer applies to instruments where their name begins with a component matching the `NAME` value.

To change the timer, update the `NAME` value. For example, to use the `NANOSECOND` timer for the `wait` timer:

```
mysql> UPDATE setup_timers SET TIMER_NAME = 'NANOSECOND'
       WHERE NAME = 'wait';
mysql> SELECT * FROM setup_timers;
```

| NAME        | TIMER_NAME  |
|-------------|-------------|
| idle        | MICROSECOND |
| wait        | NANOSECOND  |
| stage       | NANOSECOND  |
| statement   | NANOSECOND  |
| transaction | NANOSECOND  |

For discussion of timers, see [Section 24.3.1, “Performance Schema Event Timing”](#).

The `setup_instruments` and `setup_consumers` tables list the instruments for which events can be collected and the types of consumers for which event information actually is collected, respectively. Other setup tables enable further modification of the monitoring configuration. [Section 24.3.2, “Performance Schema Event Filtering”](#), discusses how you can modify these tables to affect event collection.

If there are Performance Schema configuration changes that must be made at runtime using SQL statements and you would like these changes to take effect each time the server starts, put the statements in a file and start the server with the `--init-file=file_name` option. This strategy can also be useful if you have multiple monitoring configurations, each tailored to produce a different kind of monitoring, such as casual server health monitoring, incident investigation, application behavior

troubleshooting, and so forth. Put the statements for each monitoring configuration into their own file and specify the appropriate file as the `--init-file` argument when you start the server.

### 24.3.1 Performance Schema Event Timing

Events are collected by means of instrumentation added to the server source code. Instruments time events, which is how the Performance Schema provides an idea of how long events take. It is also possible to configure instruments not to collect timing information. This section discusses the available timers and their characteristics, and how timing values are represented in events.

#### Performance Schema Timers

Two Performance Schema tables provide timer information:

- `performance_timers` lists the available timers and their characteristics.
- `setup_timers` indicates which timers are used for which instruments.

Each timer row in `setup_timers` must refer to one of the timers listed in `performance_timers`.

Timers vary in precision and amount of overhead. To see what timers are available and their characteristics, check the `performance_timers` table:

```
mysql> SELECT * FROM performance_timers;
```

| TIMER_NAME  | TIMER_FREQUENCY | TIMER_RESOLUTION | TIMER_OVERHEAD |
|-------------|-----------------|------------------|----------------|
| CYCLE       | 2389029850      | 1                | 72             |
| NANOSECOND  | 1000000000      | 1                | 112            |
| MICROSECOND | 1000000         | 1                | 136            |
| MILLISECOND | 1036            | 1                | 168            |
| TICK        | 105             | 1                | 2416           |

The columns have these meanings:

- The `TIMER_NAME` column shows the names of the available timers. `CYCLE` refers to the timer that is based on the CPU (processor) cycle counter. The timers in `setup_timers` that you can use are those that do not have `NULL` in the other columns. If the values associated with a given timer name are `NULL`, that timer is not supported on your platform.
- `TIMER_FREQUENCY` indicates the number of timer units per second. For a cycle timer, the frequency is generally related to the CPU speed. The value shown was obtained on a system with a 2.4GHz processor. The other timers are based on fixed fractions of seconds. For `TICK`, the frequency may vary by platform (for example, some use 100 ticks/second, others 1000 ticks/second).
- `TIMER_RESOLUTION` indicates the number of timer units by which timer values increase at a time. If a timer has a resolution of 10, its value increases by 10 each time.
- `TIMER_OVERHEAD` is the minimal number of cycles of overhead to obtain one timing with the given timer. The overhead per event is twice the value displayed because the timer is invoked at the beginning and end of the event.

To see which timers are in effect or to change timers, access the `setup_timers` table:

```
mysql> SELECT * FROM setup_timers;
```

| NAME  | TIMER_NAME  |
|-------|-------------|
| idle  | MICROSECOND |
| wait  | CYCLE       |
| stage | NANOSECOND  |

```

| statement | NANOSECOND |
| transaction | NANOSECOND |
+-----+-----+

mysql> UPDATE setup_timers SET TIMER_NAME = 'MICROSECOND'
      WHERE NAME = 'idle';
mysql> SELECT * FROM setup_timers;
+-----+-----+
| NAME      | TIMER_NAME |
+-----+-----+
| idle      | MICROSECOND |
| wait      | CYCLE      |
| stage     | NANOSECOND |
| statement | NANOSECOND |
| transaction | NANOSECOND |
+-----+-----+

```

By default, the Performance Schema uses the best timer available for each instrument type, but you can select a different one.

To time wait events, the most important criterion is to reduce overhead, at the possible expense of the timer accuracy, so using the [CYCLE](#) timer is the best.

The time a statement (or stage) takes to execute is in general orders of magnitude larger than the time it takes to execute a single wait. To time statements, the most important criterion is to have an accurate measure, which is not affected by changes in processor frequency, so using a timer which is not based on cycles is the best. The default timer for statements is [NANOSECOND](#). The extra “overhead” compared to the [CYCLE](#) timer is not significant, because the overhead caused by calling a timer twice (once when the statement starts, once when it ends) is orders of magnitude less compared to the CPU time used to execute the statement itself. Using the [CYCLE](#) timer has no benefit here, only drawbacks.

The precision offered by the cycle counter depends on processor speed. If the processor runs at 1 GHz (one billion cycles/second) or higher, the cycle counter delivers sub-nanosecond precision. Using the cycle counter is much cheaper than getting the actual time of day. For example, the standard [gettimeofday\(\)](#) function can take hundreds of cycles, which is an unacceptable overhead for data gathering that may occur thousands or millions of times per second.

Cycle counters also have disadvantages:

- End users expect to see timings in wall-clock units, such as fractions of a second. Converting from cycles to fractions of seconds can be expensive. For this reason, the conversion is a quick and fairly rough multiplication operation.
- Processor cycle rate might change, such as when a laptop goes into power-saving mode or when a CPU slows down to reduce heat generation. If a processor's cycle rate fluctuates, conversion from cycles to real-time units is subject to error.
- Cycle counters might be unreliable or unavailable depending on the processor or the operating system. For example, on Pentiums, the instruction is [RDTSC](#) (an assembly-language rather than a C instruction) and it is theoretically possible for the operating system to prevent user-mode programs from using it.
- Some processor details related to out-of-order execution or multiprocessor synchronization might cause the counter to seem fast or slow by up to 1000 cycles.

MySQL works with cycle counters on x386 (Windows, OS X, Linux, Solaris, and other Unix flavors), PowerPC, and IA-64.

## Performance Schema Timer Representation in Events

Rows in Performance Schema tables that store current events and historical events have three columns to represent timing information: [TIMER\\_START](#) and [TIMER\\_END](#) indicate when an event started and finished, and [TIMER\\_WAIT](#) indicates event duration.

The `setup_instruments` table has an `ENABLED` column to indicate the instruments for which to collect events. The table also has a `TIMED` column to indicate which instruments are timed. If an instrument is not enabled, it produces no events. If an enabled instrument is not timed, events produced by the instrument have `NULL` for the `TIMER_START`, `TIMER_END`, and `TIMER_WAIT` timer values. This in turn causes those values to be ignored when calculating the sum, minimum, maximum, and average time values in summary tables.

Internally, times within events are stored in units given by the timer in effect when event timing begins. For display when events are retrieved from Performance Schema tables, times are shown in picoseconds (trillionths of a second) to normalize them to a standard unit, regardless of which timer is selected.

Modifications to the `setup_timers` table affect monitoring immediately. Events already in progress may use the original timer for the begin time and the new timer for the end time. To avoid unpredictable results after you make timer changes, use `TRUNCATE TABLE` to reset Performance Schema statistics.

The timer baseline (“time zero”) occurs at Performance Schema initialization during server startup. `TIMER_START` and `TIMER_END` values in events represent picoseconds since the baseline. `TIMER_WAIT` values are durations in picoseconds.

Picosecond values in events are approximate. Their accuracy is subject to the usual forms of error associated with conversion from one unit to another. If the `CYCLE` timer is used and the processor rate varies, there might be drift. For these reasons, it is not reasonable to look at the `TIMER_START` value for an event as an accurate measure of time elapsed since server startup. On the other hand, it is reasonable to use `TIMER_START` or `TIMER_WAIT` values in `ORDER BY` clauses to order events by start time or duration.

The choice of picoseconds in events rather than a value such as microseconds has a performance basis. One implementation goal was to show results in a uniform time unit, regardless of the timer. In an ideal world this time unit would look like a wall-clock unit and be reasonably precise; in other words, microseconds. But to convert cycles or nanoseconds to microseconds, it would be necessary to perform a division for every instrumentation. Division is expensive on many platforms. Multiplication is not expensive, so that is what is used. Therefore, the time unit is an integer multiple of the highest possible `TIMER_FREQUENCY` value, using a multiplier large enough to ensure that there is no major precision loss. The result is that the time unit is “picoseconds.” This precision is spurious, but the decision enables overhead to be minimized.

Before MySQL 5.7.8, while a wait, stage, statement, or transaction event is executing, the respective current-event tables display the event with `TIMER_START` populated, but with `TIMER_END` and `TIMER_WAIT` set to `NULL`:

```
events_waits_current
events_stages_current
events_statements_current
events_transactions_current
```

As of MySQL 5.7.8, current-event timing provides more information. To make it possible to determine how long a not-yet-completed event has been running, the timer columns are set as follows:

- `TIMER_START` is populated (unchanged from previous behavior)
- `TIMER_END` is populated with the current timer value
- `TIMER_WAIT` is populated with the time elapsed so far ( $TIMER\_END - TIMER\_START$ )

Events that have not yet completed have an `END_EVENT_ID` value of `NULL`. To assess time elapsed so far for an event, use the `TIMER_WAIT` column. Therefore, to identify events that have not yet completed and have taken longer than *N* picoseconds thus far, monitoring applications can use this expression in queries:

```
WHERE END_EVENT_ID IS NULL AND TIMER_WAIT > N
```

Event identification as just described assumes that the corresponding instruments have [ENABLED](#) and [TIMED](#) set to [YES](#) and that the relevant consumers are enabled.

## 24.3.2 Performance Schema Event Filtering

Events are processed in a producer/consumer fashion:

- Instrumented code is the source for events and produces events to be collected. The [setup\\_instruments](#) table lists the instruments for which events can be collected, whether they are enabled, and (for enabled instruments) whether to collect timing information:

```
mysql> SELECT * FROM setup_instruments;
```

| NAME  | ENABLED | TIMED |
|---|---------|-------|
| ...   |         |       |
| wait/synch/mutex/sql/LOCK_global_read_lock        | YES     | YES   |
| wait/synch/mutex/sql/LOCK_global_system_variables | YES     | YES   |
| wait/synch/mutex/sql/LOCK_lock_db                 | YES     | YES   |
| wait/synch/mutex/sql/LOCK_manager                 | YES     | YES   |
| ...   |         |       |

The [setup\\_instruments](#) table provides the most basic form of control over event production. To further refine event production based on the type of object or thread being monitored, other tables may be used as described in [Section 24.3.3, “Event Pre-Filtering”](#).

- Performance Schema tables are the destinations for events and consume events. The [setup\\_consumers](#) table lists the types of consumers to which event information can be sent and whether they are enabled:

```
mysql> SELECT * FROM setup_consumers;
```

| NAME                             | ENABLED |
|----------------------------------|---------|
| events_stages_current            | NO      |
| events_stages_history            | NO      |
| events_stages_history_long       | NO      |
| events_statements_current        | YES     |
| events_statements_history        | YES     |
| events_statements_history_long   | NO      |
| events_transactions_current      | NO      |
| events_transactions_history      | NO      |
| events_transactions_history_long | NO      |
| events_waits_current             | NO      |
| events_waits_history             | NO      |
| events_waits_history_long        | NO      |
| global_instrumentation           | YES     |
| thread_instrumentation           | YES     |
| statements_digest                | YES     |

Filtering can be done at different stages of performance monitoring:

- Pre-filtering.** This is done by modifying Performance Schema configuration so that only certain types of events are collected from producers, and collected events update only certain consumers. To do this, enable or disable instruments or consumers. Pre-filtering is done by the Performance Schema and has a global effect that applies to all users.

Reasons to use pre-filtering:

- To reduce overhead. Performance Schema overhead should be minimal even with all instruments enabled, but perhaps you want to reduce it further. Or you do not care about timing events and want to disable the timing code to eliminate timing overhead.

- To avoid filling the current-events or history tables with events in which you have no interest. Pre-filtering leaves more “room” in these tables for instances of rows for enabled instrument types. If you enable only file instruments with pre-filtering, no rows are collected for nonfile instruments. With post-filtering, nonfile events are collected, leaving fewer rows for file events.
- To avoid maintaining some kinds of event tables. If you disable a consumer, the server does not spend time maintaining destinations for that consumer. For example, if you do not care about event histories, you can disable the history table consumers to improve performance.
- **Post-filtering.** This involves the use of `WHERE` clauses in queries that select information from Performance Schema tables, to specify which of the available events you want to see. Post-filtering is performed on a per-user basis because individual users select which of the available events are of interest.

Reasons to use post-filtering:

- To avoid making decisions for individual users about which event information is of interest.
- To use the Performance Schema to investigate a performance issue when the restrictions to impose using pre-filtering are not known in advance.

The following sections provide more detail about pre-filtering and provide guidelines for naming instruments or consumers in filtering operations. For information about writing queries to retrieve information (post-filtering), see [Section 24.4, “Performance Schema Queries”](#).

### 24.3.3 Event Pre-Filtering

Pre-filtering is done by the Performance Schema and has a global effect that applies to all users. Pre-filtering can be applied to either the producer or consumer stage of event processing:

- To configure pre-filtering at the producer stage, several tables can be used:
  - `setup_instruments` indicates which instruments are available. An instrument disabled in this table produces no events regardless of the contents of the other production-related setup tables. An instrument enabled in this table is permitted to produce events, subject to the contents of the other tables.
  - `setup_objects` controls whether the Performance Schema monitors particular table and stored program objects.
  - `threads` indicates whether monitoring is enabled for each server thread.
  - `setup_actors` determines the initial monitoring state for new foreground threads.
- To configure pre-filtering at the consumer stage, modify the `setup_consumers` table. This determines the destinations to which events are sent. `setup_consumers` also implicitly affects event production. If a given event will not be sent to any destination (that is, will not be consumed), the Performance Schema does not produce it.

Modifications to any of these tables affect monitoring immediately, with some exceptions:

- Modifications to some instruments in the `setup_instruments` table are effective only at server startup; changing them at runtime has no effect. This affects primarily mutexes, conditions, and rwlocks in the server, although there may be other instruments for which this is true. This restriction is lifted as of MySQL 5.7.12.
- Modifications to the `setup_actors` table affect only foreground threads created subsequent to the modification, not existing threads.

When you change the monitoring configuration, the Performance Schema does not flush the history tables. Events already collected remain in the current-events and history tables until displaced by

newer events. If you disable instruments, you might need to wait a while before events for them are displaced by newer events of interest. Alternatively, use `TRUNCATE TABLE` to empty the history tables.

After making instrumentation changes, you might want to truncate the summary tables. Generally, the effect is to reset the summary columns to 0 or `NULL`, not to remove rows. This enables you to clear collected values and restart aggregation. That might be useful, for example, after you have made a runtime configuration change. Exceptions to this truncation behavior are noted in individual summary table sections.

The following sections describe how to use specific tables to control Performance Schema pre-filtering.

## 24.3.4 Pre-Filtering by Instrument

The `setup_instruments` table lists the available instruments:

```
mysql> SELECT * FROM setup_instruments;
```

| NAME  | ENABLED | TIMED |
|---|---------|-------|
| ...   |         |       |
| wait/synch/mutex/sql/LOCK_global_read_lock        | YES     | YES   |
| wait/synch/mutex/sql/LOCK_global_system_variables | YES     | YES   |
| wait/synch/mutex/sql/LOCK_lock_db                 | YES     | YES   |
| wait/synch/mutex/sql/LOCK_manager                 | YES     | YES   |
| ...   |         |       |
| wait/synch/rwlock/sql/LOCK_grant                  | YES     | YES   |
| wait/synch/rwlock/sql/LOCK_logger                 | YES     | YES   |
| wait/synch/rwlock/sql/LOCK_sys_init_connect       | YES     | YES   |
| wait/synch/rwlock/sql/LOCK_sys_init_slave         | YES     | YES   |
| ...   |         |       |
| wait/io/file/sql/binlog                           | YES     | YES   |
| wait/io/file/sql/binlog_index                     | YES     | YES   |
| wait/io/file/sql/casetest                         | YES     | YES   |
| wait/io/file/sql/dbopt                            | YES     | YES   |
| ...   |         |       |

To control whether an instrument is enabled, set its `ENABLED` column to `YES` or `NO`. To configure whether to collect timing information for an enabled instrument, set its `TIMED` value to `YES` or `NO`. Setting the `TIMED` column affects Performance Schema table contents as described in [Section 24.3.1, “Performance Schema Event Timing”](#).

Modifications to most `setup_instruments` rows affect monitoring immediately. For some instruments, modifications are effective only at server startup; changing them at runtime has no effect. This affects primarily mutexes, conditions, and rwlocks in the server, although there may be other instruments for which this is true.

The `setup_instruments` table provides the most basic form of control over event production. To further refine event production based on the type of object or thread being monitored, other tables may be used as described in [Section 24.3.3, “Event Pre-Filtering”](#).

The following examples demonstrate possible operations on the `setup_instruments` table. These changes, like other pre-filtering operations, affect all users. Some of these queries use the `LIKE` operator and a pattern match instrument names. For additional information about specifying patterns to select instruments, see [Section 24.3.9, “Naming Instruments or Consumers for Filtering Operations”](#).

- Disable all instruments:

```
mysql> UPDATE setup_instruments SET ENABLED = 'NO';
```

Now no events will be collected.

- Disable all file instruments, adding them to the current set of disabled instruments:

```
mysql> UPDATE setup_instruments SET ENABLED = 'NO'
      WHERE NAME LIKE 'wait/io/file/%';
```

- Disable only file instruments, enable all other instruments:

```
mysql> UPDATE setup_instruments
      SET ENABLED = IF(NAME LIKE 'wait/io/file/%', 'NO', 'YES');
```

- Enable all but those instruments in the `mysys` library:

```
mysql> UPDATE setup_instruments
      SET ENABLED = CASE WHEN NAME LIKE '%/mysys/%' THEN 'YES' ELSE 'NO' END;
```

- Disable a specific instrument:

```
mysql> UPDATE setup_instruments SET ENABLED = 'NO'
      WHERE NAME = 'wait/synch/mutex/mysys/TMPDIR_mutex';
```

- To toggle the state of an instrument, “flip” its `ENABLED` value:

```
mysql> UPDATE setup_instruments
      SET ENABLED = IF(ENABLED = 'YES', 'NO', 'YES')
      WHERE NAME = 'wait/synch/mutex/mysys/TMPDIR_mutex';
```

- Disable timing for all events:

```
mysql> UPDATE setup_instruments SET TIMED = 'NO';
```

## 24.3.5 Pre-Filtering by Object

The `setup_objects` table controls whether the Performance Schema monitors particular table and stored program objects. The initial `setup_objects` contents look like this:

```
mysql> SELECT * FROM setup_objects;
```

| OBJECT_TYPE | OBJECT_SCHEMA      | OBJECT_NAME | ENABLED | TIMED |
|-------------|--------------------|-------------|---------|-------|
| EVENT       | mysql              | %           | NO      | NO    |
| EVENT       | performance_schema | %           | NO      | NO    |
| EVENT       | information_schema | %           | NO      | NO    |
| EVENT       | %                  | %           | YES     | YES   |
| FUNCTION    | mysql              | %           | NO      | NO    |
| FUNCTION    | performance_schema | %           | NO      | NO    |
| FUNCTION    | information_schema | %           | NO      | NO    |
| FUNCTION    | %                  | %           | YES     | YES   |
| PROCEDURE   | mysql              | %           | NO      | NO    |
| PROCEDURE   | performance_schema | %           | NO      | NO    |
| PROCEDURE   | information_schema | %           | NO      | NO    |
| PROCEDURE   | %                  | %           | YES     | YES   |
| TABLE       | mysql              | %           | NO      | NO    |
| TABLE       | performance_schema | %           | NO      | NO    |
| TABLE       | information_schema | %           | NO      | NO    |
| TABLE       | %                  | %           | YES     | YES   |
| TRIGGER     | mysql              | %           | NO      | NO    |
| TRIGGER     | performance_schema | %           | NO      | NO    |
| TRIGGER     | information_schema | %           | NO      | NO    |
| TRIGGER     | %                  | %           | YES     | YES   |

Modifications to the `setup_objects` table affect object monitoring immediately.

The `OBJECT_TYPE` column indicates the type of object to which a row applies. `TABLE` filtering affects table I/O events (`wait/io/table/sql/handler` instrument) and table lock events (`wait/lock/table/sql/handler` instrument).

The `OBJECT_SCHEMA` and `OBJECT_NAME` columns should contain a literal schema or object name, or `'%'` to match any name.

The `ENABLED` column indicates whether matching objects are monitored, and `TIMED` indicates whether to collect timing information. Setting the `TIMED` column affects Performance Schema table contents as described in [Section 24.3.1, “Performance Schema Event Timing”](#).

The effect of the default object configuration is to instrument all objects except those in the `mysql`, `INFORMATION_SCHEMA`, and `performance_schema` databases. (Tables in the `INFORMATION_SCHEMA` database are not instrumented regardless of the contents of `setup_objects`; the row for `information_schema.%` simply makes this default explicit.)

When the Performance Schema checks for a match in `setup_objects`, it tries to find more specific matches first. For rows that match a given `OBJECT_TYPE`, the Performance Schema checks rows in this order:

- Rows with `OBJECT_SCHEMA='literal'` and `OBJECT_NAME='literal'`.
- Rows with `OBJECT_SCHEMA='literal'` and `OBJECT_NAME='%'`.
- Rows with `OBJECT_SCHEMA='%'` and `OBJECT_NAME='%'`.

For example, with a table `db1.t1`, the Performance Schema looks in `TABLE` rows for a match for `'db1'` and `'t1'`, then for `'db1'` and `'%'`, then for `'%'` and `'%'`. The order in which matching occurs matters because different matching `setup_objects` rows can have different `ENABLED` and `TIMED` values.

For table-related events, the Performance Schema combines the contents of `setup_objects` with `setup_instruments` to determine whether to enable instruments and whether to time enabled instruments:

- For tables that match a row in `setup_objects`, table instruments produce events only if `ENABLED` is `YES` in both `setup_instruments` and `setup_objects`.
- The `TIMED` values in the two tables are combined, so that timing information is collected only when both values are `YES`.

For stored program objects, the Performance Schema takes the `ENABLED` and `TIMED` columns directly from the `setup_objects` row. There is no combining of values with `setup_instruments`.

Suppose that `setup_objects` contains the following `TABLE` rows that apply to `db1`, `db2`, and `db3`:

| OBJECT_TYPE | OBJECT_SCHEMA | OBJECT_NAME | ENABLED | TIMED |
|-------------|---------------|-------------|---------|-------|
| TABLE       | db1           | t1          | YES     | YES   |
| TABLE       | db1           | t2          | NO      | NO    |
| TABLE       | db2           | %           | YES     | YES   |
| TABLE       | db3           | %           | NO      | NO    |
| TABLE       | %             | %           | YES     | YES   |

If an object-related instrument in `setup_instruments` has an `ENABLED` value of `NO`, events for the object are not monitored. If the `ENABLED` value is `YES`, event monitoring occurs according to the `ENABLED` value in the relevant `setup_objects` row:

- `db1.t1` events are monitored
- `db1.t2` events are not monitored
- `db2.t3` events are monitored
- `db3.t4` events are not monitored

- `db4.t5` events are monitored

Similar logic applies for combining the `TIMED` columns from the `setup_instruments` and `setup_objects` tables to determine whether to collect event timing information.

If a persistent table and a temporary table have the same name, matching against `setup_objects` rows occurs the same way for both. It is not possible to enable monitoring for one table but not the other. However, each table is instrumented separately.

### 24.3.6 Pre-Filtering by Thread

The `threads` table contains a row for each server thread. Each row contains information about a thread and indicates whether monitoring is enabled for it. For the Performance Schema to monitor a thread, these things must be true:

- The `thread_instrumentation` consumer in the `setup_consumers` table must be `YES`.
- The `threads.INSTRUMENTED` column must be `YES`.
- Monitoring occurs only for those thread events produced from instruments that are enabled in the `setup_instruments` table.

The `threads` table also indicates for each server thread whether to perform historical event logging. This includes wait, stage, statement, and transaction events and affects logging to these tables:

```
events_waits_history
events_waits_history_long
events_stages_history
events_stages_history_long
events_statements_history
events_statements_history_long
events_transactions_history
events_transactions_history_long
```

For historical event logging to occur, these things must be true:

- The appropriate history-related consumers in the `setup_consumers` table must be enabled. For example, wait event logging in the `events_waits_history` and `events_waits_history_long` tables requires the corresponding `events_waits_history` and `events_waits_history_long` consumers to be `YES`.
- The `threads.HISTORY` column must be `YES`.
- Logging occurs only for those thread events produced from instruments that are enabled in the `setup_instruments` table.

For foreground threads (resulting from client connections), the initial values of the `INSTRUMENTED` and `HISTORY` columns in `threads` table rows are determined by whether the user account associated with a thread matches any row in the `setup_actors` table. The values come from the `ENABLED` and `HISTORY` columns of the matching `setup_actors` table row.

For background threads, there is no associated user. `INSTRUMENTED` and `HISTORY` are `YES` by default and `setup_actors` is not consulted.

The initial `setup_actors` contents look like this:

```
mysql> SELECT * FROM setup_actors;
+-----+-----+-----+-----+-----+
| HOST | USER | ROLE | ENABLED | HISTORY |
+-----+-----+-----+-----+-----+
| %    | %    | %    | YES     | YES     |
+-----+-----+-----+-----+-----+
```

The `HOST` and `USER` columns should contain a literal host or user name, or `'%'` to match any name.

The `ENABLED` and `HISTORY` columns indicate whether to enable instrumentation and historical event logging for matching threads, subject to the other conditions described previously.

When the Performance Schema checks for a match for each new foreground thread in `setup_actors`, it tries to find more specific matches first, using the `USER` and `HOST` columns (`ROLE` is unused):

- Rows with `USER='literal'` and `HOST='literal'`.
- Rows with `USER='literal'` and `HOST='%'`.
- Rows with `USER='%'` and `HOST='literal'`.
- Rows with `USER='%'` and `HOST='%'`.

The order in which matching occurs matters because different matching `setup_actors` rows can have different `USER` and `HOST` values. This enables instrumenting and historical event logging to be applied selectively per host, user, or account (user and host combination), based on the `ENABLED` and `HISTORY` column values:

- When the best match is a row with `ENABLED=YES`, the `INSTRUMENTED` value for the thread becomes `YES`. When the best match is a row with `HISTORY=YES`, the `HISTORY` value for the thread becomes `YES`.
- When the best match is a row with `ENABLED=NO`, the `INSTRUMENTED` value for the thread becomes `NO`. When the best match is a row with `HISTORY=NO`, the `HISTORY` value for the thread becomes `NO`.
- When no match is found, the `INSTRUMENTED` and `HISTORY` values for the thread become `NO`.

The `ENABLED` and `HISTORY` columns in `setup_actors` rows can be set to `YES` or `NO` independent of one another. This means you can enable instrumentation separately from whether you collect historical events.

Before MySQL 5.7.6, there is no `ENABLED` column. The `INSTRUMENTED` value for the thread becomes `YES` if any row matches, `NO` otherwise.

Before MySQL 5.7.8, there is no `HISTORY` column. The Performance Schema logs historical events either for all threads or no threads, depending on which history consumers are enabled or disabled.

By default, monitoring and historical event collection are enabled for all new foreground threads because the `setup_actors` table initially contains a row with `'%'` for both `HOST` and `USER`. To perform more limited matching such as to enable monitoring only for some foreground threads, you must change this row because it matches any connection, and add rows for more specific `HOST/USER` combinations.

Suppose that you modify `setup_actors` as follows:

```
UPDATE setup_actors SET ENABLED = 'NO', HISTORY = 'NO'
WHERE HOST = '%' AND USER = '%';
INSERT INTO setup_actors (HOST,USER,ROLE,ENABLED,HISTORY)
VALUES('localhost','joe','%','YES','YES');
INSERT INTO setup_actors (HOST,USER,ROLE,ENABLED,HISTORY)
VALUES('hosta.example.com','joe','%','YES','NO');
INSERT INTO setup_actors (HOST,USER,ROLE,ENABLED,HISTORY)
VALUES('%','sam','%','NO','YES');
```

The `UPDATE` statement changes the default match to disable instrumentation and historical event collection. The `INSERT` statements add rows for more specific matches.

Now the Performance Schema determines how to set the `INSTRUMENTED` and `HISTORY` values for new connection threads as follows:

- If `joe` connects from the local host, the connection matches the first inserted row. The `INSTRUMENTED` and `HISTORY` values for the thread become `YES`.

- If `joe` connects from `hosta.example.com`, the connection matches the second inserted row. The `INSTRUMENTED` value for the thread becomes `YES` and the `HISTORY` value becomes `NO`.
- If `joe` connects from any other host, there is no match. The `INSTRUMENTED` and `HISTORY` values for the thread become `NO`.
- If `sam` connects from any host, the connection matches the third inserted row. The `INSTRUMENTED` value for the thread becomes `NO` and the `HISTORY` value becomes `YES`.
- For any other connection, the row with `HOST` and `USER` set to `'%'` matches. This row now has `ENABLED` and `HISTORY` set to `NO`, so the `INSTRUMENTED` and `HISTORY` values for the thread become `NO`.

Modifications to the `setup_actors` table affect only foreground threads created subsequent to the modification, not existing threads. To affect existing threads, modify the `INSTRUMENTED` and `HISTORY` columns of `threads` table rows.

## 24.3.7 Pre-Filtering by Consumer

The `setup_consumers` table lists the available consumer types and which are enabled:

```
mysql> SELECT * FROM setup_consumers;
```

| NAME                             | ENABLED |
|----------------------------------|---------|
| events_stages_current            | NO      |
| events_stages_history            | NO      |
| events_stages_history_long       | NO      |
| events_statements_current        | YES     |
| events_statements_history        | YES     |
| events_statements_history_long   | NO      |
| events_transactions_current      | NO      |
| events_transactions_history      | NO      |
| events_transactions_history_long | NO      |
| events_waits_current             | NO      |
| events_waits_history             | NO      |
| events_waits_history_long        | NO      |
| global_instrumentation           | YES     |
| thread_instrumentation           | YES     |
| statements_digest                | YES     |

Modify the `setup_consumers` table to affect pre-filtering at the consumer stage and determine the destinations to which events are sent. To enable or disable a consumer, set its `ENABLED` value to `YES` or `NO`.

Modifications to the `setup_consumers` table affect monitoring immediately.

If you disable a consumer, the server does not spend time maintaining destinations for that consumer. For example, if you do not care about historical event information, disable the history consumers:

```
mysql> UPDATE setup_consumers
      SET ENABLED = 'NO' WHERE NAME LIKE '%history%';
```

The consumer settings in the `setup_consumers` table form a hierarchy from higher levels to lower. The following principles apply:

- Destinations associated with a consumer receive no events unless the Performance Schema checks the consumer and the consumer is enabled.
- A consumer is checked only if all consumers it depends on (if any) are enabled.
- If a consumer is not checked, or is checked but is disabled, other consumers that depend on it are not checked.

- Dependent consumers may have their own dependent consumers.
- If an event would not be sent to any destination, the Performance Schema does not produce it.

The following lists describe the available consumer values. For discussion of several representative consumer configurations and their effect on instrumentation, see [Section 24.3.8, “Example Consumer Configurations”](#).

### Global and Thread Consumers

- `global_instrumentation` is the highest level consumer. If `global_instrumentation` is `NO`, it disables global instrumentation. All other settings are lower level and are not checked; it does not matter what they are set to. No global or per thread information is maintained and no individual events are collected in the current-events or event-history tables. If `global_instrumentation` is `YES`, the Performance Schema maintains information for global states and also checks the `thread_instrumentation` consumer.
- `thread_instrumentation` is checked only if `global_instrumentation` is `YES`. Otherwise, if `thread_instrumentation` is `NO`, it disables thread-specific instrumentation and all lower-level settings are ignored. No information is maintained per thread and no individual events are collected in the current-events or event-history tables. If `thread_instrumentation` is `YES`, the Performance Schema maintains thread-specific information and also checks `events_xxx_current` consumers.

### Wait Event Consumers

These consumers require both `global_instrumentation` and `thread_instrumentation` to be `YES` or they are not checked. If checked, they act as follows:

- `events_waits_current`, if `NO`, disables collection of individual wait events in the `events_waits_current` table. If `YES`, it enables wait event collection and the Performance Schema checks the `events_waits_history` and `events_waits_history_long` consumers.
- `events_waits_history` is not checked if `event_waits_current` is `NO`. Otherwise, an `events_waits_history` value of `NO` or `YES` disables or enables collection of wait events in the `events_waits_history` table.
- `events_waits_history_long` is not checked if `event_waits_current` is `NO`. Otherwise, an `events_waits_history_long` value of `NO` or `YES` disables or enables collection of wait events in the `events_waits_history_long` table.

### Stage Event Consumers

These consumers require both `global_instrumentation` and `thread_instrumentation` to be `YES` or they are not checked. If checked, they act as follows:

- `events_stages_current`, if `NO`, disables collection of individual stage events in the `events_stages_current` table. If `YES`, it enables stage event collection and the Performance Schema checks the `events_stages_history` and `events_stages_history_long` consumers.
- `events_stages_history` is not checked if `event_stages_current` is `NO`. Otherwise, an `events_stages_history` value of `NO` or `YES` disables or enables collection of stage events in the `events_stages_history` table.
- `events_stages_history_long` is not checked if `event_stages_current` is `NO`. Otherwise, an `events_stages_history_long` value of `NO` or `YES` disables or enables collection of stage events in the `events_stages_history_long` table.

### Statement Event Consumers

These consumers require both `global_instrumentation` and `thread_instrumentation` to be `YES` or they are not checked. If checked, they act as follows:

- `events_statements_current`, if `NO`, disables collection of individual statement events in the `events_statements_current` table. If `YES`, it enables statement event collection and the Performance Schema checks the `events_statements_history` and `events_statements_history_long` consumers.
- `events_statements_history` is not checked if `events_statements_current` is `NO`. Otherwise, an `events_statements_history` value of `NO` or `YES` disables or enables collection of statement events in the `events_statements_history` table.
- `events_statements_history_long` is not checked if `events_statements_current` is `NO`. Otherwise, an `events_statements_history_long` value of `NO` or `YES` disables or enables collection of statement events in the `events_statements_history_long` table.

### Transaction Event Consumers

These consumers require both `global_instrumentation` and `thread_instrumentation` to be `YES` or they are not checked. If checked, they act as follows:

- `events_transactions_current`, if `NO`, disables collection of individual transaction events in the `events_transactions_current` table. If `YES`, it enables transaction event collection and the Performance Schema checks the `events_transactions_history` and `events_transactions_history_long` consumers.
- `events_transactions_history` is not checked if `events_transactions_current` is `NO`. Otherwise, an `events_transactions_history` value of `NO` or `YES` disables or enables collection of transaction events in the `events_transactions_history` table.
- `events_transactions_history_long` is not checked if `events_transactions_current` is `NO`. Otherwise, an `events_transactions_history_long` value of `NO` or `YES` disables or enables collection of transaction events in the `events_transactions_history_long` table.

### Statement Digest Consumer

This consumer requires `global_instrumentation` to be `YES` or it is not checked. There is no dependency on the statement event consumers, so you can obtain statistics per digest without having to collect statistics in `events_statements_current`, which is advantageous in terms of overhead. Conversely, you can get detailed statements in `events_statements_current` without digests (the `DIGEST` and `DIGEST_TEXT` columns will be `NULL`).

## 24.3.8 Example Consumer Configurations

The consumer settings in the `setup_consumers` table form a hierarchy from higher levels to lower. The following discussion describes how consumers work, showing specific configurations and their effects as consumer settings are enabled progressively from high to low. The consumer values shown are representative. The general principles described here apply to other consumer values that may be available.

The configuration descriptions occur in order of increasing functionality and overhead. If you do not need the information provided by enabling lower-level settings, disable them and the Performance Schema will execute less code on your behalf and you will have less information to sift through.

The `setup_consumers` table contains the following hierarchy of values:

```
global_instrumentation
thread_instrumentation
  events_waits_current
  events_waits_history
  events_waits_history_long
events_stages_current
  events_stages_history
  events_stages_history_long
events_statements_current
```

```
events_statements_history
events_statements_history_long
events_transactions_current
events_transactions_history
events_transactions_history_long
statements_digest
```

### Note

In the consumer hierarchy, the consumers for waits, stages, statements, and transactions are all at the same level. This differs from the event nesting hierarchy, for which wait events nest within stage events, which nest within statement events, which nest within transaction events.

If a given consumer setting is **NO**, the Performance Schema disables the instrumentation associated with the consumer and ignores all lower-level settings. If a given setting is **YES**, the Performance Schema enables the instrumentation associated with it and checks the settings at the next lowest level. For a description of the rules for each consumer, see [Section 24.3.7, “Pre-Filtering by Consumer”](#).

For example, if `global_instrumentation` is enabled, `thread_instrumentation` is checked. If `thread_instrumentation` is enabled, the `events_xxx_current` consumers are checked. If of these `events_waits_current` is enabled, `events_waits_history` and `events_waits_history_long` are checked.

Each of the following configuration descriptions indicates which setup elements the Performance Schema checks and which output tables it maintains (that is, for which tables it collects information).

## No Instrumentation

Server configuration state:

```
mysql> SELECT * FROM setup_consumers;
+-----+-----+
| NAME                                | ENABLED |
+-----+-----+
| global_instrumentation              | NO      |
| ...                                |         |
+-----+-----+
```

In this configuration, nothing is instrumented.

Setup elements checked:

- Table `setup_consumers`, consumer `global_instrumentation`

Output tables maintained:

- None

## Global Instrumentation Only

Server configuration state:

```
mysql> SELECT * FROM setup_consumers;
+-----+-----+
| NAME                                | ENABLED |
+-----+-----+
| global_instrumentation              | YES     |
| thread_instrumentation              | NO      |
| ...                                |         |
+-----+-----+
```

In this configuration, instrumentation is maintained only for global states. Per-thread instrumentation is disabled.

Additional setup elements checked, relative to the preceding configuration:

- Table `setup_consumers`, consumer `thread_instrumentation`
- Table `setup_instruments`
- Table `setup_objects`
- Table `setup_timers`

Additional output tables maintained, relative to the preceding configuration:

- `mutex_instances`
- `rwlock_instances`
- `cond_instances`
- `file_instances`
- `users`
- `hosts`
- `accounts`
- `socket_summary_by_event_name`
- `file_summary_by_instance`
- `file_summary_by_event_name`
- `objects_summary_global_by_type`
- `memory_summary_global_by_event_name`
- `table_lock_waits_summary_by_table`
- `table_io_waits_summary_by_index_usage`
- `table_io_waits_summary_by_table`
- `events_waits_summary_by_instance`
- `events_waits_summary_global_by_event_name`
- `events_stages_summary_global_by_event_name`
- `events_statements_summary_global_by_event_name`
- `events_transactions_summary_global_by_event_name`

## Global and Thread Instrumentation Only

Server configuration state:

```
mysql> SELECT * FROM setup_consumers;
+-----+
| NAME                                | ENABLED |
+-----+-----+
| global_instrumentation              | YES     |
| thread_instrumentation              | YES     |
| events_waits_current                | NO      |
| ...                                |         |
| events_stages_current               | NO      |
| ...                                |         |
| events_statements_current           | NO      |
+-----+-----+
```

```

...
| events_transactions_current      | NO      |
...
+-----+-----+

```

In this configuration, instrumentation is maintained globally and per thread. No individual events are collected in the current-events or event-history tables.

Additional setup elements checked, relative to the preceding configuration:

- Table `setup_consumers`, consumers `events_xxx_current`, where `xxx` is `waits`, `stages`, `statements`, `transactions`
- Table `setup_actors`
- Column `threads.instrumented`

Additional output tables maintained, relative to the preceding configuration:

- `events_xxx_summary_by_yyy_by_event_name`, where `xxx` is `waits`, `stages`, `statements`, `transactions`; and `yyy` is `thread`, `user`, `host`, `account`

## Global, Thread, and Current-Event Instrumentation

Server configuration state:

```

mysql> SELECT * FROM setup_consumers;
+-----+-----+
| NAME                                | ENABLED |
+-----+-----+
| global_instrumentation              | YES     |
| thread_instrumentation              | YES     |
| events_waits_current                 | YES     |
| events_waits_history                 | NO      |
| events_waits_history_long            | NO      |
| events_stages_current                | YES     |
| events_stages_history                 | NO      |
| events_stages_history_long           | NO      |
| events_statements_current            | YES     |
| events_statements_history             | YES     |
| events_statements_history_long       | NO      |
| events_transactions_current          | YES     |
| events_transactions_history           | YES     |
| events_transactions_history_long     | NO      |
...
+-----+-----+

```

In this configuration, instrumentation is maintained globally and per thread. Individual events are collected in the current-events table, but not in the event-history tables.

Additional setup elements checked, relative to the preceding configuration:

- Consumers `events_xxx_history`, where `xxx` is `waits`, `stages`, `statements`, `transactions`
- Consumers `events_xxx_history_long`, where `xxx` is `waits`, `stages`, `statements`, `transactions`

Additional output tables maintained, relative to the preceding configuration:

- `events_xxx_current`, where `xxx` is `waits`, `stages`, `statements`, `transactions`

## Global, Thread, Current-Event, and Event-History instrumentation

The preceding configuration collects no event history because the `events_xxx_history` and `events_xxx_history_long` consumers are disabled. Those consumers can be enabled separately or together to collect event history per thread, globally, or both.

This configuration collects event history per thread, but not globally:

```
mysql> SELECT * FROM setup_consumers;
+-----+-----+
| NAME                                     | ENABLED |
+-----+-----+
| global_instrumentation                   | YES     |
| thread_instrumentation                   | YES     |
| events_waits_current                     | YES     |
| events_waits_history                     | YES     |
| events_waits_history_long                 | NO      |
| events_stages_current                     | YES     |
| events_stages_history                     | YES     |
| events_stages_history_long                 | NO      |
| events_statements_current                 | YES     |
| events_statements_history                 | YES     |
| events_statements_history_long             | NO      |
| events_transactions_current               | YES     |
| events_transactions_history               | YES     |
| events_transactions_history_long           | NO      |
| ...                                     |         |
+-----+-----+
```

Event-history tables maintained for this configuration:

- `events_XXX_history`, where `XXX` is `waits`, `stages`, `statements`, `transactions`

This configuration collects event history globally, but not per thread:

```
mysql> SELECT * FROM setup_consumers;
+-----+-----+
| NAME                                     | ENABLED |
+-----+-----+
| global_instrumentation                   | YES     |
| thread_instrumentation                   | YES     |
| events_waits_current                     | YES     |
| events_waits_history                     | NO      |
| events_waits_history_long                 | YES     |
| events_stages_current                     | YES     |
| events_stages_history                     | NO      |
| events_stages_history_long                 | YES     |
| events_statements_current                 | YES     |
| events_statements_history                 | YES     |
| events_statements_history_long             | YES     |
| events_transactions_current               | YES     |
| events_transactions_history               | YES     |
| events_transactions_history_long           | YES     |
| ...                                     |         |
+-----+-----+
```

Event-history tables maintained for this configuration:

- `events_XXX_history_long`, where `XXX` is `waits`, `stages`, `statements`, `transactions`

This configuration collects event history per thread and globally:

```
mysql> SELECT * FROM setup_consumers;
+-----+-----+
| NAME                                     | ENABLED |
+-----+-----+
| global_instrumentation                   | YES     |
| thread_instrumentation                   | YES     |
| events_waits_current                     | YES     |
| events_waits_history                     | YES     |
| events_waits_history_long                 | YES     |
| events_stages_current                     | YES     |
| events_stages_history                     | YES     |
| events_stages_history_long                 | YES     |
| ...                                     |         |
+-----+-----+
```

|                                  |     |  |
|----------------------------------|-----|--|
| events_statements_current        | YES |  |
| events_statements_history        | YES |  |
| events_statements_history_long   | YES |  |
| events_transactions_current      | YES |  |
| events_transactions_history      | YES |  |
| events_transactions_history_long | YES |  |
| ...                              |     |  |
| +-----+-----+                    |     |  |

Event-history tables maintained for this configuration:

- `events_xxx_history`, where `xxx` is `waits`, `stages`, `statements`, `transactions`
- `events_xxx_history_long`, where `xxx` is `waits`, `stages`, `statements`, `transactions`

## 24.3.9 Naming Instruments or Consumers for Filtering Operations

Names given for filtering operations can be as specific or general as required. To indicate a single instrument or consumer, specify its name in full:

```
mysql> UPDATE setup_instruments
        SET ENABLED = 'NO'
        WHERE NAME = 'wait/synch/mutex/myisammrg/MYRG_INFO::mutex';

mysql> UPDATE setup_consumers
        SET ENABLED = 'NO' WHERE NAME = 'events_waits_current';
```

To specify a group of instruments or consumers, use a pattern that matches the group members:

```
mysql> UPDATE setup_instruments
        SET ENABLED = 'NO'
        WHERE NAME LIKE 'wait/synch/mutex/%';

mysql> UPDATE setup_consumers
        SET ENABLED = 'NO' WHERE NAME LIKE '%history%';
```

If you use a pattern, it should be chosen so that it matches all the items of interest and no others. For example, to select all file I/O instruments, it is better to use a pattern that includes the entire instrument name prefix:

```
... WHERE NAME LIKE 'wait/io/file/%';
```

A pattern of `%/file/%` will match other instruments that have a component of `/file/` anywhere in the name. Even less suitable is the pattern `%file%` because it will match instruments with `'file'` anywhere in the name, such as `wait/synch/mutex/sql/LOCK_des_key_file`.

To check which instrument or consumer names a pattern matches, perform a simple test:

```
mysql> SELECT NAME FROM setup_instruments WHERE NAME LIKE 'pattern';

mysql> SELECT NAME FROM setup_consumers WHERE NAME LIKE 'pattern';
```

For information about the types of names that are supported, see [Section 24.5, “Performance Schema Instrument Naming Conventions”](#).

## 24.3.10 Determining What Is Instrumented

It is always possible to determine what instruments the Performance Schema includes by checking the `setup_instruments` table. For example, to see what file-related events are instrumented for the `InnoDB` storage engine, use this query:

```
mysql> SELECT * FROM setup_instruments WHERE NAME LIKE 'wait/io/file/innodb/%';
+-----+-----+
```

| NAME                                 | ENABLED | TIMED |
|--------------------------------------|---------|-------|
| wait/io/file/innodb/innodb_data_file | YES     | YES   |
| wait/io/file/innodb/innodb_log_file  | YES     | YES   |
| wait/io/file/innodb/innodb_temp_file | YES     | YES   |

An exhaustive description of precisely what is instrumented is not given in this documentation, for several reasons:

- What is instrumented is the server code. Changes to this code occur often, which also affects the set of instruments.
- It is not practical to list all the instruments because there are hundreds of them.
- As described earlier, it is possible to find out by querying the `setup_instruments` table. This information is always up to date for your version of MySQL, also includes instrumentation for instrumented plugins you might have installed that are not part of the core server, and can be used by automated tools.

## 24.4 Performance Schema Queries

Pre-filtering limits which event information is collected and is independent of any particular user. By contrast, post-filtering is performed by individual users through the use of queries with appropriate `WHERE` clauses that restrict what event information to select from the events available after pre-filtering has been applied.

In [Section 24.3.3, “Event Pre-Filtering”](#), an example showed how to pre-filter for file instruments. If the event tables contain both file and nonfile information, post-filtering is another way to see information only for file events. Add a `WHERE` clause to queries to restrict event selection appropriately:

```
mysql> SELECT THREAD_ID, NUMBER_OF_BYTES
        FROM events_waits_history
        WHERE EVENT_NAME LIKE 'wait/io/file/%'
        AND NUMBER_OF_BYTES IS NOT NULL;
```

| THREAD_ID | NUMBER_OF_BYTES |
|-----------|-----------------|
| 11        | 66              |
| 11        | 47              |
| 11        | 139             |
| 5         | 24              |
| 5         | 834             |

## 24.5 Performance Schema Instrument Naming Conventions

An instrument name consists of a sequence of components separated by `'/'` characters. Example names:

```
wait/io/file/myisam/log
wait/io/file/mysys/charset
wait/lock/table/sql/handler
wait/synch/cond/mysys/COND_alarm
wait/synch/cond/sql/BINLOG::update_cond
wait/synch/mutex/mysys/BITMAP_mutex
wait/synch/mutex/sql/LOCK_delete
wait/synch/rwlock/sql/Query_cache_query::lock
stage/sql/closing_tables
stage/sql/Sorting_result
statement/com/Execute
statement/com/Query
statement/sql/create_table
statement/sql/lock_tables
```

The instrument name space has a tree-like structure. The components of an instrument name from left to right provide a progression from more general to more specific. The number of components a name has depends on the type of instrument.

The interpretation of a given component in a name depends on the components to the left of it. For example, `myisam` appears in both of the following names, but `myisam` in the first name is related to file I/O, whereas in the second it is related to a synchronization instrument:

```
wait/io/file/myisam/log
wait/synch/cond/myisam/MI_SORT_INFO::cond
```

Instrument names consist of a prefix with a structure defined by the Performance Schema implementation and a suffix defined by the developer implementing the instrument code. The top-level component of an instrument prefix indicates the type of instrument. This component also determines which event timer in the `setup_timers` table applies to the instrument. For the prefix part of instrument names, the top level indicates the type of instrument.

The suffix part of instrument names comes from the code for the instruments themselves. Suffixes may include levels such as these:

- A name for the major component (a server module such as `myisam`, `innodb`, `mysys`, or `sql`) or a plugin name.
- The name of a variable in the code, in the form `XXX` (a global variable) or `CCC::MMM` (a member `MMM` in class `CCC`). Examples: `COND_thread_cache`, `THR_LOCK_myisam`, `BINLOG::LOCK_index`.

### Top-Level Instrument Components

- `idle`: An instrumented idle event. This instrument has no further components.
- `memory`: An instrumented memory event.
- `stage`: An instrumented stage event.
- `statement`: An instrumented statement event.
- `transaction`: An instrumented transaction event. This instrument has no further components.
- `wait`: An instrumented wait event.

### Idle Instrument Components

The `idle` instrument is used for idle events, which The Performance Schema generates as discussed in the description of the `socket_instances.STATE` column in [Section 24.10.3.5, “The socket\\_instances Table”](#).

### Memory Instrument Components

Most memory instrumentation is disabled by default, and can be enabled or disabled dynamically by updating the `ENABLED` column of the relevant instruments in the `setup_instruments` table. Memory instruments have names of the form `memory/code_area/instrument_name` where `code_area` is a value such as `sql` or `myisam`, and `instrument_name` is the instrument detail.

Instruments named with the prefix `memory/performance_schema/` expose how much memory is allocated for internal buffers in the Performance Schema. The `memory/performance_schema/` instruments are built in, always enabled, and cannot be disabled at startup or runtime. The built-in memory instruments are displayed only in the `memory_summary_global_by_event_name` table. For more information, see [Section 24.15, “The Performance Schema Memory-Allocation Model”](#).

### Stage Instrument Components

Stage instruments have names of the form `stage/code_area/stage_name`, where `code_area` is a value such as `sql` or `myisam`, and `stage_name` indicates the stage of statement processing, such

as `Sorting result` or `Sending data`. Stages correspond to the thread states displayed by `SHOW PROCESSLIST` or that are visible in the `INFORMATION_SCHEMA.PROCESSLIST` table.

### Statement Instrument Components

- `statement/abstract/*`: An abstract instrument for statement operations. Abstract instruments are used during the early stages of statement classification before the exact statement type is known, then changed to a more specific statement instrument when the type is known. For a description of this process, see [Section 24.10.6, “Performance Schema Statement Event Tables”](#).
- `statement/com`: An instrumented command operation. These have names corresponding to `COM_xxx` operations (see the `mysql_com.h` header file and `sql/sql_parse.cc`. For example, the `statement/com/Connect` and `statement/com/Init DB` instruments correspond to the `COM_CONNECT` and `COM_INIT_DB` commands.
- `statement/scheduler/event`: A single instrument to track all events executed by the Event Scheduler. This instrument comes into play when a scheduled event begins executing.
- `statement/sp`: An instrumented internal instruction executed by a stored program. For example, the `statement/sp/cfetch` and `statement/sp/freturn` instruments are used cursor fetch and function return instructions.
- `statement/sql`: An instrumented SQL statement operation. For example, the `statement/sql/create_db` and `statement/sql/select` instruments are used for `CREATE DATABASE` and `SELECT` statements.

### Wait Instrument Components

- `wait/io`

An instrumented I/O operation.

- `wait/io/file`

An instrumented file I/O operation. For files, the wait is the time waiting for the file operation to complete (for example, a call to `fwrite()`). Due to caching, the physical file I/O on the disk might not happen within this call.

- `wait/io/socket`

An instrumented socket operation. Socket instruments have names of the form `wait/io/socket/sql/socket_type`. The server has a listening socket for each network protocol that it supports. The instruments associated with listening sockets for TCP/IP or Unix socket file connections have a `socket_type` value of `server_tcpip_socket` or `server_unix_socket`, respectively. When a listening socket detects a connection, the server transfers the connection to a new socket managed by a separate thread. The instrument for the new connection thread has a `socket_type` value of `client_connection`.

- `wait/io/table`

An instrumented table I/O operation. These include row-level accesses to persistent base tables or temporary tables. Operations that affect rows are fetch, insert, update, and delete. For a view, waits are associated with base tables referenced by the view.

Unlike most waits, a table I/O wait can include other waits. For example, table I/O might include file I/O or memory operations. Thus, `events_waits_current` for a table I/O wait usually has two rows. For more information, see [Section 24.7, “Performance Schema Atom and Molecule Events”](#).

Some row operations might cause multiple table I/O waits. For example, an insert might activate a trigger that causes an update.

- `wait/lock`

An instrumented lock operation.

- `wait/lock/table`

An instrumented table lock operation.

- `wait/lock/metadata/sql/mdl`

An instrumented metadata lock operation (disabled by default).

- `wait/synch`

An instrumented synchronization object. For synchronization objects, the `TIMER_WAIT` time includes the amount of time blocked while attempting to acquire a lock on the object, if any.

- `wait/synch/cond`

A condition is used by one thread to signal to other threads that something they were waiting for has happened. If a single thread was waiting for a condition, it can wake up and proceed with its execution. If several threads were waiting, they can all wake up and compete for the resource for which they were waiting.

- `wait/synch/mutex`

A mutual exclusion object used to permit access to a resource (such as a section of executable code) while preventing other threads from accessing the resource.

- `wait/synch/rwlock`

A [read/write lock](#) object used to lock a specific variable for access while preventing its use by other threads. A shared read lock can be acquired simultaneously by multiple threads. An exclusive write lock can be acquired by only one thread at a time.

- `wait/synch/sxlock`

A shared-exclusive (SX) lock is a type of [rwlock](#) lock object that provides write access to a common resource while permitting inconsistent reads by other threads. `sxlocks` were introduced in MySQL 5.7 to optimize concurrency and improve scalability for read-write workloads.

## 24.6 Performance Schema Status Monitoring

There are several status variables associated with the Performance Schema:

```
mysql> SHOW STATUS LIKE 'perf%';
```

| Variable_name                            | Value |
|--|-------|
| Performance_schema_accounts_lost         | 0     |
| Performance_schema_cond_classes_lost     | 0     |
| Performance_schema_cond_instances_lost   | 0     |
| Performance_schema_digest_lost           | 0     |
| Performance_schema_file_classes_lost     | 0     |
| Performance_schema_file_handles_lost     | 0     |
| Performance_schema_file_instances_lost   | 0     |
| Performance_schema_hosts_lost            | 0     |
| Performance_schema_locker_lost           | 0     |
| Performance_schema_memory_classes_lost   | 0     |
| Performance_schema_metadata_lock_lost    | 0     |
| Performance_schema_mutex_classes_lost    | 0     |
| Performance_schema_mutex_instances_lost  | 0     |
| Performance_schema_nested_statement_lost | 0     |
| Performance_schema_program_lost          | 0     |
| Performance_schema_rwlock_classes_lost   | 0     |

|   |   |
|---|---|
| Performance_schema_rwlock_instances_lost      | 0 |
| Performance_schema_session_connect_attrs_lost | 0 |
| Performance_schema_socket_classes_lost        | 0 |
| Performance_schema_socket_instances_lost      | 0 |
| Performance_schema_stage_classes_lost         | 0 |
| Performance_schema_statement_classes_lost     | 0 |
| Performance_schema_table_handles_lost         | 0 |
| Performance_schema_table_instances_lost       | 0 |
| Performance_schema_thread_classes_lost        | 0 |
| Performance_schema_thread_instances_lost      | 0 |
| Performance_schema_users_lost                 | 0 |

The Performance Schema status variables provide information about instrumentation that could not be loaded or created due to memory constraints. Names for these variables have several forms:

- `Performance_schema_xxx_classes_lost` indicates how many instruments of type `xxx` could not be loaded.
- `Performance_schema_xxx_instances_lost` indicates how many instances of object type `xxx` could not be created.
- `Performance_schema_xxx_handles_lost` indicates how many instances of object type `xxx` could not be opened.
- `Performance_schema_locker_lost` indicates how many events are “lost” or not recorded.

For example, if a mutex is instrumented in the server source but the server cannot allocate memory for the instrumentation at runtime, it increments `Performance_schema_mutex_classes_lost`. The mutex still functions as a synchronization object (that is, the server continues to function normally), but performance data for it will not be collected. If the instrument can be allocated, it can be used for initializing instrumented mutex instances. For a singleton mutex such as a global mutex, there will be only one instance. Other mutexes have an instance per connection, or per page in various caches and data buffers, so the number of instances varies over time. Increasing the maximum number of connections or the maximum size of some buffers will increase the maximum number of instances that might be allocated at once. If the server cannot create a given instrumented mutex instance, it increments `Performance_schema_mutex_instances_lost`.

Suppose that the following conditions hold:

- The server was started with the `--performance_schema_max_mutex_classes=200` option and thus has room for 200 mutex instruments.
- 150 mutex instruments have been loaded already.
- The plugin named `plugin_a` contains 40 mutex instruments.
- The plugin named `plugin_b` contains 20 mutex instruments.

The server allocates mutex instruments for the plugins depending on how many they need and how many are available, as illustrated by the following sequence of statements:

```
INSTALL PLUGIN plugin_a
```

The server now has  $150+40 = 190$  mutex instruments.

```
UNINSTALL PLUGIN plugin_a;
```

The server still has 190 instruments. All the historical data generated by the plugin code is still available, but new events for the instruments are not collected.

```
INSTALL PLUGIN plugin_a;
```

The server detects that the 40 instruments are already defined, so no new instruments are created, and previously assigned internal memory buffers are reused. The server still has 190 instruments.

```
INSTALL PLUGIN plugin_b;
```

The server has room for  $200 - 190 = 10$  instruments (in this case, mutex classes), and sees that the plugin contains 20 new instruments. 10 instruments are loaded, and 10 are discarded or “lost.” The `Performance_schema_mutex_classes_lost` indicates the number of instruments (mutex classes) lost:

```
mysql> SHOW STATUS LIKE "perf%mutex_classes_lost";
+-----+-----+
| Variable_name                | Value |
+-----+-----+
| Performance_schema_mutex_classes_lost | 10    |
+-----+-----+
1 row in set (0.10 sec)
```

The instrumentation still works and collects (partial) data for `plugin_b`.

When the server cannot create a mutex instrument, these results occur:

- No row for the instrument is inserted into the `setup_instruments` table.
- `Performance_schema_mutex_classes_lost` increases by 1.
- `Performance_schema_mutex_instances_lost` does not change. (When the mutex instrument is not created, it cannot be used to create instrumented mutex instances later.)

The pattern just described applies to all types of instruments, not just mutexes.

A value of `Performance_schema_mutex_classes_lost` greater than 0 can happen in two cases:

- To save a few bytes of memory, you start the server with `--performance_schema_max_mutex_classes=N`, where *N* is less than the default value. The default value is chosen to be sufficient to load all the plugins provided in the MySQL distribution, but this can be reduced if some plugins are never loaded. For example, you might choose not to load some of the storage engines in the distribution.
- You load a third-party plugin that is instrumented for the Performance Schema but do not allow for the plugin's instrumentation memory requirements when you start the server. Because it comes from a third party, the instrument memory consumption of this engine is not accounted for in the default value chosen for `performance_schema_max_mutex_classes`.

If the server has insufficient resources for the plugin's instruments and you do not explicitly allocate more using `--performance_schema_max_mutex_classes=N`, loading the plugin leads to starvation of instruments.

If the value chosen for `performance_schema_max_mutex_classes` is too small, no error is reported in the error log and there is no failure at runtime. However, the content of the tables in the `performance_schema` database will miss events. The `Performance_schema_mutex_classes_lost` status variable is the only visible sign to indicate that some events were dropped internally due to failure to create instruments.

If an instrument is not lost, it is known to the Performance Schema, and is used when instrumenting instances. For example, `wait/synch/mutex/sql/LOCK_delete` is the name of a mutex instrument in the `setup_instruments` table. This single instrument is used when creating a mutex in the code (in `THD::LOCK_delete`) however many instances of the mutex are needed as the server runs. In this case, `LOCK_delete` is a mutex that is per connection (`THD`), so if a server has 1000 connections, there are 1000 threads, and 1000 instrumented `LOCK_delete` mutex instances (`THD::LOCK_delete`).

If the server does not have room for all these 1000 instrumented mutexes (instances), some mutexes are created with instrumentation, and some are created without instrumentation. If the server can create only 800 instances, 200 instances are lost. The server continues to run, but increments `Performance_schema_mutex_instances_lost` by 200 to indicate that instances could not be created.

A value of `Performance_schema_mutex_instances_lost` greater than 0 can happen when the code initializes more mutexes at runtime than were allocated for `--performance_schema_max_mutex_instances=N`.

The bottom line is that if `SHOW STATUS LIKE 'perf%'` says that nothing was lost (all values are zero), the Performance Schema data is accurate and can be relied upon. If something was lost, the data is incomplete, and the Performance Schema could not record everything given the insufficient amount of memory it was given to use. In this case, the specific `Performance_schema_XXX_lost` variable indicates the problem area.

It might be appropriate in some cases to cause deliberate instrument starvation. For example, if you do not care about performance data for file I/O, you can start the server with all Performance Schema parameters related to file I/O set to 0. No memory will be allocated for file-related classes, instances, or handles, and all file events will be lost.

Use `SHOW ENGINE PERFORMANCE_SCHEMA STATUS` to inspect the internal operation of the Performance Schema code:

```
mysql> SHOW ENGINE PERFORMANCE_SCHEMA STATUS\G
...
***** 3. row *****
  Type: performance_schema
  Name: events_waits_history.size
Status: 76
***** 4. row *****
  Type: performance_schema
  Name: events_waits_history.count
Status: 10000
***** 5. row *****
  Type: performance_schema
  Name: events_waits_history.memory
Status: 760000
...
***** 57. row *****
  Type: performance_schema
  Name: performance_schema.memory
Status: 26459600
...
```

This statement is intended to help the DBA understand the effects that different Performance Schema options have on memory requirements. For a description of the field meanings, see [Section 14.7.5.15, “SHOW ENGINE Syntax”](#).

## 24.7 Performance Schema Atom and Molecule Events

For a table I/O event, there are usually two rows in `events_waits_current`, not one. For example, a row fetch might result in rows like this:

| Row# | EVENT_NAME                | TIMER_START | TIMER_END |
|------|---------------------------|-------------|-----------|
| 1    | wait/io/file/myisam/dfile | 10001       | 10002     |
| 2    | wait/io/table/sql/handler | 10000       | NULL      |

The row fetch causes a file read. In the example, the table I/O fetch event started before the file I/O event but has not finished (its `TIMER_END` value is `NULL`). The file I/O event is “nested” within the table I/O event.

This occurs because, unlike other “atomic” wait events such as for mutexes or file I/O, table I/O events are “molecular” and include (overlap with) other events. In `events_waits_current`, the table I/O event usually has two rows:

- One row for the most recent table I/O wait event
- One row for the most recent wait event of any kind

Usually, but not always, the “of any kind” wait event differs from the table I/O event. As each subsidiary event completes, it disappears from `events_waits_current`. At this point, and until the next subsidiary event begins, the table I/O wait is also the most recent wait of any kind.

## 24.8 Performance Schema Statement Digests

The MySQL server is capable of maintaining statement digest information. The digesting process converts an SQL statement to normalized form and computes a hash value for the result. Normalization permits statements that are similar to be grouped and summarized to expose information about the types of statements the server is executing and how often they occur. This section describes how statement normalizing occurs and how it can be useful.

### Note

Before MySQL 5.7.4, statement digesting was a function of the Performance Schema. As of 5.7.4, digesting occurs at the SQL level regardless of whether the Performance Schema is available, so that other server functions such as query rewrite plugins have access to statement digests.

In the Performance Schema, statement digesting involves these components:

- A `statement_digest` consumer in the `setup_consumers` table controls whether the Performance Schema maintains digest information.
- The statement event tables (`events_statements_current`, `events_statements_history`, and `events_statements_history_long`) have columns that contain digests and the corresponding digest hash values:
  - `DIGEST_TEXT` is the text of the normalized statement digest.
  - `DIGEST` is the digest MD5 hash value.

The maximum space available for digest computation is 1024 bytes by default. This value can be changed at server startup by setting the `performance_schema_max_digest_length` system variable. In MySQL 5.7.6 and 5.7.7, use `max_digest_length` instead. Before 5.7.6, the value cannot be changed.

- The statement event tables also have a `SQL_TEXT` column that contains the original SQL statement. The maximum space available for statement display is 1024 bytes by default. As of MySQL 5.7.6, this value can be changed at server startup by setting the `performance_schema_max_sql_text_length` system variable. Before 5.7.6, the value cannot be changed.
- An `events_statements_summary_by_digest` table provides aggregated statement digest information.

Statement normalization transforms the statement text to a more standardized digest string representation that preserves the general statement structure while removing information not essential to the structure:

- Object identifiers such as database and table names are preserved.
- Literal values are converted to parameter markers. A normalized statement does not retain information such as names, passwords, dates, and so forth.

- Comments are removed and whitespace is adjusted.

Consider these statements:

```
SELECT * FROM orders WHERE customer_id=10 AND quantity>20
SELECT * FROM orders WHERE customer_id = 20 AND quantity > 100
```

To normalize these statements, the Performance Schema replaces data values by ? and adjusts whitespace. Both statements yield the same normalized form and thus are considered “the same”:

```
SELECT * FROM orders WHERE customer_id = ? AND quantity > ?
```

The normalized statement contains less information but is still representative of the original statement. Other similar statements that have different comparison values have the same normalized form.

Now consider these statements:

```
SELECT * FROM customers WHERE customer_id = 1000
SELECT * FROM orders WHERE customer_id = 1000
```

In this case, the statements are not “the same.” The object identifiers differ, so the statements yield different normalized forms:

```
SELECT * FROM customers WHERE customer_id = ?
SELECT * FROM orders WHERE customer_id = ?
```

If normalization produces a statement that exceeds the space available in the digest buffer, the text ends with “...”. Long statements that differ only in the part that occurs following the “...” are considered to be the same. Consider these statements:

```
SELECT * FROM mytable WHERE cola = 10 AND colb = 20
SELECT * FROM mytable WHERE cola = 10 AND colc = 20
```

If the cutoff happens to be right after the [AND](#), both statements have this normalized form:

```
SELECT * FROM mytable WHERE cola = ? AND ...
```

In this case, the difference in the second column name is lost and both statements are considered the same.

For each normalized statement, the Performance Schema computes a hash digest value and stores the statement and its MD5 hash value in the [DIGEST\\_TEXT](#) and [DIGEST](#) columns of the statement event tables ([events\\_statements\\_current](#), [events\\_statements\\_history](#), and [events\\_statements\\_history\\_long](#)). In addition, statement digests are summarized in the [events\\_statements\\_summary\\_by\\_digest](#) table, which aggregates information for statements that have the same [SCHEMA\\_NAME](#) and [DIGEST](#) values. The Performance Schema uses MD5 hash values because they are fast to compute and have a favorable statistical distribution that minimizes collisions.

The statement digest summary table provides a profile of the statements executed by the server. It shows what kinds of statements an application is executing and how often. An application developer can use this information together with other information in the table to assess the application's performance characteristics. For example, table columns that show wait times, lock times, or index use may highlight types of queries that are inefficient. This gives the developer insight into which parts of the application need attention.

The [events\\_statements\\_summary\\_by\\_digest](#) summary table has a fixed size. When it becomes full, statements that have [SCHEMA\\_NAME](#) and [DIGEST](#) values not matching existing values in the table are grouped in a special row with [SCHEMA\\_NAME](#) and [DIGEST](#) set to [NULL](#). This permits all statements to be counted. However, if the special row accounts for a significant percentage of the statements executed, it might be desirable to increase the size of the summary table by setting the

`performance_schema_digests_size` system variable to a larger value at server startup. If no `performance_schema_digests_size` value is given, the Performance Schema estimates the value to use at startup.

The `performance_schema_max_digest_length` system variable determines the maximum number of bytes available in the digest buffer for digest computation. However, the display length of statement digests may be longer than the available buffer size due to internal encoding of statement components such as keywords and literal values. Consequently, values selected from the `DIGEST_TEXT` column of statement event tables may appear to exceed the `performance_schema_max_digest_length` value.

For applications that generate very long statements that differ only at the end, increasing `performance_schema_max_digest_length` enables computation of digests that distinguish statements that would otherwise aggregate to the same digest. Conversely, decreasing `performance_schema_max_digest_length` causes the server to devote less memory to digest storage but increases the likelihood of longer statements aggregating to the same digest. Administrators should keep in mind that larger values result in correspondingly increased memory requirements, particularly for workloads that involve large numbers of simultaneous sessions (`performance_schema_max_digest_length` bytes are allocated per session).

To assess the amount of memory used for SQL statement storage and digest computation, use the `SHOW ENGINE PERFORMANCE_SCHEMA STATUS` statement, or monitor these instruments:

```
mysql> SELECT NAME FROM setup_instruments
      WHERE NAME LIKE '%.sqltext';
+-----+-----+
| NAME                                     |
+-----+-----+
| memory/performance_schema/events_statements_history.sqltext |
| memory/performance_schema/events_statements_current.sqltext |
| memory/performance_schema/events_statements_history_long.sqltext |
+-----+-----+

mysql> SELECT NAME FROM setup_instruments
      WHERE NAME LIKE 'memory/performance_schema/%.tokens';
+-----+-----+
| NAME                                     |
+-----+-----+
| memory/performance_schema/events_statements_history.tokens |
| memory/performance_schema/events_statements_current.tokens |
| memory/performance_schema/events_statements_summary_by_digest.tokens |
| memory/performance_schema/events_statements_history_long.tokens |
+-----+-----+
```

## 24.9 Performance Schema General Table Characteristics

The name of the `performance_schema` database is lowercase, as are the names of tables within it. Queries should specify the names in lowercase.

Many tables in the `performance_schema` database are read only and cannot be modified:

```
mysql> TRUNCATE TABLE setup_instruments;
ERROR 1683 (HY000): Invalid performance_schema usage.
```

Some of the setup tables have columns that can be modified to affect Performance Schema operation; some also permit rows to be inserted or deleted. Truncation is permitted to clear collected events, so `TRUNCATE TABLE` can be used on tables containing those kinds of information, such as tables named with a prefix of `events_waits_`.

Summary tables can be truncated with `TRUNCATE TABLE`. Generally, the effect is to reset the summary columns to 0 or `NULL`, not to remove rows. This enables you to clear collected values and restart aggregation. That might be useful, for example, after you have made a runtime configuration change. Exceptions to this truncation behavior are noted in individual summary table sections.

Privileges are as for other databases and tables:

- To retrieve from `performance_schema` tables, you must have the `SELECT` privilege.
- To change those columns that can be modified, you must have the `UPDATE` privilege.
- To truncate tables that can be truncated, you must have the `DROP` privilege.

Because only a limited set of privileges apply to Performance Schema tables, attempts to use `GRANT ALL` as shorthand for granting privileges at the database or table level fail with an error:

```
mysql> GRANT ALL ON performance_schema.*
      TO 'u1'@'localhost';
ERROR 1044 (42000): Access denied for user 'root'@'localhost'
to database 'performance_schema'
mysql> GRANT ALL ON performance_schema.setup_instruments
      TO 'u2'@'localhost';
ERROR 1044 (42000): Access denied for user 'root'@'localhost'
to database 'performance_schema'
```

Instead, grant exactly the desired privileges:

```
mysql> GRANT SELECT ON performance_schema.*
      TO 'u1'@'localhost';
Query OK, 0 rows affected (0.03 sec)

mysql> GRANT SELECT, UPDATE ON performance_schema.setup_instruments
      TO 'u2'@'localhost';
Query OK, 0 rows affected (0.02 sec)
```

## 24.10 Performance Schema Table Descriptions

Tables in the `performance_schema` database can be grouped as follows:

- Setup tables. These tables are used to configure and display monitoring characteristics.
- Current events tables. The `events_waits_current` table contains the most recent event for each thread. Other similar tables contain current events at different levels of the event hierarchy: `events_stages_current` for stage events, `events_statements_current` for statement events, and `events_transactions_current` for transaction events.
- History tables. These tables have the same structure as the current events tables, but contain more rows. For example, for wait events, `events_waits_history` table contains the most recent 10 events per thread. `events_waits_history_long` contains the most recent 10,000 events. Other similar tables exist for stage, statement, and transaction histories.

To change the sizes of the history tables, set the appropriate system variables at server startup. For example, to set the sizes of the wait event history tables, set `performance_schema_events_waits_history_size` and `performance_schema_events_waits_history_long_size`.

- Summary tables. These tables contain information aggregated over groups of events, including those that have been discarded from the history tables.
- Instance tables. These tables document what types of objects are instrumented. An instrumented object, when used by the server, produces an event. These tables provide event names and explanatory notes or status information.
- Miscellaneous tables. These do not fall into any of the other table groups.

### 24.10.1 Performance Schema Table Index

The following table lists each Performance Schema table and provides a short description of each one.

**Table 24.1 Performance Schema Tables**

| Table Name   | Description                                     |
|--|---|
| <a href="#">accounts</a>   | Connection statistics per client account        |
| <a href="#">cond_instances</a>                                       | synchronization object instances                |
| <a href="#">events_stages_current</a>                                | Current stage events                            |
| <a href="#">events_stages_history</a>                                | Most recent stage events for each thread        |
| <a href="#">events_stages_history_long</a>                           | Most recent stage events overall                |
| <a href="#">events_stages_summary_by_account_by_event_name</a>       | Stage events per account and event name         |
| <a href="#">events_stages_summary_by_host_by_event_name</a>          | Stage events per host name and event name       |
| <a href="#">events_stages_summary_by_thread_by_event_name</a>        | Stage waits per thread and event name           |
| <a href="#">events_stages_summary_by_user_by_event_name</a>          | Stage events per user name and event name       |
| <a href="#">events_stages_summary_global_by_event_name</a>           | Stage waits per event name                      |
| <a href="#">events_statements_current</a>                            | Current statement events                        |
| <a href="#">events_statements_history</a>                            | Most recent statement events for each thread    |
| <a href="#">events_statements_history_long</a>                       | Most recent statement events overall            |
| <a href="#">events_statements_summary_by_account_by_event_name</a>   | Statement events per account and event name     |
| <a href="#">events_statements_summary_by_digest</a>                  | Statement events per schema and digest value    |
| <a href="#">events_statements_summary_by_host_by_event_name</a>      | Statement events per host name and event name   |
| <a href="#">events_statements_summary_by_program</a>                 | Statement events per stored program             |
| <a href="#">events_statements_summary_by_thread_by_event_name</a>    | Statement events per thread and event name      |
| <a href="#">events_statements_summary_by_user_by_event_name</a>      | Statement events per user name and event name   |
| <a href="#">events_statements_summary_global_by_event_name</a>       | Statement events per event name                 |
| <a href="#">events_transactions_current</a>                          | Current transaction events                      |
| <a href="#">events_transactions_history</a>                          | Most recent transaction events for each thread  |
| <a href="#">events_transactions_history_long</a>                     | Most recent transaction events overall          |
| <a href="#">events_transactions_summary_by_account_by_event_name</a> | Transaction events per account and event name   |
| <a href="#">events_transactions_summary_by_host_by_event_name</a>    | Transaction events per host name and event name |
| <a href="#">events_transactions_summary_by_thread_by_event_name</a>  | Transaction events per thread and event name    |
| <a href="#">events_transactions_summary_by_user_by_event_name</a>    | Transaction events per user name and event name |
| <a href="#">events_transactions_summary_global_by_event_name</a>     | Transaction events per event name               |
| <a href="#">events_waits_current</a>                                 | Current wait events                             |
| <a href="#">events_waits_history</a>                                 | Most recent wait events for each thread         |
| <a href="#">events_waits_history_long</a>                            | Most recent wait events overall                 |
| <a href="#">events_waits_summary_by_account_by_event_name</a>        | Wait events per account and event name          |
| <a href="#">events_waits_summary_by_host_by_event_name</a>           | Wait events per host name and event name        |

| Table Name   | Description   |
|--|---|
| <a href="#">events_waits_summary_by_instance</a>             | Wait events per instance  |
| <a href="#">events_waits_summary_by_thread_by_event_name</a> | Wait events per thread and event name                               |
| <a href="#">events_waits_summary_by_user_by_event_name</a>   | Wait events per user name and event name                            |
| <a href="#">events_waits_summary_global_by_event_name</a>    | Wait events per event name  |
| <a href="#">file_instances</a>                               | File instances  |
| <a href="#">file_summary_by_event_name</a>                   | File events per event name  |
| <a href="#">file_summary_by_instance</a>                     | File events per file instance                                       |
| <a href="#">global_status</a>                                | Global status variables   |
| <a href="#">global_variables</a>                             | Global system variables   |
| <a href="#">host_cache</a>                                   | Information from the internal host cache                            |
| <a href="#">hosts</a>  | Connection statistics per client host name                          |
| <a href="#">memory_summary_by_account_by_event_name</a>      | Memory operations per account and event name                        |
| <a href="#">memory_summary_by_host_by_event_name</a>         | Memory operations per host and event name                           |
| <a href="#">memory_summary_by_thread_by_event_name</a>       | Memory operations per thread and event name                         |
| <a href="#">memory_summary_by_user_by_event_name</a>         | Memory operations per user and event name                           |
| <a href="#">memory_summary_global_by_event_name</a>          | Memory operations globally per event name                           |
| <a href="#">metadata_locks</a>                               | Metadata locks and lock requests                                    |
| <a href="#">mutex_instances</a>                              | Mutex synchronization object instances                              |
| <a href="#">objects_summary_global_by_type</a>               | Object summaries  |
| <a href="#">performance_timers</a>                           | Which event timers are available                                    |
| <a href="#">prepared_statements_instances</a>                | Prepared statement instances and statistics                         |
| <a href="#">replication_applier_configuration</a>            | Configuration parameters for the transaction applier on the slave   |
| <a href="#">replication_applier_status</a>                   | Current status of the transaction applier on the slave              |
| <a href="#">replication_applier_status_by_coordinator</a>    | SQL or coordinator thread applier status                            |
| <a href="#">replication_applier_status_by_worker</a>         | Worker thread applier status (empty unless slave is multi-threaded) |
| <a href="#">replication_connection_configuration</a>         | Configuration parameters for connecting to the master               |
| <a href="#">replication_connection_status</a>                | Current status of the connection to the master                      |
| <a href="#">rwlock_instances</a>                             | Lock synchronization object instances                               |
| <a href="#">session_account_connect_attrs</a>                | Connection attributes per for the current session                   |
| <a href="#">session_connect_attrs</a>                        | Connection attributes for all sessions                              |
| <a href="#">session_status</a>                               | Status variables for current session                                |
| <a href="#">session_variables</a>                            | System variables for current session                                |
| <a href="#">setup_actors</a>                                 | How to initialize monitoring for new foreground threads             |
| <a href="#">setup_consumers</a>                              | Consumers for which event information can be stored                 |

| Table Name  | Description   |
|---|---|
| <a href="#">setup_instruments</a>                     | Classes of instrumented objects for which events can be collected |
| <a href="#">setup_objects</a>                         | Which objects should be monitored                                 |
| <a href="#">setup_timers</a>                          | Current event timer   |
| <a href="#">socket_instances</a>                      | Active connection instances                                       |
| <a href="#">socket_summary_by_event_name</a>          | Socket waits and I/O per event name                               |
| <a href="#">socket_summary_by_instance</a>            | Socket waits and I/O per instance                                 |
| <a href="#">status_by_account</a>                     | Session status variables per account                              |
| <a href="#">status_by_host</a>                        | Session status variables per host name                            |
| <a href="#">status_by_thread</a>                      | Session status variables per session                              |
| <a href="#">status_by_user</a>                        | Session status variables per user name                            |
| <a href="#">table_handles</a>                         | Table locks and lock requests                                     |
| <a href="#">table_io_waits_summary_by_index_usage</a> | Table I/O waits per index   |
| <a href="#">table_io_waits_summary_by_table</a>       | Table I/O waits per table   |
| <a href="#">table_lock_waits_summary_by_table</a>     | Table lock waits per table  |
| <a href="#">threads</a>                               | Information about server threads                                  |
| <a href="#">user_variables_by_thread</a>              | User-defined variables per thread                                 |
| <a href="#">users</a>                                 | Connection statistics per client user name                        |
| <a href="#">variables_by_thread</a>                   | Session system variables per session                              |

## 24.10.2 Performance Schema Setup Tables

The setup tables provide information about the current instrumentation and enable the monitoring configuration to be changed. For this reason, some columns in these tables can be changed if you have the [UPDATE](#) privilege.

The use of tables rather than individual variables for setup information provides a high degree of flexibility in modifying Performance Schema configuration. For example, you can use a single statement with standard SQL syntax to make multiple simultaneous configuration changes.

These setup tables are available:

- [setup\\_actors](#): How to initialize monitoring for new foreground threads
- [setup\\_consumers](#): The destinations to which event information can be sent and stored
- [setup\\_instruments](#): The classes of instrumented objects for which events can be collected
- [setup\\_objects](#): Which objects should be monitored
- [setup\\_timers](#): The current event timer

### 24.10.2.1 The [setup\\_actors](#) Table

The [setup\\_actors](#) table contains information that determines whether to enable monitoring and historical event logging for new foreground server threads (threads associated with client connections). This table has a maximum size of 100 rows by default. To change the table size, modify the [performance\\_schema\\_setup\\_actors\\_size](#) system variable at server startup.

For each new foreground thread, the Performance Schema matches the user and host for the thread against the rows of the [setup\\_actors](#) table. If a row from that table matches, its [ENABLED](#) and [HISTORY](#) column values are used to set the [INSTRUMENTED](#) and [HISTORY](#) columns, respectively,

of the `threads` table row for the thread. This enables instrumenting and historical event logging to be applied selectively per host, user, or account (user and host combination). If there is no match, the `INSTRUMENTED` and `HISTORY` columns for the thread are set to `NO`.

For background threads, there is no associated user. `INSTRUMENTED` and `HISTORY` are `YES` by default and `setup_actors` is not consulted.

The initial contents of the `setup_actors` table match any user and host combination, so monitoring and historical event collection are enabled by default for all foreground threads:

```
mysql> SELECT * FROM setup_actors;
+-----+-----+-----+-----+-----+
| HOST | USER | ROLE | ENABLED | HISTORY |
+-----+-----+-----+-----+-----+
| %    | %    | %    | YES     | YES     |
+-----+-----+-----+-----+-----+
```

For information about how to use the `setup_actors` table to affect event monitoring, see [Section 24.3.6, “Pre-Filtering by Thread”](#).

Modifications to the `setup_actors` table affect only foreground threads created subsequent to the modification, not existing threads. To affect existing threads, modify the `INSTRUMENTED` and `HISTORY` columns of `threads` table rows.

The `setup_actors` table has these columns:

- `HOST`

The host name. This should be a literal name, or `' % '` to mean “any host.”

- `USER`

The user name. This should be a literal name, or `' % '` to mean “any user.”

- `ROLE`

Unused.

- `ENABLED`

Whether to enable instrumentation for foreground threads matched by the row. The value is `YES` or `NO`.

This column was added in MySQL 5.7.6. For earlier versions in which it is not present, the Performance Schema enables instrumentation only for foreground threads matched by some row in the table; instrumentation is implicitly disabled for nonmatching threads.

- `HISTORY`

Whether to log historical events for foreground threads matched by the row. The value is `YES` or `NO`.

This column was added in MySQL 5.7.8. For earlier versions in which it is not present, the Performance Schema logs historical events either for all threads or no threads, depending on which history consumers are enabled or disabled.

`TRUNCATE TABLE` is permitted for the `setup_actors` table. It removes the rows.

### 24.10.2.2 The `setup_consumers` Table

The `setup_consumers` table lists the types of consumers for which event information can be stored and which are enabled:

```
mysql> SELECT * FROM setup_consumers;
```

| NAME                             | ENABLED |
|----------------------------------|---------|
| events_stages_current            | NO      |
| events_stages_history            | NO      |
| events_stages_history_long       | NO      |
| events_statements_current        | YES     |
| events_statements_history        | YES     |
| events_statements_history_long   | NO      |
| events_transactions_current      | NO      |
| events_transactions_history      | NO      |
| events_transactions_history_long | NO      |
| events_waits_current             | NO      |
| events_waits_history             | NO      |
| events_waits_history_long        | NO      |
| global_instrumentation           | YES     |
| thread_instrumentation           | YES     |
| statements_digest                | YES     |

The consumer settings in the `setup_consumers` table form a hierarchy from higher levels to lower. For detailed information about the effect of enabling different consumers, see [Section 24.3.7, “Pre-Filtering by Consumer”](#).

Modifications to the `setup_consumers` table affect monitoring immediately.

The `setup_consumers` table has these columns:

- **NAME**

The consumer name.

- **ENABLED**

Whether the consumer is enabled. The value is `YES` or `NO`. This column can be modified. If you disable a consumer, the server does not spend time adding event information to it.

`TRUNCATE TABLE` is not permitted for the `setup_consumers` table.

### 24.10.2.3 The `setup_instruments` Table

The `setup_instruments` table lists classes of instrumented objects for which events can be collected:

```
mysql> SELECT * FROM setup_instruments;
```

| NAME  | ENABLED | TIMED |
|---|---------|-------|
| ...   |         |       |
| wait/synch/mutex/sql/LOCK_global_read_lock        | YES     | YES   |
| wait/synch/mutex/sql/LOCK_global_system_variables | YES     | YES   |
| wait/synch/mutex/sql/LOCK_lock_db                 | YES     | YES   |
| wait/synch/mutex/sql/LOCK_manager                 | YES     | YES   |
| ...   |         |       |
| wait/synch/rwlock/sql/LOCK_grant                  | YES     | YES   |
| wait/synch/rwlock/sql/LOGGER::LOCK_logger         | YES     | YES   |
| wait/synch/rwlock/sql/LOCK_sys_init_connect       | YES     | YES   |
| wait/synch/rwlock/sql/LOCK_sys_init_slave         | YES     | YES   |
| ...   |         |       |
| wait/io/file/sql/binlog                           | YES     | YES   |
| wait/io/file/sql/binlog_index                     | YES     | YES   |
| wait/io/file/sql/casetest                         | YES     | YES   |
| wait/io/file/sql/dbopt                            | YES     | YES   |
| ...   |         |       |

Each instrument added to the source code provides a row for this table, even when the instrumented code is not executed. When an instrument is enabled and executed, instrumented instances are created, which are visible in the `*_instances` tables.

Modifications to most `setup_instruments` rows affect monitoring immediately. For some instruments, modifications are effective only at server startup; changing them at runtime has no effect. This affects primarily mutexes, conditions, and rwlocks in the server, although there may be other instruments for which this is true.

For more information about the role of the `setup_instruments` table in event filtering, see [Section 24.3.3, “Event Pre-Filtering”](#).

The `setup_instruments` table has these columns:

- **NAME**

The instrument name. Instrument names may have multiple parts and form a hierarchy, as discussed in [Section 24.5, “Performance Schema Instrument Naming Conventions”](#). Events produced from execution of an instrument have an `EVENT_NAME` value that is taken from the instrument `NAME` value. (Events do not really have a “name,” but this provides a way to associate events with instruments.)

- **ENABLED**

Whether the instrument is enabled. The value is `YES` or `NO`. This column can be modified. A disabled instrument produces no events.

- **TIMED**

Whether the instrument is timed. This column can be modified.

For memory instruments, the `TIMED` column in `setup_instruments` is ignored because memory operations are not timed.

If an enabled instrument is not timed, the instrument code is enabled, but the timer is not. Events produced by the instrument have `NULL` for the `TIMER_START`, `TIMER_END`, and `TIMER_WAIT` timer values. This in turn causes those values to be ignored when calculating the sum, minimum, maximum, and average time values in summary tables.

`TRUNCATE TABLE` is not permitted for the `setup_instruments` table.

#### 24.10.2.4 The `setup_objects` Table

The `setup_objects` table controls whether the Performance Schema monitors particular objects. This table has a maximum size of 100 rows by default. To change the table size, modify the `performance_schema_setup_objects_size` system variable at server startup.

The initial `setup_objects` contents look like this:

```
mysql> SELECT * FROM setup_objects;
```

| OBJECT_TYPE | OBJECT_SCHEMA      | OBJECT_NAME | ENABLED | TIMED |
|-------------|--------------------|-------------|---------|-------|
| EVENT       | mysql              | %           | NO      | NO    |
| EVENT       | performance_schema | %           | NO      | NO    |
| EVENT       | information_schema | %           | NO      | NO    |
| EVENT       | %                  | %           | YES     | YES   |
| FUNCTION    | mysql              | %           | NO      | NO    |
| FUNCTION    | performance_schema | %           | NO      | NO    |
| FUNCTION    | information_schema | %           | NO      | NO    |
| FUNCTION    | %                  | %           | YES     | YES   |
| PROCEDURE   | mysql              | %           | NO      | NO    |
| PROCEDURE   | performance_schema | %           | NO      | NO    |
| PROCEDURE   | information_schema | %           | NO      | NO    |
| PROCEDURE   | %                  | %           | YES     | YES   |
| TABLE       | mysql              | %           | NO      | NO    |
| TABLE       | performance_schema | %           | NO      | NO    |
| TABLE       | information_schema | %           | NO      | NO    |
| TABLE       | %                  | %           | YES     | YES   |
| TRIGGER     | mysql              | %           | NO      | NO    |

|         |                    |   |     |     |
|---------|--------------------|---|-----|-----|
| TRIGGER | performance_schema | % | NO  | NO  |
| TRIGGER | information_schema | % | NO  | NO  |
| TRIGGER | %                  | % | YES | YES |

Modifications to the `setup_objects` table affect object monitoring immediately.

For object types listed in `setup_objects`, the Performance Schema uses the table to how to monitor them. Object matching is based on the `OBJECT_SCHEMA` and `OBJECT_NAME` columns. Objects for which there is no match are not monitored.

The effect of the default object configuration is to instrument all tables except those in the `mysql`, `INFORMATION_SCHEMA`, and `performance_schema` databases. (Tables in the `INFORMATION_SCHEMA` database are not instrumented regardless of the contents of `setup_objects`; the row for `information_schema.%` simply makes this default explicit.)

When the Performance Schema checks for a match in `setup_objects`, it tries to find more specific matches first. For example, with a table `db1.t1`, it looks for a match for `'db1'` and `'t1'`, then for `'db1'` and `'%'`, then for `'%'` and `'%'`. The order in which matching occurs matters because different matching `setup_objects` rows can have different `ENABLED` and `TIMED` values.

Rows can be inserted into or deleted from `setup_objects` by users with the `INSERT` or `DELETE` privilege on the table. For existing rows, only the `ENABLED` and `TIMED` columns can be modified, by users with the `UPDATE` privilege on the table.

For more information about the role of the `setup_objects` table in event filtering, see [Section 24.3.3, “Event Pre-Filtering”](#).

The `setup_objects` table has these columns:

- `OBJECT_TYPE`

The type of object to instrument. The value is one of `'EVENT'` (Event Scheduler event), `'FUNCTION'` (stored function), `'PROCEDURE'` (stored procedure), `'TABLE'` (base table), or `'TRIGGER'` (trigger). Before MySQL 5.7.2, the value is always `'TABLE'`.

`TABLE` filtering affects table I/O events (`wait/io/table/sql/handler` instrument) and table lock events (`wait/lock/table/sql/handler` instrument).

- `OBJECT_SCHEMA`

The schema that contains the object. This should be a literal name, or `'%'` to mean “any schema.”

- `OBJECT_NAME`

The name of the instrumented object. This should be a literal name, or `'%'` to mean “any object.”

- `ENABLED`

Whether events for the object are instrumented. The value is `YES` or `NO`. This column can be modified.

- `TIMED`

Whether events for the object are timed. This column can be modified.

`TRUNCATE TABLE` is permitted for the `setup_objects` table. It removes the rows.

### 24.10.2.5 The `setup_timers` Table

The `setup_timers` table shows the currently selected event timers:

```
mysql> SELECT * FROM setup_timers;
+-----+
```

| NAME        | TIMER_NAME  |
|-------------|-------------|
| idle        | MICROSECOND |
| wait        | CYCLE       |
| stage       | NANOSECOND  |
| statement   | NANOSECOND  |
| transaction | NANOSECOND  |

The `setup_timers.TIMER_NAME` value can be changed to select a different timer. The value can be any of the values in the `performance_timers.TIMER_NAME` column. For an explanation of how event timing occurs, see [Section 24.3.1, “Performance Schema Event Timing”](#).

Modifications to the `setup_timers` table affect monitoring immediately. Events already in progress may use the original timer for the begin time and the new timer for the end time. To avoid unpredictable results after you make timer changes, use `TRUNCATE TABLE` to reset Performance Schema statistics.

The `setup_timers` table has these columns:

- `NAME`

The type of instrument the timer is used for.

- `TIMER_NAME`

The timer that applies to the instrument type. This column can be modified.

`TRUNCATE TABLE` is not permitted for the `setup_timers` table.

### 24.10.3 Performance Schema Instance Tables

Instance tables document what types of objects are instrumented. They provide event names and explanatory notes or status information:

- `cond_instances`: Condition synchronization object instances
- `file_instances`: File instances
- `mutex_instances`: Mutex synchronization object instances
- `rwlock_instances`: Lock synchronization object instances
- `socket_instances`: Active connection instances

These tables list instrumented synchronization objects, files, and connections. There are three types of synchronization objects: `cond`, `mutex`, and `rwlock`. Each instance table has an `EVENT_NAME` or `NAME` column to indicate the instrument associated with each row. Instrument names may have multiple parts and form a hierarchy, as discussed in [Section 24.5, “Performance Schema Instrument Naming Conventions”](#).

The `mutex_instances.LOCKED_BY_THREAD_ID` and `rwlock_instances.WRITE_LOCKED_BY_THREAD_ID` columns are extremely important for investigating performance bottlenecks or deadlocks. For examples of how to use them for this purpose, see [Section 24.17, “Using the Performance Schema to Diagnose Problems”](#)

#### 24.10.3.1 The `cond_instances` Table

The `cond_instances` table lists all the conditions seen by the Performance Schema while the server executes. A condition is a synchronization mechanism used in the code to signal that a specific event has happened, so that a thread waiting for this condition can resume work.

When a thread is waiting for something to happen, the condition name is an indication of what the thread is waiting for, but there is no immediate way to tell which other thread, or threads, will cause the condition to happen.

The `cond_instances` table has these columns:

- `NAME`

The instrument name associated with the condition.

- `OBJECT_INSTANCE_BEGIN`

The address in memory of the instrumented condition.

`TRUNCATE TABLE` is not permitted for the `cond_instances` table.

### 24.10.3.2 The `file_instances` Table

The `file_instances` table lists all the files seen by the Performance Schema when executing file I/O instrumentation. If a file on disk has never been opened, it will not be in `file_instances`. When a file is deleted from the disk, it is also removed from the `file_instances` table.

The `file_instances` table has these columns:

- `FILE_NAME`

The file name.

- `EVENT_NAME`

The instrument name associated with the file.

- `OPEN_COUNT`

The count of open handles on the file. If a file was opened and then closed, it was opened 1 time, but `OPEN_COUNT` will be 0. To list all the files currently opened by the server, use `WHERE OPEN_COUNT > 0`.

`TRUNCATE TABLE` is not permitted for the `file_instances` table.

### 24.10.3.3 The `mutex_instances` Table

The `mutex_instances` table lists all the mutexes seen by the Performance Schema while the server executes. A mutex is a synchronization mechanism used in the code to enforce that only one thread at a given time can have access to some common resource. The resource is said to be “protected” by the mutex.

When two threads executing in the server (for example, two user sessions executing a query simultaneously) do need to access the same resource (a file, a buffer, or some piece of data), these two threads will compete against each other, so that the first query to obtain a lock on the mutex will cause the other query to wait until the first is done and unlocks the mutex.

The work performed while holding a mutex is said to be in a “critical section,” and multiple queries do execute this critical section in a serialized way (one at a time), which is a potential bottleneck.

The `mutex_instances` table has these columns:

- `NAME`

The instrument name associated with the mutex.

- `OBJECT_INSTANCE_BEGIN`

The address in memory of the instrumented mutex.

- `LOCKED_BY_THREAD_ID`

When a thread currently has a mutex locked, `LOCKED_BY_THREAD_ID` is the `THREAD_ID` of the locking thread, otherwise it is `NULL`.

`TRUNCATE TABLE` is not permitted for the `mutex_instances` table.

For every mutex instrumented in the code, the Performance Schema provides the following information.

- The `setup_instruments` table lists the name of the instrumentation point, with the prefix `wait/synch/mutex/`.
- When some code creates a mutex, a row is added to the `mutex_instances` table. The `OBJECT_INSTANCE_BEGIN` column is a property that uniquely identifies the mutex.
- When a thread attempts to lock a mutex, the `events_waits_current` table shows a row for that thread, indicating that it is waiting on a mutex (in the `EVENT_NAME` column), and indicating which mutex is waited on (in the `OBJECT_INSTANCE_BEGIN` column).
- When a thread succeeds in locking a mutex:
  - `events_waits_current` shows that the wait on the mutex is completed (in the `TIMER_END` and `TIMER_WAIT` columns)
  - The completed wait event is added to the `events_waits_history` and `events_waits_history_long` tables
  - `mutex_instances` shows that the mutex is now owned by the thread (in the `THREAD_ID` column).
- When a thread unlocks a mutex, `mutex_instances` shows that the mutex now has no owner (the `THREAD_ID` column is `NULL`).
- When a mutex object is destroyed, the corresponding row is removed from `mutex_instances`.

By performing queries on both of the following tables, a monitoring application or a DBA can detect bottlenecks or deadlocks between threads that involve mutexes:

- `events_waits_current`, to see what mutex a thread is waiting for
- `mutex_instances`, to see which other thread currently owns a mutex

#### 24.10.3.4 The `rwlock_instances` Table

The `rwlock_instances` table lists all the `rwlock` (read write lock) instances seen by the Performance Schema while the server executes. An `rwlock` is a synchronization mechanism used in the code to enforce that threads at a given time can have access to some common resource following certain rules. The resource is said to be “protected” by the `rwlock`. The access is either shared (many threads can have a read lock at the same time), exclusive (only one thread can have a write lock at a given time), or shared-exclusive (a thread can have a write lock while permitting inconsistent reads by other threads). Shared-exclusive access is otherwise known as an `sxlock` and was introduced in MySQL 5.7 to optimize concurrency and improve scalability for read-write workloads.

Depending on how many threads are requesting a lock, and the nature of the locks requested, access can be either granted in shared mode, exclusive mode, shared-exclusive mode or not granted at all, waiting for other threads to finish first.

The `rwlock_instances` table has these columns:

- `NAME`

The instrument name associated with the lock.

- `OBJECT_INSTANCE_BEGIN`

The address in memory of the instrumented lock.

- `WRITE_LOCKED_BY_THREAD_ID`

When a thread currently has an `rwlock` locked in exclusive (write) mode, `WRITE_LOCKED_BY_THREAD_ID` is the `THREAD_ID` of the locking thread, otherwise it is `NULL`.

- `READ_LOCKED_BY_COUNT`

When a thread currently has an `rwlock` locked in shared (read) mode, `READ_LOCKED_BY_COUNT` is incremented by 1. This is a counter only, so it cannot be used directly to find which thread holds a read lock, but it can be used to see whether there is a read contention on an `rwlock`, and see how many readers are currently active.

`TRUNCATE TABLE` is not permitted for the `rwlock_instances` table.

By performing queries on both of the following tables, a monitoring application or a DBA may detect some bottlenecks or deadlocks between threads that involve locks:

- `events_waits_current`, to see what `rwlock` a thread is waiting for
- `rwlock_instances`, to see which other thread currently owns an `rwlock`

There is a limitation: The `rwlock_instances` can be used only to identify the thread holding a write lock, but not the threads holding a read lock.

### 24.10.3.5 The `socket_instances` Table

The `socket_instances` table provides a real-time snapshot of the active connections to the MySQL server. The table contains one row per TCP/IP or Unix socket file connection. Information available in this table provides a real-time snapshot of the active connections to the server. (Additional information is available in socket summary tables, including network activity such as socket operations and number of bytes transmitted and received; see [Section 24.10.15.8, “Socket Summary Tables”](#)).

```
mysql> SELECT * FROM socket_instances\G
***** 1. row *****
      EVENT_NAME: wait/io/socket/sql/server_unix_socket
OBJECT_INSTANCE_BEGIN: 4316619408
      THREAD_ID: 1
      SOCKET_ID: 16
        IP:
      PORT: 0
      STATE: ACTIVE
***** 2. row *****
      EVENT_NAME: wait/io/socket/sql/client_connection
OBJECT_INSTANCE_BEGIN: 4316644608
      THREAD_ID: 21
      SOCKET_ID: 39
        IP: 127.0.0.1
      PORT: 55233
      STATE: ACTIVE
***** 3. row *****
      EVENT_NAME: wait/io/socket/sql/server_tcpip_socket
OBJECT_INSTANCE_BEGIN: 4316699040
      THREAD_ID: 1
      SOCKET_ID: 14
        IP: 0.0.0.0
      PORT: 50603
      STATE: ACTIVE
```

Socket instruments have names of the form `wait/io/socket/sql/socket_type` and are used like this:

1. The server has a listening socket for each network protocol that it supports. The instruments associated with listening sockets for TCP/IP or Unix socket file connections have a `socket_type` value of `server_tcpip_socket` or `server_unix_socket`, respectively.

2. When a listening socket detects a connection, the server transfers the connection to a new socket managed by a separate thread. The instrument for the new connection thread has a `socket_type` value of `client_connection`.
3. When a connection terminates, the row in `socket_instances` corresponding to it is deleted.

The `socket_instances` table has these columns:

- `EVENT_NAME`

The name of the `wait/io/socket/*` instrument that produced the event. This is a `NAME` value from the `setup_instruments` table. Instrument names may have multiple parts and form a hierarchy, as discussed in [Section 24.5, “Performance Schema Instrument Naming Conventions”](#).

- `OBJECT_INSTANCE_BEGIN`

This column uniquely identifies the socket. The value is the address of an object in memory.

- `THREAD_ID`

The internal thread identifier assigned by the server. Each socket is managed by a single thread, so each socket can be mapped to a thread which can be mapped to a server process.

- `SOCKET_ID`

The internal file handle assigned to the socket.

- `IP`

The client IP address. The value may be either an IPv4 or IPv6 address, or blank to indicate a Unix socket file connection.

- `PORT`

The TCP/IP port number, in the range from 0 to 65535.

- `STATE`

The socket status, either `IDLE` or `ACTIVE`. Wait times for active sockets are tracked using the corresponding socket instrument. Wait times for idle sockets are tracked using the `idle` instrument.

A socket is idle if it is waiting for a request from the client. When a socket becomes idle, the event row in `socket_instances` that is tracking the socket switches from a status of `ACTIVE` to `IDLE`. The `EVENT_NAME` value remains `wait/io/socket/*`, but timing for the instrument is suspended. Instead, an event is generated in the `events_waits_current` table with an `EVENT_NAME` value of `idle`.

When the next request is received, the `idle` event terminates, the socket instance switches from `IDLE` to `ACTIVE`, and timing of the socket instrument resumes.

`TRUNCATE TABLE` is not permitted for the `socket_instances` table.

The `IP:PORT` column combination value identifies the connection. This combination value is used in the `OBJECT_NAME` column of the `events_waits_XXX` tables, to identify the connection from which socket events come:

- For the Unix domain listener socket (`server_unix_socket`), the port is 0, and the IP is ''.
- For client connections via the Unix domain listener (`client_connection`), the port is 0, and the IP is ''.
- For the TCP/IP server listener socket (`server_tcpip_socket`), the port is always the master port (for example, 3306), and the IP is always 0.0.0.0.

- For client connections via the TCP/IP listener (`client_connection`), the port is whatever the server assigns, but never 0. The IP is the IP of the originating host (`127.0.0.1` or `:::1` for the local host)

## 24.10.4 Performance Schema Wait Event Tables

These tables store wait events:

- `events_waits_current`: Current wait events
- `events_waits_history`: The most recent wait events for each thread
- `events_waits_history_long`: The most recent wait events overall

The following sections describe those tables. There are also summary tables that aggregate information about wait events; see [Section 24.10.15.1, “Wait Event Summary Tables”](#).

### Wait Event Configuration

To enable collection of wait events, enable the relevant instruments and consumers.

The `setup_instruments` table contains instruments with names that begin with `wait`. For example:

```
mysql> SELECT * FROM setup_instruments
      WHERE NAME LIKE 'wait/io/file/innodb%';
```

| NAME                                 | ENABLED | TIMED |
|--------------------------------------|---------|-------|
| wait/io/file/innodb/innodb_data_file | YES     | YES   |
| wait/io/file/innodb/innodb_log_file  | YES     | YES   |
| wait/io/file/innodb/innodb_temp_file | YES     | YES   |

```
mysql> SELECT * FROM setup_instruments WHERE
      NAME LIKE 'wait/io/socket/%';
```

| NAME                                   | ENABLED | TIMED |
|--|---------|-------|
| wait/io/socket/sql/server_tcpip_socket | NO      | NO    |
| wait/io/socket/sql/server_unix_socket  | NO      | NO    |
| wait/io/socket/sql/client_connection   | NO      | NO    |

To modify collection of wait events, change the `ENABLED` and `TIMING` columns of the relevant instruments. For example:

```
mysql> UPDATE setup_instruments SET ENABLED = 'YES', TIMED = 'YES'
      WHERE NAME LIKE 'wait/io/socket/sql/%';
```

The `setup_consumers` table contains consumer values with names corresponding to the current and recent wait event table names. These consumers may be used to filter collection of wait events. The wait consumers are disabled by default:

```
mysql> SELECT * FROM setup_consumers WHERE NAME LIKE '%waits%';
```

| NAME                      | ENABLED |
|---------------------------|---------|
| events_waits_current      | NO      |
| events_waits_history      | NO      |
| events_waits_history_long | NO      |

To enable all wait consumers, do this:

```
mysql> UPDATE setup_consumers SET ENABLED = 'YES'
      WHERE NAME LIKE '%waits%';
```

The `setup_timers` table contains a row with a `NAME` value of `wait` that indicates the unit for wait event timing. The default unit is `CYCLE`.

```
mysql> SELECT * FROM setup_timers WHERE NAME = 'wait';
+-----+-----+
| NAME | TIMER_NAME |
+-----+-----+
| wait | CYCLE      |
+-----+-----+
```

To change the timing unit, modify the `TIMER_NAME` value:

```
mysql> UPDATE setup_timers SET TIMER_NAME = 'NANOSECOND'
      WHERE NAME = 'wait';
```

For additional information about configuring event collection, see [Section 24.3, “Performance Schema Runtime Configuration”](#).

#### 24.10.4.1 The `events_waits_current` Table

The `events_waits_current` table contains current wait events, one row per thread showing the current status of the thread's most recent monitored wait event.

Of the tables that contain wait event rows, `events_waits_current` is the most fundamental. Other tables that contain wait event rows are logically derived from the current events. For example, the `events_waits_history` and `events_waits_history_long` tables are collections of the most recent wait events, up to a fixed number of rows.

For information about configuration of wait event collection, see [Section 24.10.4, “Performance Schema Wait Event Tables”](#).

The `events_waits_current` table has these columns:

- `THREAD_ID`, `EVENT_ID`

The thread associated with the event and the thread current event number when the event starts. The `THREAD_ID` and `EVENT_ID` values taken together uniquely identify the row. No two rows have the same pair of values.

- `END_EVENT_ID`

This column is set to `NULL` when the event starts and updated to the thread current event number when the event ends.

- `EVENT_NAME`

The name of the instrument that produced the event. This is a `NAME` value from the `setup_instruments` table. Instrument names may have multiple parts and form a hierarchy, as discussed in [Section 24.5, “Performance Schema Instrument Naming Conventions”](#).

- `SOURCE`

The name of the source file containing the instrumented code that produced the event and the line number in the file at which the instrumentation occurs. This enables you to check the source to determine exactly what code is involved. For example, if a mutex or lock is being blocked, you can check the context in which this occurs.

- `TIMER_START`, `TIMER_END`, `TIMER_WAIT`

Timing information for the event. The unit for these values is picoseconds (trillionths of a second). The `TIMER_START` and `TIMER_END` values indicate when event timing started and ended. `TIMER_WAIT` is the event elapsed time (duration).

If an event has not finished, `TIMER_END` and `TIMER_WAIT` are `NULL` before MySQL 5.7.8. As of 5.7.8, `TIMER_END` is the current timer value and `TIMER_WAIT` is the time elapsed so far (`TIMER_END - TIMER_START`).

If an event is produced from an instrument that has `TIMED = NO`, timing information is not collected, and `TIMER_START`, `TIMER_END`, and `TIMER_WAIT` are all `NULL`.

For discussion of picoseconds as the unit for event times and factors that affect time values, see [Section 24.3.1, “Performance Schema Event Timing”](#).

- `SPINS`

For a mutex, the number of spin rounds. If the value is `NULL`, the code does not use spin rounds or spinning is not instrumented.

- `OBJECT_SCHEMA`, `OBJECT_NAME`, `OBJECT_TYPE`, `OBJECT_INSTANCE_BEGIN`

These columns identify the object “being acted on.” What that means depends on the object type.

For a synchronization object (`cond`, `mutex`, `rwlock`):

- `OBJECT_SCHEMA`, `OBJECT_NAME`, and `OBJECT_TYPE` are `NULL`.
- `OBJECT_INSTANCE_BEGIN` is the address of the synchronization object in memory.

For a file I/O object:

- `OBJECT_SCHEMA` is `NULL`.
- `OBJECT_NAME` is the file name.
- `OBJECT_TYPE` is `FILE`.
- `OBJECT_INSTANCE_BEGIN` is an address in memory.

For a socket object:

- `OBJECT_NAME` is the `IP:PORT` value for the socket.
- `OBJECT_INSTANCE_BEGIN` is an address in memory.

For a table I/O object:

- `OBJECT_SCHEMA` is the name of the schema that contains the table.
- `OBJECT_NAME` is the table name.
- `OBJECT_TYPE` is `TABLE` for a persistent base table or `TEMPORARY TABLE` for a temporary table.
- `OBJECT_INSTANCE_BEGIN` is an address in memory.

An `OBJECT_INSTANCE_BEGIN` value itself has no meaning, except that different values indicate different objects. `OBJECT_INSTANCE_BEGIN` can be used for debugging. For example, it can be used with `GROUP BY OBJECT_INSTANCE_BEGIN` to see whether the load on 1,000 mutexes (that protect, say, 1,000 pages or blocks of data) is spread evenly or just hitting a few bottlenecks. This can help you correlate with other sources of information if you see the same object address in a log file or another debugging or performance tool.

- `INDEX_NAME`

The name of the index used. `PRIMARY` indicates the table primary index. `NULL` means that no index was used.

- `NESTING_EVENT_ID`

The `EVENT_ID` value of the event within which this event is nested.

- `NESTING_EVENT_TYPE`

The nesting event type. The value is `TRANSACTION`, `STATEMENT`, `STAGE`, or `WAIT`.

- `OPERATION`

The type of operation performed, such as `lock`, `read`, or `write`.

- `NUMBER_OF_BYTES`

The number of bytes read or written by the operation. For table I/O waits (events for the `wait/io/table/sql/handler` instrument), `NUMBER_OF_BYTES` is `NULL` before MySQL 5.7.5. For table I/O events as of 5.7.5, this column indicates the number of rows. If the value is greater than 1, the event is for a batch I/O operation. The following discussion describes the difference between exclusively single-row reporting and reporting that reflects batch I/O.

MySQL executes joins using a nested-loop implementation. The job of the Performance Schema instrumentation is to provide row count and accumulated execution time per table in the join. Assume a join query of the following form that is executed using a table join order of `t1`, `t2`, `t3`:

```
SELECT ... FROM t1 JOIN t2 ON ... JOIN t3 ON ...
```

Table “fanout” is the increase or decrease in number of rows from adding a table during join processing. If the fanout for table `t3` is greater than 1, the majority of row-fetch operations are for that table. Suppose that the join accesses 10 rows from `t1`, 20 rows from `t2` per row from `t1`, and 30 rows from `t3` per row of table `t2`. With single-row reporting, the total number of instrumented operations is:

$$10 + (10 * 20) + (10 * 20 * 30) = 6210$$

A significant reduction in the number of instrumented operations is achievable by aggregating them per scan (that is, per unique combination of rows from `t1` and `t2`). With batch I/O reporting, the Performance Schema produces an event for each scan of the innermost table `t3` rather than for each row, and the number of instrumented row operations reduces to:

$$10 + (10 * 20) + (10 * 20) = 410$$

That is a reduction of 93%, illustrating how the batch-reporting strategy significantly reduces Performance Schema overhead for table I/O by reducing the number of reporting calls. The tradeoff is lesser accuracy for event timing. Rather than time for an individual row operation as in per-row reporting, timing for batch I/O includes time spent for operations such as join buffering, aggregation, and returning rows to the client.

For batch I/O reporting to occur, these conditions must be true:

- Query execution accesses the innermost table of a query block (for a single-table query, that table counts as innermost)
- Query execution does not request a single row from the table (so, for example, `eq_ref` access prevents use of batch reporting)
- Query execution does not evaluate a subquery containing table access for the table

- `FLAGS`

Reserved for future use.

`TRUNCATE TABLE` is permitted for the `events_waits_current` table. It removes the rows.

#### 24.10.4.2 The `events_waits_history` Table

The `events_waits_history` table contains the most recent *N* wait events per thread. The value of *N* is autosized at server startup. To set the table size explicitly, set the `performance_schema_events_waits_history_size` system variable at server startup. Wait events are not added to the table until they have ended. As new events are added, older events are discarded if the table is full.

The `events_waits_history` table has the same structure as `events_waits_current`. See [Section 24.10.4.1, “The `events\_waits\_current` Table”](#).

`TRUNCATE TABLE` is permitted for the `events_waits_history` table. It removes the rows.

For information about configuration of wait event collection, see [Section 24.10.4, “Performance Schema Wait Event Tables”](#).

#### 24.10.4.3 The `events_waits_history_long` Table

The `events_waits_history_long` table contains the most recent *N* wait events. The value of *N* is autosized at server startup. To set the table size explicitly, set the `performance_schema_events_waits_history_long_size` system variable at server startup. Wait events are not added to the table until they have ended. As new events are added, older events are discarded if the table is full. When a thread ends, its rows are removed from the table.

The `events_waits_history_long` table has the same structure as `events_waits_current`. See [Section 24.10.4.1, “The `events\_waits\_current` Table”](#).

`TRUNCATE TABLE` is permitted for the `events_waits_history_long` table. It removes the rows.

For information about configuration of wait event collection, see [Section 24.10.4, “Performance Schema Wait Event Tables”](#).

### 24.10.5 Performance Schema Stage Event Tables

The Performance Schema instruments stages, which are steps during the statement-execution process, such as parsing a statement, opening a table, or performing a `filesort` operation. Stages correspond to the thread states displayed by `SHOW PROCESSLIST` or that are visible in the `INFORMATION_SCHEMA.PROCESSLIST` table. Stages begin and end when state values change.

Within the event hierarchy, wait events nest within stage events, which nest within statement events, which nest within transaction events.

These tables store stage events:

- `events_stages_current`: Current stage events
- `events_stages_history`: The most recent stage events for each thread
- `events_stages_history_long`: The most recent stage events overall

The following sections describe those tables. There are also summary tables that aggregate information about stage events; see [Section 24.10.15.2, “Stage Summary Tables”](#).

#### Stage Event Configuration

To enable collection of stage events, enable the relevant instruments and consumers.

The `setup_instruments` table contains instruments with names that begin with `stage`. Other than those instruments that provide statement progress information, these instruments are disabled by default. For example:

```
mysql> SELECT * FROM setup_instruments WHERE NAME RLIKE 'stage/sql/[a-c]';
```

| NAME   | ENABLED | TIMED |
|--|---------|-------|
| stage/sql/After create                             | NO      | NO    |
| stage/sql/allocating local table                   | NO      | NO    |
| stage/sql/altering table                           | NO      | NO    |
| stage/sql/committing alter table to storage engine | NO      | NO    |
| stage/sql/Changing master                          | NO      | NO    |
| stage/sql/Checking master version                  | NO      | NO    |
| stage/sql/checking permissions                     | NO      | NO    |
| stage/sql/checking privileges on cached query      | NO      | NO    |
| stage/sql/checking query cache for query           | NO      | NO    |
| stage/sql/cleaning up                              | NO      | NO    |
| stage/sql/closing tables                           | NO      | NO    |
| stage/sql/Connecting to master                     | NO      | NO    |
| stage/sql/converting HEAP to MyISAM                | NO      | NO    |
| stage/sql/Copying to group table                   | NO      | NO    |
| stage/sql/Copying to tmp table                     | NO      | NO    |
| stage/sql/copy to tmp table                        | NO      | NO    |
| stage/sql/Creating sort index                      | NO      | NO    |
| stage/sql/creating table                           | NO      | NO    |
| stage/sql/Creating tmp table                       | NO      | NO    |

As of MySQL 5.7.7, stage event instruments that provide statement progress information are enabled and timed by default:

```
mysql> SELECT * FROM setup_instruments WHERE
      ENABLED='YES' AND NAME LIKE "stage/%";
```

| NAME   | ENABLED | TIMED |
|--|---------|-------|
| stage/sql/copy to tmp table                          | YES     | YES   |
| stage/innodb/alter table (end)                       | YES     | YES   |
| stage/innodb/alter table (flush)                     | YES     | YES   |
| stage/innodb/alter table (insert)                    | YES     | YES   |
| stage/innodb/alter table (log apply index)           | YES     | YES   |
| stage/innodb/alter table (log apply table)           | YES     | YES   |
| stage/innodb/alter table (merge sort)                | YES     | YES   |
| stage/innodb/alter table (read PK and internal sort) | YES     | YES   |
| stage/innodb/buffer pool load                        | YES     | YES   |

To modify collection of stage events, change the `ENABLED` and `TIMING` columns of the relevant instruments. For example:

```
mysql> UPDATE setup_instruments SET ENABLED = 'YES', TIMED = 'YES'
      WHERE NAME = 'stage/sql/altering table';
```

The `setup_consumers` table contains consumer values with names corresponding to the current and recent stage event table names. These consumers may be used to filter collection of stage events. The stage consumers are disabled by default:

```
mysql> SELECT * FROM setup_consumers WHERE NAME LIKE '%stages%';
```

| NAME                       | ENABLED |
|----------------------------|---------|
| events_stages_current      | NO      |
| events_stages_history      | NO      |
| events_stages_history_long | NO      |

To enable all stage consumers, do this:

```
mysql> UPDATE setup_consumers SET ENABLED = 'YES'
      WHERE NAME LIKE '%stages%';
```

The `setup_timers` table contains a row with a `NAME` value of `stage` that indicates the unit for stage event timing. The default unit is `NANOSECOND`.

```
mysql> SELECT * FROM setup_timers WHERE NAME = 'stage';
+-----+-----+
| NAME | TIMER_NAME |
+-----+-----+
| stage | NANOSECOND |
+-----+-----+
```

To change the timing unit, modify the `TIMER_NAME` value:

```
mysql> UPDATE setup_timers SET TIMER_NAME = 'MICROSECOND'
      WHERE NAME = 'stage';
```

For additional information about configuring event collection, see [Section 24.3, “Performance Schema Runtime Configuration”](#).

## Stage Event Progress Information

As of MySQL 5.7.5, the Performance Schema stage event tables contain two columns that, taken together, provide a stage progress indicator for each row:

- `WORK_COMPLETED`: The number of work units completed for the stage
- `WORK_ESTIMATED`: The number of work units expected for the stage

Each column is `NULL` if no progress information is provided for an instrument. Interpretation of the information, if it is available, depends entirely on the instrument implementation. The Performance Schema tables provide a container to store progress data, but make no assumptions about the semantics of the metric itself:

- A “work unit” is an integer metric that increases over time during execution, such as the number of bytes, rows, files, or tables processed. The definition of “work unit” for a particular instrument is left to the instrumentation code providing the data.
- The `WORK_COMPLETED` value can increase one or many units at a time, depending on the instrumented code.
- The `WORK_ESTIMATED` value can change during the stage, depending on the instrumented code.

Instrumentation for a stage event progress indicator can implement any of the following behaviors:

- No progress instrumentation

This is the most typical case, where no progress data is provided. The `WORK_COMPLETED` and `WORK_ESTIMATED` columns are both `NULL`.

- Unbounded progress instrumentation

Only the `WORK_COMPLETED` column is meaningful. No data is provided for the `WORK_ESTIMATED` column, which displays 0.

By querying the `events_stages_current` table for the monitored session, a monitoring application can report how much work has been performed so far, but cannot report whether the stage is near completion. Currently, no stages are instrumented like this.

- Bounded progress instrumentation

The `WORK_COMPLETED` and `WORK_ESTIMATED` columns are both meaningful.

This type of progress indicator is appropriate for an operation with a defined completion criterion, such as the table-copy instrument described later. By querying the `events_stages_current` table for the monitored session, a monitoring application can report how much work has been performed so far, and can report the overall completion percentage for the stage, by computing the `WORK_COMPLETED` / `WORK_ESTIMATED` ratio.

The `stage/sql/copy to tmp table` instrument illustrates how progress indicators work. During execution of an `ALTER TABLE` statement, the `stage/sql/copy to tmp table` stage is used, and this stage can execute potentially for a long time, depending on the size of the data to copy.

The table-copy task has a defined termination (all rows copied), and the `stage/sql/copy to tmp table` stage is instrumented to provide bounded progress information: The work unit used is number of rows copied, `WORK_COMPLETED` and `WORK_ESTIMATED` are both meaningful, and their ratio indicates task percentage complete.

To enable the instrument and the relevant consumers, execute these statements:

```
mysql> UPDATE setup_instruments SET ENABLED='YES'
      WHERE NAME='stage/sql/copy to tmp table';
mysql> UPDATE setup_consumers SET ENABLED='YES'
      WHERE NAME LIKE 'events_stages_%';
```

To see the progress of an ongoing `ALTER TABLE` statement, select from the `events_stages_current` table.

### 24.10.5.1 The `events_stages_current` Table

The `events_stages_current` table contains current stage events, one row per thread showing the current status of the thread's most recent monitored stage event.

Of the tables that contain stage event rows, `events_stages_current` is the most fundamental. Other tables that contain stage event rows are logically derived from the current events. For example, the `events_stages_history` and `events_stages_history_long` tables are collections of the most recent stage events, up to a fixed number of rows.

For information about configuration of stage event collection, see [Section 24.10.5, “Performance Schema Stage Event Tables”](#).

The `events_stages_current` table has these columns:

- `THREAD_ID`, `EVENT_ID`

The thread associated with the event and the thread current event number when the event starts. The `THREAD_ID` and `EVENT_ID` values taken together uniquely identify the row. No two rows have the same pair of values.

- `END_EVENT_ID`

This column is set to `NULL` when the event starts and updated to the thread current event number when the event ends.

- `EVENT_NAME`

The name of the instrument that produced the event. This is a `NAME` value from the `setup_instruments` table. Instrument names may have multiple parts and form a hierarchy, as discussed in [Section 24.5, “Performance Schema Instrument Naming Conventions”](#).

- `SOURCE`

The name of the source file containing the instrumented code that produced the event and the line number in the file at which the instrumentation occurs. This enables you to check the source to determine exactly what code is involved.

- `TIMER_START`, `TIMER_END`, `TIMER_WAIT`

Timing information for the event. The unit for these values is picoseconds (trillionths of a second). The `TIMER_START` and `TIMER_END` values indicate when event timing started and ended. `TIMER_WAIT` is the event elapsed time (duration).

If an event has not finished, `TIMER_END` and `TIMER_WAIT` are `NULL` before MySQL 5.7.8. As of 5.7.8, `TIMER_END` is the current timer value and `TIMER_WAIT` is the time elapsed so far (`TIMER_END - TIMER_START`).

If an event is produced from an instrument that has `TIMED = NO`, timing information is not collected, and `TIMER_START`, `TIMER_END`, and `TIMER_WAIT` are all `NULL`.

For discussion of picoseconds as the unit for event times and factors that affect time values, see [Section 24.3.1, “Performance Schema Event Timing”](#).

- `WORK_COMPLETED`, `WORK_ESTIMATED`

These columns provide stage progress information, for instruments that have been implemented to produce such information. `WORK_COMPLETED` indicates how many work units have been completed for the stage, and `WORK_ESTIMATED` indicates how many work units are expected for the stage. For more information, see [Stage Event Progress Information](#).

These columns were added in MySQL 5.7.5.

- `NESTING_EVENT_ID`

The `EVENT_ID` value of the event within which this event is nested. The nesting event for a stage event is usually a statement event.

- `NESTING_EVENT_TYPE`

The nesting event type. The value is `TRANSACTION`, `STATEMENT`, `STAGE`, or `WAIT`.

`TRUNCATE TABLE` is permitted for the `events_stages_current` table. It removes the rows.

### 24.10.5.2 The `events_stages_history` Table

The `events_stages_history` table contains the most recent *N* stage events per thread. The value of *N* is autosized at server startup. To set the table size explicitly, set the `performance_schema_events_stages_history_size` system variable at server startup. Stage events are not added to the table until they have ended. As new events are added, older events are discarded if the table is full.

The `events_stages_history` table has the same structure as `events_stages_current`. See [Section 24.10.5.1, “The `events\_stages\_current` Table”](#).

`TRUNCATE TABLE` is permitted for the `events_stages_history` table. It removes the rows.

For information about configuration of stage event collection, see [Section 24.10.5, “Performance Schema Stage Event Tables”](#).

### 24.10.5.3 The `events_stages_history_long` Table

The `events_stages_history_long` table contains the most recent *N* stage events. The value of *N* is autosized at server startup. To set the table size explicitly, set the `performance_schema_events_stages_history_long_size` system variable at server startup.

Stage events are not added to the table until they have ended. As new events are added, older events are discarded if the table is full. When a thread ends, its rows are removed from the table.

The `events_stages_history_long` table has the same structure as `events_stages_current`. See [Section 24.10.5.1, “The events\\_stages\\_current Table”](#).

`TRUNCATE TABLE` is permitted for the `events_stages_history_long` table. It removes the rows.

For information about configuration of stage event collection, see [Section 24.10.5, “Performance Schema Stage Event Tables”](#).

## 24.10.6 Performance Schema Statement Event Tables

The Performance Schema instruments statement execution. Statement events occur at a high level of the event hierarchy: Wait events nest within stage events, which nest within statement events, which nest within transaction events.

These tables store statement events:

- `events_statements_current`: Current statement events
- `events_statements_history`: The most recent statement events for each thread
- `events_statements_history_long`: The most recent statement events overall
- `prepared_statements_instances`: Prepared statement instances and statistics (added in MySQL 5.7.4)

The following sections describe those tables. There are also summary tables that aggregate information about statement events; see [Section 24.10.15.3, “Statement Summary Tables”](#).

### Statement Event Configuration

To enable collection of statement events, enable the relevant instruments and consumers.

The `setup_instruments` table contains instruments with names that begin with `statement`. These instruments are enabled by default:

```
mysql> SELECT * FROM setup_instruments WHERE NAME LIKE 'statement/%';
```

| NAME                           | ENABLED | TIMED |
|--------------------------------|---------|-------|
| statement/sql/select           | YES     | YES   |
| statement/sql/create_table     | YES     | YES   |
| statement/sql/create_index     | YES     | YES   |
| ...                            |         |       |
| statement/sp/stmt              | YES     | YES   |
| statement/sp/set               | YES     | YES   |
| statement/sp/set_trigger_field | YES     | YES   |
| statement/scheduler/event      | YES     | YES   |
| statement/com/Sleep            | YES     | YES   |
| statement/com/Quit             | YES     | YES   |
| statement/com/Init DB          | YES     | YES   |
| ...                            |         |       |
| statement/abstract/Query       | YES     | YES   |
| statement/abstract/new_packet  | YES     | YES   |
| statement/abstract/relay_log   | YES     | YES   |

To modify collection of statement events, change the `ENABLED` and `TIMING` columns of the relevant instruments. For example:

```
mysql> UPDATE setup_instruments SET ENABLED = 'NO'
WHERE NAME LIKE 'statement/com/%';
```

The `setup_consumers` table contains consumer values with names corresponding to the current and recent statement event table names, and the statement digest consumer. These consumers may be used to filter collection of statement events and statement digesting. `events_statements_current`, `events_statements_history`, and `statements_digest` are enabled by default (before MySQL 5.7.5, `events_statements_history` is disabled by default):

```
mysql> SELECT * FROM setup_consumers WHERE NAME LIKE '%statements%';
```

| NAME                           | ENABLED |
|--------------------------------|---------|
| events_statements_current      | YES     |
| events_statements_history      | YES     |
| events_statements_history_long | NO      |
| statements_digest              | YES     |

To enable all statement consumers, do this:

```
mysql> UPDATE setup_consumers SET ENABLED = 'YES'
      WHERE NAME LIKE '%statements%';
```

The `setup_timers` table contains a row with a `NAME` value of `statement` that indicates the unit for statement event timing. The default unit is `NANOSECOND`.

```
mysql> SELECT * FROM setup_timers WHERE NAME = 'statement';
```

| NAME      | TIMER_NAME |
|-----------|------------|
| statement | NANOSECOND |

To change the timing unit, modify the `TIMER_NAME` value:

```
mysql> UPDATE setup_timers SET TIMER_NAME = 'MICROSECOND'
      WHERE NAME = 'statement';
```

For additional information about configuring event collection, see [Section 24.3, “Performance Schema Runtime Configuration”](#).

## Statement Monitoring

Statement monitoring begins from the moment the server sees that activity is requested on a thread, to the moment when all activity has ceased. Typically, this means from the time the server gets the first packet from the client to the time the server has finished sending the response. Before MySQL 5.7.2, monitoring occurs only for top-level statements. Statements within stored programs and subqueries are not seen separately. As of 5.7.2, statements within stored programs are monitored like other statements.

When the Performance Schema instruments a request (server command or SQL statement), it uses instrument names that proceed in stages from more general (or “abstract”) to more specific until it arrives at a final instrument name.

Final instrument names correspond to server commands and SQL statements:

- Server commands correspond to the `COM_xxx` codes defined in the `mysql_com.h` header file and processed in `sql/sql_parse.cc`. Examples are `COM_PING` and `COM_QUIT`. Instruments for commands have names that begin with `statement/com`, such as `statement/com/Ping` and `statement/com/Quit`.
- SQL statements are expressed as text, such as `DELETE FROM t1` or `SELECT * FROM t2`. Instruments for SQL statements have names that begin with `statement/sql`, such as `statement/sql/delete` and `statement/sql/select`.

Some final instrument names are specific to error handling:

- `statement/com/Error` accounts for messages received by the server that are out of band. It can be used to detect commands sent by clients that the server does not understand. This may be helpful for purposes such as identifying clients that are misconfigured or using a version of MySQL more recent than that of the server, or clients that are attempting to attack the server.
- `statement/sql/error` accounts for SQL statements that fail to parse. It can be used to detect malformed queries sent by clients. A query that fails to parse differs from a query that parses but fails due to an error during execution. For example, `SELECT * FROM` is malformed, and the `statement/sql/error` instrument is used. By contrast, `SELECT *` parses but fails with a `No tables used` error. In this case, `statement/sql/select` is used and the statement event contains information to indicate the nature of the error.

A request can be obtained from any of these sources:

- As a command or statement request from a client, which sends the request as packets
- As a statement string read from the relay log on a replication slave (as of MySQL 5.7.2)
- As an event from the Event Scheduler (as of MySQL 5.7.2)

The details for a request are not initially known and the Performance Schema proceeds from abstract to specific instrument names in a sequence that depends on the source of the request.

For a request received from a client:

1. When the server detects a new packet at the socket level, a new statement is started with an abstract instrument name of `statement/abstract/new_packet`.
2. When the server reads the packet number, it knows more about the type of request received, and the Performance Schema refines the instrument name. For example, if the request is a `COM_PING` packet, the instrument name becomes `statement/com/Ping` and that is the final name. If the request is a `COM_QUERY` packet, it is known to correspond to an SQL statement but not the particular type of statement. In this case, the instrument changes from one abstract name to a more specific but still abstract name, `statement/abstract/Query`, and the request requires further classification.
3. If the request is a statement, the statement text is read and given to the parser. After parsing, the exact statement type is known. If the request is, for example, an `INSERT` statement, the Performance Schema refines the instrument name from `statement/abstract/Query` to `statement/sql/insert`, which is the final name.

For a request read as a statement from the relay log on a replication slave:

1. Statements in the relay log are stored as text and are read as such. There is no network protocol, so the `statement/abstract/new_packet` instrument is not used. Instead, the initial instrument is `statement/abstract/relay_log`.
2. When the statement is parsed, the exact statement type is known. If the request is, for example, an `INSERT` statement, the Performance Schema refines the instrument name from `statement/abstract/Query` to `statement/sql/insert`, which is the final name.

The preceding description applies only for statement-based replication. For row-based replication, table I/O done on the slave as it processes row changes can be instrumented, but row events in the relay log do not appear as discrete statements.

For a request received from the Event Scheduler:

The event execution is instrumented using the name `statement/scheduler/event`. This is the final name.

Statements executed within the event body are instrumented using `statement/sql/*` names, without use of any preceding abstract instrument. An event is a stored program, and stored programs are precompiled in memory before execution. Consequently, there is no parsing at runtime and the type of each statement is known by the time it executes.

Statements executed within the event body are child statements. For example, if an event executes an `INSERT` statement, execution of the event itself is the parent, instrumented using `statement/scheduler/event`, and the `INSERT` is the child, instrumented using `statement/sql/insert`. The parent/child relationship holds *between* separate instrumented operations. This differs from the sequence of refinement that occurs *within* a single instrumented operation, from abstract to final instrument names.

For statistics to be collected for statements, it is not sufficient to enable only the final `statement/sql/*` instruments used for individual statement types. The abstract `statement/abstract/*` instruments must be enabled as well. This should not normally be an issue because all statement instruments are enabled by default. However, an application that enables or disables statement instruments selectively must take into account that disabling abstract instruments also disables statistics collection for the individual statement instruments. For example, to collect statistics for `INSERT` statements, `statement/sql/insert` must be enabled, but also `statement/abstract/new_packet` and `statement/abstract/Query`. Similarly, for replicated statements to be instrumented, `statement/abstract/relay_log` must be enabled.

No statistics are aggregated for abstract instruments such as `statement/abstract/Query` because no statement is ever classified with an abstract instrument as the final statement name.

The abstract instrument names in the preceding discussion are as of MySQL 5.7.3. In earlier 5.7 versions, there was some renaming before those names were settled on:

- `statement/abstract/new_packet` was `statement/com/` before MySQL 5.7.3.
- `statement/abstract/Query` was `statement/com/Query` before MySQL 5.7.3.
- `statement/abstract/relay_log` was `statement/rpl/relay_log` in MySQL 5.7.2 and did not exist before that.

#### 24.10.6.1 The `events_statements_current` Table

The `events_statements_current` table contains current statement events, one row per thread showing the current status of the thread's most recent monitored statement event.

Of the tables that contain statement event rows, `events_statements_current` is the most fundamental. Other tables that contain statement event rows are logically derived from the current events. For example, the `events_statements_history` and `events_statements_history_long` tables are collections of the most recent statement events, up to a fixed number of rows.

For information about configuration of statement event collection, see [Section 24.10.6, “Performance Schema Statement Event Tables”](#).

The `events_statements_current` table has these columns:

- `THREAD_ID`, `EVENT_ID`

The thread associated with the event and the thread current event number when the event starts. The `THREAD_ID` and `EVENT_ID` values taken together uniquely identify the row. No two rows have the same pair of values.

- `END_EVENT_ID`

This column is set to `NULL` when the event starts and updated to the thread current event number when the event ends.

- `EVENT_NAME`

The name of the instrument from which the event was collected. This is a [NAME](#) value from the [setup\\_instruments](#) table. Instrument names may have multiple parts and form a hierarchy, as discussed in [Section 24.5, “Performance Schema Instrument Naming Conventions”](#).

For SQL statements, the [EVENT\\_NAME](#) value initially is `statement/com/Query` until the statement is parsed, then changes to a more appropriate value, as described in [Section 24.10.6, “Performance Schema Statement Event Tables”](#).

- [SOURCE](#)

The name of the source file containing the instrumented code that produced the event and the line number in the file at which the instrumentation occurs. This enables you to check the source to determine exactly what code is involved.

- [TIMER\\_START](#), [TIMER\\_END](#), [TIMER\\_WAIT](#)

Timing information for the event. The unit for these values is picoseconds (trillionths of a second). The [TIMER\\_START](#) and [TIMER\\_END](#) values indicate when event timing started and ended. [TIMER\\_WAIT](#) is the event elapsed time (duration).

If an event has not finished, [TIMER\\_END](#) and [TIMER\\_WAIT](#) are `NULL` before MySQL 5.7.8. As of 5.7.8, [TIMER\\_END](#) is the current timer value and [TIMER\\_WAIT](#) is the time elapsed so far ([TIMER\\_END](#) - [TIMER\\_START](#)).

If an event is produced from an instrument that has [TIMED](#) = `NO`, timing information is not collected, and [TIMER\\_START](#), [TIMER\\_END](#), and [TIMER\\_WAIT](#) are all `NULL`.

For discussion of picoseconds as the unit for event times and factors that affect time values, see [Section 24.3.1, “Performance Schema Event Timing”](#).

- [LOCK\\_TIME](#)

The time spent waiting for table locks. This value is computed in microseconds but normalized to picoseconds for easier comparison with other Performance Schema timers.

- [SQL\\_TEXT](#)

The text of the SQL statement. For a command not associated with an SQL statement, the value is `NULL`.

As of MySQL 5.7.6, the maximum number of bytes to display can be changed by changing the [performance\\_schema\\_max\\_sql\\_text\\_length](#) system variable at server startup. Before 5.7.6, the maximum is fixed at 1024.

- [DIGEST](#)

The statement digest MD5 value as a string of 32 hexadecimal characters, or `NULL` if the [statement\\_digest](#) consumer is `no`. For more information about statement digesting, see [Section 24.8, “Performance Schema Statement Digests”](#).

- [DIGEST\\_TEXT](#)

The normalized statement digest text, or `NULL` if the [statement\\_digest](#) consumer is `no`. For more information about statement digesting, see [Section 24.8, “Performance Schema Statement Digests”](#).

The [performance\\_schema\\_max\\_digest\\_length](#) system variable determines the maximum number of bytes available for computing statement digests. However, the display length of statement digests may be longer than the available buffer size due to encoding of statement components such as keywords and literal values in digest buffer. Consequently, values selected from the [DIGEST\\_TEXT](#) column of statement event tables may appear to exceed the [performance\\_schema\\_max\\_digest\\_length](#) value.

This variable was added in MySQL 5.7.8. In MySQL 5.7.6 and 5.7.7, use `max_digest_length` instead. Before 5.7.6, the value cannot be changed.

- `CURRENT_SCHEMA`

The default database for the statement, `NULL` if there is none.

- `OBJECT_SCHEMA`, `OBJECT_NAME`, `OBJECT_TYPE`

For nested statements (stored programs), these columns contain information about the parent statement. Otherwise they are `NULL`.

- `OBJECT_INSTANCE_BEGIN`

This column identifies the statement. The value is the address of an object in memory.

- `MYSQL_ERRNO`

The statement error number, from the statement diagnostics area.

- `RETURNED_SQLSTATE`

The statement SQLSTATE value, from the statement diagnostics area.

- `MESSAGE_TEXT`

The statement error message, from the statement diagnostics area.

- `ERRORS`

Whether an error occurred for the statement. The value is 0 if the SQLSTATE value begins with `00` (completion) or `01` (warning). The value is 1 if the SQLSTATE value is anything else.

- `WARNINGS`

The number of warnings, from the statement diagnostics area.

- `ROWS_AFFECTED`

The number of rows affected by the statement. For a description of the meaning of “affected,” see [Section 26.8.7.1, “mysql\\_affected\\_rows\(\)”](#).

- `ROWS_SENT`

The number of rows returned by the statement.

- `ROWS_EXAMINED`

The number of rows read from storage engines during statement execution.

- `CREATED_TMP_DISK_TABLES`

Like the `Created_tmp_disk_tables` status variable, but specific to the statement.

- `CREATED_TMP_TABLES`

Like the `Created_tmp_tables` status variable, but specific to the statement.

- `SELECT_FULL_JOIN`

Like the `Select_full_join` status variable, but specific to the statement.

- `SELECT_FULL_RANGE_JOIN`

Like the `Select_full_range_join` status variable, but specific to the statement.

- `SELECT_RANGE`

Like the `Select_range` status variable, but specific to the statement.

- `SELECT_RANGE_CHECK`

Like the `Select_range_check` status variable, but specific to the statement.

- `SELECT_SCAN`

Like the `Select_scan` status variable, but specific to the statement.

- `SORT_MERGE_PASSES`

Like the `Sort_merge_passes` status variable, but specific to the statement.

- `SORT_RANGE`

Like the `Sort_range` status variable, but specific to the statement.

- `SORT_ROWS`

Like the `Sort_rows` status variable, but specific to the statement.

- `SORT_SCAN`

Like the `Sort_scan` status variable, but specific to the statement.

- `NO_INDEX_USED`

1 if the statement performed a table scan without using an index, 0 otherwise.

- `NO_GOOD_INDEX_USED`

1 if the server found no good index to use for the statement, 0 otherwise. For additional information, see the description of the `Extra` column from `EXPLAIN` output for the `Range checked for each record` value in [Section 9.8.2, “EXPLAIN Output Format”](#).

- `NESTING_EVENT_ID`, `NESTING_EVENT_TYPE`, `NESTING_EVENT_LEVEL`

Before MySQL 5.7.2, only `NESTING_EVENT_ID` and `NESTING_EVENT_TYPE` exist and are always `NULL`.

As of MySQL 5.7.2, all three columns exist and are used with other columns to provide information as follows for top-level (unnested) statements and nested statements (executed within a stored program).

For top level statements:

```
OBJECT_TYPE = NULL
OBJECT_SCHEMA = NULL
OBJECT_NAME = NULL
NESTING_EVENT_ID = NULL
NESTING_EVENT_TYPE = NULL
NESTING_LEVEL = 0
```

For nested statements:

```
OBJECT_TYPE = the parent statement object type
OBJECT_SCHEMA = the parent statement object schema
```

```

OBJECT_NAME = the parent statement object name
NESTING_EVENT_ID = the parent statement EVENT_ID
NESTING_EVENT_TYPE = 'STATEMENT'
NESTING_LEVEL = the parent statement NESTING_LEVEL plus one

```

`TRUNCATE TABLE` is permitted for the `events_statements_current` table. It removes the rows.

### 24.10.6.2 The `events_statements_history` Table

The `events_statements_history` table contains the most recent *N* statement events per thread. The value of *N* is autosized at server startup. To set the table size explicitly, set the `performance_schema_events_statements_history_size` system variable at server startup. Statement events are not added to the table until they have ended. As new events are added, older events are discarded if the table is full.

The `events_statements_history` table has the same structure as `events_statements_current`. See [Section 24.10.6.1, “The `events\_statements\_current` Table”](#).

`TRUNCATE TABLE` is permitted for the `events_statements_history` table. It removes the rows.

For information about configuration of statement event collection, see [Section 24.10.6, “Performance Schema Statement Event Tables”](#).

### 24.10.6.3 The `events_statements_history_long` Table

The `events_statements_history_long` table contains the most recent *N* statement events. The value of *N* is autosized at server startup. To set the table size explicitly, set the `performance_schema_events_statements_history_long_size` system variable at server startup. Statement events are not added to the table until they have ended. As new events are added, older events are discarded if the table is full. When a thread ends, its rows are removed from the table.

The `events_statements_history_long` table has the same structure as `events_statements_current`. See [Section 24.10.6.1, “The `events\_statements\_current` Table”](#).

`TRUNCATE TABLE` is permitted for the `events_statements_history_long` table. It removes the rows.

For information about configuration of statement event collection, see [Section 24.10.6, “Performance Schema Statement Event Tables”](#).

### 24.10.6.4 The `prepared_statements_instances` Table

As of MySQL 5.7.4, the Performance Schema provides instrumentation for prepared statements, for which there are two protocols:

- The binary protocol. This is accessed through the MySQL C API and maps onto underlying server commands as shown in the following table.

| C API Function                    | Corresponding Server Command  |
|-----------------------------------|-------------------------------|
| <code>mysql_stmt_prepare()</code> | <code>COM_STMT_PREPARE</code> |
| <code>mysql_stmt_execute()</code> | <code>COM_STMT_EXECUTE</code> |
| <code>mysql_stmt_close()</code>   | <code>COM_STMT_CLOSE</code>   |

- The text protocol. This is accessed using SQL statements and maps onto underlying server commands as shown in the following table.

| SQL Statement        | Corresponding Server Command |
|----------------------|------------------------------|
| <code>PREPARE</code> | <code>SQLCOM_PREPARE</code>  |
| <code>EXECUTE</code> | <code>SQLCOM_EXECUTE</code>  |

| SQL Statement                    | Corresponding Server Command |
|----------------------------------|------------------------------|
| DEALLOCATE PREPARE, DROP PREPARE | SQLCOM_DEALLOCATE PREPARE    |

Performance Schema prepared statement instrumentation covers both protocols. The following discussion refers to the server commands rather than the C API functions or SQL statements.

Information about prepared statements is available in the `prepared_statements_instances` table. This table enables inspection of prepared statements used in the server and provides aggregated statistics about them. To control the size of this table, set the `performance_schema_max_prepared_statements_instances` system variable at server startup.

Collection of prepared statement information depends on the statement instruments shown in the following table. These instruments are enabled by default. To modify them, update the `setup_instruments` table.

| Instrument                             | Server Command                |
|--|-------------------------------|
| <code>statement/com/Prepare</code>     | <code>COM_STMT_PREPARE</code> |
| <code>statement/com/Execute</code>     | <code>COM_STMT_EXECUTE</code> |
| <code>statement/sql/prepare_sql</code> | <code>SQLCOM_PREPARE</code>   |
| <code>statement/sql/execute_sql</code> | <code>SQLCOM_EXECUTE</code>   |

The Performance Schema manages the contents of the `prepared_statements_instances` table as follows:

- Statement preparation

A `COM_STMT_PREPARE` or `SQLCOM_PREPARE` command creates a prepared statement in the server. If the statement is successfully instrumented, a new row is added to the `prepared_statements_instances` table. If the statement cannot be instrumented, `Performance_schema_prepared_statements_lost` status variable is incremented.

- Prepared statement execution

Execution of a `COM_STMT_EXECUTE` or `SQLCOM_EXECUTE` command for an instrumented prepared statement instance updates the corresponding `prepared_statements_instances` table row.

- Prepared statement deallocation

Execution of a `COM_STMT_CLOSE` or `SQLCOM_DEALLOCATE_PREPARE` command for an instrumented prepared statement instance removes the corresponding `prepared_statements_instances` table row. To avoid resource leaks, removal occurs even if the prepared statement instruments described previously are disabled.

The `prepared_statements_instances` table has these columns:

- `OBJECT_INSTANCE_BEGIN`

The address in memory of the instrumented prepared statement.

- `STATEMENT_ID`

The internal statement ID assigned by the server. The text and binary protocols both use statement IDs.

- `STATEMENT_NAME`

For the binary protocol, this column is `NULL`. For the text protocol, this column is the external statement name assigned by the user. For example, for the following SQL statement, the name of the prepared statement is `stmt`:

```
PREPARE stmt FROM 'SELECT 1';
```

- [SQL\\_TEXT](#)

The prepared statement text, with `?` placeholder markers.

- [OWNER\\_THREAD\\_ID](#), [OWNER\\_EVENT\\_ID](#)

These columns indicate the event that created the prepared statement.

- [OWNER\\_OBJECT\\_TYPE](#), [OWNER\\_OBJECT\\_SCHEMA](#), [OWNER\\_OBJECT\\_NAME](#)

For a prepared statement created by a client session, these columns are `NULL`. For a prepared statement created by a stored program, these columns point to the stored program. A typical user error is forgetting to deallocate prepared statements. These columns can be used to find stored programs that leak prepared statements:

```
SELECT OWNER_OBJECT_TYPE, OWNER_OBJECT_SCHEMA, OWNER_OBJECT_NAME,
STATEMENT_NAME, SQL_TEXT
FROM performance_schema.prepared_statements_instances
WHERE OWNER_OBJECT_TYPE IS NOT NULL;
```

- [TIMER\\_PREPARE](#)

The time spent executing the statement preparation itself.

- [COUNT\\_REPREPARE](#)

The number of times the statement was reprepared internally (see [Section 9.10.4, “Caching of Prepared Statements and Stored Programs”](#)). Timing statistics for reparation are not available because it is counted as part of statement execution, not as a separate operation.

- [COUNT\\_EXECUTE](#), [SUM\\_TIMER\\_EXECUTE](#), [MIN\\_TIMER\\_EXECUTE](#), [AVG\\_TIMER\\_EXECUTE](#), [MAX\\_TIMER\\_EXECUTE](#)

Aggregated statistics for executions of the prepared statement.

- [SUM\\_xxx](#)

The remaining [SUM\\_xxx](#) columns are the same as for the statement summary tables (see [Section 24.10.15.3, “Statement Summary Tables”](#)).

`TRUNCATE TABLE` resets the statistics columns of the [prepared\\_statements\\_instances](#) table.

## 24.10.7 Performance Schema Transaction Tables

As of MySQL 5.7.3, the Performance Schema instruments transactions. Within the event hierarchy, wait events nest within stage events, which nest within statement events, which nest within transaction events.

These tables store transaction events:

- [events\\_transactions\\_current](#): Current transaction events
- [events\\_transactions\\_history](#): The most recent transaction events for each thread
- [events\\_transactions\\_history\\_long](#): The most recent transaction events overall

The following sections describe those tables. There are also summary tables that aggregate information about transaction events; see [Section 24.10.15.4, “Transaction Summary Tables”](#).

## Transaction Event Configuration

To enable collection of transaction events, enable the relevant instruments and consumers.

The `setup_instruments` table contains an instrument named `transaction`. This instrument is disabled by default:

```
mysql> SELECT * FROM setup_instruments WHERE NAME = 'transaction';
```

| NAME        | ENABLED | TIMED |
|-------------|---------|-------|
| transaction | NO      | NO    |

To enable collection of transaction events, including timing information, do this:

```
mysql> UPDATE setup_instruments SET ENABLED = 'YES', TIMED = 'YES'
      WHERE NAME = 'transaction';
```

The `setup_consumers` table contains consumer values with names corresponding to the current and recent transaction event table names. These consumers may be used to filter collection of transaction events:

```
mysql> SELECT * FROM setup_consumers WHERE NAME LIKE '%transactions%';
```

| NAME                             | ENABLED |
|----------------------------------|---------|
| events_transactions_current      | NO      |
| events_transactions_history      | NO      |
| events_transactions_history_long | NO      |

To enable all transaction consumers, do this:

```
mysql> UPDATE setup_consumers SET ENABLED = 'YES'
      WHERE NAME LIKE '%transactions%';
```

To enable collection of transaction events only for specific transaction event tables, enable the corresponding transaction consumers.

The `setup_timers` table contains a row with a `NAME` value of `transaction` that indicates the unit for transaction event timing. The default unit is `NANOSECOND`.

```
mysql> SELECT * FROM setup_timers WHERE NAME = 'transaction';
```

| NAME        | TIMER_NAME |
|-------------|------------|
| transaction | NANOSECOND |

To change the timing unit, modify the `TIMER_NAME` value:

```
mysql> UPDATE setup_timers SET TIMER_NAME = 'MICROSECOND'
      WHERE NAME = 'transaction';
```

For additional information about configuring event collection, see [Section 24.3, “Performance Schema Runtime Configuration”](#).

## Transaction Boundaries

In MySQL Server, transactions start explicitly with these statements:

---

```
START TRANSACTION | BEGIN | XA START | XA BEGIN
```

Transactions also start implicitly. For example, when the `autocommit` system variable is enabled, the start of each statement starts a new transaction.

When `autocommit` is disabled, the first statement following a committed transaction marks the start of a new transaction. Subsequent statements are part of the transaction until it is committed.

Transactions explicitly end with these statements:

```
COMMIT | ROLLBACK | XA COMMIT | XA ROLLBACK
```

Transactions also end implicitly, by execution of DDL statements, locking statements, and server administration statements.

In the following discussion, references to `START TRANSACTION` also apply to `BEGIN`, `XA START`, and `XA BEGIN`. Similarly, references to `COMMIT` and `ROLLBACK` apply to `XA COMMIT` and `XA ROLLBACK`, respectively.

The Performance Schema defines transaction boundaries similarly to that of the server. The start and end of a transaction event closely match the corresponding state transitions in the server:

- For an explicitly started transaction, the transaction event starts during processing of the `START TRANSACTION` statement.
- For an implicitly started transaction, the transaction event starts on the first statement that uses a transactional engine after the previous transaction has ended.
- For any transaction, whether explicitly or implicitly ended, the transaction event ends when the server transitions out of the active transaction state during the processing of `COMMIT` or `ROLLBACK`.

There are subtle implications to this approach:

- Transaction events in the Performance Schema do not fully include the statement events associated with the corresponding `START TRANSACTION`, `COMMIT`, or `ROLLBACK` statements. There is a trivial amount of timing overlap between the transaction event and these statements.
- Statements that work with nontransactional engines have no effect on the transaction state of the connection. For implicit transactions, the transaction event begins with the first statement that uses a transactional engine. This means that statements operating exclusively on nontransactional tables are ignored, even following `START TRANSACTION`.

To illustrate, consider the following scenario:

```
1. SET autocommit = OFF;
2. CREATE TABLE t1 (a INT) ENGINE = InnoDB;
3. START TRANSACTION;                -- Transaction 1 START
4. INSERT INTO t1 VALUES (1), (2), (3);
5. CREATE TABLE t2 (a INT) ENGINE = MyISAM; -- Transaction 1 COMMIT
                                           -- (implicit; DDL forces commit)
6. INSERT INTO t2 VALUES (1), (2), (3); -- Update nontransactional table
7. UPDATE t2 SET a = a + 1;             -- ... and again
8. INSERT INTO t1 VALUES (4), (5), (6); -- Write to transactional table
                                           -- Transaction 2 START (implicit)
9. COMMIT;                             -- Transaction 2 COMMIT
```

From the perspective of the server, Transaction 1 ends when table `t2` is created. Transaction 2 does not start until a transactional table is accessed, despite the intervening updates to nontransactional tables.

From the perspective of the Performance Schema, Transaction 2 starts when the server transitions into an active transaction state. Statements 6 and 7 are not included within the boundaries of Transaction 2, which is consistent with how the server writes transactions to the binary log.

## Transaction Instrumentation

Three attributes define transactions:

- Access mode (read only, read write)
- Isolation level (`SERIALIZABLE`, `REPEATABLE READ`, and so forth)
- Implicit (`autocommit` enabled) or explicit (`autocommit` disabled)

To reduce complexity of the transaction instrumentation and to ensure that the collected transaction data provides complete, meaningful results, all transactions are instrumented independently of access mode, isolation level, or autocommit mode.

To selectively examine transaction history, use the attribute columns in the transaction event tables: `ACCESS_MODE`, `ISOLATION_LEVEL`, and `AUTOCOMMIT`.

The cost of transaction instrumentation can be reduced various ways, such as enabling or disabling transaction instrumentation according to user, account, host, or thread (client connection).

## Transactions and Nested Events

The parent of a transaction event is the event that initiated the transaction. For an explicitly started transaction, this includes the `START TRANSACTION` and `COMMIT AND CHAIN` statements. For an implicitly started transaction, it is the first statement that uses a transactional engine after the previous transaction ends.

In general, a transaction is the top-level parent to all events initiated during the transaction, including statements that explicitly end the transaction such as `COMMIT` and `ROLLBACK`. Exceptions are statements that implicitly end a transaction, such as DDL statements, in which case the current transaction must be committed before the new statement is executed.

## Transactions and Stored Programs

Transactions and stored program events are related as follows:

- Stored Procedures

Stored procedures operate independently of transactions. A stored procedure can be started within a transaction, and a transaction can be started or ended from within a stored procedure. If called from within a transaction, a stored procedure can execute statements that force a commit of the parent transaction and then start a new transaction.

If a stored procedure is started within a transaction, that transaction is the parent of the stored procedure event.

If a transaction is started by a stored procedure, the stored procedure is the parent of the transaction event.

- Stored Functions

Stored functions are restricted from causing an explicit or implicit commit or rollback. Stored function events can reside within a parent transaction event.

- Triggers

Triggers activate as part of a statement that accesses the table with which it is associated, so the parent of a trigger event is always the statement that activates it.

Triggers cannot issue statements that cause an explicit or implicit commit or rollback of a transaction.

- Scheduled Events

The execution of the statements in the body of a scheduled event takes place in a new connection. Nesting of a scheduled event within a parent transaction is not applicable.

## Transactions and Savepoints

Savepoint statements are recorded as separate statement events. Transaction events include separate counters for `SAVEPOINT`, `ROLLBACK TO SAVEPOINT`, and `RELEASE SAVEPOINT` statements issued during the transaction.

## Transactions and Errors

Errors and warnings that occur within a transaction are recorded in statement events, but not in the corresponding transaction event. This includes transaction-specific errors and warnings, such as a rollback on a nontransactional table or GTID consistency errors.

### 24.10.7.1 The `events_transactions_current` Table

The `events_transactions_current` table (added in MySQL 5.7.3) contains current transaction events, one row per thread showing the current status of the thread's most recent monitored transaction event. For example:

```
mysql> SELECT * FROM events_transactions_current LIMIT 1\G
***** 1. row *****
      THREAD_ID: 26
      EVENT_ID: 7
    END_EVENT_ID: NULL
      EVENT_NAME: transaction
          STATE: ACTIVE
         TRX_ID: NULL
          GTID: 3E11FA47-71CA-11E1-9E33-C80AA9429562:56
           XID: NULL
        XA_STATE: NULL
        SOURCE: transaction.cc:150
    TIMER_START: 420833537900000
      TIMER_END: NULL
    TIMER_WAIT: NULL
    ACCESS_MODE: READ WRITE
ISOLATION_LEVEL: REPEATABLE READ
    AUTOCOMMIT: NO
NUMBER_OF_SAVEPOINTS: 0
NUMBER_OF_ROLLBACK_TO_SAVEPOINT: 0
NUMBER_OF_RELEASE_SAVEPOINT: 0
OBJECT_INSTANCE_BEGIN: NULL
    NESTING_EVENT_ID: 6
    NESTING_EVENT_TYPE: STATEMENT
```

Of the tables that contain transaction event rows, `events_transactions_current` is the most fundamental. Other tables that contain transaction event rows are logically derived from the current events. For example, the `events_transactions_history` and `events_transactions_history_long` tables are collections of the most recent transaction events, up to a fixed number of rows.

For information about configuration of transaction event collection, see [Section 24.10.7, “Performance Schema Transaction Tables”](#).

The `events_transactions_current` table has these columns:

- `THREAD_ID`, `EVENT_ID`

The thread associated with the event and the thread current event number when the event starts. The `THREAD_ID` and `EVENT_ID` values taken together uniquely identify the row. No two rows have the same pair of values.

- `END_EVENT_ID`

This column is set to `NULL` when the event starts and updated to the thread current event number when the event ends.

- `EVENT_NAME`

The name of the instrument from which the event was collected. This is a `NAME` value from the `setup_instruments` table. Instrument names may have multiple parts and form a hierarchy, as discussed in [Section 24.5, “Performance Schema Instrument Naming Conventions”](#).

- `STATE`

The current transaction state. The value is `ACTIVE` (after `START TRANSACTION` or `BEGIN`), `COMMITTED` (after `COMMIT`), or `ROLLED BACK` (after `ROLLBACK`).

- `TRX_ID`

Unused.

- `GTID`

This column changed in MySQL 5.7.6.

- Versions of MySQL prior to 5.7.6:

If `gtid_mode=OFF`, the value is `NULL`. If `gtid_mode=ON`, this is the value of `gtid_next` when the transaction started. If `gtid_next=AUTOMATIC` the value is `AUTOMATIC`, otherwise the value is a GTID in `UUID:NUMBER` format.

- Versions of MySQL 5.7.6 and later:

The GTID column contains the value of `gtid_next`, which can be one of `ANONYMOUS`, `AUTOMATIC`, or a GTID using the format `UUID:NUMBER`. For transactions that use `gtid_next=AUTOMATIC`, which is all normal client transactions, the GTID column changes when the transaction commits and the actual GTID is assigned. If `gtid_mode` is either `ON` or `ON_PERMISSIVE`, the GTID column changes to the transaction's GTID. If `gtid_mode` is either `OFF` or `OFF_PERMISSIVE`, the GTID column changes to `ANONYMOUS`.

- `XID`

The XA transaction identifier. It has the format described in [Section 14.3.7.1, “XA Transaction SQL Syntax”](#). This column was removed in MySQL 5.7.7 and replaced with the `XID_FORMAT_ID`, `XID_GTRID`, and `XID_BQUAL` columns representing the components of XID values.

- `XID_FORMAT_ID`, `XID_GTRID`, and `XID_BQUAL`

The components of the XA transaction identifier. They have the format described in [Section 14.3.7.1, “XA Transaction SQL Syntax”](#). These columns were added in MySQL 5.7.7 as replacements for the `XID` column.

- `XA_STATE`

The state of the XA transaction. The value is `ACTIVE` (after `XA START`), `IDLE` (after `XA END`), `PREPARED` (after `XA PREPARE`), `ROLLED BACK` (after `XA ROLLBACK`), or `COMMITTED` (after `XA COMMIT`).

- `SOURCE`

The name of the source file containing the instrumented code that produced the event and the line number in the file at which the instrumentation occurs. This enables you to check the source to determine exactly what code is involved.

- `TIMER_START`, `TIMER_END`, `TIMER_WAIT`

Timing information for the event. The unit for these values is picoseconds (trillionths of a second). The `TIMER_START` and `TIMER_END` values indicate when event timing started and ended. `TIMER_WAIT` is the event elapsed time (duration).

If an event has not finished, `TIMER_END` and `TIMER_WAIT` are `NULL` before MySQL 5.7.8. As of 5.7.8, `TIMER_END` is the current timer value and `TIMER_WAIT` is the time elapsed so far (`TIMER_END - TIMER_START`).

If an event is produced from an instrument that has `TIMED = NO`, timing information is not collected, and `TIMER_START`, `TIMER_END`, and `TIMER_WAIT` are all `NULL`.

For discussion of picoseconds as the unit for event times and factors that affect time values, see [Section 24.3.1, “Performance Schema Event Timing”](#).

- `ACCESS_MODE`

The transaction access mode. The value is `READ ONLY` or `READ WRITE`.

- `ISOLATION_LEVEL`

The transaction isolation level. The value is `REPEATABLE READ`, `READ COMMITTED`, `READ UNCOMMITTED`, or `SERIALIZABLE`.

- `AUTOCOMMIT`

Whether autocommit mode was enabled when the transaction started.

- `NUMBER_OF_SAVEPOINTS`, `NUMBER_OF_ROLLBACK_TO_SAVEPOINT`,  
`NUMBER_OF_RELEASE_SAVEPOINT`

The number of `SAVEPOINT`, `ROLLBACK TO SAVEPOINT`, and `RELEASE SAVEPOINT` statements issued during the transaction.

- `OBJECT_INSTANCE_BEGIN`

Unused.

- `NESTING_EVENT_ID`

The `EVENT_ID` value of the event within which this event is nested.

- `NESTING_EVENT_TYPE`

The nesting event type. The value is `TRANSACTION`, `STATEMENT`, `STAGE`, or `WAIT`. (`TRANSACTION` will not appear because transactions cannot be nested.)

`TRUNCATE TABLE` is permitted for the `events_transactions_current` table. It removes the rows.

### 24.10.7.2 The `events_transactions_history` Table

The `events_transactions_history` table (added in MySQL 5.7.3) contains the most recent *N* transaction events per thread. The value of *N* is autosized at server startup. To set the table size explicitly, set the `performance_schema_events_transactions_history_size` system variable at server startup. Transaction events are not added to the table until they have ended. As new events are added, older events are discarded if the table is full.

The `events_transactions_history` table has the same structure as `events_transactions_current`. See [Section 24.10.7.1, “The `events\_transactions\_current` Table”](#).

`TRUNCATE TABLE` is permitted for the `events_transactions_history` table. It removes the rows.

For information about configuration of transaction event collection, see [Section 24.10.7, “Performance Schema Transaction Tables”](#).

### 24.10.7.3 The `events_transactions_history_long` Table

The `events_transactions_history_long` table (added in MySQL 5.7.3) contains the most recent *N* transaction events. The value of *N* is autosized at server startup. To set the table size explicitly, set the `performance_schema_events_transactions_history_long_size` system variable at server startup. Transaction events are not added to the table until they have ended. As new events are added, older events are discarded if the table is full. When a thread ends, its rows are removed from the table.

The `events_transactions_history_long` table has the same structure as `events_transactions_current`. See [Section 24.10.7.1, “The `events\_transactions\_current` Table”](#).

`TRUNCATE TABLE` is permitted for the `events_transactions_history_long` table. It removes the rows.

For information about configuration of transaction event collection, see [Section 24.10.7, “Performance Schema Transaction Tables”](#).

## 24.10.8 Performance Schema Connection Tables

When a client connects to the MySQL server, it does so under a particular user name and from a particular host. The Performance Schema provides statistics about these connections, tracking them per account (user and host combination) as well as separately per user name and per host name, using these tables:

- `accounts`: Connection statistics per client account
- `hosts`: Connection statistics per client host name
- `users`: Connection statistics per client user name

The meaning of “account” in the connection tables is similar to its meaning in the MySQL grant tables in the `mysql` system database, in the sense that the term refers to a combination of user and host values. They differ in that, for grant tables, the host part of an account can be a pattern, whereas for Performance Schema tables, the host value is always a specific nonpattern host name.

Each connection table has `CURRENT_CONNECTIONS` and `TOTAL_CONNECTIONS` columns to track the current and total number of connections per “tracking value” on which its statistics are based. The tables differ in what they use for the tracking value. The `accounts` table has `USER` and `HOST` columns to track connections per user and host combination. The `users` and `hosts` tables have a `USER` and `HOST` column, respectively, to track connections per user name and per host name.

The Performance Schema also counts internal threads and threads for user sessions that failed to authenticate, using rows with `USER` and `HOST` column values of `NULL`.

Suppose that clients named `user1` and `user2` each connect one time from `hosta` and `hostb`. The Performance Schema tracks the connections as follows:

- The `accounts` table has four rows, for the `user1/hosta`, `user1/hostb`, `user2/hosta`, and `user2/hostb` account values, each row counting one connection per account.
- The `hosts` table has two rows, for `hosta` and `hostb`, each row counting two connections per host name.
- The `users` table has two rows, for `user1` and `user2`, each row counting two connections per user name.

When a client connects, the Performance Schema determines which row in each connection table applies, using the tracking value appropriate to each table. If there is no such row, one is added. Then the Performance Schema increments by one the `CURRENT_CONNECTIONS` and `TOTAL_CONNECTIONS` columns in that row.

When a client disconnects, the Performance Schema decrements by one the `CURRENT_CONNECTIONS` column in the row and leaves the `TOTAL_CONNECTIONS` column unchanged.

`TRUNCATE TABLE` is permitted for connection tables. It has these effects:

- Rows are removed for accounts, hosts, or users that have no current connections (rows with `CURRENT_CONNECTIONS = 0`).
- Nonremoved rows are reset to count only current connections: For rows with `CURRENT_CONNECTIONS > 0`, `TOTAL_CONNECTIONS` is reset to `CURRENT_CONNECTIONS`.
- Summary tables that depend on the connection table are implicitly truncated, as described later in this section.

The Performance Schema maintains summary tables that aggregate connection statistics for various event types by account, host, or user. These tables have `_summary_by_account`, `_summary_by_host`, or `_summary_by_user` in the name. To identify them, use this query:

```
mysql> SELECT TABLE_NAME FROM INFORMATION_SCHEMA.TABLES
      WHERE TABLE_SCHEMA = 'performance_schema'
      AND TABLE_NAME REGEXP '_summary_by_(account|host|user)'
      ORDER BY TABLE_NAME;
```

| TABLE_NAME   |
|--|
| events_stages_summary_by_account_by_event_name       |
| events_stages_summary_by_host_by_event_name          |
| events_stages_summary_by_user_by_event_name          |
| events_statements_summary_by_account_by_event_name   |
| events_statements_summary_by_host_by_event_name      |
| events_statements_summary_by_user_by_event_name      |
| events_transactions_summary_by_account_by_event_name |
| events_transactions_summary_by_host_by_event_name    |
| events_transactions_summary_by_user_by_event_name    |
| events_waits_summary_by_account_by_event_name        |
| events_waits_summary_by_host_by_event_name           |
| events_waits_summary_by_user_by_event_name           |
| memory_summary_by_account_by_event_name              |
| memory_summary_by_host_by_event_name                 |
| memory_summary_by_user_by_event_name                 |

For details about individual connection summary tables, consult the section that describes tables for the summarized event type:

- Wait event summaries: [Section 24.10.15.1, “Wait Event Summary Tables”](#)
- Stage event summaries: [Section 24.10.15.2, “Stage Summary Tables”](#)
- Statement event summaries: [Section 24.10.15.3, “Statement Summary Tables”](#)
- Transaction event summaries: [Section 24.10.15.4, “Transaction Summary Tables”](#)
- Memory event summaries: [Section 24.10.15.9, “Memory Summary Tables”](#)

`TRUNCATE TABLE` is permitted for connection summary tables. It removes rows for accounts, hosts, or users with no connections, and resets the summary columns to zero for the remaining rows. In addition, each summary table that is aggregated by account, host, user, or thread is implicitly truncated by truncation of the connection table on which it depends. The following table describes the relationship between connection table truncation and implicitly truncated tables.

**Table 24.2 Implicit Effects of Connection Table Truncation**

| Truncated Connection Table | Implicitly Truncated Summary Tables   |
|----------------------------|---|
| <code>accounts</code>      | Tables with names containing <code>_summary_by_account</code> , <code>_summary_by_thread</code>                                 |
| <code>hosts</code>         | Tables with names containing <code>_summary_by_account</code> , <code>_summary_by_host</code> , <code>_summary_by_thread</code> |
| <code>users</code>         | Tables with names containing <code>_summary_by_account</code> , <code>_summary_by_user</code> , <code>_summary_by_thread</code> |

Truncating a `_summary_global` summary table also implicitly truncates its corresponding connection and thread summary tables. For example, truncating `events_waits_summary_global_by_event_name` implicitly truncates the wait event summary tables that are aggregated by account, host, user, or thread.

### 24.10.8.1 The `accounts` Table

The `accounts` table contains a row for each account that has connected to the MySQL server. For each account, the table counts the current and total number of connections. The table size is autosized at server startup. To set the table size explicitly, set the `performance_schema_accounts_size` system variable at server startup. To disable account statistics, set this variable to 0.

The `accounts` table has the following columns. For a description of how the Performance Schema maintains rows in this table, including the effect of `TRUNCATE TABLE`, see [Section 24.10.8, “Performance Schema Connection Tables”](#).

- `USER`

The client user name for the connection. This is `NULL` for an internal thread, or for a user session that failed to authenticate.

- `HOST`

The host from which the client connected. This is `NULL` for an internal thread, or for a user session that failed to authenticate.

- `CURRENT_CONNECTIONS`

The current number of connections for the account.

- `TOTAL_CONNECTIONS`

The total number of connections for the account.

### 24.10.8.2 The `hosts` Table

The `hosts` table contains a row for each host from which clients have connected to the MySQL server. For each host name, the table counts the current and total number of connections. The table size is autosized at server startup. To set the table size explicitly, set the `performance_schema_hosts_size` system variable at server startup. To disable host statistics, set this variable to 0.

The `hosts` table has the following columns. For a description of how the Performance Schema maintains rows in this table, including the effect of `TRUNCATE TABLE`, see [Section 24.10.8, “Performance Schema Connection Tables”](#).

- `HOST`

The host from which the client connected. This is `NULL` for an internal thread, or for a user session that failed to authenticate.

- `CURRENT_CONNECTIONS`

The current number of connections for the host.

- `TOTAL_CONNECTIONS`

The total number of connections for the host.

### 24.10.8.3 The users Table

The `users` table contains a row for each user who has connected to the MySQL server. For each user name, the table counts the current and total number of connections. The table size is autosized at server startup. To set the table size explicitly, set the `performance_schema_users_size` system variable at server startup. To disable user statistics, set this variable to 0.

The `users` table has the following columns. For a description of how the Performance Schema maintains rows in this table, including the effect of `TRUNCATE TABLE`, see [Section 24.10.8, “Performance Schema Connection Tables”](#).

- `USER`

The client user name for the connection. This is `NULL` for an internal thread, or for a user session that failed to authenticate.

- `CURRENT_CONNECTIONS`

The current number of connections for the user.

- `TOTAL_CONNECTIONS`

The total number of connections for the user.

### 24.10.9 Performance Schema Connection Attribute Tables

Application programs can provide key/value pairs as connection attributes to be passed to the server at connect time. For the C API, define the attribute set using the `mysql_options()` and `mysql_options4()` functions. Other MySQL Connectors may provide their own attribute-definition methods.

These tables expose attribute information:

- `session_account_connect_attrs`: Connection attributes for the current session, and other sessions associated with the session account
- `session_connect_attrs`: Connection attributes for all sessions

Attribute names that begin with an underscore (`_`) are reserved for internal use and should not be created by application programs. This convention permits new attributes to be introduced by MySQL without colliding with application attributes.

The set of connection attributes visible on a given connection varies depending on your platform and MySQL Connector used to establish the connection.

The `libmysqlclient` client library (provided in MySQL and MySQL Connector/C distributions) sets these attributes:

- `_client_name`: The client name (`libmysql` for the client library)
- `_client_version`: The client library version
- `_os`: The operating system (for example, `Linux`, `Win64`)
- `_pid`: The client process ID

- `_platform`: The machine platform (for example, `x86_64`)
- `_thread`: The client thread ID (Windows only)

Other MySQL Connectors may define their own connection attributes.

MySQL Connector/J defines these attributes:

- `_client_license`: The connector license type
- `_runtime_vendor`: The Java runtime environment (JRE) vendor
- `_runtime_version`: The Java runtime environment (JRE) version

MySQL Connector/Net defines these attributes:

- `_client_version`: The client library version
- `_os`: The operating system (for example, `Linux`, `Win64`)
- `_pid`: The client process ID
- `_platform`: The machine platform (for example, `x86_64`)
- `_program_name`: The client name
- `_thread`: The client thread ID (Windows only)

PHP defines attributes that depend on how it was compiled:

- Compiled using `libmysqlclient`: The standard `libmysqlclient` attributes, described previously
- Compiled using `mysqlnd`: Only the `_client_name` attribute, with a value of `mysqlnd`

Many MySQL client programs set a `program_name` attribute with a value equal to the client name. For example, `mysqladmin` and `mysqldump` set `program_name` to `mysqladmin` and `mysqldump`, respectively.

Some MySQL client programs define additional attributes:

- `mysqlbinlog` defines the `_client_role` attribute as `binary_log_listener`.
- Replication slave connections define `program_name` as `mysqld`, `_client_role` as `binary_log_listener`, and `_client_replication_channel_name` as the channel name.
- `FEDERATED` storage engine connections define `program_name` as `mysqld` and `_client_role` as `federated_storage`.

There are limits on the amount of connection attribute data transmitted from client to server: A fixed limit imposed by the client prior to connect time; a fixed limit imposed by the server at connect time; and a configurable limit imposed by the Performance Schema at connect time.

For connections initiated using the C API, the `libmysqlclient` library imposes a limit of 64KB on the aggregate size of connection attribute data on the client side: Calls to `mysql_options()` that cause this limit to be exceeded produce a `CR_INVALID_PARAMETER_NO` error. Other MySQL Connectors may impose their own client-side limits on how much connection attribute data can be transmitted to the server.

On the server side, these size checks on connection attribute data occur:

- The server imposes a limit of 64KB on the aggregate size of connection attribute data it will accept. If a client attempts to send more than 64KB of attribute data, the server rejects the connection.

- For accepted connections, the Performance Schema checks aggregate attribute size against the value of the `performance_schema_session_connect_attrs_size` system variable. If attribute size exceeds this value, these actions take place:
  - The Performance Schema truncates the attribute data and increments the `performance_schema_session_connect_attrs_lost` status variable, which indicates the number of connections for which attribute truncation occurred.
  - The Performance Schema writes a message to the error log if the `log_warnings` system variable is greater than zero:

```
[Warning] Connection attributes of length N were truncated
```

### 24.10.9.1 The `session_account_connect_attrs` Table

Application programs can provide key/value connection attributes to be passed to the server at connect time, using the `mysql_options()` and `mysql_options4()` C API functions. For descriptions of common attributes, see [Section 24.10.9, “Performance Schema Connection Attribute Tables”](#).

The `session_account_connect_attrs` table contains connection attributes only for sessions for your own account. To see connection attributes for all sessions, look in the `session_connect_attrs` table.

The `session_account_connect_attrs` table contains these columns:

- `PROCESSLIST_ID`

The connection identifier for the session.

- `ATTR_NAME`

The attribute name.

- `ATTR_VALUE`

The attribute value.

- `ORDINAL_POSITION`

The order in which the attribute was added to the set of connection attributes.

`TRUNCATE TABLE` is not permitted for the `session_account_connect_attrs` table.

### 24.10.9.2 The `session_connect_attrs` Table

Application programs can provide key/value connection attributes to be passed to the server at connect time, using the `mysql_options()` and `mysql_options4()` C API functions. For descriptions of common attributes, see [Section 24.10.9, “Performance Schema Connection Attribute Tables”](#).

The `session_connect_attrs` table contains connection attributes for all sessions. To see connection attributes only for sessions for your own account, look in the `session_account_connect_attrs` table.

The `session_connect_attrs` table contains these columns:

- `PROCESSLIST_ID`

The connection identifier for the session.

- `ATTR_NAME`

The attribute name.

- `ATTR_VALUE`

The attribute value.

- `ORDINAL_POSITION`

The order in which the attribute was added to the set of connection attributes.

`TRUNCATE TABLE` is not permitted for the `session_connect_attrs` table.

## 24.10.10 Performance Schema User Variable Tables

As of MySQL 5.7.5, the Performance Schema provides a `user_variables_by_thread` table that exposes user-defined variables. These are variables defined within a specific session and include a `@` character preceding the name; see [Section 10.4, “User-Defined Variables”](#).

The `user_variables_by_thread` table contains these columns:

- `THREAD_ID`

The thread identifier of the session in which the variable is defined.

- `VARIABLE_NAME`

The variable name, without the leading `@` character.

- `VARIABLE_VALUE`

The variable value.

`TRUNCATE TABLE` is not permitted for the `user_variables_by_thread` table.

## 24.10.11 Performance Schema Replication Tables

As of MySQL 5.7.2, the Performance Schema provides tables that expose replication information. This is similar to the information available from the `SHOW SLAVE STATUS` statement, but representation in table form is more accessible and has usability benefits:

- `SHOW SLAVE STATUS` output is useful for visual inspection, but not so much for programmatic use. By contrast, using the Performance Schema tables, information about slave status can be searched using general `SELECT` queries, including complex `WHERE` conditions, joins, and so forth.
- Query results can be saved in tables for further analysis, or assigned to variables and thus used in stored procedures.
- The replication tables provide better diagnostic information. For multi-threaded slave operation, `SHOW SLAVE STATUS` reports all coordinator and worker thread errors using the `Last_SQL_Errno` and `Last_SQL_Error` fields, so only the most recent of those errors is visible and information can be lost. The replication tables store errors on a per-thread basis without loss of information.
- The last seen transaction is visible in the replication tables on a per-worker basis. This is information not available from `SHOW SLAVE STATUS`.
- Developers familiar with the Performance Schema interface can extend the replication tables to provide additional information by adding rows to the tables.

### Replication Table Descriptions

The Performance Schema provides several replication-related tables:

- Tables that contain information about the connection of the slave server to the master server:

- `replication_connection_configuration`: Configuration parameters for connecting to the master
- `replication_connection_status`: Current status of the connection to the master
- Tables that contain general (not thread-specific) information about the transaction applier:
  - `replication_applier_configuration`: Configuration parameters for the transaction applier on the slave. Renamed from `replication_execute_configuration` in MySQL 5.7.6.
  - `replication_applier_status`: Current status of the transaction applier on the slave. Renamed from `replication_execute_status` in MySQL 5.7.6.
- Tables that contain information about specific threads responsible for applying transactions received from the master:
  - `replication_applier_status_by_coordinator`: Status of the applier (formerly SQL or coordinator) thread. Renamed from `replication_execute_status_by_coordinator` in MySQL 5.7.6.
  - `replication_applier_status_by_worker`: Worker thread applier status (empty unless slave is multi-threaded). Renamed from `replication_execute_status_by_worker` in MySQL 5.7.6.
- Tables that contain information about replication group members:
  - `replication_group_members`: Provides network and status information for group members.
  - `replication_group_member_stats`: Provides statistical information about group members and transaction in which they participate.

The following sections describe each replication table in more detail, including the correspondence between the columns produced by `SHOW SLAVE STATUS` and the replication table columns in which the same information appears.

The remainder of this introduction to the replication tables describes how the Performance Schema populates them and which fields from `SHOW SLAVE STATUS` are not represented in the tables.

## Replication Table Life Cycle

The Performance Schema populates the replication tables as follows:

- Prior to execution of `CHANGE MASTER TO`, the tables are empty.
- After `CHANGE MASTER TO`, the configuration parameters can be seen in the tables. At this time, there are no active slave threads, so the `THREAD_ID` columns are `NULL` and the `SERVICE_STATE` columns have a value of `OFF`.
- After `START SLAVE`, non-`NULL` `THREAD_ID` values can be seen. Threads that are idle or active have a `SERVICE_STATE` value of `ON`. The thread that connects to the master server has a value of `CONNECTING` while it establishes the connection, and `ON` thereafter as long as the connection lasts.
- After `STOP SLAVE`, the `THREAD_ID` columns become `NULL` and the `SERVICE_STATE` columns for threads that no longer exist have a value of `OFF`.
- The tables are preserved after `STOP SLAVE` or threads dying due to an error.
- The `replication_applier_status_by_worker` table is nonempty only when the slave is operating in multi-threaded mode. That is, if the `slave_parallel_workers` system variable is greater than 0, this table is populated when `START SLAVE` is executed, and the number of rows shows the number of workers.

## SHOW SLAVE STATUS Information Not In the Replication Tables

The information in the Performance Schema replication tables differs somewhat from the information available from `SHOW SLAVE STATUS` because the tables are oriented toward use of global transaction identifiers (GTIDs), not file names and positions, and they represent server UUID values, not server ID values. Due to these differences, several `SHOW SLAVE STATUS` columns are not preserved in the Performance Schema replication tables, or are represented a different way:

- The following fields refer to file names and positions and are not preserved:

```
Master_Log_File
Read_Master_Log_Pos
Relay_Log_File
Relay_Log_Pos
Relay_Master_Log_File
Exec_Master_Log_Pos
Until_Condition
Until_Log_File
Until_Log_Pos
```

- The `Master_Info_File` field is not preserved. It refers to the `master.info` file.
- The following fields are based on `server_id`, not `server_uuid`, and are not preserved:

```
Master_Server_Id
Replicate_Ignore_Server_Ids
```

- The `Skip_Counter` field is based on event counts, not GTIDs, and is not preserved.
- These error fields are aliases for `Last_SQL_Errno` and `Last_SQL_Error`, so they are not preserved:

```
Last_Errno
Last_Error
```

In the Performance Schema, this error information is available in the `LAST_ERROR_NUMBER` and `LAST_ERROR_MESSAGE` columns of the `replication_applier_status_by_coordinator` table (and `replication_applier_status_by_worker` if the slave is multi-threaded). Those tables provide more specific per-thread error information than is available from `Last_Errno` and `Last_Error`.

- Fields that provide information about command-line filtering options is not preserved:

```
Replicate_Do_DB
Replicate_Ignore_DB
Replicate_Do_Table
Replicate_Ignore_Table
Replicate_Wild_Do_Table
Replicate_Wild_Ignore_Table
```

- The `Slave_IO_State` and `Slave_SQL_Running_State` fields are not preserved. If needed, these values can be obtained from the process list by using the `THREAD_ID` column of the appropriate replication table and joining it with the `ID` column in the `INFORMATION_SCHEMA.PROCESSLIST` table to select the `STATE` column of the latter table.
- The `Executed_Gtid_Set` field can show a large set with a great deal of text. Instead, the Performance Schema tables show GTIDs of transactions that are currently being applied by the slave. Alternatively, the set of executed GTIDs can be obtained from the value of the `gtid_executed` system variable.
- The `Seconds_Behind_Master` and `Relay_Log_Space` fields are in to-be-decided status and are not preserved.

## Status Variables Moved to Replication Tables

As of MySQL version 5.7.5, the following status variables (previously monitored using `SHOW STATUS`) were moved to the Performance Schema replication tables:

- `Slave_retried_transactions`
- `Slave_last_heartbeat`
- `Slave_received_heartbeats`
- `Slave_heartbeat_period`
- `Slave_running`

These status variables are now only relevant when a single replication channel is being used because they *only* report the status of the default replication channel. When multiple replication channels exist, use the Performance Schema replication tables described in this section, which report these variables for each existing replication channel.

## Replication Channels

The first column of the replication Performance Schema tables is `CHANNEL_NAME`. This enables the tables to be viewed per replication channel, added in MySQL 5.7.6. When you are using multiple replication channels on a slave, you can filter the tables per replication channel to monitor a specific replication channel. See [Section 18.2.3, “Replication Channels”](#) and [Section 18.1.4.3, “Multi-Source Replication Monitoring”](#) for more information.

### 24.10.11.1 The `replication_connection_configuration` Table

This table shows the configuration parameters used by the slave server for connecting to the master server. Parameters stored in the table can be changed at runtime with the `CHANGE MASTER TO` statement, as indicated in the column descriptions. This table was added in MySQL 5.7.2.

Compared to the `replication_connection_status` table, `replication_connection_configuration` changes less frequently. It contains values that define how the slave connects to the master and that remain constant during the connection, whereas `replication_connection_status` contains values that change during the connection.

The `replication_connection_configuration` table has these columns:

- `CHANNEL_NAME`

The replication channel which this row is displaying. There is always a default replication channel, and more replication channels can be added. See [Section 18.2.3, “Replication Channels”](#) for more information.

- `HOST`

The master host that the slave is connected to. (`CHANGE MASTER TO` option: `MASTER_HOST`)

- `PORT`

The port used to connect to the master. (`CHANGE MASTER TO` option: `MASTER_PORT`)

- `USER`

The user name of the account used to connect to the master. (`CHANGE MASTER TO` option: `MASTER_USER`)

- `NETWORK_INTERFACE`

The network interface that the slave is bound to, if any. (`CHANGE MASTER TO` option: `MASTER_BIND`)

- `AUTO_POSITION`

1 if autopositioning is in use; otherwise 0. (`CHANGE MASTER TO` option: `MASTER_AUTO_POSITION`)

- `SSL_ALLOWED`, `SSL_CA_FILE`, `SSL_CA_PATH`, `SSL_CERTIFICATE`, `SSL_CIPHER`, `SSL_KEY`, `SSL_VERIFY_SERVER_CERTIFICATE`, `SSL_CRL_FILE`, `SSL_CRL_PATH`

These columns show the SSL parameters used by the slave to connect to the master, if any.

`SSL_ALLOWED` has these values:

- `Yes` if an SSL connection to the master is permitted
- `No` if an SSL connection to the master is not permitted
- `Ignored` if an SSL connection is permitted but the slave server does not have SSL support enabled

`CHANGE MASTER TO` options for the other SSL columns: `MASTER_SSL_CA`, `MASTER_SSL_CAPATH`, `MASTER_SSL_CERT`, `MASTER_SSL_CIPHER`, `MASTER_SSL_CRL`, `MASTER_SSL_CRLPATH`, `MASTER_SSL_KEY`, `MASTER_SSL_VERIFY_SERVER_CERT`.

Prior to MySQL 5.7.4, the value of `SSL_CRL_PATH` was not displayed correctly. (Bug #18174719)

- `CONNECTION_RETRY_INTERVAL`

The number of seconds between connect retries. (`CHANGE MASTER TO` option: `MASTER_CONNECT_RETRY`)

- `CONNECTION_RETRY_COUNT`

The number of times the slave can attempt to reconnect to the master in the event of a lost connection. (`CHANGE MASTER TO` option: `MASTER_RETRY_COUNT`)

- `HEARTBEAT_INTERVAL`

The replication heartbeat interval on a slave, measured in seconds. Added in MySQL 5.7.5.

`TRUNCATE TABLE` is not permitted for the `replication_connection_configuration` table.

The following table shows the correspondence between `replication_connection_configuration` columns and `SHOW SLAVE STATUS` columns.

| <code>replication_connection_configuration</code> Column | <code>SHOW SLAVE STATUS</code> Column      |
|--|--|
| <code>HOST</code>  | <code>Master_Host</code>                   |
| <code>PORT</code>  | <code>Master_Port</code>                   |
| <code>USER</code>  | <code>Master_User</code>                   |
| <code>NETWORK_INTERFACE</code>                           | <code>Master_Bind</code>                   |
| <code>AUTO_POSITION</code>                               | <code>Auto_Position</code>                 |
| <code>SSL_ALLOWED</code>                                 | <code>Master_SSL_Allowed</code>            |
| <code>SSL_CA_FILE</code>                                 | <code>Master_SSL_CA_File</code>            |
| <code>SSL_CA_PATH</code>                                 | <code>Master_SSL_CA_Path</code>            |
| <code>SSL_CERTIFICATE</code>                             | <code>Master_SSL_Cert</code>               |
| <code>SSL_CIPHER</code>                                  | <code>Master_SSL_Cipher</code>             |
| <code>SSL_KEY</code>                                     | <code>Master_SSL_Key</code>                |
| <code>SSL_VERIFY_SERVER_CERTIFICATE</code>               | <code>Master_SSL_Verify_Server_Cert</code> |
| <code>SSL_CRL_FILE</code>                                | <code>Master_SSL_Crl</code>                |

| <code>replication_connection_configuration</code> Column | <code>SHOW SLAVE STATUS</code> Column |
|--|---------------------------------------|
| <code>SSL_CRL_PATH</code>                                | <code>Master_SSL_Crlpath</code>       |
| <code>CONNECTION_RETRY_INTERVAL</code>                   | <code>Connect_Retry</code>            |
| <code>CONNECTION_RETRY_COUNT</code>                      | <code>Master_Retry_Count</code>       |

#### 24.10.11.2 The `replication_connection_status` Table

As of MySQL 5.7.2, this table shows the current status of the I/O thread that handles the slave server connection to the master server.

Compared to the `replication_connection_configuration` table, `replication_connection_status` changes more frequently. It contains values that change during the connection, whereas `replication_connection_configuration` contains values which define how the slave connects to the master and that remain constant during the connection.

The `replication_connection_status` table has these columns:

- `CHANNEL_NAME`

The replication channel which this row is displaying. There is always a default replication channel, and more replication channels can be added. See [Section 18.2.3, “Replication Channels”](#) for more information.

- `GROUP_NAME`

This column is reserved for future use. Added in MySQL 5.7.6.

- `SOURCE_UUID`

The `server_uuid` value from the master.

- `THREAD_ID`

The I/O thread ID.

- `SERVICE_STATE`

`ON` (thread exists and is active or idle), `OFF` (thread no longer exists), or `CONNECTING` (thread exists and is connecting to the master).

- `RECEIVED_TRANSACTION_SET`

The set of global transaction IDs (GTIDs) corresponding to all transactions received by this slave. Empty if GTIDs are not in use. See [GTID Sets](#) for more information.

- `LAST_ERROR_NUMBER`, `LAST_ERROR_MESSAGE`

The error number and error message of the most recent error that caused the I/O thread to stop. An error number of 0 and message of the empty string mean “no error.” If the `LAST_ERROR_MESSAGE` value is not empty, the error values also appear in the slave's error log.

Issuing `RESET MASTER` or `RESET SLAVE` resets the values shown in these columns.

- `LAST_ERROR_TIMESTAMP`

A timestamp in `YYMMDD HH:MM:SS` format that shows when the most recent I/O error took place.

- `LAST_HEARTBEAT_TIMESTAMP`

A timestamp in `YYMMDD HH:MM:SS` format that shows when the most recent heartbeat signal was received by a replication slave. Added in MySQL 5.7.5.

- `COUNT_RECEIVED_HEARTBEATS`

The total number of heartbeat signals that a replication slave received since the last time it was restarted or reset, or a `CHANGE MASTER TO` statement was issued. Added in MySQL 5.7.5.

`TRUNCATE TABLE` is not permitted for the `replication_connection_status` table.

The following table shows the correspondence between `replication_connection_status` columns and `SHOW SLAVE STATUS` columns.

| <code>replication_connection_status</code> Column | <code>SHOW SLAVE STATUS</code> Column |
|---|---------------------------------------|
| <code>SOURCE_UUID</code>                          | <code>Master_UUID</code>              |
| <code>THREAD_ID</code>                            | <code>None</code>                     |
| <code>SERVICE_STATE</code>                        | <code>Slave_IO_Running</code>         |
| <code>RECEIVED_TRANSACTION_SET</code>             | <code>Retrieved_Gtid_Set</code>       |
| <code>LAST_ERROR_NUMBER</code>                    | <code>Last_IO_Errno</code>            |
| <code>LAST_ERROR_MESSAGE</code>                   | <code>Last_IO_Error</code>            |
| <code>LAST_ERROR_TIMESTAMP</code>                 | <code>Last_IO_Error_Timestamp</code>  |

### 24.10.11.3 The `replication_applier_configuration` Table

This table shows the configuration parameters that affect transactions applied by the slave server. Parameters stored in the table can be changed at runtime with the `CHANGE MASTER TO` statement, as indicated in the column descriptions. This table was added in MySQL 5.7.2 with the name `replication_execute_configuration`, and renamed to `replication_applier_configuration` in MySQL 5.7.6.

The `replication_applier_configuration` table has these columns:

- `CHANNEL_NAME`

The replication channel which this row is displaying. There is always a default replication channel, and more replication channels can be added. See [Section 18.2.3, “Replication Channels”](#) for more information.

- `DESIRED_DELAY`

The number of seconds that the slave must lag the master. (`CHANGE MASTER TO` option: `MASTER_DELAY`)

`TRUNCATE TABLE` is not permitted for the `replication_applier_configuration` table.

The following table shows the correspondence between `replication_applier_configuration` columns and `SHOW SLAVE STATUS` columns.

| <code>replication_applier_configuration</code> Column | <code>SHOW SLAVE STATUS</code> Column |
|---|---------------------------------------|
| <code>DESIRED_DELAY</code>                            | <code>SQL_Delay</code>                |

### 24.10.11.4 The `replication_applier_status` Table

This table shows the current general transaction execution status on the slave server. This table was added in MySQL 5.7.2 with the name `replication_execute_status`, and renamed to `replication_applier_configuration` in MySQL 5.7.6.

This table provides information about general aspects of transaction applier status that are not specific to any thread involved. Thread-specific status information is available in the `replication_applier_status_by_coordinator` table (and `replication_applier_status_by_worker` if the slave is multi-threaded).

The `replication_applier_status` table has these columns:

- `CHANNEL_NAME`

The replication channel which this row is displaying. There is always a default replication channel, and more replication channels can be added. See [Section 18.2.3, “Replication Channels”](#) for more information.

- `SERVICE_STATE`

Shows `ON` when the replication channel's applier threads are active or idle, `OFF` means that the applier threads are not active.

- `REMAINING_DELAY`

If the slave is waiting for `DESIRED_DELAY` seconds to pass since the master applied an event, this field contains the number of delay seconds remaining. At other times, this field is `NULL`. (The `DESIRED_DELAY` value is stored in the `replication_applier_configuration` table.)

- `COUNT_TRANSACTIONS_RETRIES`

Added in MySQL 5.7.5, shows the number of retries that were made because the slave SQL thread failed to apply a transaction.

`TRUNCATE TABLE` is not permitted for the `replication_applier_status` table.

The following table shows the correspondence between `replication_applier_status` columns and `SHOW SLAVE STATUS` columns.

| <code>replication_applier_status</code> Column | <code>SHOW SLAVE STATUS</code> Column |
|--|---------------------------------------|
| <code>SERVICE_STATE</code>                     | None                                  |
| <code>REMAINING_DELAY</code>                   | <code>SQL_Remaining_Delay</code>      |

#### 24.10.11.5 The `replication_applier_status_by_coordinator` Table

For a multi-threaded slave, the slave uses multiple worker threads and a coordinator thread to manage them, and this table shows the status of the coordinator thread. In MySQL 5.7.9 and later, for a single-threaded slave, this table is empty. (Previously, this table showed the applier thread status for a single-threaded slave; this information can now be found in the `replication_applier_status_by_worker` table in such cases. See Bug #74765, Bug #20001173.) This table was added in MySQL 5.7.2 as `replication_execute_status_by_coordinator`, and renamed `replication_applier_status_by_coordinator` in MySQL 5.7.6. For a multi-threaded slave, the `replication_applier_status_by_worker` table shows the status of the worker threads.

The `replication_applier_status_by_coordinator` table has these columns:

- `CHANNEL_NAME`

The replication channel which this row is displaying. There is always a default replication channel, and more replication channels can be added. See [Section 18.2.3, “Replication Channels”](#) for more information.

- `THREAD_ID`

The SQL/coordinator thread ID.

- `SERVICE_STATE`

`ON` (thread exists and is active or idle) or `OFF` (thread no longer exists).

- `LAST_ERROR_NUMBER`, `LAST_ERROR_MESSAGE`

The error number and error message of the most recent error that caused the SQL/coordinator thread to stop. An error number of 0 and message of the empty string mean “no error.” If the `LAST_ERROR_MESSAGE` value is not empty, the error values also appear in the slave’s error log.

Issuing `RESET MASTER` or `RESET SLAVE` resets the values shown in these columns.

All error codes and messages displayed in the `LAST_ERROR_NUMBER` and `LAST_ERROR_MESSAGE` columns correspond to error values listed in [Section B.3, “Server Error Codes and Messages”](#).

- `LAST_ERROR_TIMESTAMP`

A timestamp in `YYMMDD HH:MM:SS` format that shows when the most recent SQL/coordinator error occurred.

`TRUNCATE TABLE` is not permitted for the `replication_applier_status_by_coordinator` table.

The following table shows the correspondence between `replication_applier_status_by_coordinator` columns and `SHOW SLAVE STATUS` columns.

| <code>replication_applier_status_by_coordinator</code> Column | <code>SHOW SLAVE STATUS</code> Column |
|---|---------------------------------------|
| <code>THREAD_ID</code>  | None                                  |
| <code>SERVICE_STATE</code>                                    | <code>Slave_SQL_Running</code>        |
| <code>LAST_ERROR_NUMBER</code>                                | <code>Last_SQL_Errno</code>           |
| <code>LAST_ERROR_MESSAGE</code>                               | <code>Last_SQL_Error</code>           |
| <code>LAST_ERROR_TIMESTAMP</code>                             | <code>Last_SQL_Error_Timestamp</code> |

#### 24.10.11.6 The `replication_applier_status_by_worker` Table

In MySQL 5.7.9 and later, if the slave is not multi-threaded, this table shows the status of the applier thread. (Previously, this table was empty in such cases, and this information was reported in the `replication_applier_status_by_coordinator` table; see Bug #74765, Bug #2000173.) Otherwise, the slave uses multiple worker threads and a coordinator thread to manage them, and this table shows the status of the worker threads. This table was added in MySQL 5.7.2 as `replication_execute_status_by_worker`, and renamed `replication_applier_status_by_worker` in MySQL 5.7.6. For a multi-threaded slave, the `replication_applier_status_by_coordinator` table shows the status of the coordinator thread.

The `replication_applier_status_by_worker` table has these columns:

- `CHANNEL_NAME`

The replication channel which this row is displaying. There is always a default replication channel, and more replication channels can be added. See [Section 18.2.3, “Replication Channels”](#) for more information.

- `WORKER_ID`

The worker identifier (same value as the `id` column in the `mysql.slave_worker_info` table). After `STOP SLAVE`, the `THREAD_ID` column becomes `NULL`, but the `WORKER_ID` value is preserved.

- `THREAD_ID`

The worker thread ID.

- `SERVICE_STATE`

`ON` (thread exists and is active or idle) or `OFF` (thread no longer exists).

- `LAST_SEEN_TRANSACTION`

The transaction that the worker has last seen. The worker has not necessarily applied this transaction because it could still be in the process of doing so.

If the `gtid_mode` system variable value is `OFF`, this column is `ANONYMOUS`, indicating that transactions do not have global transaction identifiers (GTIDs) and are identified by file and position only.

If `gtid_mode` is `ON`, the column value is defined as follows:

- If no transaction has executed, the column is empty.
- When a transaction has executed, the column is set from `gtid_next` as soon as `gtid_next` is set. From this moment, the column always shows a GTID.
- The GTID is preserved until the next transaction is executed. If an error occurs, the column value is the GTID of the transaction being executed by the worker when the error occurred.
- When the next GTID log event is picked up by this worker thread, this column is updated from `gtid_next` soon after `gtid_next` is set.

- `LAST_ERROR_NUMBER`, `LAST_ERROR_MESSAGE`

The error number and error message of the most recent error that caused the worker thread to stop. An error number of 0 and message of the empty string mean “no error”. If the `LAST_ERROR_MESSAGE` value is not empty, the error values also appear in the slave's error log.

Issuing `RESET MASTER` or `RESET SLAVE` resets the values shown in these columns.

All error codes and messages displayed in the `LAST_ERROR_NUMBER` and `LAST_ERROR_MESSAGE` columns correspond to error values listed in [Section B.3, “Server Error Codes and Messages”](#).

- `LAST_ERROR_TIMESTAMP`

A timestamp in `YYMMDD HH:MM:SS` format that shows when the most recent worker error occurred.

`TRUNCATE TABLE` is not permitted for the `replication_applier_status_by_worker` table.

The following table shows the correspondence between `replication_applier_status_by_worker` columns and `SHOW SLAVE STATUS` columns.

| <code>replication_applier_status_by_worker</code> Column | <code>SHOW SLAVE STATUS</code> Column |
|--|---------------------------------------|
| <code>WORKER_ID</code>                                   | None                                  |
| <code>THREAD_ID</code>                                   | None                                  |
| <code>SERVICE_STATE</code>                               | None                                  |
| <code>LAST_SEEN_TRANSACTION</code>                       | None                                  |
| <code>LAST_ERROR_NUMBER</code>                           | <code>Last_SQL_Errno</code>           |
| <code>LAST_ERROR_MESSAGE</code>                          | <code>Last_SQL_Error</code>           |
| <code>LAST_ERROR_TIMESTAMP</code>                        | <code>Last_SQL_Error_Timestamp</code> |

#### 24.10.11.7 The `replication_group_members` Table

This table shows network and status information for replication group members. It was added in MySQL 5.7.6 and is reserved for future use.

The `replication_group_members` table has the following columns:

- `CHANNEL_NAME`  
Name of the group replication channel.
- `MEMBER_ID`  
Identifier for this member; same as the server UUID.
- `MEMBER_HOST`  
Network address of this member (host name or IP address).
- `MEMBER_PORT`  
Port on which the server is listening.
- `MEMBER_STATE`  
Current state of this member; can be any one of the following:
  - `OFFLINE`: The group replication plugin is installed but has not been started.
  - `RECOVERING`: The server has joined a group from which it is retrieving data.
  - `ONLINE`: The member is in a fully functioning state.

`TRUNCATE TABLE` is not permitted for the `replication_group_members` table.

#### 24.10.11.8 The `replication_group_member_stats` Table

This table shows statistical information for replication group members. It was added in MySQL 5.7.6 and is reserved for future use.

The `replication_group_member_stats` table has the following columns:

- `CHANNEL_NAME`  
Name of the group replication channel
- `VIEW_ID`  
Current view identifier for this group.
- `MEMBER_ID`  
Identifier for this member; same as the server UUID.
- `COUNT_TRANSACTIONS_IN_QUEUE`  
Number of transactions pending certification
- `COUNT_TRANSACTIONS_CHECKED`  
Number of transactions already certified by this member.
- `COUNT_CONFLICTS_DETECTED`  
Number of transactions that were negatively certified.
- `COUNT_TRANSACTIONS_VALIDATING`  
Number of transactions with which one can execute certification with them, but have not been garbage collected.

- [TRANSACTIONS\\_COMMITTED\\_ALL\\_MEMBERS](#)

Set of stable group transactions.

- [LAST\\_CONFLICT\\_FREE\\_TRANSACTION](#)

Latest transaction certified without conflicts.

[TRUNCATE TABLE](#) is not permitted for the [replication\\_group\\_member\\_stats](#) table.

## 24.10.12 Performance Schema Lock Tables

The Performance Schema exposes lock information through these tables:

- [metadata\\_locks](#): Metadata locks held and requested
- [table\\_handles](#): Table locks held and requested

The following sections describe these tables in more detail.

### 24.10.12.1 The [metadata\\_locks](#) Table

As of MySQL 5.7.3, the Performance Schema exposes metadata lock information through the [metadata\\_locks](#) table:

- Locks that have been granted (shows which sessions own which current metadata locks)
- Locks that have been requested but not yet granted (shows which sessions are waiting for which metadata locks).
- Lock requests that have been killed by the deadlock detector or timed out and are waiting for the requesting session's lock request to be discarded

This information enables you to understand metadata lock dependencies between sessions. You can see not only which lock a session is waiting for, but which session currently holds that lock.

The [metadata\\_locks](#) table is read only and cannot be updated. It is autosized by default; to configure the table size, set the [performance\\_schema\\_max\\_metadata\\_locks](#) system variable at server startup.

Metadata lock instrumentation is disabled by default. To enable it, enable the [wait/lock/metadata/sql/mdl](#) instrument in the [setup\\_instruments](#) table.

The Performance Schema maintains [metadata\\_locks](#) table content as follows, using the [LOCK\\_STATUS](#) column to indicate the status of each lock:

- When a metadata lock is requested and obtained immediately, a row with a status of [GRANTED](#) is inserted.
- When a metadata lock is requested and not obtained immediately, a row with a status of [PENDING](#) is inserted.
- When a metadata lock previously requested is granted, its row status is updated to [GRANTED](#).
- When a metadata lock is released, its row is deleted.
- When a pending lock request is canceled by the deadlock detector to break a deadlock ([ER\\_LOCK\\_DEADLOCK](#)), its row status is updated from [PENDING](#) to [VICTIM](#).
- When a pending lock request times out ([ER\\_LOCK\\_WAIT\\_TIMEOUT](#)), its row status is updated from [PENDING](#) to [TIMEOUT](#).
- When granted lock or pending lock request is killed, its row status is updated from [GRANTED](#) or [PENDING](#) to [KILLED](#).

- The `VICTIM`, `TIMEOUT`, and `KILLED` status values are brief and signify that the lock row is about to be deleted.
- The `PRE_ACQUIRE_NOTIFY` and `POST_RELEASE_NOTIFY` status values are brief and signify that the metadata locking subsystem is notifying interested storage engines while entering lock acquisition or leaving lock release operations. These status values were added in MySQL 5.7.11.

The `metadata_locks` table has these columns:

- `OBJECT_TYPE`

The type of lock used in the metadata lock subsystem: The value is one of `GLOBAL`, `SCHEMA`, `TABLE`, `FUNCTION`, `PROCEDURE`, `TRIGGER` (currently unused), `EVENT`, `COMMIT`, `USER LEVEL LOCK`, `TABLESPACE`, or `LOCKING SERVICE`.

A value of `USER LEVEL LOCK` indicates a lock acquired with `GET_LOCK()`. A value of `LOCKING SERVICE` indicates a lock acquired using the locking service described in [Section 27.3.1, “The Locking Service”](#).

- `OBJECT_SCHEMA`

The schema that contains the object.

- `OBJECT_NAME`

The name of the instrumented object.

- `OBJECT_INSTANCE_BEGIN`

The address in memory of the instrumented object.

- `LOCK_TYPE`

The lock type from the metadata lock subsystem. The value is one of `INTENTION_EXCLUSIVE`, `SHARED`, `SHARED_HIGH_PRIO`, `SHARED_READ`, `SHARED_WRITE`, `SHARED_UPGRADABLE`, `SHARED_NO_WRITE`, `SHARED_NO_READ_WRITE`, or `EXCLUSIVE`.

- `LOCK_DURATION`

The lock duration from the metadata lock subsystem. The value is one of `STATEMENT`, `TRANSACTION`, or `EXPLICIT`. The `STATEMENT` and `TRANSACTION` values are for locks that are released at statement or transaction end, respectively. The `EXPLICIT` value is for locks that survive statement or transaction end and are released explicitly, such as global locks acquired with `FLUSH TABLES WITH READ LOCK`.

- `LOCK_STATUS`

The lock status from the metadata lock subsystem. The value is one of `PENDING`, `GRANTED`, `VICTIM`, `TIMEOUT`, `KILLED`, `PRE_ACQUIRE_NOTIFY`, or `POST_RELEASE_NOTIFY`. The Performance Schema assigns these values as described earlier in this section.

- `SOURCE`

The name of the source file containing the instrumented code that produced the event and the line number in the file at which the instrumentation occurs. This enables you to check the source to determine exactly what code is involved.

- `OWNER_THREAD_ID`

The thread requesting a metadata lock.

- `OWNER_EVENT_ID`

The event requesting a metadata lock.

`TRUNCATE TABLE` is not permitted for the `metadata_locks` table.

### 24.10.12.2 The `table_handles` Table

As of MySQL 5.7.3, the Performance Schema exposes table lock information through the `table_handles` table to show the table locks currently in effect for each opened table handle. `table_handles` reports what is recorded by the table lock instrumentation. This information shows which table handles the server has open, how they are locked, and by which sessions.

The `table_handles` table is read only and cannot be updated. It is autosized by default; to configure the table size, set the `performance_schema_max_table_handles` system variable at server startup.

The `table_handles` table has these columns:

- `OBJECT_TYPE`

The table opened by a table handle.

- `OBJECT_SCHEMA`

The schema that contains the object.

- `OBJECT_NAME`

The name of the instrumented object.

- `OBJECT_INSTANCE_BEGIN`

The table handle address in memory.

- `OWNER_THREAD_ID`

The thread owning the table handle.

- `OWNER_EVENT_ID`

The event which caused the table handle to be opened.

- `INTERNAL_LOCK`

The table lock used at the SQL level. The value is one of `READ`, `READ WITH SHARED LOCKS`, `READ HIGH PRIORITY`, `READ NO INSERT`, `WRITE ALLOW WRITE`, `WRITE CONCURRENT INSERT`, `WRITE LOW PRIORITY`, or `WRITE`. For information about these lock types, see the `include/thr_lock.h` source file.

- `EXTERNAL_LOCK`

The table lock used at the storage engine level. The value is one of `READ EXTERNAL` or `WRITE EXTERNAL`.

`TRUNCATE TABLE` is not permitted for the `table_handles` table.

### 24.10.13 Performance Schema System Variable Tables

#### Note

The value of the `show_compatibility_56` system variable affects the information available from the tables described here. For details, see the description of that variable in [Section 6.1.5, “Server System Variables”](#).

The MySQL server maintains many system variables that indicate how it is configured (see [Section 6.1.5, “Server System Variables”](#)). As of MySQL 5.7.6, system variable information is available in these Performance Schema tables:

- `global_variables`: Global system variables. An application that wants only global values should use this table.
- `session_variables`: System variables for the current session. An application that wants all system variable values for its own session should use this table. It includes the session variables for its session, as well as the values of global variables that have no session counterpart. (In MySQL 5.7.6 and 5.7.7, the table does not fully reflect all system variable values in effect for the current session; it includes no rows for global variables that have no session counterpart. This is corrected in MySQL 5.7.8.)
- `variables_by_thread`: Session system variables for each active session. An application that wants to know the session variable values for specific sessions should use this table. It includes session variables only, identified by thread ID.

The session variable tables (`session_variables`, `variables_by_thread`) contain information only for active sessions, not terminated sessions.

`TRUNCATE TABLE` is not supported for Performance Schema system variable tables.

The `global_variables` and `session_variables` tables have these columns:

- `VARIABLE_NAME`  
The system variable name.
- `VARIABLE_VALUE`  
The system variable value. For `global_variables`, this column contains the global value. For `session_variables`, this column contains the variable value in effect for the current session.

The `variables_by_thread` table has these columns:

- `THREAD_ID`  
The thread identifier of the session in which the system variable is defined.
- `VARIABLE_NAME`  
The system variable name.
- `VARIABLE_VALUE`  
The session variable value for the session named by the `THREAD_ID` column.

The `variables_by_thread` table contains system variable information only about foreground threads. If not all threads are instrumented by the Performance Schema, this table will miss some rows. In this case, the `performance_schema_thread_instances_lost` status variable will be greater than zero.

## 24.10.14 Performance Schema Status Variable Tables

### Note

The value of the `show_compatibility_56` system variable affects the information available from the tables described here. For details, see the description of that variable in [Section 6.1.5, “Server System Variables”](#).

The MySQL server maintains many status variables that provide information about its operation (see [Section 6.1.7, “Server Status Variables”](#)). As of MySQL 5.7.6, status variable information is available in these Performance Schema tables:

- `global_status`: Global status variables. An application that wants only global values should use this table.
- `session_status`: Status variables for the current session. An application that wants all status variable values for its own session should use this table. It includes the session variables for its session, as well as the values of global variables that have no session counterpart. (In MySQL 5.7.6 and 5.7.7, the table does not fully reflect all status variable values in effect for the current session; it includes no rows for global variables that have no session counterpart. This is corrected in MySQL 5.7.8.)
- `status_by_thread`: Session status variables for each active session. An application that wants to know the session variable values for specific sessions should use this table. It includes session variables only, identified by thread ID.

There are also summary tables that provide status variable information aggregated by account, host name, and user name. See [Section 24.10.15.10, “Status Variable Summary Tables”](#).

The session variable tables (`session_status`, `status_by_thread`) contain information only for active sessions, not terminated sessions.

The Performance Schema collects statistics for global status variables only for threads for which the `INSTRUMENTED` value is `YES` in the `threads` table. Statistics for session status variables are always collected, regardless of the `INSTRUMENTED` value.

The Performance Schema does not collect statistics for `Com_xxx` status variables in the status variable tables. To obtain global and per-session statement execution counts, use the `events_statements_summary_global_by_event_name` and `events_statements_summary_by_thread_by_event_name` tables, respectively. For example:

```
SELECT EVENT_NAME, COUNT_STAR
FROM events_statements_summary_global_by_event_name
WHERE EVENT_NAME LIKE 'statement/sql/%';
```

The `global_status` and `session_status` tables have these columns:

- `VARIABLE_NAME`

The status variable name.

- `VARIABLE_VALUE`

The status variable value. For `global_status`, this column contains the global value. For `session_status`, this column contains the variable value for the current session.

The `status_by_thread` table contains the status of each active thread. It has these columns:

- `THREAD_ID`

The thread identifier of the session in which the status variable is defined.

- `VARIABLE_NAME`

The status variable name.

- `VARIABLE_VALUE`

The session variable value for the session named by the `THREAD_ID` column.

The `status_by_thread` table contains status variable information only about foreground threads. If the `performance_schema_max_thread_instances` system variable is not autoscaled (set to `-1`) and the maximum permitted number of instrumented thread objects is not greater than the number of background threads, the table will be empty.

The Performance Schema supports `TRUNCATE TABLE` for status variable tables as follows:

- `global_status`: Resets thread, account, host, and user status. Resets global status variables except those that the server never resets.
- `session_status`: Not supported.
- `status_by_thread`: Aggregates status for all threads to the global status and account status, then resets thread status. If account statistics are not collected, the session status is added to host and user status, if host and user status are collected.

Account, host, and user statistics are not collected if the `performance_schema_accounts_size`, `performance_schema_hosts_size`, and `performance_schema_users_size` system variables, respectively, are set to 0.

`FLUSH STATUS` adds the session status from all active sessions to the global status variables, resets the status of all active sessions, and resets account, host, and user status values aggregated from disconnected sessions.

## 24.10.15 Performance Schema Summary Tables

Summary tables provide aggregated information for terminated events over time. The tables in this group summarize event data in different ways.

### Wait Event Summaries:

- `events_waits_summary_by_account_by_event_name`: Wait events summarized per account and event name
- `events_waits_summary_by_host_by_event_name`: Wait events summarized per host name and event name
- `events_waits_summary_by_instance`: Wait events summarized per instance
- `events_waits_summary_by_thread_by_event_name`: Wait events summarized per thread and event name
- `events_waits_summary_by_user_by_event_name`: Wait events summarized per user name and event name
- `events_waits_summary_global_by_event_name`: Wait events summarized per event name

### Stage Summaries:

- `events_stages_summary_by_account_by_event_name`: Stage events summarized per account and event name
- `events_stages_summary_by_host_by_event_name`: Stage events summarized per host name and event name
- `events_stages_summary_by_thread_by_event_name`: Stage waits summarized per thread and event name
- `events_stages_summary_by_user_by_event_name`: Stage events summarized per user name and event name
- `events_stages_summary_global_by_event_name`: Stage waits summarized per event name

### Statement Summaries:

- `events_statements_summary_by_account_by_event_name`: Statement events summarized per account and event name

- [events\\_statements\\_summary\\_by\\_digest](#): Statement events summarized per schema and digest value
- [events\\_statements\\_summary\\_by\\_host\\_by\\_event\\_name](#): Statement events summarized per host name and event name
- [events\\_statements\\_summary\\_by\\_program](#): Statement events summarized per stored program (stored procedures and functions, triggers, and events) (added in MySQL 5.7.2)
- [events\\_statements\\_summary\\_by\\_thread\\_by\\_event\\_name](#): Statement events summarized per thread and event name
- [events\\_statements\\_summary\\_by\\_user\\_by\\_event\\_name](#): Statement events summarized per user name and event name
- [events\\_statements\\_summary\\_global\\_by\\_event\\_name](#): Statement events summarized per event name
- [prepared\\_statements\\_instances](#): Prepared statement instances and statistics (added in MySQL 5.7.4)

**Transaction Summaries:**

- [events\\_transactions\\_summary\\_by\\_account\\_by\\_event\\_name](#): Transaction events per account and event name (added in MySQL 5.7.3)
- [events\\_transactions\\_summary\\_by\\_host\\_by\\_event\\_name](#): Transaction events per host name and event name (added in MySQL 5.7.3)
- [events\\_transactions\\_summary\\_by\\_thread\\_by\\_event\\_name](#): Transaction events per thread and event name (added in MySQL 5.7.3)
- [events\\_transactions\\_summary\\_by\\_user\\_by\\_event\\_name](#): Transaction events per user name and event name (added in MySQL 5.7.3)
- [events\\_transactions\\_summary\\_global\\_by\\_event\\_name](#): Transaction events per event name (added in MySQL 5.7.3)

**Object Wait Summaries:**

- [objects\\_summary\\_global\\_by\\_type](#): Object summaries

**File I/O Summaries:**

- [file\\_summary\\_by\\_event\\_name](#): File events summarized per event name
- [file\\_summary\\_by\\_instance](#): File events summarized per file instance

**Table I/O and Lock Wait Summaries:**

- [table\\_io\\_waits\\_summary\\_by\\_index\\_usage](#): Table I/O waits per index
- [table\\_io\\_waits\\_summary\\_by\\_table](#): Table I/O waits per table
- [table\\_lock\\_waits\\_summary\\_by\\_table](#): Table lock waits per table

**Socket Summaries:**

- [socket\\_summary\\_by\\_instance](#): Socket waits and I/O summarized per instance
- [socket\\_summary\\_by\\_event\\_name](#): Socket waits and I/O summarized per event name

**Memory Summaries:**

- [memory\\_summary\\_by\\_account\\_by\\_event\\_name](#): Memory operations summarized per account and event name (added in MySQL 5.7.2)
- [memory\\_summary\\_by\\_host\\_by\\_event\\_name](#): Memory operations summarized per host and event name (added in MySQL 5.7.2)
- [memory\\_summary\\_by\\_thread\\_by\\_event\\_name](#): Memory operations summarized per thread and event name (added in MySQL 5.7.2)
- [memory\\_summary\\_by\\_user\\_by\\_event\\_name](#): Memory operations summarized per user and event name (added in MySQL 5.7.2)
- [memory\\_summary\\_global\\_by\\_event\\_name](#): Memory operations summarized globally per event name (added in MySQL 5.7.2)

#### Status Variable Summaries:

- [status\\_by\\_account](#): Status variables summarized by account (added in MySQL 5.7.6)
- [status\\_by\\_host](#): Status variables summarized by host name (added in MySQL 5.7.6)
- [status\\_by\\_user](#): Status variables summarized by user name (added in MySQL 5.7.6)

Each summary table has grouping columns that determine how to group the data to be aggregated, and summary columns that contain the aggregated values. Tables that summarize events in similar ways often have similar sets of summary columns and differ only in the grouping columns used to determine how events are aggregated.

Summary tables can be truncated with [TRUNCATE TABLE](#). Generally, the effect is to reset the summary columns to 0 or [NULL](#), not to remove rows. This enables you to clear collected values and restart aggregation. That might be useful, for example, after you have made a runtime configuration change. Exceptions to this truncation behavior are noted in individual summary table sections.

### 24.10.15.1 Wait Event Summary Tables

The Performance Schema maintains tables for collecting current and recent wait events, and aggregates that information in summary tables. [Section 24.10.4, “Performance Schema Wait Event Tables”](#) describes the events on which wait summaries are based. See that discussion for information about the content of wait events, the current and recent wait event tables, and how to control wait event collection, which is disabled by default.

Example wait event summary information:

```
mysql> SELECT * FROM events_waits_summary_global_by_event_name\G
...
***** 6. row *****
EVENT_NAME: wait/synch/mutex/sql/BINARY_LOG::LOCK_index
COUNT_STAR: 8
SUM_TIMER_WAIT: 2119302
MIN_TIMER_WAIT: 196092
AVG_TIMER_WAIT: 264912
MAX_TIMER_WAIT: 569421
...
***** 9. row *****
EVENT_NAME: wait/synch/mutex/sql/hash_filo::lock
COUNT_STAR: 69
SUM_TIMER_WAIT: 16848828
MIN_TIMER_WAIT: 0
AVG_TIMER_WAIT: 244185
MAX_TIMER_WAIT: 735345
...
```

Each wait event summary table has one or more grouping columns to indicate how the table aggregates events. Event names refer to names of event instruments in the [setup\\_instruments](#) table.

- `events_waits_summary_by_account_by_event_name` has `EVENT_NAME`, `USER`, and `HOST` columns. Each row summarizes events for a given account (user and host combination) and event name.
- `events_waits_summary_by_host_by_event_name` has `EVENT_NAME` and `HOST` columns. Each row summarizes events for a given host and event name.
- `events_waits_summary_by_instance` has `EVENT_NAME` and `OBJECT_INSTANCE_BEGIN` columns. Each row summarizes events for a given event name and object. If an instrument is used to create multiple instances, each instance has a unique `OBJECT_INSTANCE_BEGIN` value and is summarized separately in this table.
- `events_waits_summary_by_thread_by_event_name` has `THREAD_ID` and `EVENT_NAME` columns. Each row summarizes events for a given thread and event name.
- `events_waits_summary_by_user_by_event_name` has `EVENT_NAME` and `USER` columns. Each row summarizes events for a given user and event name.
- `events_waits_summary_global_by_event_name` has an `EVENT_NAME` column. Each row summarizes events for a given event name. An instrument might be used to create multiple instances of the instrumented object. For example, if there is an instrument for a mutex that is created for each connection, there are as many instances as there are connections. The summary row for the instrument summarizes over all these instances.

Each wait event summary table has these summary columns containing aggregated values:

- `COUNT_STAR`

The number of summarized events. This value includes all events, whether timed or nontimed.

- `SUM_TIMER_WAIT`

The total wait time of the summarized timed events. This value is calculated only for timed events because nontimed events have a wait time of `NULL`. The same is true for the other `xxx_TIMER_WAIT` values.

- `MIN_TIMER_WAIT`

The minimum wait time of the summarized timed events.

- `AVG_TIMER_WAIT`

The average wait time of the summarized timed events.

- `MAX_TIMER_WAIT`

The maximum wait time of the summarized timed events.

`TRUNCATE TABLE` is permitted for wait summary tables. It has these effects:

- For summary tables not aggregated by account, host, or user, truncation resets the summary columns to zero rather than removing rows.
- For summary tables aggregated by account, host, or user, truncation removes rows for accounts, hosts, or users with no connections, and resets the summary columns to zero for the remaining rows.

In addition, each wait summary table that is aggregated by account, host, user, or thread is implicitly truncated by truncation of the connection table on which it depends, or truncation of `events_waits_summary_global_by_event_name`. For details, see [Section 24.10.8, “Performance Schema Connection Tables”](#).

## 24.10.15.2 Stage Summary Tables

The Performance Schema maintains tables for collecting current and recent stage events, and aggregates that information in summary tables. [Section 24.10.5, “Performance Schema Stage Event Tables”](#) describes the events on which stage summaries are based. See that discussion for information about the content of stage events, the current and recent stage event tables, and how to control stage event collection, which is disabled by default.

Example stage event summary information:

```
mysql> SELECT * FROM events_stages_summary_global_by_event_name\G
...
***** 5. row *****
EVENT_NAME: stage/sql/checking permissions
COUNT_STAR: 57
SUM_TIMER_WAIT: 26501888880
MIN_TIMER_WAIT: 7317456
AVG_TIMER_WAIT: 464945295
MAX_TIMER_WAIT: 12858936792
...
***** 9. row *****
EVENT_NAME: stage/sql/closing tables
COUNT_STAR: 37
SUM_TIMER_WAIT: 662606568
MIN_TIMER_WAIT: 1593864
AVG_TIMER_WAIT: 17907891
MAX_TIMER_WAIT: 437977248
...
```

Each stage summary table has one or more grouping columns to indicate how the table aggregates events. Event names refer to names of event instruments in the [setup\\_instruments](#) table.

- [events\\_stages\\_summary\\_by\\_account\\_by\\_event\\_name](#) has [EVENT\\_NAME](#), [USER](#), and [HOST](#) columns. Each row summarizes events for a given account (user and host combination) and event name.
- [events\\_stages\\_summary\\_by\\_host\\_by\\_event\\_name](#) has [EVENT\\_NAME](#) and [HOST](#) columns. Each row summarizes events for a given host and event name.
- [events\\_stages\\_summary\\_by\\_thread\\_by\\_event\\_name](#) has [THREAD\\_ID](#) and [EVENT\\_NAME](#) columns. Each row summarizes events for a given thread and event name.
- [events\\_stages\\_summary\\_by\\_user\\_by\\_event\\_name](#) has [EVENT\\_NAME](#) and [USER](#) columns. Each row summarizes events for a given user and event name.
- [events\\_stages\\_summary\\_global\\_by\\_event\\_name](#) has an [EVENT\\_NAME](#) column. Each row summarizes events for a given event name.

Each stage summary table has these summary columns containing aggregated values: [COUNT\\_STAR](#), [SUM\\_TIMER\\_WAIT](#), [MIN\\_TIMER\\_WAIT](#), [AVG\\_TIMER\\_WAIT](#), and [MAX\\_TIMER\\_WAIT](#). These columns are analogous to the columns of the same names in the wait event summary tables (see [Section 24.10.15.1, “Wait Event Summary Tables”](#)), except that the stage summary tables aggregate events from [events\\_stages\\_current](#) rather than [events\\_waits\\_current](#).

[TRUNCATE TABLE](#) is permitted for stage summary tables. It has these effects:

- For summary tables not aggregated by account, host, or user, truncation resets the summary columns to zero rather than removing rows.
- For summary tables aggregated by account, host, or user, truncation removes rows for accounts, hosts, or users with no connections, and resets the summary columns to zero for the remaining rows.

In addition, each stage summary table that is aggregated by account, host, user, or thread is implicitly truncated by truncation of the connection table on which it depends, or truncation of [events\\_stages\\_summary\\_global\\_by\\_event\\_name](#). For details, see [Section 24.10.8, “Performance Schema Connection Tables”](#).

### 24.10.15.3 Statement Summary Tables

The Performance Schema maintains tables for collecting current and recent statement events, and aggregates that information in summary tables. [Section 24.10.6, “Performance Schema Statement Event Tables”](#) describes the events on which statement summaries are based. See that discussion for information about the content of statement events, the current and recent statement event tables, and how to control statement event collection, which is partially disabled by default.

Example statement event summary information:

```
mysql> SELECT * FROM events_statements_summary_global_by_event_name\G
***** 1. row *****
          EVENT_NAME: statement/sql/select
          COUNT_STAR: 25
          SUM_TIMER_WAIT: 1535983999000
          MIN_TIMER_WAIT: 209823000
          AVG_TIMER_WAIT: 61439359000
          MAX_TIMER_WAIT: 1363397650000
          SUM_LOCK_TIME: 20186000000
          SUM_ERRORS: 0
          SUM_WARNINGS: 0
          SUM_ROWS_AFFECTED: 0
          SUM_ROWS_SENT: 388
          SUM_ROWS_EXAMINED: 370
SUM_CREATED_TMP_DISK_TABLES: 0
          SUM_CREATED_TMP_TABLES: 0
          SUM_SELECT_FULL_JOIN: 0
          SUM_SELECT_FULL_RANGE_JOIN: 0
          SUM_SELECT_RANGE: 0
          SUM_SELECT_RANGE_CHECK: 0
          SUM_SELECT_SCAN: 6
          SUM_SORT_MERGE_PASSES: 0
          SUM_SORT_RANGE: 0
          SUM_SORT_ROWS: 0
          SUM_SORT_SCAN: 0
          SUM_NO_INDEX_USED: 6
          SUM_NO_GOOD_INDEX_USED: 0
...

```

Each statement summary table has one or more grouping columns to indicate how the table aggregates events. Event names refer to names of event instruments in the [setup\\_instruments](#) table.

- [events\\_statements\\_summary\\_by\\_account\\_by\\_event\\_name](#) has [EVENT\\_NAME](#), [USER](#), and [HOST](#) columns. Each row summarizes events for a given account (user and host combination) and event name.
- [events\\_statements\\_summary\\_by\\_digest](#) has [SCHEMA\\_NAME](#) and [DIGEST](#) columns. Each row summarizes events for given schema/digest values. (The [DIGEST\\_TEXT](#) column contains the corresponding normalized statement digest text, but is neither a grouping nor summary column.)

The maximum number of rows in the table is autosized at server startup. To set this maximum explicitly, set the [performance\\_schema\\_digests\\_size](#) system variable at server startup.

- [events\\_statements\\_summary\\_by\\_host\\_by\\_event\\_name](#) has [EVENT\\_NAME](#) and [HOST](#) columns. Each row summarizes events for a given host and event name.
- [events\\_statements\\_summary\\_by\\_program](#) has [OBJECT\\_TYPE](#), [OBJECT\\_SCHEMA](#), and [OBJECT\\_NAME](#) columns. Each row summarizes events for a given stored program (stored procedure or function, trigger, or event).
- [events\\_statements\\_summary\\_by\\_thread\\_by\\_event\\_name](#) has [THREAD\\_ID](#) and [EVENT\\_NAME](#) columns. Each row summarizes events for a given thread and event name.
- [events\\_statements\\_summary\\_by\\_user\\_by\\_event\\_name](#) has [EVENT\\_NAME](#) and [USER](#) columns. Each row summarizes events for a given user and event name.

- `events_statements_summary_global_by_event_name` has an `EVENT_NAME` column. Each row summarizes events for a given event name.
- `prepared_statements_instances` has an `OBJECT_INSTANCE_BEGIN` column. Each row summarizes events for a given prepared statement.

Each statement summary table has these summary columns containing aggregated values (with exceptions as noted):

- `COUNT_STAR`, `SUM_TIMER_WAIT`, `MIN_TIMER_WAIT`, `AVG_TIMER_WAIT`, `MAX_TIMER_WAIT`

These columns are analogous to the columns of the same names in the wait event summary tables (see [Section 24.10.15.1, “Wait Event Summary Tables”](#)), except that the statement summary tables aggregate events from `events_statements_current` rather than `events_waits_current`.

The `prepared_statements_instances` table does not have these columns.

- `SUM_xxx`

The aggregate of the corresponding `xxx` column in the `events_statements_current` table. For example, the `SUM_LOCK_TIME` and `SUM_ERRORS` columns in statement summary tables are the aggregates of the `LOCK_TIME` and `ERRORS` columns in `events_statements_current` table.

The `events_statements_summary_by_digest` table has these additional summary columns:

- `FIRST_SEEN_TIMESTAMP`, `LAST_SEEN_TIMESTAMP`

The times at which a statement with the given digest value were first seen and most recently seen.

The `events_statements_summary_by_program` table has these additional summary columns:

- `COUNT_STATEMENTS`, `SUM_STATEMENTS_WAIT`, `MIN_STATEMENTS_WAIT`, `AVG_STATEMENTS_WAIT`, `MAX_STATEMENTS_WAIT`

Statistics about nested statements invoked during stored program execution.

The `prepared_statements_instances` table has these additional summary columns:

- `COUNT_EXECUTE`, `SUM_TIMER_EXECUTE`, `MIN_TIMER_EXECUTE`, `AVG_TIMER_EXECUTE`, `MAX_TIMER_EXECUTE`

Aggregated statistics for executions of the prepared statement.

`TRUNCATE TABLE` is permitted for statement summary tables. It has these effects:

- For `events_statements_summary_by_digest`, it removes the rows.
- For other summary tables not aggregated by account, host, or user, truncation resets the summary columns to zero rather than removing rows.
- For other summary tables aggregated by account, host, or user, truncation removes rows for accounts, hosts, or users with no connections, and resets the summary columns to zero for the remaining rows.

In addition, each statement summary table that is aggregated by account, host, user, or thread is implicitly truncated by truncation of the connection table on which it depends, or truncation of `events_statements_summary_global_by_event_name`. For details, see [Section 24.10.8, “Performance Schema Connection Tables”](#).

## Statement Digest Aggregation Rules

If the `statement_digest` consumer is enabled, aggregation into `events_statements_summary_by_digest` occurs as follows when a statement completes. Aggregation is based on the `DIGEST` value computed for the statement.

- If a `events_statements_summary_by_digest` row already exists with the digest value for the statement that just completed, statistics for the statement are aggregated to that row. The `LAST_SEEN` column is updated to the current time.
- If no row has the digest value for the statement that just completed, and the table is not full, a new row is created for the statement. The `FIRST_SEEN` and `LAST_SEEN` columns are initialized with the current time.
- If no row has the statement digest value for the statement that just completed, and the table is full, the statistics for the statement that just completed are added to a special “catch-all” row with `DIGEST = NULL`, which is created if necessary. If the row is created, the `FIRST_SEEN` and `LAST_SEEN` columns are initialized with the current time. Otherwise, the `LAST_SEEN` column is updated with the current time.

The row with `DIGEST = NULL` is maintained because Performance Schema tables have a maximum size due to memory constraints. The `DIGEST = NULL` row permits digests that do not match other rows to be counted even if the summary table is full, using a common “other” bucket. This row helps you estimate whether the digest summary is representative:

- A `DIGEST = NULL` row that has a `COUNT_STAR` value that represents 5% of all digests shows that the digest summary table is very representative; the other rows cover 95% of the statements seen.
- A `DIGEST = NULL` row that has a `COUNT_STAR` value that represents 50% of all digests shows that the digest summary table is not very representative; the other rows cover only half the statements seen. Most likely the DBA should increase the maximum table size so that more of the rows counted in the `DIGEST = NULL` row would be counted using more specific rows instead. To do this, set the `performance_schema_digests_size` system variable to a larger value at server startup. The default size is 200.

## Stored Program Instrumentation Behavior

For stored program types for which instrumentation is enabled in the `setup_objects` table, `events_statements_summary_by_program` maintains statistics for stored programs as follows:

- A row is added for an object when it is first used in the server.
- The row for an object is removed when the object is dropped.
- Statistics are aggregated in the row for an object as it executes.

See also [Section 24.3.3, “Event Pre-Filtering”](#).

## 24.10.15.4 Transaction Summary Tables

As of MySQL 5.7.3, the Performance Schema maintains tables for collecting current and recent transaction events, and aggregates that information in summary tables. [Section 24.10.7, “Performance Schema Transaction Tables”](#) describes the events on which transaction summaries are based. See that discussion for information about the content of transaction events, the current and recent transaction event tables, and how to control transaction event collection, which is disabled by default.

Example transaction event summary information:

```
mysql> SELECT * FROM events_transactions_summary_global_by_event_name LIMIT 1\G
***** 1. row *****
      EVENT_NAME: transaction
      COUNT_STAR: 5
      SUM_TIMER_WAIT: 19550092000
      MIN_TIMER_WAIT: 2954148000
      AVG_TIMER_WAIT: 3910018000
      MAX_TIMER_WAIT: 5486275000
      COUNT_READ_WRITE: 5
```

```
SUM_TIMER_READ_WRITE: 19550092000
MIN_TIMER_READ_WRITE: 2954148000
AVG_TIMER_READ_WRITE: 3910018000
MAX_TIMER_READ_WRITE: 5486275000
COUNT_READ_ONLY: 0
SUM_TIMER_READ_ONLY: 0
MIN_TIMER_READ_ONLY: 0
AVG_TIMER_READ_ONLY: 0
MAX_TIMER_READ_ONLY: 0
```

Each transaction summary table has one or more grouping columns to indicate how the table aggregates events. Event names refer to names of event instruments in the [setup\\_instruments](#) table.

- [events\\_transactions\\_summary\\_by\\_account\\_by\\_event\\_name](#) has [USER](#), [HOST](#), and [EVENT\\_NAME](#) columns. Each row summarizes events for a given account (user and host combination) and event name.
- [events\\_transactions\\_summary\\_by\\_host\\_by\\_event\\_name](#) has [HOST](#) and [EVENT\\_NAME](#) columns. Each row summarizes events for a given host and event name.
- [events\\_transactions\\_summary\\_by\\_thread\\_by\\_event\\_name](#) has [THREAD\\_ID](#) and [EVENT\\_NAME](#) columns. Each row summarizes events for a given thread and event name.
- [events\\_transactions\\_summary\\_by\\_user\\_by\\_event\\_name](#) has [USER](#) and [EVENT\\_NAME](#) columns. Each row summarizes events for a given user and event name.
- [events\\_transactions\\_summary\\_global\\_by\\_event\\_name](#) has an [EVENT\\_NAME](#) column. Each row summarizes events for a given event name.

Each transaction summary table has these summary columns containing aggregated values:

- [COUNT\\_STAR](#), [SUM\\_TIMER\\_WAIT](#), [MIN\\_TIMER\\_WAIT](#), [AVG\\_TIMER\\_WAIT](#), [MAX\\_TIMER\\_WAIT](#)

These columns are analogous to the columns of the same names in the wait event summary tables (see [Section 24.10.15.1, “Wait Event Summary Tables”](#)), except that the transaction summary tables aggregate events from [events\\_transactions\\_current](#) rather than [events\\_waits\\_current](#). These columns summarize read-write and read-only transactions.

- [COUNT\\_READ\\_WRITE](#), [SUM\\_TIMER\\_READ\\_WRITE](#), [MIN\\_TIMER\\_READ\\_WRITE](#), [AVG\\_TIMER\\_READ\\_WRITE](#), [MAX\\_TIMER\\_READ\\_WRITE](#)

These are similar to the [COUNT\\_STAR](#) and [xxx\\_TIMER\\_WAIT](#) columns, but summarize read-write transactions only.

- [COUNT\\_READ\\_ONLY](#), [SUM\\_TIMER\\_READ\\_ONLY](#), [MIN\\_TIMER\\_READ\\_ONLY](#), [AVG\\_TIMER\\_READ\\_ONLY](#), [MAX\\_TIMER\\_READ\\_ONLY](#)

These are similar to the [COUNT\\_STAR](#) and [xxx\\_TIMER\\_WAIT](#) columns, but summarize read-only transactions only.

[TRUNCATE TABLE](#) is permitted for transaction summary tables. It has these effects:

- For summary tables not aggregated by account, host, or user, truncation resets the summary columns to zero rather than removing rows.
- For summary tables aggregated by account, host, or user, truncation removes rows for accounts, hosts, or users with no connections, and resets the summary columns to zero for the remaining rows.

In addition, each transaction summary table that is aggregated by account, host, user, or thread is implicitly truncated by truncation of the connection table on which it depends, or truncation of [events\\_transactions\\_summary\\_global\\_by\\_event\\_name](#). For details, see [Section 24.10.8, “Performance Schema Connection Tables”](#).

## Transaction Aggregation Rules

Transaction event collection occurs without regard to isolation level, access mode, or autocommit mode.

Read-write transactions are generally more resource intensive than read-only transactions, therefore transaction summary tables include separate aggregate columns for read-write and read-only transactions.

Resource requirements may also vary with transaction isolation level. However, presuming that only one isolation level would be used per server, aggregation by isolation level is not provided.

### 24.10.15.5 Object Wait Summary Table

The Performance Schema maintains the `objects_summary_global_by_type` table for aggregating object wait events.

Example object wait event summary information:

```
mysql> SELECT * FROM objects_summary_global_by_type\G
...
***** 3. row *****
OBJECT_TYPE: TABLE
OBJECT_SCHEMA: test
OBJECT_NAME: t
COUNT_STAR: 3
SUM_TIMER_WAIT: 263126976
MIN_TIMER_WAIT: 1522272
AVG_TIMER_WAIT: 87708678
MAX_TIMER_WAIT: 258428280
...
***** 10. row *****
OBJECT_TYPE: TABLE
OBJECT_SCHEMA: mysql
OBJECT_NAME: user
COUNT_STAR: 14
SUM_TIMER_WAIT: 365567592
MIN_TIMER_WAIT: 1141704
AVG_TIMER_WAIT: 26111769
MAX_TIMER_WAIT: 334783032
...
```

The `objects_summary_global_by_type` table has these grouping columns to indicate how the table aggregates events: `OBJECT_TYPE`, `OBJECT_SCHEMA`, and `OBJECT_NAME`. Each row summarizes events for the given object.

`objects_summary_global_by_type` has the same summary columns as the `events_waits_summary_by_xxx` tables. See [Section 24.10.15.1, “Wait Event Summary Tables”](#).

`TRUNCATE TABLE` is permitted for the object summary table. It resets the summary columns to zero rather than removing rows.

### 24.10.15.6 File I/O Summary Tables

The Performance Schema maintains file I/O summary tables that aggregate information about I/O operations.

Example file I/O event summary information:

```
mysql> SELECT * FROM file_summary_by_event_name\G
...
***** 2. row *****
EVENT_NAME: wait/io/file/sql/binlog
COUNT_STAR: 31
SUM_TIMER_WAIT: 8243784888
```

```

        MIN_TIMER_WAIT: 0
        AVG_TIMER_WAIT: 265928484
        MAX_TIMER_WAIT: 6490658832
...
mysql> SELECT * FROM file_summary_by_instance\G
...
***** 2. row *****
        FILE_NAME: /var/mysql/share/english/errmsg.sys
        EVENT_NAME: wait/io/file/sql/ERRMSG
        EVENT_NAME: wait/io/file/sql/ERRMSG
        OBJECT_INSTANCE_BEGIN: 4686193384
        COUNT_STAR: 5
        SUM_TIMER_WAIT: 13990154448
        MIN_TIMER_WAIT: 26349624
        AVG_TIMER_WAIT: 2798030607
        MAX_TIMER_WAIT: 8150662536
...

```

Each file I/O summary table has one or more grouping columns to indicate how the table aggregates events. Event names refer to names of event instruments in the `setup_instruments` table.

- `file_summary_by_event_name` has an `EVENT_NAME` column. Each row summarizes events for a given event name.
- `file_summary_by_instance` has `FILE_NAME`, `EVENT_NAME`, and `OBJECT_INSTANCE_BEGIN` columns. Each row summarizes events for a given file and event name.

Each file I/O summary table has the following summary columns containing aggregated values. Some columns are more general and have values that are the same as the sum of the values of more fine-grained columns. In this way, aggregations at higher levels are available directly without the need for user-defined views that sum lower-level columns.

- `COUNT_STAR`, `SUM_TIMER_WAIT`, `MIN_TIMER_WAIT`, `AVG_TIMER_WAIT`, `MAX_TIMER_WAIT`

These columns aggregate all I/O operations.

- `COUNT_READ`, `SUM_TIMER_READ`, `MIN_TIMER_READ`, `AVG_TIMER_READ`, `MAX_TIMER_READ`, `SUM_NUMBER_OF_BYTES_READ`

These columns aggregate all read operations, including `FGETS`, `FGETC`, `FREAD`, and `READ`.

- `COUNT_WRITE`, `SUM_TIMER_WRITE`, `MIN_TIMER_WRITE`, `AVG_TIMER_WRITE`, `MAX_TIMER_WRITE`, `SUM_NUMBER_OF_BYTES_WRITE`

These columns aggregate all write operations, including `FPUTS`, `FPUTC`, `FPRINTF`, `VFPRINTF`, `FWRITE`, and `PWRITE`.

- `COUNT_MISC`, `SUM_TIMER_MISC`, `MIN_TIMER_MISC`, `AVG_TIMER_MISC`, `MAX_TIMER_MISC`

These columns aggregate all other I/O operations, including `CREATE`, `DELETE`, `OPEN`, `CLOSE`, `STREAM_OPEN`, `STREAM_CLOSE`, `SEEK`, `TELL`, `FLUSH`, `STAT`, `FSTAT`, `CHSIZE`, `RENAME`, and `SYNC`. There are no byte counts for these operations.

`TRUNCATE TABLE` is permitted for file I/O summary tables. It resets the summary columns to zero rather than removing rows.

The MySQL server uses several techniques to avoid I/O operations by caching information read from files, so it is possible that statements you might expect to result in I/O events will not. You may be able to ensure that I/O does occur by flushing caches or restarting the server to reset its state.

### 24.10.15.7 Table I/O and Lock Wait Summary Tables

The following sections describe the table I/O and lock wait summary tables:

- `table_io_waits_summary_by_index_usage`: Table I/O waits per index

- `table_io_waits_summary_by_table`: Table I/O waits per table
- `table_lock_waits_summary_by_table`: Table lock waits per table

### The `table_io_waits_summary_by_table` Table

The `table_io_waits_summary_by_table` table aggregates all table I/O wait events, as generated by the `wait/io/table/sql/handler` instrument. The grouping is by table.

The `table_io_waits_summary_by_table` table has these grouping columns to indicate how the table aggregates events: `OBJECT_TYPE`, `OBJECT_SCHEMA`, and `OBJECT_NAME`. These columns have the same meaning as in the `events_waits_current` table. They identify the table to which the row applies.

`table_io_waits_summary_by_table` has the following summary columns containing aggregated values. As indicated in the column descriptions, some columns are more general and have values that are the same as the sum of the values of more fine-grained columns. For example, columns that aggregate all writes hold the sum of the corresponding columns that aggregate inserts, updates, and deletes. In this way, aggregations at higher levels are available directly without the need for user-defined views that sum lower-level columns.

- `COUNT_STAR`, `SUM_TIMER_WAIT`, `MIN_TIMER_WAIT`, `AVG_TIMER_WAIT`, `MAX_TIMER_WAIT`

These columns aggregate all I/O operations. They are the same as the sum of the corresponding `xxx_READ` and `xxx_WRITE` columns.

- `COUNT_READ`, `SUM_TIMER_READ`, `MIN_TIMER_READ`, `AVG_TIMER_READ`, `MAX_TIMER_READ`

These columns aggregate all read operations. They are the same as the sum of the corresponding `xxx_FETCH` columns.

- `COUNT_WRITE`, `SUM_TIMER_WRITE`, `MIN_TIMER_WRITE`, `AVG_TIMER_WRITE`, `MAX_TIMER_WRITE`

These columns aggregate all write operations. They are the same as the sum of the corresponding `xxx_INSERT`, `xxx_UPDATE`, and `xxx_DELETE` columns.

- `COUNT_FETCH`, `SUM_TIMER_FETCH`, `MIN_TIMER_FETCH`, `AVG_TIMER_FETCH`, `MAX_TIMER_FETCH`

These columns aggregate all fetch operations.

- `COUNT_INSERT`, `SUM_TIMER_INSERT`, `MIN_TIMER_INSERT`, `AVG_TIMER_INSERT`, `MAX_TIMER_INSERT`

These columns aggregate all insert operations.

- `COUNT_UPDATE`, `SUM_TIMER_UPDATE`, `MIN_TIMER_UPDATE`, `AVG_TIMER_UPDATE`, `MAX_TIMER_UPDATE`

These columns aggregate all update operations.

- `COUNT_DELETE`, `SUM_TIMER_DELETE`, `MIN_TIMER_DELETE`, `AVG_TIMER_DELETE`, `MAX_TIMER_DELETE`

These columns aggregate all delete operations.

`TRUNCATE TABLE` is permitted for table I/O summary tables. It resets the summary columns to zero rather than removing rows. Truncating this table also truncates the `table_io_waits_summary_by_index_usage` table.

### The `table_io_waits_summary_by_index_usage` Table

The `table_io_waits_summary_by_index_usage` table aggregates all table index I/O wait events, as generated by the `wait/io/table/sql/handler` instrument. The grouping is by table index.

The columns of `table_io_waits_summary_by_index_usage` are nearly identical to `table_io_waits_summary_by_table`. The only difference is the additional group column, `INDEX_NAME`, which corresponds to the name of the index that was used when the table I/O wait event was recorded:

- A value of `PRIMARY` indicates that table I/O used the primary index.
- A value of `NULL` means that table I/O used no index.
- Inserts are counted against `INDEX_NAME = NULL`.

`TRUNCATE TABLE` is permitted for table I/O summary tables. It resets the summary columns to zero rather than removing rows. This table is also truncated by truncation of the `table_io_waits_summary_by_table` table. A DDL operation that changes the index structure of a table may cause the per-index statistics to be reset.

### The `table_lock_waits_summary_by_table` Table

The `table_lock_waits_summary_by_table` table aggregates all table lock wait events, as generated by the `wait/lock/table/sql/handler` instrument. The grouping is by table.

This table contains information about internal and external locks:

- An internal lock corresponds to a lock in the SQL layer. This is currently implemented by a call to `thr_lock()`. In event rows, these locks are distinguished by the `OPERATION` column, which has one of these values:

```
read normal
read with shared locks
read high priority
read no insert
write allow write
write concurrent insert
write delayed
write low priority
write normal
```

- An external lock corresponds to a lock in the storage engine layer. This is currently implemented by a call to `handler::external_lock()`. In event rows, these locks are distinguished by the `OPERATION` column, which has one of these values:

```
read external
write external
```

The `table_lock_waits_summary_by_table` table has these grouping columns to indicate how the table aggregates events: `OBJECT_TYPE`, `OBJECT_SCHEMA`, and `OBJECT_NAME`. These columns have the same meaning as in the `events_waits_current` table. They identify the table to which the row applies.

`table_lock_waits_summary_by_table` has the following summary columns containing aggregated values. As indicated in the column descriptions, some columns are more general and have values that are the same as the sum of the values of more fine-grained columns. For example, columns that aggregate all locks hold the sum of the corresponding columns that aggregate read and write locks. In this way, aggregations at higher levels are available directly without the need for user-defined views that sum lower-level columns.

- `COUNT_STAR`, `SUM_TIMER_WAIT`, `MIN_TIMER_WAIT`, `AVG_TIMER_WAIT`, `MAX_TIMER_WAIT`

These columns aggregate all lock operations. They are the same as the sum of the corresponding `xxx_READ` and `xxx_WRITE` columns.

- `COUNT_READ`, `SUM_TIMER_READ`, `MIN_TIMER_READ`, `AVG_TIMER_READ`, `MAX_TIMER_READ`

These columns aggregate all read-lock operations. They are the same as the sum of the corresponding `xxx_READ_NORMAL`, `xxx_READ_WITH_SHARED_LOCKS`, `xxx_READ_HIGH_PRIORITY`, and `xxx_READ_NO_INSERT` columns.

- `COUNT_WRITE`, `SUM_TIMER_WRITE`, `MIN_TIMER_WRITE`, `AVG_TIMER_WRITE`, `MAX_TIMER_WRITE`

These columns aggregate all write-lock operations. They are the same as the sum of the corresponding `xxx_WRITE_ALLOW_WRITE`, `xxx_WRITE_CONCURRENT_INSERT`, `xxx_WRITE_LOW_PRIORITY`, and `xxx_WRITE_NORMAL` columns.

- `COUNT_READ_NORMAL`, `SUM_TIMER_READ_NORMAL`, `MIN_TIMER_READ_NORMAL`, `AVG_TIMER_READ_NORMAL`, `MAX_TIMER_READ_NORMAL`

These columns aggregate internal read locks.

- `COUNT_READ_WITH_SHARED_LOCKS`, `SUM_TIMER_READ_WITH_SHARED_LOCKS`, `MIN_TIMER_READ_WITH_SHARED_LOCKS`, `AVG_TIMER_READ_WITH_SHARED_LOCKS`, `MAX_TIMER_READ_WITH_SHARED_LOCKS`

These columns aggregate internal read locks.

- `COUNT_READ_HIGH_PRIORITY`, `SUM_TIMER_READ_HIGH_PRIORITY`, `MIN_TIMER_READ_HIGH_PRIORITY`, `AVG_TIMER_READ_HIGH_PRIORITY`, `MAX_TIMER_READ_HIGH_PRIORITY`

These columns aggregate internal read locks.

- `COUNT_READ_NO_INSERT`, `SUM_TIMER_READ_NO_INSERT`, `MIN_TIMER_READ_NO_INSERT`, `AVG_TIMER_READ_NO_INSERT`, `MAX_TIMER_READ_NO_INSERT`

These columns aggregate internal read locks.

- `COUNT_READ_EXTERNAL`, `SUM_TIMER_READ_EXTERNAL`, `MIN_TIMER_READ_EXTERNAL`, `AVG_TIMER_READ_EXTERNAL`, `MAX_TIMER_READ_EXTERNAL`

These columns aggregate external read locks.

- `COUNT_WRITE_ALLOW_WRITE`, `SUM_TIMER_WRITE_ALLOW_WRITE`, `MIN_TIMER_WRITE_ALLOW_WRITE`, `AVG_TIMER_WRITE_ALLOW_WRITE`, `MAX_TIMER_WRITE_ALLOW_WRITE`

These columns aggregate internal write locks.

- `COUNT_WRITE_CONCURRENT_INSERT`, `SUM_TIMER_WRITE_CONCURRENT_INSERT`, `MIN_TIMER_WRITE_CONCURRENT_INSERT`, `AVG_TIMER_WRITE_CONCURRENT_INSERT`, `MAX_TIMER_WRITE_CONCURRENT_INSERT`

These columns aggregate internal write locks.

- `COUNT_WRITE_LOW_PRIORITY`, `SUM_TIMER_WRITE_LOW_PRIORITY`, `MIN_TIMER_WRITE_LOW_PRIORITY`, `AVG_TIMER_WRITE_LOW_PRIORITY`, `MAX_TIMER_WRITE_LOW_PRIORITY`

These columns aggregate internal write locks.

- `COUNT_WRITE_NORMAL`, `SUM_TIMER_WRITE_NORMAL`, `MIN_TIMER_WRITE_NORMAL`, `AVG_TIMER_WRITE_NORMAL`, `MAX_TIMER_WRITE_NORMAL`

These columns aggregate internal write locks.

- `COUNT_WRITE_EXTERNAL`, `SUM_TIMER_WRITE_EXTERNAL`, `MIN_TIMER_WRITE_EXTERNAL`, `AVG_TIMER_WRITE_EXTERNAL`, `MAX_TIMER_WRITE_EXTERNAL`

These columns aggregate external write locks.

`TRUNCATE TABLE` is permitted for table lock summary tables. It resets the summary columns to zero rather than removing rows.

### 24.10.15.8 Socket Summary Tables

These socket summary tables aggregate timer and byte count information for socket operations:

- `socket_summary_by_event_name`: Aggregate timer and byte count statistics generated by the `wait/io/socket/*` instruments for all socket I/O operations, per socket instrument.
- `socket_summary_by_instance`: Aggregate timer and byte count statistics generated by the `wait/io/socket/*` instruments for all socket I/O operations, per socket instance. When a connection terminates, the row in `socket_summary_by_instance` corresponding to it is deleted.

The socket summary tables do not aggregate waits generated by `idle` events while sockets are waiting for the next request from the client. For `idle` event aggregations, use the wait-event summary tables; see [Section 24.10.15.1, “Wait Event Summary Tables”](#).

Each socket summary table has one or more grouping columns to indicate how the table aggregates events. Event names refer to names of event instruments in the `setup_instruments` table.

- `socket_summary_by_event_name` has an `EVENT_NAME` column. Each row summarizes events for a given event name.
- `socket_summary_by_instance` has an `OBJECT_INSTANCE_BEGIN` column. Each row summarizes events for a given object.

Each socket summary table has these summary columns containing aggregated values:

- `COUNT_STAR`, `SUM_TIMER_WAIT`, `MIN_TIMER_WAIT`, `AVG_TIMER_WAIT`, `MAX_TIMER_WAIT`

These columns aggregate all operations.

- `COUNT_READ`, `SUM_TIMER_READ`, `MIN_TIMER_READ`, `AVG_TIMER_READ`, `MAX_TIMER_READ`, `SUM_NUMBER_OF_BYTES_READ`

These columns aggregate all receive operations (`RECV`, `RECVFROM`, and `RECVMSG`).

- `COUNT_WRITE`, `SUM_TIMER_WRITE`, `MIN_TIMER_WRITE`, `AVG_TIMER_WRITE`, `MAX_TIMER_WRITE`, `SUM_NUMBER_OF_BYTES_WRITE`

These columns aggregate all send operations (`SEND`, `SENDTO`, and `SENDMSG`).

- `COUNT_MISC`, `SUM_TIMER_MISC`, `MIN_TIMER_MISC`, `AVG_TIMER_MISC`, `MAX_TIMER_MISC`

These columns aggregate all other socket operations, such as `CONNECT`, `LISTEN`, `ACCEPT`, `CLOSE`, and `SHUTDOWN`. There are no byte counts for these operations.

The `socket_summary_by_instance` table also has an `EVENT_NAME` column that indicates the class of the socket: `client_connection`, `server_tcpip_socket`, `server_unix_socket`. This column can be grouped on to isolate, for example, client activity from that of the server listening sockets.

`TRUNCATE TABLE` is permitted for socket summary tables. Except for `events_statements_summary_by_digest`, it resets the summary columns to zero rather than removing rows.

### 24.10.15.9 Memory Summary Tables

The Performance Schema instruments memory usage and aggregates memory usage statistics, detailed by these factors:

- Type of memory used (various caches, internal buffers, and so forth)
- Thread, account, user, host indirectly performing the memory operation

The Performance Schema instruments the following aspects of memory use

- Memory sizes used
- Operation counts
- Low and high water marks

Memory sizes help to understand or tune the memory consumption of the server.

Operation counts help to understand or tune the overall pressure the server is putting on the memory allocator, which has an impact on performance. Allocating a single byte one million times is not the same as allocating one million bytes a single time; tracking both sizes and counts can expose the difference.

Low and high water marks are critical to detect workload spikes, overall workload stability, and possible memory leaks.

Memory summary tables do not contain timing information because memory events are not timed.

Collection of memory information is described in [Memory Instrumentation Behavior](#).

Example memory event summary information:

```
mysql> SELECT * FROM memory_summary_global_by_event_name
        WHERE EVENT_NAME = 'memory/sql/TABLE'\G
***** 1. row *****
          EVENT_NAME: memory/sql/TABLE
          COUNT_ALLOC: 1381
          COUNT_FREE: 924
SUM_NUMBER_OF_BYTES_ALLOC: 2059873
SUM_NUMBER_OF_BYTES_FREE: 1407432
          LOW_COUNT_USED: 0
          CURRENT_COUNT_USED: 457
          HIGH_COUNT_USED: 461
          LOW_NUMBER_OF_BYTES_USED: 0
CURRENT_NUMBER_OF_BYTES_USED: 652441
          HIGH_NUMBER_OF_BYTES_USED: 669269
```

Each memory summary table has one or more grouping columns to indicate how the table aggregates events. Event names refer to names of event instruments in the [setup\\_instruments](#) table.

- [memory\\_summary\\_by\\_account\\_by\\_event\\_name](#) has [USER](#), [HOST](#), and [EVENT\\_NAME](#) columns. Each row summarizes events for a given account (user and host combination) and event name.
- [memory\\_summary\\_by\\_host\\_by\\_event\\_name](#) has [HOST](#) and [EVENT\\_NAME](#) columns. Each row summarizes events for a given host and event name.
- [memory\\_summary\\_by\\_thread\\_by\\_event\\_name](#) has [THREAD\\_ID](#) and [EVENT\\_NAME](#) columns. Each row summarizes events for a given thread and event name.
- [memory\\_summary\\_by\\_user\\_by\\_event\\_name](#) has [USER](#) and [EVENT\\_NAME](#) columns. Each row summarizes events for a given user and event name.
- [memory\\_summary\\_global\\_by\\_event\\_name](#) has an [EVENT\\_NAME](#) column. Each row summarizes events for a given event name.

Each memory summary table has these summary columns containing aggregated values:

- [COUNT\\_ALLOC](#), [COUNT\\_FREE](#)

The aggregated numbers of calls to malloc-like and free-like functions.

- [SUM\\_NUMBER\\_OF\\_BYTES\\_ALLOC](#), [SUM\\_NUMBER\\_OF\\_BYTES\\_FREE](#)

The aggregated sizes of allocated and freed memory blocks.

- [CURRENT\\_COUNT\\_USED](#)

The aggregated number of currently allocated blocks that have not been freed yet. This is a convenience column, equal to [COUNT\\_ALLOC](#) – [COUNT\\_FREE](#).

- [CURRENT\\_NUMBER\\_OF\\_BYTES\\_USED](#)

The aggregated size of currently allocated memory blocks that have not been freed yet. This is a convenience column, equal to [SUM\\_NUMBER\\_OF\\_BYTES\\_ALLOC](#) – [SUM\\_NUMBER\\_OF\\_BYTES\\_FREE](#).

- [LOW\\_COUNT\\_USED](#), [HIGH\\_COUNT\\_USED](#)

The low and high water marks corresponding to the [CURRENT\\_COUNT\\_USED](#) column.

- [LOW\\_NUMBER\\_OF\\_BYTES\\_USED](#), [HIGH\\_NUMBER\\_OF\\_BYTES\\_USED](#)

The low and high water marks corresponding to the [CURRENT\\_NUMBER\\_OF\\_BYTES\\_USED](#) column.

[TRUNCATE TABLE](#) is permitted for memory summary tables. It has these effects:

- In general, truncation resets the baseline for statistics, but does not change the server state. That is, truncating a memory table does not free memory.
- [COUNT\\_ALLOC](#) and [COUNT\\_FREE](#) are reset to a new baseline, by reducing each counter by the same value.
- Likewise, [SUM\\_NUMBER\\_OF\\_BYTES\\_ALLOC](#) and [SUM\\_NUMBER\\_OF\\_BYTES\\_FREE](#) are reset to a new baseline.
- [LOW\\_COUNT\\_USED](#) and [HIGH\\_COUNT\\_USED](#) are reset to [CURRENT\\_COUNT\\_USED](#).
- [LOW\\_NUMBER\\_OF\\_BYTES\\_USED](#) and [HIGH\\_NUMBER\\_OF\\_BYTES\\_USED](#) are reset to [CURRENT\\_NUMBER\\_OF\\_BYTES\\_USED](#).

In addition, each memory summary table that is aggregated by account, host, user, or thread is implicitly truncated by truncation of the connection table on which it depends, or truncation of [memory\\_summary\\_global\\_by\\_event\\_name](#). For details, see [Section 24.10.8, “Performance Schema Connection Tables”](#).

## Memory Instrumentation Behavior

Most memory instrumentation is disabled by default, and can be enabled or disabled dynamically by updating the [ENABLED](#) column of the relevant instruments in the [setup\\_instruments](#) table. Memory instruments have names of the form [memory/code\\_area/instrument\\_name](#).

To enable all memory instruments, execute this statement:

```
mysql> UPDATE setup_instruments SET ENABLED='YES'
      WHERE NAME LIKE 'memory/%';
```

Instruments named with the prefix [memory/performance\\_schema/](#) expose how much memory is allocated for internal buffers in the Performance Schema itself. The [memory/performance\\_schema/](#) instruments are built in, always enabled, and cannot be disabled at startup or runtime. The built-in memory instruments are displayed only in the [memory\\_summary\\_global\\_by\\_event\\_name](#) table.

For memory instruments, the [TIMED](#) column in [setup\\_instruments](#) is ignored because memory operations are not timed.

When a thread in the server executes a memory allocation that has been instrumented, these rules apply:

- If the thread is not instrumented or the memory instrument is not enabled, the memory block allocated is not instrumented.
- Otherwise (that is, both the thread and the instrument are enabled), the memory block allocated is instrumented.

For deallocation, these rules apply:

- If a thread is instrumented, and a memory block is not instrumented, the free operation is not instrumented; no statistics are changed.
- If a thread is not instrumented, and a memory block is instrumented, the free operation is instrumented, and statistics are changed.

For the per-thread statistics, the following rules apply.

When an instrumented memory block of size *N* is allocated, the Performance Schema makes these updates to memory summary table columns:

- `COUNT_ALLOC`: Increased by 1
- `CURRENT_COUNT_USED`: Increased by 1
- `HIGH_COUNT_USED`: Increased if `CURRENT_COUNT_USED` is a new maximum
- `SUM_NUMBER_OF_BYTES_ALLOC`: Increased by *N*
- `CURRENT_NUMBER_OF_BYTES_USED`: Increased by *N*
- `HIGH_NUMBER_OF_BYTES_USED`: Increased if `CURRENT_NUMBER_OF_BYTES_USED` is a new maximum

When an instrumented memory block is deallocated, the Performance Schema makes these updates to memory summary table columns:

- `COUNT_FREE`: Increased by 1
- `CURRENT_COUNT_USED`: Decreased by 1
- `LOW_COUNT_USED`: Decreased if `CURRENT_COUNT_USED` is a new minimum
- `SUM_NUMBER_OF_BYTES_FREE`: Increased by *N*
- `CURRENT_NUMBER_OF_BYTES_USED`: Decreased by *N*
- `LOW_NUMBER_OF_BYTES_USED`: Decreased if `CURRENT_NUMBER_OF_BYTES_USED` is a new minimum

For higher-level aggregates (global, by account, by user, by host), the same rules apply as expected for low and high water marks.

- `LOW_COUNT_USED` and `LOW_NUMBER_OF_BYTES_USED` are lower estimates. The value reported by the Performance Schema is guaranteed to be less than or equal to the lowest count or size of memory effectively used at runtime.
- `HIGH_COUNT_USED` and `HIGH_NUMBER_OF_BYTES_USED` are higher estimates. The value reported by the Performance Schema is guaranteed to be greater than or equal to the highest count or size of memory effectively used at runtime.

For lower estimates in summary tables other than `memory_summary_global_by_event_name`, it is possible for values to go negative if memory ownership is transferred between threads.

Here is an example of estimate computation; but note that estimate implementation is subject to change:

Thread 1 uses memory in the range from 1MB to 2MB during execution, as reported by the `LOW_NUMBER_OF_BYTES_USED` and `HIGH_NUMBER_OF_BYTES_USED` columns of the `memory_summary_by_thread_by_event_name` table.

Thread 2 uses memory in the range from 10MB to 12MB during execution, as reported likewise.

When these two threads belong to the same user account, the per-account summary estimates that this account used memory in the range from 11MB to 14MB. That is, the `LOW_NUMBER_OF_BYTES_USED` for the higher level aggregate is the sum of each `LOW_NUMBER_OF_BYTES_USED` (assuming the worst case). Likewise, the `HIGH_NUMBER_OF_BYTES_USED` for the higher level aggregate is the sum of each `HIGH_NUMBER_OF_BYTES_USED` (assuming the worst case).

11MB is a lower estimate that can occur only if both threads hit the low usage mark at the same time.

14MB is a higher estimate that can occur only if both threads hit the high usage mark at the same time.

The real memory usage for this account could have been in the range from 11.5MB to 13.5MB.

For capacity planning, reporting the worst case is actually the desired behavior, as it shows what can potentially happen when sessions are uncorrelated, which is typically the case.

#### 24.10.15.10 Status Variable Summary Tables

##### Note

The value of the `show_compatibility_56` system variable affects the information available from the tables described here. For details, see the description of that variable in [Section 6.1.5, “Server System Variables”](#).

As of MySQL 5.7.6, the Performance Schema makes status variable information available in the tables described in [Section 24.10.14, “Performance Schema Status Variable Tables”](#). It also makes aggregated status variable information available in summary tables, described here. Each status variable summary table has one or more grouping columns to indicate how the table aggregates status values:

- `status_by_account` has `USER`, `HOST`, and `VARIABLE_NAME` columns to summarize status variables by account.
- `status_by_host` has `HOST` and `VARIABLE_NAME` columns to summarize status variables by the host from which clients connected.
- `status_by_user` has `USER` and `VARIABLE_NAME` columns to summarize status variables by client user name.

Each status variable summary table has this summary column containing aggregated values:

- `VARIABLE_VALUE`

The aggregated status variable value for active and terminated sessions.

The meaning of “account” in these tables is similar to its meaning in the MySQL grant tables in the `mysql` system database, in the sense that the term refers to a combination of user and host values. They differ in that, for grant tables, the host part of an account can be a pattern, whereas for Performance Schema tables, the host value is always a specific nonpattern host name.

Account status is collected when sessions terminate. The session status counters are added to the global status counters and the corresponding account status counters. If account statistics are not collected, the session status is added to host and user status, if host and user status are collected.

Account, host, and user statistics are not collected if the `performance_schema_accounts_size`, `performance_schema_hosts_size`, and `performance_schema_users_size` system variables, respectively, are set to 0.

The Performance Schema supports `TRUNCATE TABLE` for status variable summary tables as follows; in all cases, status for active sessions is unaffected:

- `status_by_account`: Aggregates account status from terminated sessions to user and host status, then resets account status.
- `status_by_host`: Resets aggregated host status from terminated sessions.
- `status_by_user`: Resets aggregated user status from terminated sessions.

`FLUSH STATUS` adds the session status from all active sessions to the global status variables, resets the status of all active sessions, and resets account, host, and user status values aggregated from disconnected sessions.

## 24.10.16 Performance Schema Miscellaneous Tables

The following sections describe tables that do not fall into the table categories discussed in the preceding sections:

- `host_cache`: Information from the internal host cache
- `performance_timers`: Which event timers are available
- `threads`: Information about server threads

### 24.10.16.1 The `host_cache` Table

The `host_cache` table provides access to the contents of the host cache, which contains client host name and IP address information and is used to avoid DNS lookups. (See [Section 9.12.5.2, “DNS Lookup Optimization and the Host Cache”](#).) The `host_cache` table exposes the contents of the host cache so that it can be examined using `SELECT` statements. The Performance Schema must be enabled or this table is empty.

The `host_cache` table has these columns:

- `IP`

The IP address of the client that connected to the server, expressed as a string.

- `HOST`

The resolved DNS host name for that client IP, or `NULL` if the name is unknown.

- `HOST_VALIDATED`

Whether the IP-to-host name-to-IP DNS resolution was performed successfully for the client IP. If `HOST_VALIDATED` is `YES`, the `HOST` column is used as the host name corresponding to the IP so that calls to DNS can be avoided. While `HOST_VALIDATED` is `NO`, DNS resolution is attempted again for each connect, until it eventually completes with either a valid result or a permanent error. This information enables the server to avoid caching bad or missing host names during temporary DNS failures, which would affect clients forever.

- `SUM_CONNECT_ERRORS`

The number of connection errors that are deemed “blocking” (assessed against the `max_connect_errors` system variable). Only protocol handshake errors are counted, and only for hosts that passed validation (`HOST_VALIDATED = YES`).

- `COUNT_HOST_BLOCKED_ERRORS`

The number of connections that were blocked because [SUM\\_CONNECT\\_ERRORS](#) exceeded the value of the [max\\_connect\\_errors](#) system variable.

- [COUNT\\_NAMEINFO\\_TRANSIENT\\_ERRORS](#)

The number of transient errors during IP-to-host name DNS resolution.

- [COUNT\\_NAMEINFO\\_PERMANENT\\_ERRORS](#)

The number of permanent errors during IP-to-host name DNS resolution.

- [COUNT\\_FORMAT\\_ERRORS](#)

The number of host name format errors. MySQL does not perform matching of [Host](#) column values in the [mysql.user](#) table against host names for which one or more of the initial components of the name are entirely numeric, such as [1.2.example.com](#). The client IP address is used instead. For the rationale why this type of matching does not occur, see [Section 7.2.3, “Specifying Account Names”](#).

- [COUNT\\_ADDRINFO\\_TRANSIENT\\_ERRORS](#)

The number of transient errors during host name-to-IP reverse DNS resolution.

- [COUNT\\_ADDRINFO\\_PERMANENT\\_ERRORS](#)

The number of permanent errors during host name-to-IP reverse DNS resolution.

- [COUNT\\_FCRDNS\\_ERRORS](#)

The number of forward-confirmed reverse DNS errors. These errors occur when IP-to-host name-to-IP DNS resolution produces an IP address that does not match the client originating IP address.

- [COUNT\\_HOST\\_ACL\\_ERRORS](#)

The number of errors that occur because no user from the client host can possibly log in. In such cases, the server returns [ER\\_HOST\\_NOT\\_PRIVILEGED](#) and does not even ask for a user name or password.

- [COUNT\\_NO\\_AUTH\\_PLUGIN\\_ERRORS](#)

The number of errors due to requests for an unavailable authentication plugin. A plugin can be unavailable if, for example, it was never loaded or a load attempt failed.

- [COUNT\\_AUTH\\_PLUGIN\\_ERRORS](#)

The number of errors reported by authentication plugins.

An authentication plugin can report different error codes to indicate the root cause of a failure. Depending on the type of error, one of these columns is incremented: [COUNT\\_AUTHENTICATION\\_ERRORS](#), [COUNT\\_AUTH\\_PLUGIN\\_ERRORS](#), [COUNT\\_HANDSHAKE\\_ERRORS](#). New return codes are an optional extension to the existing plugin API. Unknown or unexpected plugin errors are counted in the [COUNT\\_AUTH\\_PLUGIN\\_ERRORS](#) column.

- [COUNT\\_HANDSHAKE\\_ERRORS](#)

The number of errors detected at the wire protocol level.

- [COUNT\\_PROXY\\_USER\\_ERRORS](#)

The number of errors detected when a proxy user A is proxied to another user B who does not exist.

- [COUNT\\_PROXY\\_USER\\_ACL\\_ERRORS](#)

The number of errors detected when a proxy user A is proxied to another user B who does exist but for whom A does not have the [PROXY](#) privilege.

- [COUNT\\_AUTHENTICATION\\_ERRORS](#)

The number of errors caused by failed authentication.

- [COUNT\\_SSL\\_ERRORS](#)

The number of errors due to SSL problems.

- [COUNT\\_MAX\\_USER\\_CONNECTIONS\\_ERRORS](#)

The number of errors caused by exceeding per-user connection quotas. See [Section 7.3.4, “Setting Account Resource Limits”](#).

- [COUNT\\_MAX\\_USER\\_CONNECTIONS\\_PER\\_HOUR\\_ERRORS](#)

The number of errors caused by exceeding per-user connections-per-hour quotas. See [Section 7.3.4, “Setting Account Resource Limits”](#).

- [COUNT\\_DEFAULT\\_DATABASE\\_ERRORS](#)

The number of errors related to the default database. For example, the database did not exist or the user had no privileges for accessing it.

- [COUNT\\_INIT\\_CONNECT\\_ERRORS](#)

The number of errors caused by execution failures of statements in the [init\\_connect](#) system variable value.

- [COUNT\\_LOCAL\\_ERRORS](#)

The number of errors local to the server implementation and not related to the network, authentication, or authorization. For example, out-of-memory conditions fall into this category.

- [COUNT\\_UNKNOWN\\_ERRORS](#)

The number of other, unknown errors not accounted for by other columns in this table. This column is reserved for future use, in case new error conditions must be reported, and if preserving the backward compatibility and table structure of the [host\\_cache](#) table is required.

- [FIRST\\_SEEN](#)

The timestamp of the first connection attempt seen from the client in the [IP](#) column.

- [LAST\\_SEEN](#)

The timestamp of the last connection attempt seen from the client in the [IP](#) column.

- [FIRST\\_ERROR\\_SEEN](#)

The timestamp of the first error seen from the client in the [IP](#) column.

- [LAST\\_ERROR\\_SEEN](#)

The timestamp of the last error seen from the client in the [IP](#) column.

[FLUSH HOSTS](#) and [TRUNCATE TABLE host\\_cache](#) have the same effect: They clear the host cache. This also removes rows from the [host\\_cache](#) table (because it is the visible representation of the cache) and unblocks any blocked hosts (see [Section B.5.2.6, “Host 'host\\_name' is blocked”](#).) [FLUSH HOSTS](#) requires the [RELOAD](#) privilege. [TRUNCATE TABLE](#) requires the [DROP](#) privilege for the [host\\_cache](#) table.

### 24.10.16.2 The performance\_timers Table

The `performance_timers` table shows which event timers are available:

```
mysql> SELECT * FROM performance_timers;
```

| TIMER_NAME  | TIMER_FREQUENCY | TIMER_RESOLUTION | TIMER_OVERHEAD |
|-------------|-----------------|------------------|----------------|
| CYCLE       | 2389029850      | 1                | 72             |
| NANOSECOND  | 1000000000      | 1                | 112            |
| MICROSECOND | 1000000         | 1                | 136            |
| MILLISECOND | 1036            | 1                | 168            |
| TICK        | 105             | 1                | 2416           |

The timers in `setup_timers` that you can use are those that do not have `NULL` in the other columns. If the values associated with a given timer name are `NULL`, that timer is not supported on your platform.

The `performance_timers` table has these columns:

- **TIMER\_NAME**

The name by which to refer to the timer when configuring the `setup_timers` table.

- **TIMER\_FREQUENCY**

The number of timer units per second. For a cycle timer, the frequency is generally related to the CPU speed. For example, on a system with a 2.4GHz processor, the `CYCLE` may be close to 2400000000.

- **TIMER\_RESOLUTION**

Indicates the number of timer units by which timer values increase. If a timer has a resolution of 10, its value increases by 10 each time.

- **TIMER\_OVERHEAD**

The minimal number of cycles of overhead to obtain one timing with the given timer. The Performance Schema determines this value by invoking the timer 20 times during initialization and picking the smallest value. The total overhead really is twice this amount because the instrumentation invokes the timer at the start and end of each event. The timer code is called only for timed events, so this overhead does not apply for nontimed events.

`TRUNCATE TABLE` is not permitted for the `performance_timers` table.

### 24.10.16.3 The threads Table

The `threads` table contains a row for each server thread. Each row contains information about a thread and indicates whether monitoring and historical event logging are enabled for it:

```
mysql> SELECT * FROM threads\G
***** 1. row *****
      THREAD_ID: 1
        NAME: thread/sql/main
        TYPE: BACKGROUND
PROCESSLIST_ID: NULL
PROCESSLIST_USER: NULL
PROCESSLIST_HOST: NULL
PROCESSLIST_DB: NULL
PROCESSLIST_COMMAND: NULL
PROCESSLIST_TIME: 80284
PROCESSLIST_STATE: NULL
PROCESSLIST_INFO: NULL
PARENT_THREAD_ID: NULL
        ROLE: NULL
```

```

    INSTRUMENTED: YES
    HISTORY: YES
    CONNECTION_TYPE: NULL
    THREAD_OS_ID: 489803
...
***** 4. row *****
    THREAD_ID: 51
    NAME: thread/sql/one_connection
    TYPE: FOREGROUND
    PROCESSLIST_ID: 34
    PROCESSLIST_USER: isabella
    PROCESSLIST_HOST: localhost
    PROCESSLIST_DB: performance_schema
    PROCESSLIST_COMMAND: Query
    PROCESSLIST_TIME: 0
    PROCESSLIST_STATE: Sending data
    PROCESSLIST_INFO: SELECT * FROM threads
    PARENT_THREAD_ID: 1
    ROLE: NULL
    INSTRUMENTED: YES
    HISTORY: YES
    CONNECTION_TYPE: SSL/TLS
    THREAD_OS_ID: 755399
...

```

When the Performance Schema initializes, it populates the `threads` table based on the threads in existence then. Thereafter, a new row is added each time the server creates a thread.

The `INSTRUMENTED` and `HISTORY` column values for new threads are determined by the contents of the `setup_actors` table. For information about how to use the `setup_actors` table to control these columns, see [Section 24.3.6, “Pre-Filtering by Thread”](#).

Removal of rows from the `threads` table occurs when threads end. For a thread associated with a client session, removal occurs when the session ends. If a client has auto-reconnect enabled and the session reconnects after a disconnect, the session becomes associated with a new row in the `threads` table that has a different `PROCESSLIST_ID` value. The initial `INSTRUMENTED` and `HISTORY` values for the new thread may be different from those of the original thread: The `setup_actors` table may have changed in the meantime, and if the `INSTRUMENTED` or `HISTORY` value for the original thread was changed after the row was initialized, the change does not carry over to the new thread.

The `threads` table columns with names having a prefix of `PROCESSLIST_` provide information similar to that available from the `INFORMATION_SCHEMA.PROCESSLIST` table or the `SHOW PROCESSLIST` statement. Thus, all three sources provide thread-monitoring information. Use of `threads` differs from use of the other two sources in these ways:

- Access to `threads` does not require a mutex and has minimal impact on server performance. `INFORMATION_SCHEMA.PROCESSLIST` and `SHOW PROCESSLIST` have negative performance consequences because they require a mutex.
- `threads` provides additional information for each thread, such as whether it is a foreground or background thread, and the location within the server associated with the thread.
- `threads` provides information about background threads, so it can be used to monitor activity the other thread information sources cannot.
- You can enable or disable thread monitoring (that is, whether events executed by the thread are instrumented) and historical event logging. To control the initial `INSTRUMENTED` and `HISTORY` values for new foreground threads, use the `setup_actors` table. To control these aspects of existing threads, set the `INSTRUMENTED` and `HISTORY` columns of `threads` table rows. (For more information about the conditions under which thread monitoring and historical event logging occur, see the descriptions of the `INSTRUMENTED` and `HISTORY` columns.)

For these reasons, DBAs who perform server monitoring using `INFORMATION_SCHEMA.PROCESSLIST` or `SHOW PROCESSLIST` may wish to monitor using the `threads` table instead.

**Note**

For `INFORMATION_SCHEMA.PROCESSLIST` and `SHOW PROCESSLIST`, information about threads for other users is shown only if the current user has the `PROCESS` privilege. That is not true of the `threads` table; all rows are shown to any user who has the `SELECT` privilege for the table. Users who should not be able to see threads for other users should not be given that privilege.

The `threads` table has these columns:

- `THREAD_ID`

A unique thread identifier.

- `NAME`

The name associated with the thread instrumentation code in the server. For example, `thread/sql/one_connection` corresponds to the thread function in the code responsible for handling a user connection, and `thread/sql/main` stands for the `main()` function of the server.

- `TYPE`

The thread type, either `FOREGROUND` or `BACKGROUND`. User connection threads are foreground threads. Threads associated with internal server activity are background threads. Examples are internal `InnoDB` threads, “binlog dump” threads sending information to slaves, and slave I/O and SQL threads.

- `PROCESSLIST_ID`

For threads that are displayed in the `INFORMATION_SCHEMA.PROCESSLIST` table, this is the same value displayed in the `ID` column of that table. It is also the value displayed in the `Id` column of `SHOW PROCESSLIST` output, and the value that `CONNECTION_ID()` would return within that thread.

For background threads (threads not associated with a user connection), `PROCESSLIST_ID` is `NULL`, so the values are not unique.

- `PROCESSLIST_USER`

The user associated with a foreground thread, `NULL` for a background thread.

- `PROCESSLIST_HOST`

The host name of the client associated with a foreground thread, `NULL` for a background thread.

Unlike the `HOST` column of the `INFORMATION_SCHEMA.PROCESSLIST` table or the `Host` column of `SHOW PROCESSLIST` output, the `PROCESSLIST_HOST` column does not include the port number for TCP/IP connections. To obtain this information from the Performance Schema, enable the socket instrumentation (which is not enabled by default) and examine the `socket_instances` table:

```
mysql> SELECT * FROM setup_instruments WHERE NAME LIKE 'wait/io/socket%';
+-----+-----+-----+
| NAME                                     | ENABLED | TIMED |
+-----+-----+-----+
| wait/io/socket/sql/server_tcpip_socket | NO      | NO    |
| wait/io/socket/sql/server_unix_socket  | NO      | NO    |
| wait/io/socket/sql/client_connection   | NO      | NO    |
+-----+-----+-----+
3 rows in set (0.01 sec)

mysql> UPDATE setup_instruments SET ENABLED='YES' WHERE NAME LIKE 'wait/io/socket%';
Query OK, 3 rows affected (0.00 sec)
Rows matched: 3  Changed: 3  Warnings: 0
```

```
mysql> SELECT * FROM socket_instances\G
***** 1. row *****
EVENT_NAME: wait/io/socket/sql/client_connection
OBJECT_INSTANCE_BEGIN: 140612577298432
  THREAD_ID: 31
  SOCKET_ID: 53
    IP: ::ffff:127.0.0.1
    PORT: 55642
    STATE: ACTIVE
...
```

- [PROCESSLIST\\_DB](#)

The default database for the thread, or [NULL](#) if there is none.

- [PROCESSLIST\\_COMMAND](#)

For foreground threads, the type of command the thread is executing on behalf of the client, or [Sleep](#) if the session is idle. For descriptions of thread commands, see [Section 9.14, “Examining Thread Information”](#). The value of this column corresponds to the [COM\\_xxx](#) commands of the client/server protocol and [Com\\_xxx](#) status variables. See [Section 6.1.7, “Server Status Variables”](#)

Background threads do not execute commands on behalf of clients, so this column may be [NULL](#).

- [PROCESSLIST\\_TIME](#)

The time in seconds that the thread has been in its current state.

- [PROCESSLIST\\_STATE](#)

An action, event, or state that indicates what the thread is doing. For descriptions of [PROCESSLIST\\_STATE](#) values, see [Section 9.14, “Examining Thread Information”](#). If the value is [NULL](#), the thread may correspond to an idle client session or the work it is doing is not instrumented with stages.

Most states correspond to very quick operations. If a thread stays in a given state for many seconds, there might be a problem that bears investigation.

- [PROCESSLIST\\_INFO](#)

The statement the thread is executing, or [NULL](#) if it is not executing any statement. The statement might be the one sent to the server, or an innermost statement if the statement executes other statements. For example, if a [CALL](#) statement executes a stored procedure that is executing a [SELECT](#) statement, the [PROCESSLIST\\_INFO](#) value shows the [SELECT](#) statement.

- [PARENT\\_THREAD\\_ID](#)

If this thread is a subthread (spawned by another thread), this is the [THREAD\\_ID](#) value of the spawning thread.

- [ROLE](#)

Unused.

- [INSTRUMENTED](#)

Whether events executed by the thread are instrumented. The value is [YES](#) or [NO](#).

- For foreground threads, the initial [INSTRUMENTED](#) value is determined by whether the user account associated with the thread matches any row in the [setup\\_actors](#) table. Matching is based on the values of the [PROCESSLIST\\_USER](#) and [PROCESSLIST\\_HOST](#) columns.

If the thread spawns a subthread, matching occurs again for the [threads](#) table row created for the subthread.

- For background threads, `INSTRUMENTED` is `YES` by default. `setup_actors` is not consulted because there is no associated user for background threads.

- For any thread, its `INSTRUMENTED` value can be changed during the lifetime of the thread.

For monitoring of events executed by the thread to occur, these things must be true:

- The `thread_instrumentation` consumer in the `setup_consumers` table must be `YES`.
- The `threads.INSTRUMENTED` column must be `YES`.
- Monitoring occurs only for those thread events produced from instruments that have the `ENABLED` column set to `YES` in the `setup_instruments` table.

- `HISTORY`

Whether to log historical events for the thread. The value is `YES` or `NO`.

- For foreground threads, the initial `HISTORY` value is determined by whether the user account associated with the thread matches any row in the `setup_actors` table. Matching is based on the values of the `PROCESSLIST_USER` and `PROCESSLIST_HOST` columns.

If the thread spawns a subthread, matching occurs again for the `threads` table row created for the subthread.

- For background threads, `HISTORY` is `YES` by default. `setup_actors` is not consulted because there is no associated user for background threads.
- For any thread, its `HISTORY` value can be changed during the lifetime of the thread.

For historical event logging for the thread to occur, these things must be true:

- The appropriate history-related consumers in the `setup_consumers` table must be enabled. For example, wait event logging in the `events_waits_history` and `events_waits_history_long` tables requires the corresponding `events_waits_history` and `events_waits_history_long` consumers to be `YES`.
- The `threads.HISTORY` column must be `YES`.
- Logging occurs only for those thread events produced from instruments that have the `ENABLED` column set to `YES` in the `setup_instruments` table.

The `HISTORY` column was added in MySQL 5.7.8. For earlier versions in which it is not present, the Performance Schema logs historical events either for all threads or no threads, depending on which history consumers are enabled or disabled.

- `CONNECTION_TYPE`

The protocol used to establish the connection, or `NULL` for background threads. Permitted values are `TCP/IP` (TCP/IP connection established without SSL), `SSL/TLS` (TCP/IP connection established with SSL), `Socket` (Unix socket file connection), `Named Pipe` (Windows named pipe connection), and `Shared Memory` (Windows shared memory connection).

This column was added in MySQL 5.7.8.

- `THREAD_OS_ID`

The thread or task identifier as defined by the underlying operating system, if there is one:

- When a MySQL thread is associated with the same operating system thread for its lifetime, `THREAD_OS_ID` contains the operating system thread ID.

- When a MySQL thread is not associated with the same operating system thread for its lifetime, `THREAD_OS_ID` contains `NULL`. This is typical for user sessions when the thread pool plugin is used (see [Section 6.5.4, “MySQL Enterprise Thread Pool”](#)).

For Windows, `THREAD_OS_ID` corresponds to the thread ID visible in Process Explorer (<https://technet.microsoft.com/en-us/sysinternals/bb896653.aspx>).

For Linux, `THREAD_OS_ID` corresponds to the value of the `gettid()` function. This value is exposed, for example, using the `perf` or `ps -L` commands, or in the `proc` file system (`/proc/[pid]/task/[tid]`). For more information, see the `perf-stat(1)`, `ps(1)`, and `proc(5)` man pages.

This column was added in MySQL 5.7.9.

`TRUNCATE TABLE` is not permitted for the `threads` table.

## 24.11 Performance Schema Option and Variable Reference

**Table 24.3 Performance Schema Variable Reference**

| Name   | Cmd-Line | Option File | System Var | Status Var | Var Scope | Dynamic |
|--|----------|-------------|------------|------------|-----------|---------|
| <a href="#">performance_schema</a>                                     | Yes      | Yes         | Yes        |            | Global    | No      |
| <a href="#">Performance_schema_accounts_lost</a>                       |          |             |            | Yes        | Global    | No      |
| <a href="#">performance_schema_accounts_lost</a>                       | Yes      | Yes         | Yes        |            | Global    | No      |
| <a href="#">Performance_schema_cond_classes_lost</a>                   |          |             |            | Yes        | Global    | No      |
| <a href="#">Performance_schema_cond_instances_lost</a>                 |          |             |            | Yes        | Global    | No      |
| <a href="#">performance-schema-consumer-events-stages-current</a>      | Yes      | Yes         |            |            |           |         |
| <a href="#">performance-schema-consumer-events-stages-history</a>      | Yes      | Yes         |            |            |           |         |
| <a href="#">performance-schema-consumer-events-stages-history-long</a> | Yes      | Yes         |            |            |           |         |
| <a href="#">performance-schema-consumer-events-statements-current</a>  | Yes      | Yes         |            |            |           |         |
| <a href="#">performance-schema-consumer-events-statements-history</a>  | Yes      | Yes         |            |            |           |         |

| Name   | Cmd-Line | Option File | System Var | Status Var | Var Scope | Dynamic |

## 24.12 Performance Schema Command Options

Performance Schema parameters can be specified at server startup on the command line or in option files to configure Performance Schema instruments and consumers. Runtime configuration is also possible in many cases (see [Section 24.3, “Performance Schema Runtime Configuration”](#)), but startup configuration must be used when runtime configuration is too late to affect instruments that have already been initialized during the startup process.

Performance Schema consumers and instruments can be configured at startup using the following syntax. For additional details, see [Section 24.2.2, “Performance Schema Startup Configuration”](#).

- `--performance-schema-consumer-consumer_name=value`

Configure a Performance Schema consumer. Consumer names in the `setup_consumers` table use underscores, but for consumers set at startup, dashes and underscores within the name are equivalent. Options for configuring individual consumers are detailed later in this section.

- `--performance-schema-instrument=instrument_name=value`

Configure a Performance Schema instrument. The name may be given as a pattern to configure instruments that match the pattern.

The following items configure individual consumers:

- `--performance-schema-consumer-events-stages-current=value`

Configure the `events-stages-current` consumer.

- `--performance-schema-consumer-events-stages-history=value`

Configure the `events-stages-history` consumer.

- `--performance-schema-consumer-events-stages-history-long=value`

Configure the `events-stages-history-long` consumer.

- `--performance-schema-consumer-events-statements-current=value`

Configure the `events-statements-current` consumer.

- `--performance-schema-consumer-events-statements-history=value`

Configure the `events-statements-history` consumer.

- `--performance-schema-consumer-events-statements-history-long=value`

Configure the `events-statements-history-long` consumer.

- `--performance-schema-consumer-events-transactions-current=value`

Configure the Performance Schema `events-transactions-current` consumer. This option was added in MySQL 5.7.3.

- `--performance-schema-consumer-events-transactions-history=value`

Configure the Performance Schema `events-transactions-history` consumer. This option was added in MySQL 5.7.3.

- `--performance-schema-consumer-events-transactions-history-long=value`

Configure the Performance Schema `events-transactions-history-long` consumer. This option was added in MySQL 5.7.3.

- `--performance-schema-consumer-events-waits-current=value`

Configure the `events-waits-current` consumer.

- `--performance-schema-consumer-events-waits-history=value`

Configure the `events-waits-history` consumer.

- `--performance-schema-consumer-events-waits-history-long=value`

Configure the `events-waits-history-long` consumer.

- `--performance-schema-consumer-global-instrumentation=value`

Configure the `global-instrumentation` consumer.

- `--performance-schema-consumer-statements-digest=value`

Configure the `statements-digest` consumer.

- `--performance-schema-consumer-thread-instrumentation=value`

Configure the `thread-instrumentation` consumer.

## 24.13 Performance Schema System Variables

The Performance Schema implements several system variables that provide configuration information:

```
mysql> SHOW VARIABLES LIKE 'perf%';
```

| Variable_name  | Value |
|--|-------|
| performance_schema                                       | ON    |
| performance_schema_accounts_size                         | -1    |
| performance_schema_digests_size                          | 10000 |
| performance_schema_events_stages_history_long_size       | 10000 |
| performance_schema_events_stages_history_size            | 10    |
| performance_schema_events_statements_history_long_size   | 10000 |
| performance_schema_events_statements_history_size        | 10    |
| performance_schema_events_transactions_history_long_size | 10000 |
| performance_schema_events_transactions_history_size      | 10    |
| performance_schema_events_waits_history_long_size        | 10000 |
| performance_schema_events_waits_history_size             | 10    |
| performance_schema_hosts_size                            | -1    |
| performance_schema_max_cond_classes                      | 80    |
| performance_schema_max_cond_instances                    | -1    |
| performance_schema_max_digest_length                     | 1024  |
| performance_schema_max_file_classes                      | 50    |
| performance_schema_max_file_handles                      | 32768 |
| performance_schema_max_file_instances                    | -1    |
| performance_schema_max_index_stat                        | -1    |
| performance_schema_max_memory_classes                    | 320   |
| performance_schema_max_metadata_locks                    | -1    |
| performance_schema_max_mutex_classes                     | 200   |
| performance_schema_max_mutex_instances                   | -1    |
| performance_schema_max_prepared_statements_instances     | -1    |
| performance_schema_max_program_instances                 | -1    |
| performance_schema_max_rwlock_classes                    | 40    |
| performance_schema_max_rwlock_instances                  | -1    |
| performance_schema_max_socket_classes                    | 10    |
| performance_schema_max_socket_instances                  | -1    |
| performance_schema_max_sql_text_length                   | 1024  |
| performance_schema_max_stage_classes                     | 150   |
| performance_schema_max_statement_classes                 | 192   |
| performance_schema_max_statement_stack                   | 10    |
| performance_schema_max_table_handles                     | -1    |
| performance_schema_max_table_instances                   | -1    |
| performance_schema_max_table_lock_stat                   | -1    |
| performance_schema_max_thread_classes                    | 50    |
| performance_schema_max_thread_instances                  | -1    |
| performance_schema_session_connect_attrs_size            | 512   |
| performance_schema_setup_actors_size                     | -1    |
| performance_schema_setup_objects_size                    | -1    |
| performance_schema_users_size                            | -1    |

Performance Schema system variables can be set at server startup on the command line or in option files, and many can be set at runtime. See [Section 24.11, “Performance Schema Option and Variable Reference”](#).

The Performance Schema automatically sizes the values of several of its parameters at server startup if they are not set explicitly. For more information, see [Section 24.2.2, “Performance Schema Startup Configuration”](#).

Performance Schema system variables have the following meanings:

- `performance_schema`

|                            |                                     |                                 |
|----------------------------|-------------------------------------|---------------------------------|
| <b>Command-Line Format</b> | <code>--performance_schema=#</code> |                                 |
| <b>System Variable</b>     | <b>Name</b>                         | <code>performance_schema</code> |

|                         |                         |         |
|-------------------------|-------------------------|---------|
|                         | <b>Variable Scope</b>   | Global  |
|                         | <b>Dynamic Variable</b> | No      |
| <b>Permitted Values</b> | <b>Type</b>             | boolean |
|                         | <b>Default</b>          | ON      |

The value of this variable is [ON](#) or [OFF](#) to indicate whether the Performance Schema is enabled. By default, the value is [ON](#) by default. At server startup, you can specify this variable with no value or a value of [ON](#) or 1 to enable it, or with a value of [OFF](#) or 0 to disable it.

As of MySQL 5.7.8, even when the Performance Schema is disabled, it continues to populate the [global\\_variables](#), [session\\_variables](#), [global\\_status](#), and [session\\_status](#) tables. This occurs as necessary to permit the results for the [SHOW VARIABLES](#) and [SHOW STATUS](#) statements to be drawn from those tables, depending on the setting of the [show\\_compatibility\\_56](#) system variable.

- [performance\\_schema\\_accounts\\_size](#)

|                                       |  |  |
|---------------------------------------|--|--|
| <b>Command-Line Format</b>            | <a href="#">--performance_schema_accounts_size=#</a> |  |
| <b>System Variable</b>                | <b>Name</b>  | <a href="#">performance_schema_accounts_size</a> |
|                                       | <b>Variable Scope</b>                                | Global   |
|                                       | <b>Dynamic Variable</b>                              | No   |
| <b>Permitted Values (&lt;= 5.7.5)</b> | <b>Type</b>  | integer  |
|                                       | <b>Default</b>                                       | <a href="#">-1 (autosized)</a>                   |
|                                       | <b>Min Value</b>                                     | <a href="#">-1 (autosized)</a>                   |
|                                       | <b>Max Value</b>                                     | <a href="#">1048576</a>                          |
| <b>Permitted Values (&gt;= 5.7.6)</b> | <b>Type</b>  | integer  |
|                                       | <b>Default</b>                                       | <a href="#">-1 (autoscaled)</a>                  |
|                                       | <b>Min Value</b>                                     | <a href="#">-1 (autoscaled)</a>                  |
|                                       | <b>Max Value</b>                                     | <a href="#">1048576</a>                          |

The number of rows in the [accounts](#) table. If this variable is 0, the Performance Schema does not maintain connection statistics in the [accounts](#) table or status variable information in the [status\\_by\\_account](#) table.

- [performance\\_schema\\_digests\\_size](#)

|                            |   |   |
|----------------------------|---|---|
| <b>Command-Line Format</b> | <a href="#">--performance_schema_digests_size=#</a> |   |
| <b>System Variable</b>     | <b>Name</b>   | <a href="#">performance_schema_digests_size</a> |
|                            | <b>Variable Scope</b>                               | Global  |
|                            | <b>Dynamic Variable</b>                             | No  |
| <b>Permitted Values</b>    | <b>Type</b>   | integer   |

## Performance Schema System Variables

|  |                  |                |
|--|------------------|----------------|
|  | <b>Default</b>   | -1 (autosized) |
|  | <b>Min Value</b> | -1             |
|  | <b>Max Value</b> | 1048576        |

The maximum number of rows in the `events_statements_summary_by_digest` table. If this maximum is exceeded such that a digest cannot be instrumented, the Performance Schema increments the `Performance_schema_digest_lost` status variable.

- `performance_schema_events_stages_history_long_size`

|                            |   |   |
|----------------------------|---|---|
| <b>Command-Line Format</b> | --<br><code>performance_schema_events_stages_history_long_size=#</code> |   |
| <b>System Variable</b>     | <b>Name</b>   | <code>performance_schema_events_stages_history_long_size</code> |
|                            | <b>Variable Scope</b>   | Global  |
|                            | <b>Dynamic Variable</b>   | No  |
| <b>Permitted Values</b>    | <b>Type</b>   | integer   |
|                            | <b>Default</b>  | -1 (autosized)  |

The number of rows in the `events_stages_history_long` table.

- `performance_schema_events_stages_history_size`

|                            |   |  |
|----------------------------|---|--|
| <b>Command-Line Format</b> | -- <code>performance_schema_events_stages_history_size=#</code> |  |
| <b>System Variable</b>     | <b>Name</b>   | <code>performance_schema_events_stages_history_size</code> |
|                            | <b>Variable Scope</b>   | Global   |
|                            | <b>Dynamic Variable</b>   | No   |
| <b>Permitted Values</b>    | <b>Type</b>   | integer  |
|                            | <b>Default</b>  | -1 (autosized)   |

The number of rows per thread in the `events_stages_history` table.

- `performance_schema_events_statements_history_long_size`

|                            |   |   |
|----------------------------|---|---|
| <b>Command-Line Format</b> | --<br><code>performance_schema_events_statements_history_long_size=#</code> |   |
| <b>System Variable</b>     | <b>Name</b>   | <code>performance_schema_events_statements_history_long_size</code> |
|                            | <b>Variable Scope</b>   | Global  |
|                            | <b>Dynamic Variable</b>   | No  |
| <b>Permitted Values</b>    | <b>Type</b>   | integer   |
|                            | <b>Default</b>  | -1 (autosized)  |

The number of rows in the `events_statements_history_long` table.

- `performance_schema_events_statements_history_size`

|                            |  |  |
|----------------------------|--|--|
| <b>Command-Line Format</b> | <code>--performance_schema_events_statements_history_size=#</code> |  |
| <b>System Variable</b>     | <b>Name</b>  | <code>performance_schema_events_statements_history_size</code> |
|                            | <b>Variable Scope</b>  | Global   |
|                            | <b>Dynamic Variable</b>  | No   |
| <b>Permitted Values</b>    | <b>Type</b>  | integer  |
|                            | <b>Default</b>   | -1 (autosized)   |

The number of rows per thread in the `events_statements_history` table.

- `performance_schema_events_transactions_history_long_size`

|                            |   |   |
|----------------------------|---|---|
| <b>Introduced</b>          | 5.7.3   |   |
| <b>Command-Line Format</b> | <code>--performance_schema_events_transactions_history_long_size=#</code> |   |
| <b>System Variable</b>     | <b>Name</b>   | <code>performance_schema_events_transactions_history_long_size</code> |
|                            | <b>Variable Scope</b>   | Global  |
|                            | <b>Dynamic Variable</b>   | No  |
| <b>Permitted Values</b>    | <b>Type</b>   | integer   |
|                            | <b>Default</b>  | -1 (autosized)  |

The number of rows in the `events_transactions_history_long` table. This variable was added in MySQL 5.7.3.

- `performance_schema_events_transactions_history_size`

|                            |  |  |
|----------------------------|--|--|
| <b>Introduced</b>          | 5.7.3  |  |
| <b>Command-Line Format</b> | <code>--performance_schema_events_transactions_history_size=#</code> |  |
| <b>System Variable</b>     | <b>Name</b>  | <code>performance_schema_events_transactions_history_size</code> |
|                            | <b>Variable Scope</b>  | Global   |
|                            | <b>Dynamic Variable</b>  | No   |
| <b>Permitted Values</b>    | <b>Type</b>  | integer  |
|                            | <b>Default</b>   | -1 (autosized)   |

The number of rows per thread in the `events_transactions_history` table. This variable was added in MySQL 5.7.3.

- `performance_schema_events_waits_history_long_size`

|                            |  |  |
|----------------------------|--|--|
| <b>Command-Line Format</b> | <code>--performance_schema_events_waits_history_long_size=#</code> |  |
| <b>System Variable</b>     | <b>Name</b>  | <code>performance_schema_events_waits_history_long_size</code> |
|                            | <b>Variable Scope</b>  | Global   |

|                         |                         |                |
|-------------------------|-------------------------|----------------|
|                         | <b>Dynamic Variable</b> | No             |
| <b>Permitted Values</b> | <b>Type</b>             | integer        |
|                         | <b>Default</b>          | -1 (autosized) |

The number of rows in the `events_waits_history_long` table.

- `performance_schema_events_waits_history_size`

|                            |   |   |
|----------------------------|---|---|
| <b>Command-Line Format</b> | <code>--performance_schema_events_waits_history_size=#</code> |   |
| <b>System Variable</b>     | <b>Name</b>   | <code>performance_schema_events_waits_history_size</code> |
|                            | <b>Variable Scope</b>   | Global  |
|                            | <b>Dynamic Variable</b>                                       | No  |
| <b>Permitted Values</b>    | <b>Type</b>   | integer   |
|                            | <b>Default</b>  | -1 (autosized)  |

The number of rows per thread in the `events_waits_history` table.

- `performance_schema_hosts_size`

|                                       |  |  |
|---------------------------------------|--|--|
| <b>Command-Line Format</b>            | <code>--performance_schema_hosts_size=#</code> |  |
| <b>System Variable</b>                | <b>Name</b>                                    | <code>performance_schema_hosts_size</code> |
|                                       | <b>Variable Scope</b>                          | Global                                     |
|                                       | <b>Dynamic Variable</b>                        | No   |
| <b>Permitted Values (&lt;= 5.7.5)</b> | <b>Type</b>                                    | integer                                    |
|                                       | <b>Default</b>                                 | -1 (autosized)                             |
|                                       | <b>Min Value</b>                               | -1 (autosized)                             |
|                                       | <b>Max Value</b>                               | 1048576                                    |
| <b>Permitted Values (&gt;= 5.7.6)</b> | <b>Type</b>                                    | integer                                    |
|                                       | <b>Default</b>                                 | -1 (autoscaled)                            |
|                                       | <b>Min Value</b>                               | -1 (autoscaled)                            |
|                                       | <b>Max Value</b>                               | 1048576                                    |

The number of rows in the `hosts` table. If this variable is 0, the Performance Schema does not maintain connection statistics in the `hosts` table or status variable information in the `status_by_host` table.

- `performance_schema_max_cond_classes`

|                            |  |  |
|----------------------------|--|--|
| <b>Command-Line Format</b> | <code>--performance_schema_max_cond_classes=#</code> |  |
| <b>System Variable</b>     | <b>Name</b>  | <code>performance_schema_max_cond_classes</code> |
|                            | <b>Variable Scope</b>                                | Global   |

|                         |                         |         |
|-------------------------|-------------------------|---------|
|                         | <b>Dynamic Variable</b> | No      |
| <b>Permitted Values</b> | <b>Type</b>             | integer |
|                         | <b>Default</b>          | 80      |

The maximum number of condition instruments.

- `performance_schema_max_cond_instances`

|                                    |  |  |
|------------------------------------|--|--|
| <b>Command-Line Format</b>         | <code>--performance_schema_max_cond_instances=#</code> |  |
| <b>System Variable</b>             | <b>Name</b>  | <code>performance_schema_max_cond_instances</code> |
|                                    | <b>Variable Scope</b>                                  | Global   |
|                                    | <b>Dynamic Variable</b>                                | No   |
| <b>Permitted Values</b> (<= 5.7.5) | <b>Type</b>  | integer  |
|                                    | <b>Default</b>   | -1 (autosized)                                     |
| <b>Permitted Values</b> (>= 5.7.6) | <b>Type</b>  | integer  |
|                                    | <b>Default</b>   | -1 (autoscaled)                                    |

The maximum number of instrumented condition objects.

- `performance_schema_max_digest_length`

|                            |   |   |
|----------------------------|---|---|
| <b>Introduced</b>          | 5.7.8   |   |
| <b>Command-Line Format</b> | <code>--performance_schema_max_digest_length=#</code> |   |
| <b>System Variable</b>     | <b>Name</b>   | <code>performance_schema_max_digest_length</code> |
|                            | <b>Variable Scope</b>                                 | Global  |
|                            | <b>Dynamic Variable</b>                               | No  |
| <b>Permitted Values</b>    | <b>Type</b>   | integer   |
|                            | <b>Default</b>  | 1024  |
|                            | <b>Min Value</b>                                      | 0   |
|                            | <b>Max Value</b>                                      | 1048576   |

The maximum number of bytes available for computing statement digests (see [Section 24.8, “Performance Schema Statement Digests”](#)). This variable is like `max_digest_length`, but applies to the Performance Schema only. For more information, see the description of that variable in [Section 6.1.5, “Server System Variables”](#)

This variable was added in MySQL 5.7.8. In MySQL 5.7.6 and 5.7.7, use `max_digest_length` instead. Before 5.7.6, the value cannot be changed.

- `performance_schema_max_file_classes`

|                            |  |  |
|----------------------------|--|--|
| <b>Command-Line Format</b> | <code>--performance_schema_max_file_classes=#</code> |  |
| <b>System Variable</b>     | <b>Name</b>  | <code>performance_schema_max_file_classes</code> |

|                                    |                         |         |
|------------------------------------|-------------------------|---------|
|                                    | <b>Variable Scope</b>   | Global  |
|                                    | <b>Dynamic Variable</b> | No      |
| <b>Permitted Values</b> (<= 5.7.8) | <b>Type</b>             | integer |
|                                    | <b>Default</b>          | 50      |
| <b>Permitted Values</b> (>= 5.7.9) | <b>Type</b>             | integer |
|                                    | <b>Default</b>          | 80      |

The maximum number of file instruments.

- `performance_schema_max_file_handles`

|                            |  |  |
|----------------------------|--|--|
| <b>Command-Line Format</b> | <code>--performance_schema_max_file_handles=#</code> |  |
| <b>System Variable</b>     | <b>Name</b>  | <code>performance_schema_max_file_handles</code> |
|                            | <b>Variable Scope</b>                                | Global   |
|                            | <b>Dynamic Variable</b>                              | No   |
| <b>Permitted Values</b>    | <b>Type</b>  | integer  |
|                            | <b>Default</b>                                       | 32768  |

The maximum number of opened file objects.

The value of `performance_schema_max_file_handles` should be greater than the value of `open_files_limit`: `open_files_limit` affects the maximum number of open file handles the server can support and `performance_schema_max_file_handles` affects how many of these file handles can be instrumented.

- `performance_schema_max_file_instances`

|                                    |  |  |
|------------------------------------|--|--|
| <b>Command-Line Format</b>         | <code>--performance_schema_max_file_instances=#</code> |  |
| <b>System Variable</b>             | <b>Name</b>  | <code>performance_schema_max_file_instances</code> |
|                                    | <b>Variable Scope</b>                                  | Global   |
|                                    | <b>Dynamic Variable</b>                                | No   |
| <b>Permitted Values</b> (<= 5.7.5) | <b>Type</b>  | integer  |
|                                    | <b>Default</b>   | -1 (autosized)                                     |
| <b>Permitted Values</b> (>= 5.7.6) | <b>Type</b>  | integer  |
|                                    | <b>Default</b>   | -1 (autoscaled)                                    |

The maximum number of instrumented file objects.

- `performance_schema_max_index_stat`

|                            |  |  |
|----------------------------|--|--|
| <b>Introduced</b>          | 5.7.6  |  |
| <b>Command-Line Format</b> | <code>--performance_schema_max_index_stat=#</code> |  |
| <b>System Variable</b>     | <b>Name</b>  | <code>performance_schema_max_index_stat</code> |
|                            | <b>Variable Scope</b>                              | Global   |

|                         |                         |                |
|-------------------------|-------------------------|----------------|
|                         | <b>Dynamic Variable</b> | No             |
| <b>Permitted Values</b> | <b>Type</b>             | integer        |
|                         | <b>Default</b>          | -1 (autosized) |

The maximum number of indexes for which the Performance Schema maintains statistics. If this maximum is exceeded such that index statistics are lost, the Performance Schema increments the [performance\\_schema\\_index\\_stat\\_lost](#) status variable. The default value is autosized using the value of [performance\\_schema\\_max\\_table\\_instances](#).

This variable was added in MySQL 5.7.6.

- [performance\\_schema\\_max\\_memory\\_classes](#)

|                                    |  |   |
|------------------------------------|--|---|
| <b>Introduced</b>                  | 5.7.2  |   |
| <b>Command-Line Format</b>         | <code>--performance_schema_max_memory_classes=#</code> |   |
| <b>System Variable</b>             | <b>Name</b>  | <a href="#">performance_schema_max_memory_classes</a> |
|                                    | <b>Variable Scope</b>                                  | Global  |
|                                    | <b>Dynamic Variable</b>                                | No  |
| <b>Permitted Values</b> (<= 5.7.4) | <b>Type</b>  | integer   |
|                                    | <b>Default</b>   | 250   |
| <b>Permitted Values</b> (>= 5.7.5) | <b>Type</b>  | integer   |
|                                    | <b>Default</b>   | 320   |

The maximum number of memory instruments. This variable was added in MySQL 5.7.2.

- [performance\\_schema\\_max\\_metadata\\_locks](#)

|                                    |  |   |
|------------------------------------|--|---|
| <b>Introduced</b>                  | 5.7.3  |   |
| <b>Command-Line Format</b>         | <code>--performance_schema_max_metadata_locks=#</code> |   |
| <b>System Variable</b>             | <b>Name</b>  | <a href="#">performance_schema_max_metadata_locks</a> |
|                                    | <b>Variable Scope</b>                                  | Global  |
|                                    | <b>Dynamic Variable</b>                                | No  |
| <b>Permitted Values</b> (<= 5.7.5) | <b>Type</b>  | integer   |
|                                    | <b>Default</b>   | -1 (autosized)  |
| <b>Permitted Values</b> (>= 5.7.6) | <b>Type</b>  | integer   |
|                                    | <b>Default</b>   | -1 (autoscaled)                                       |

The maximum number of metadata lock instruments. This value controls the size of the [metadata\\_locks](#) table. If this maximum is exceeded such that a metadata lock cannot be instrumented, the Performance Schema increments the [performance\\_schema\\_metadata\\_lock\\_lost](#) status variable.

This variable was added in MySQL 5.7.3.

- [performance\\_schema\\_max\\_mutex\\_classes](#)

|                            |   |
|----------------------------|---|
| <b>Command-Line Format</b> | <code>--performance_schema_max_mutex_classes=#</code> |
|----------------------------|---|

|                         |                         |   |
|-------------------------|-------------------------|---|
| <b>System Variable</b>  | <b>Name</b>             | <code>performance_schema_max_mutex_classes</code> |
|                         | <b>Variable Scope</b>   | Global  |
|                         | <b>Dynamic Variable</b> | No  |
| <b>Permitted Values</b> | <b>Type</b>             | integer   |
|                         | <b>Default</b>          | 200   |

The maximum number of mutex instruments.

- `performance_schema_max_mutex_instances`

|                                    |   |   |
|------------------------------------|---|---|
| <b>Command-Line Format</b>         | <code>--performance_schema_max_mutex_instances=#</code> |   |
| <b>System Variable</b>             | <b>Name</b>   | <code>performance_schema_max_mutex_instances</code> |
|                                    | <b>Variable Scope</b>                                   | Global  |
|                                    | <b>Dynamic Variable</b>                                 | No  |
| <b>Permitted Values</b> (<= 5.7.5) | <b>Type</b>   | integer   |
|                                    | <b>Default</b>  | -1 (autosized)                                      |
| <b>Permitted Values</b> (>= 5.7.6) | <b>Type</b>   | integer   |
|                                    | <b>Default</b>  | -1 (autoscaled)                                     |

The maximum number of instrumented mutex objects.

- `performance_schema_max_prepared_statements_instances`

|                                    |   |   |
|------------------------------------|---|---|
| <b>Introduced</b>                  | 5.7.4   |   |
| <b>Command-Line Format</b>         | <code>--performance_schema_max_prepared_statements_instances=#</code> |   |
| <b>System Variable</b>             | <b>Name</b>   | <code>performance_schema_max_prepared_statements_instances</code> |
|                                    | <b>Variable Scope</b>   | Global  |
|                                    | <b>Dynamic Variable</b>   | No  |
| <b>Permitted Values</b> (<= 5.7.5) | <b>Type</b>   | integer   |
|                                    | <b>Default</b>  | -1 (autosized)  |
| <b>Permitted Values</b> (>= 5.7.6) | <b>Type</b>   | integer   |
|                                    | <b>Default</b>  | -1 (autoscaled)   |

The maximum number of rows in the `prepared_statements_instances` table. If this maximum is exceeded such that a prepared statement cannot be instrumented, the Performance Schema increments the `Performance_schema_prepared_statements_lost` status variable. The default value of this variable is autosized based on the value of the `max_prepared_stmt_count` system variable.

This variable was added in MySQL 5.7.4.

- `performance_schema_max_rwlock_classes`

|                            |  |
|----------------------------|--|
| <b>Command-Line Format</b> | <code>--performance_schema_max_rwlock_classes=#</code> |
|----------------------------|--|

|                                    |                         |   |
|------------------------------------|-------------------------|---|
| <b>System Variable</b>             | <b>Name</b>             | <a href="#">performance_schema_max_rwlock_classes</a> |
|                                    | <b>Variable Scope</b>   | Global  |
|                                    | <b>Dynamic Variable</b> | No  |
| <b>Permitted Values</b> (<= 5.7.2) | <b>Type</b>             | integer   |
|                                    | <b>Default</b>          | 30  |
| <b>Permitted Values</b> (>= 5.7.3) | <b>Type</b>             | integer   |
|                                    | <b>Default</b>          | 40  |

The maximum number of rwlock instruments.

- [performance\\_schema\\_max\\_program\\_instances](#)

|                                    |   |  |
|------------------------------------|---|--|
| <b>Introduced</b>                  | 5.7.2   |  |
| <b>Command-Line Format</b>         | <code>--performance_schema_max_program_instances=#</code> |  |
| <b>System Variable</b>             | <b>Name</b>   | <a href="#">performance_schema_max_program_instances</a> |
|                                    | <b>Variable Scope</b>                                     | Global   |
|                                    | <b>Dynamic Variable</b>                                   | No   |
| <b>Permitted Values</b> (<= 5.7.5) | <b>Type</b>   | integer  |
|                                    | <b>Default</b>  | 5000   |
| <b>Permitted Values</b> (>= 5.7.6) | <b>Type</b>   | integer  |
|                                    | <b>Default</b>  | -1 (autoscaled)  |

The maximum number of stored programs for which the Performance Schema maintains statistics. If this maximum is exceeded, the Performance Schema increments the [Performance\\_schema\\_program\\_lost](#) status variable.

This variable was added in MySQL 5.7.2.

- [performance\\_schema\\_max\\_rwlock\\_instances](#)

|                                    |  |   |
|------------------------------------|--|---|
| <b>Command-Line Format</b>         | <code>--performance_schema_max_rwlock_instances=#</code> |   |
| <b>System Variable</b>             | <b>Name</b>  | <a href="#">performance_schema_max_rwlock_instances</a> |
|                                    | <b>Variable Scope</b>                                    | Global  |
|                                    | <b>Dynamic Variable</b>                                  | No  |
| <b>Permitted Values</b> (<= 5.7.5) | <b>Type</b>  | integer   |
|                                    | <b>Default</b>   | -1 (autosized)  |
| <b>Permitted Values</b> (>= 5.7.6) | <b>Type</b>  | integer   |
|                                    | <b>Default</b>   | -1 (autoscaled)   |

The maximum number of instrumented rwlock objects.

- [performance\\_schema\\_max\\_socket\\_classes](#)

|                            |  |
|----------------------------|--|
| <b>Command-Line Format</b> | <code>--performance_schema_max_socket_classes=#</code> |
|----------------------------|--|

|                         |                         |   |
|-------------------------|-------------------------|---|
| <b>System Variable</b>  | <b>Name</b>             | <a href="#">performance_schema_max_socket_classes</a> |
|                         | <b>Variable Scope</b>   | Global  |
|                         | <b>Dynamic Variable</b> | No  |
| <b>Permitted Values</b> | <b>Type</b>             | integer   |
|                         | <b>Default</b>          | 10  |

The maximum number of socket instruments.

- [performance\\_schema\\_max\\_socket\\_instances](#)

|                                    |   |   |
|------------------------------------|---|---|
| <b>Command-Line Format</b>         | <a href="#">--performance_schema_max_socket_instances=#</a> |   |
| <b>System Variable</b>             | <b>Name</b>   | <a href="#">performance_schema_max_socket_instances</a> |
|                                    | <b>Variable Scope</b>                                       | Global  |
|                                    | <b>Dynamic Variable</b>                                     | No  |
| <b>Permitted Values</b> (<= 5.7.5) | <b>Type</b>   | integer   |
|                                    | <b>Default</b>  | -1 (autosized)  |
| <b>Permitted Values</b> (>= 5.7.6) | <b>Type</b>   | integer   |
|                                    | <b>Default</b>  | -1 (autoscaled)   |

The maximum number of instrumented socket objects.

- [performance\\_schema\\_max\\_sql\\_text\\_length](#)

|                            |  |  |
|----------------------------|--|--|
| <b>Introduced</b>          | 5.7.6  |  |
| <b>Command-Line Format</b> | <a href="#">--performance_schema_max_sql_text_length=#</a> |  |
| <b>System Variable</b>     | <b>Name</b>  | <a href="#">performance_schema_max_sql_text_length</a> |
|                            | <b>Variable Scope</b>                                      | Global   |
|                            | <b>Dynamic Variable</b>                                    | No   |
| <b>Permitted Values</b>    | <b>Type</b>  | integer  |
|                            | <b>Default</b>   | 1024   |
|                            | <b>Min Value</b>   | 0  |
|                            | <b>Max Value</b>   | 1048576  |

The maximum number of bytes used to store SQL statements in the [SQL\\_TEXT](#) column of the [events\\_statements\\_current](#), [events\\_statements\\_history](#), and [events\\_statements\\_history\\_long](#) statement event tables. Any bytes in excess of [performance\\_schema\\_max\\_sql\\_text\\_length](#) are discarded and do not appear in the [SQL\\_TEXT](#) column. Statements differing only after that many initial bytes are indistinguishable in this column.

Decreasing the [performance\\_schema\\_max\\_sql\\_text\\_length](#) value reduces memory use but causes more statements to become indistinguishable if they differ only at the end. Increasing the value increases memory use but permits longer statements to be distinguished.

This variable was added in MySQL 5.7.6.

- [performance\\_schema\\_max\\_stage\\_classes](#)

|                            |   |  |
|----------------------------|---|--|
| <b>Command-Line Format</b> | <code>--performance_schema_max_stage_classes=#</code> |  |
| <b>System Variable</b>     | <b>Name</b>   | <a href="#">performance_schema_max_stage_classes</a> |
|                            | <b>Variable Scope</b>                                 | Global   |
|                            | <b>Dynamic Variable</b>                               | No   |
| <b>Permitted Values</b>    | <b>Type</b>   | integer  |
|                            | <b>Default</b>  | 150  |

The maximum number of stage instruments.

- [performance\\_schema\\_max\\_statement\\_classes](#)

|                            |   |  |
|----------------------------|---|--|
| <b>Command-Line Format</b> | <code>--performance_schema_max_statement_classes=#</code> |  |
| <b>System Variable</b>     | <b>Name</b>   | <a href="#">performance_schema_max_statement_classes</a> |
|                            | <b>Variable Scope</b>                                     | Global   |
|                            | <b>Dynamic Variable</b>                                   | No   |
| <b>Permitted Values</b>    | <b>Type</b>   | integer  |
|                            | <b>Default</b>  | -1 (autosized)   |

The maximum number of statement instruments. The default value is calculated at server build time based on the number of commands in the client/server protocol and the number of SQL statement types supported by the server.

This variable should not be changed, unless to set it to 0 to disable all statement instrumentation and save all memory associated with it. Setting the variable to nonzero values other than the default has no benefit; in particular, values larger than the default cause more memory to be allocated than is needed.

- [performance\\_schema\\_max\\_statement\\_stack](#)

|                            |   |  |
|----------------------------|---|--|
| <b>Introduced</b>          | 5.7.2   |  |
| <b>Command-Line Format</b> | <code>--performance_schema_max_statement_stack=#</code> |  |
| <b>System Variable</b>     | <b>Name</b>   | <a href="#">performance_schema_max_statement_stack</a> |
|                            | <b>Variable Scope</b>                                   | Global   |
|                            | <b>Dynamic Variable</b>                                 | No   |
| <b>Permitted Values</b>    | <b>Type</b>   | integer  |
|                            | <b>Default</b>  | 10   |

The maximum depth of nested stored program calls for which the Performance Schema maintains statistics. When this maximum is exceeded, the Performance Schema increments the [Performance\\_schema\\_nested\\_statement\\_lost](#) status variable for each stored program statement executed.

This variable was added in MySQL 5.7.2.

- [performance\\_schema\\_max\\_table\\_handles](#)

|                                       |   |  |
|---------------------------------------|---|--|
| <b>Command-Line Format</b>            | <code>--performance_schema_max_table_handles=#</code> |  |
| <b>System Variable</b>                | <b>Name</b>   | <a href="#">performance_schema_max_table_handles</a> |
|                                       | <b>Variable Scope</b>                                 | Global   |
|                                       | <b>Dynamic Variable</b>                               | No   |
| <b>Permitted Values (&lt;= 5.7.5)</b> | <b>Type</b>   | integer  |
|                                       | <b>Default</b>  | -1 (autosized)                                       |
| <b>Permitted Values (&gt;= 5.7.6)</b> | <b>Type</b>   | integer  |
|                                       | <b>Default</b>  | -1 (autoscaled)                                      |

The maximum number of opened table objects. This value controls the size of the [table\\_handles](#) table. If this maximum is exceeded such that a table handle cannot be instrumented, the Performance Schema increments the [Performance\\_schema\\_table\\_handles\\_lost](#) status variable.

- [performance\\_schema\\_max\\_table\\_instances](#)

|                                       |   |  |
|---------------------------------------|---|--|
| <b>Command-Line Format</b>            | <code>--performance_schema_max_table_instances=#</code> |  |
| <b>System Variable</b>                | <b>Name</b>   | <a href="#">performance_schema_max_table_instances</a> |
|                                       | <b>Variable Scope</b>                                   | Global   |
|                                       | <b>Dynamic Variable</b>                                 | No   |
| <b>Permitted Values (&lt;= 5.7.5)</b> | <b>Type</b>   | integer  |
|                                       | <b>Default</b>  | -1 (autosized)   |
| <b>Permitted Values (&gt;= 5.7.6)</b> | <b>Type</b>   | integer  |
|                                       | <b>Default</b>  | -1 (autoscaled)  |

The maximum number of instrumented table objects.

- [performance\\_schema\\_max\\_table\\_lock\\_stat](#)

|                            |   |  |
|----------------------------|---|--|
| <b>Introduced</b>          | 5.7.6   |  |
| <b>Command-Line Format</b> | <code>--performance_schema_max_table_lock_stat=#</code> |  |
| <b>System Variable</b>     | <b>Name</b>   | <a href="#">performance_schema_max_table_lock_stat</a> |
|                            | <b>Variable Scope</b>                                   | Global   |
|                            | <b>Dynamic Variable</b>                                 | No   |
| <b>Permitted Values</b>    | <b>Type</b>   | integer  |
|                            | <b>Default</b>  | -1 (autosized)   |

The maximum number of tables for which the Performance Schema maintains lock statistics. If this maximum is exceeded such that table lock statistics are lost, the Performance Schema increments the [Performance\\_schema\\_table\\_lock\\_stat\\_lost](#) status variable.

This variable was added in MySQL 5.7.6.

- [performance\\_schema\\_max\\_thread\\_classes](#)

|                            |  |   |
|----------------------------|--|---|
| <b>Command-Line Format</b> | <code>--performance_schema_max_thread_classes=#</code> |   |
| <b>System Variable</b>     | <b>Name</b>  | <a href="#">performance_schema_max_thread_classes</a> |
|                            | <b>Variable Scope</b>                                  | Global  |
|                            | <b>Dynamic Variable</b>                                | No  |
| <b>Permitted Values</b>    | <b>Type</b>  | integer   |
|                            | <b>Default</b>   | 50  |

The maximum number of thread instruments.

- [performance\\_schema\\_max\\_thread\\_instances](#)

|                                       |  |   |
|---------------------------------------|--|---|
| <b>Command-Line Format</b>            | <code>--performance_schema_max_thread_instances=#</code> |   |
| <b>System Variable</b>                | <b>Name</b>  | <a href="#">performance_schema_max_thread_instances</a> |
|                                       | <b>Variable Scope</b>                                    | Global  |
|                                       | <b>Dynamic Variable</b>                                  | No  |
| <b>Permitted Values (&lt;= 5.7.5)</b> | <b>Type</b>  | integer   |
|                                       | <b>Default</b>   | -1 (autosized)  |
| <b>Permitted Values (&gt;= 5.7.6)</b> | <b>Type</b>  | integer   |
|                                       | <b>Default</b>   | -1 (autoscaled)   |

The maximum number of instrumented thread objects. The value controls the size of the [threads](#) table. If this maximum is exceeded such that a thread cannot be instrumented, the Performance Schema increments the [Performance\\_schema\\_thread\\_instances\\_lost](#) status variable.

The [max\\_connections](#) system variable affects how many threads can run in the server. [performance\\_schema\\_max\\_thread\\_instances](#) affects how many of these running threads can be instrumented.

The [variables\\_by\\_thread](#) and [status\\_by\\_thread](#) tables contain system and status variable information only about foreground threads. If not all threads are instrumented by the Performance Schema, this table will miss some rows. In this case, the [Performance\\_schema\\_thread\\_instances\\_lost](#) status variable will be greater than zero.

- [performance\\_schema\\_session\\_connect\\_attrs\\_size](#)

|                            |  |   |
|----------------------------|--|---|
| <b>Command-Line Format</b> | <code>--performance_schema_session_connect_attrs_size=#</code> |   |
| <b>System Variable</b>     | <b>Name</b>  | <a href="#">performance_schema_session_connect_attrs_size</a> |
|                            | <b>Variable Scope</b>  | Global  |
|                            | <b>Dynamic Variable</b>  | No  |
| <b>Permitted Values</b>    | <b>Type</b>  | integer   |
|                            | <b>Default</b>   | -1 (autosized)  |

|  |                  |         |
|--|------------------|---------|
|  | <b>Min Value</b> | -1      |
|  | <b>Max Value</b> | 1048576 |

The amount of preallocated memory per thread reserved to hold connection attribute key/value pairs. If the aggregate size of connection attribute data sent by a client is larger than this amount, the Performance Schema truncates the attribute data, increments the `performance_schema_session_connect_attrs_lost` status variable, and writes a message to the error log indicating that truncation occurred if the `log_warnings` system variable value is greater than zero.

The default value of `performance_schema_session_connect_attrs_size` is autosized at server startup. This value may be small, so if truncation occurs (`performance_schema_session_connect_attrs_lost` becomes nonzero), you may wish to set `performance_schema_session_connect_attrs_size` explicitly to a larger value.

Although the maximum permitted `performance_schema_session_connect_attrs_size` value is 1MB, the effective maximum is 64KB because the server imposes a limit of 64KB on the aggregate size of connection attribute data it will accept. If a client attempts to send more than 64KB of attribute data, the server rejects the connection. For more information, see [Section 24.10.9, “Performance Schema Connection Attribute Tables”](#).

- `performance_schema_setup_actors_size`

|                                       |   |   |
|---------------------------------------|---|---|
| <b>Command-Line Format</b>            | <code>--performance_schema_setup_actors_size=#</code> |   |
| <b>System Variable</b>                | <b>Name</b>   | <code>performance_schema_setup_actors_size</code> |
|                                       | <b>Variable Scope</b>                                 | Global  |
|                                       | <b>Dynamic Variable</b>                               | No  |
| <b>Permitted Values (&lt;= 5.7.5)</b> | <b>Type</b>   | integer   |
|                                       | <b>Default</b>  | 100   |
| <b>Permitted Values (&gt;= 5.7.6)</b> | <b>Type</b>   | integer   |
|                                       | <b>Default</b>  | -1 (autoscaled)                                   |

The number of rows in the `setup_actors` table.

- `performance_schema_setup_objects_size`

|                                       |  |  |
|---------------------------------------|--|--|
| <b>Command-Line Format</b>            | <code>--performance_schema_setup_objects_size=#</code> |  |
| <b>System Variable</b>                | <b>Name</b>  | <code>performance_schema_setup_objects_size</code> |
|                                       | <b>Variable Scope</b>                                  | Global   |
|                                       | <b>Dynamic Variable</b>                                | No   |
| <b>Permitted Values (&lt;= 5.7.5)</b> | <b>Type</b>  | integer  |
|                                       | <b>Default</b>   | 100  |
| <b>Permitted Values (&gt;= 5.7.6)</b> | <b>Type</b>  | integer  |
|                                       | <b>Default</b>   | -1 (autoscaled)                                    |

The number of rows in the `setup_objects` table.

- `performance_schema_users_size`

|                                       |  |  |
|---------------------------------------|--|--|
| <b>Command-Line Format</b>            | <code>--performance_schema_users_size=#</code> |  |
| <b>System Variable</b>                | <b>Name</b>                                    | <code>performance_schema_users_size</code> |
|                                       | <b>Variable Scope</b>                          | Global                                     |
|                                       | <b>Dynamic Variable</b>                        | No   |
| <b>Permitted Values (&lt;= 5.7.5)</b> | <b>Type</b>                                    | integer                                    |
|                                       | <b>Default</b>                                 | <code>-1 (autosized)</code>                |
|                                       | <b>Min Value</b>                               | <code>-1 (autosized)</code>                |
|                                       | <b>Max Value</b>                               | <code>1048576</code>                       |
| <b>Permitted Values (&gt;= 5.7.6)</b> | <b>Type</b>                                    | integer                                    |
|                                       | <b>Default</b>                                 | <code>-1 (autoscaled)</code>               |
|                                       | <b>Min Value</b>                               | <code>-1 (autoscaled)</code>               |
|                                       | <b>Max Value</b>                               | <code>1048576</code>                       |

The number of rows in the `users` table. If this variable is 0, the Performance Schema does not maintain connection statistics in the `users` table or status variable information in the `status_by_user` table.

## 24.14 Performance Schema Status Variables

The Performance Schema implements several status variables that provide information about instrumentation that could not be loaded or created due to memory constraints:

```
mysql> SHOW STATUS LIKE 'perf%';
```

| Variable_name                             | Value |
|---|-------|
| Performance_schema_accounts_lost          | 0     |
| Performance_schema_cond_classes_lost      | 0     |
| Performance_schema_cond_instances_lost    | 0     |
| Performance_schema_file_classes_lost      | 0     |
| Performance_schema_file_handles_lost      | 0     |
| Performance_schema_file_instances_lost    | 0     |
| Performance_schema_hosts_lost             | 0     |
| Performance_schema_locker_lost            | 0     |
| Performance_schema_mutex_classes_lost     | 0     |
| Performance_schema_mutex_instances_lost   | 0     |
| Performance_schema_rwlock_classes_lost    | 0     |
| Performance_schema_rwlock_instances_lost  | 0     |
| Performance_schema_socket_classes_lost    | 0     |
| Performance_schema_socket_instances_lost  | 0     |
| Performance_schema_stage_classes_lost     | 0     |
| Performance_schema_statement_classes_lost | 0     |
| Performance_schema_table_handles_lost     | 0     |
| Performance_schema_table_instances_lost   | 0     |
| Performance_schema_thread_classes_lost    | 0     |
| Performance_schema_thread_instances_lost  | 0     |
| Performance_schema_users_lost             | 0     |

Performance Schema status variables have the following meanings:

- `Performance_schema_accounts_lost`

The number of times a row could not be added to the `accounts` table because it was full.

- `Performance_schema_cond_classes_lost`

How many condition instruments could not be loaded.

- `Performance_schema_cond_instances_lost`

How many condition instrument instances could not be created.

- `Performance_schema_digest_lost`

The number of digest instances that could not be instrumented in the `events_statements_summary_by_digest` table. This can be nonzero if the value of `performance_schema_digests_size` is too small.

- `Performance_schema_file_classes_lost`

How many file instruments could not be loaded.

- `Performance_schema_file_handles_lost`

How many file instrument instances could not be opened.

- `Performance_schema_file_instances_lost`

How many file instrument instances could not be created.

- `Performance_schema_hosts_lost`

The number of times a row could not be added to the `hosts` table because it was full.

- `Performance_schema_index_stat_lost`

The number of indexes for which statistics were lost. This can be nonzero if the value of `performance_schema_max_index_stat` is too small.

This variable was added in MySQL 5.7.6.

- `Performance_schema_locker_lost`

How many events are “lost” or not recorded, due to the following conditions:

- Events are recursive (for example, waiting for A caused a wait on B, which caused a wait on C).
- The depth of the nested events stack is greater than the limit imposed by the implementation.

Events recorded by the Performance Schema are not recursive, so this variable should always be 0.

- `Performance_schema_memory_classes_lost`

The number of times a memory instrument could not be loaded. This variable was added in MySQL 5.7.2.

- `Performance_schema_metadata_lock_lost`

The number of metadata locks that could not be instrumented in the `metadata_locks` table. This can be nonzero if the value of `performance_schema_max_metadata_locks` is too small.

This variable was added in MySQL 5.7.3.

- `Performance_schema_mutex_classes_lost`

How many mutex instruments could not be loaded.

- [Performance\\_schema\\_mutex\\_instances\\_lost](#)

How many mutex instrument instances could not be created.

- [Performance\\_schema\\_nested\\_statement\\_lost](#)

The number of stored program statements for which statistics were lost. This can be nonzero if the value of [performance\\_schema\\_max\\_statement\\_stack](#) is too small.

This variable was added in MySQL 5.7.2.

- [Performance\\_schema\\_prepared\\_statements\\_lost](#)

The number of prepared statements that could not be instrumented in the [prepared\\_statements\\_instances](#) table. This can be nonzero if the value of [performance\\_schema\\_max\\_prepared\\_statements\\_instances](#) is too small.

This variable was added in MySQL 5.7.4.

- [Performance\\_schema\\_program\\_lost](#)

The number of stored programs for which statistics were lost. This can be nonzero if the value of [performance\\_schema\\_max\\_program\\_instances](#) is too small.

This variable was added in MySQL 5.7.2.

- [Performance\\_schema\\_rwlock\\_classes\\_lost](#)

How many rwlock instruments could not be loaded.

- [Performance\\_schema\\_rwlock\\_instances\\_lost](#)

How many rwlock instrument instances could not be created.

- [Performance\\_schema\\_session\\_connect\\_attrs\\_lost](#)

The number of connections for which connection attribute truncation has occurred. For a given connection, if the client sends connection attribute key/value pairs for which the aggregate size is larger than the reserved storage permitted by the value of the [performance\\_schema\\_session\\_connect\\_attrs\\_size](#) system variable, the Performance Schema truncates the attribute data and increments [Performance\\_schema\\_session\\_connect\\_attrs\\_lost](#). If this value is nonzero, you may wish to set [performance\\_schema\\_session\\_connect\\_attrs\\_size](#) to a larger value.

For more information about connection attributes, see [Section 24.10.9, “Performance Schema Connection Attribute Tables”](#).

- [Performance\\_schema\\_socket\\_classes\\_lost](#)

How many socket instruments could not be loaded.

- [Performance\\_schema\\_socket\\_instances\\_lost](#)

How many socket instrument instances could not be created.

- [Performance\\_schema\\_stage\\_classes\\_lost](#)

How many stage instruments could not be loaded.

- [Performance\\_schema\\_statement\\_classes\\_lost](#)

How many statement instruments could not be loaded.

- `Performance_schema_table_handles_lost`

How many table instrument instances could not be opened. This can be nonzero if the value of `performance_schema_max_table_handles` is too small.

- `Performance_schema_table_instances_lost`

How many table instrument instances could not be created.

- `Performance_schema_table_lock_stat_lost`

The number of tables for which lock statistics were lost. This can be nonzero if the value of `performance_schema_max_table_lock_stat` is too small.

This variable was added in MySQL 5.7.6.

- `Performance_schema_thread_classes_lost`

How many thread instruments could not be loaded.

- `Performance_schema_thread_instances_lost`

The number of thread instances that could not be instrumented in the `threads` table. This can be nonzero if the value of `performance_schema_max_thread_instances` is too small.

- `Performance_schema_users_lost`

The number of times a row could not be added to the `users` table because it was full.

For information on using these variables to check Performance Schema status, see [Section 24.6, “Performance Schema Status Monitoring”](#).

## 24.15 The Performance Schema Memory-Allocation Model

Before MySQL 5.7.6, the Performance Schema used this memory allocation model:

- Allocate all the memory needed at server startup
- Never allocate memory during server operation
- Never free memory during server operation
- Free all memory used at shutdown

With that model, the Performance Schema potentially allocates a large amount of memory unless explicit configuration is used to minimize particular types of instrumentation.

As of MySQL 5.7.6, the memory model allocates less memory by default under most circumstances:

- May allocate memory at server startup
- May allocate additional memory during server operation
- Never free memory during server operation (although it might be recycled)
- Free all memory used at shutdown

The result is to relax memory constraints so that the Performance Schema can be used with less configuration, and to decrease the memory footprint so that consumption scales with server load. Memory used depends on the load actually seen, not the load estimated or explicitly configured for.

Several Performance Schema sizing parameters are autoscaled and need not be configured explicitly unless you want to establish an explicit limit on memory allocation:

```
performance_schema_accounts_size
performance_schema_hosts_size
performance_schema_max_cond_instances
performance_schema_max_file_instances
performance_schema_max_index_stat
performance_schema_max_metadata_locks
performance_schema_max_mutex_instances
performance_schema_max_prepared_statements_instances
performance_schema_max_program_instances
performance_schema_max_rwlock_instances
performance_schema_max_socket_instances
performance_schema_max_table_handles
performance_schema_max_table_instances
performance_schema_max_table_lock_stat
performance_schema_max_thread_instances
performance_schema_users_size
```

For an autoscaled parameter, configuration works like this:

- With the value set to -1 (the default), the parameter is autoscaled:
  - The corresponding internal buffer is empty initially and no memory is allocated.
  - As the Performance Schema collects data, memory is allocated in the corresponding buffer. The buffer size is unbounded, and may grow with the load.
- With the value set to 0:
  - The corresponding internal buffer is empty initially and no memory is allocated.
- With the value set to  $N > 0$ :
  - The corresponding internal buffer is empty initially and no memory is allocated.
  - As the Performance Schema collects data, memory is allocated in the corresponding buffer, until the buffer size reaches  $N$ .
  - Once the buffer size reaches  $N$ , no more memory is allocated. Data collected by the Performance Schema for this buffer is lost, and any corresponding “lost instance” counters are incremented.

To see how much memory the Performance Schema is using, check the instruments designed for that purpose. The Performance Schema allocates memory internally and associates each buffer with a dedicated instrument so that memory consumption can be traced to individual buffers. Instruments named with the prefix `memory/performance_schema/` expose how much memory is allocated for these internal buffers. The buffers are global to the server, so the instruments are displayed only in the `memory_summary_global_by_event_name` table, and not in other `memory_summary_by_XXX_by_event_name` tables.

This query shows the information associated with the memory instruments:

```
SELECT * FROM memory_summary_global_by_event_name
WHERE EVENT_NAME LIKE 'memory/performance_schema/%';
```

## 24.16 Performance Schema and Plugins

Removing a plugin with `UNINSTALL PLUGIN` does not affect information already collected for code in that plugin. Time spent executing the code while the plugin was loaded was still spent even if the plugin is unloaded later. The associated event information, including aggregate information, remains

readable in `performance_schema` database tables. For additional information about the effect of plugin installation and removal, see [Section 24.6, “Performance Schema Status Monitoring”](#).

A plugin implementor who instruments plugin code should document its instrumentation characteristics to enable those who load the plugin to account for its requirements. For example, a third-party storage engine should include in its documentation how much memory the engine needs for mutex and other instruments.

## 24.17 Using the Performance Schema to Diagnose Problems

The Performance Schema is a tool to help a DBA do performance tuning by taking real measurements instead of “wild guesses.” This section demonstrates some ways to use the Performance Schema for this purpose. The discussion here relies on the use of event filtering, which is described in [Section 24.3.2, “Performance Schema Event Filtering”](#).

The following example provides one methodology that you can use to analyze a repeatable problem, such as investigating a performance bottleneck. To begin, you should have a repeatable use case where performance is deemed “too slow” and needs optimization, and you should enable all instrumentation (no pre-filtering at all).

1. Run the use case.
2. Using the Performance Schema tables, analyze the root cause of the performance problem. This analysis will rely heavily on post-filtering.
3. For problem areas that are ruled out, disable the corresponding instruments. For example, if analysis shows that the issue is not related to file I/O in a particular storage engine, disable the file I/O instruments for that engine. Then truncate the history and summary tables to remove previously collected events.
4. Repeat the process at step 1.

At each iteration, the Performance Schema output, particularly the `events_waits_history_long` table, will contain less and less “noise” caused by nonsignificant instruments, and given that this table has a fixed size, will contain more and more data relevant to the analysis of the problem at hand.

At each iteration, investigation should lead closer and closer to the root cause of the problem, as the “signal/noise” ratio will improve, making analysis easier.

5. Once a root cause of performance bottleneck is identified, take the appropriate corrective action, such as:
  - Tune the server parameters (cache sizes, memory, and so forth).
  - Tune a query by writing it differently,
  - Tune the database schema (tables, indexes, and so forth).
  - Tune the code (this applies to storage engine or server developers only).
6. Start again at step 1, to see the effects of the changes on performance.

The `mutex_instances.LOCKED_BY_THREAD_ID` and `rwlock_instances.WRITE_LOCKED_BY_THREAD_ID` columns are extremely important for investigating performance bottlenecks or deadlocks. This is made possible by Performance Schema instrumentation as follows:

1. Suppose that thread 1 is stuck waiting for a mutex.
2. You can determine what the thread is waiting for:

```
SELECT * FROM events_waits_current WHERE THREAD_ID = thread_1;
```

Say the query result identifies that the thread is waiting for mutex A, found in `events_waits_current.OBJECT_INSTANCE_BEGIN`.

3. You can determine which thread is holding mutex A:

```
SELECT * FROM mutex_instances WHERE OBJECT_INSTANCE_BEGIN = mutex_A;
```

Say the query result identifies that it is thread 2 holding mutex A, as found in `mutex_instances.LOCKED_BY_THREAD_ID`.

4. You can see what thread 2 is doing:

```
SELECT * FROM events_waits_current WHERE THREAD_ID = thread_2;
```

## 24.17.1 Query Profiling Using Performance Schema

The following example demonstrates how to use Performance Schema statement events and stage events to retrieve data comparable to profiling information provided by `SHOW PROFILES` and `SHOW PROFILE` statements.

As of MySQL 5.7.8, the `setup_actors` table can be used to limit the collection of historical events by host, user, or account to reduce runtime overhead and the amount of data collected in history tables. The first step of the example shows how to limit collection of historical events to a specific user.

Performance Schema displays event timer information in picoseconds (trillionths of a second) to normalize timing data to a standard unit. In the following example, `TIMER_WAIT` values are divided by 1000000000000 to show data in units of seconds. Values are also truncated to 6 decimal places to display data in the same format as `SHOW PROFILES` and `SHOW PROFILE` statements.

1. Limit the collection of historical events to the user that will run the query. By default, `setup_actors` is configured to allow monitoring and historical event collection for all foreground threads:

```
mysql> SELECT * FROM setup_actors;
+-----+-----+-----+-----+-----+
| HOST | USER | ROLE | ENABLED | HISTORY |
+-----+-----+-----+-----+-----+
| %    | %    | %    | YES     | YES     |
+-----+-----+-----+-----+-----+
```

Update the default row in the `setup_actors` table to disable historical event collection and monitoring for all foreground threads, and insert a new row that enables monitoring and historical event collection for the user that will run the query:

```
mysql> UPDATE performance_schema.setup_actors SET ENABLED = 'NO', HISTORY = 'NO'
      WHERE HOST = '%' AND USER = '%';

mysql> INSERT INTO performance_schema.setup_actors (HOST,USER,ROLE,ENABLED,HISTORY)
      VALUES ('localhost','test_user','%','YES','YES');
```

Data in the `setup_actors` table should now appear similar to the following:

```
mysql> SELECT * FROM performance_schema.setup_actors;
+-----+-----+-----+-----+-----+
| HOST | USER | ROLE | ENABLED | HISTORY |
+-----+-----+-----+-----+-----+
| %    | %    | %    | NO      | NO      |
+-----+-----+-----+-----+-----+
```

```
| localhost | test_user | % | YES | YES |
+-----+-----+-----+-----+-----+
```

2. Ensure that statement and stage instrumentation is enabled by updating the `setup_instruments` table. Some instruments may already be enabled by default.

```
mysql> UPDATE performance_schema.setup_instruments SET ENABLED = 'YES', TIMED = 'YES'
      WHERE NAME LIKE '%statement/%';

mysql> UPDATE performance_schema.setup_instruments SET ENABLED = 'YES', TIMED = 'YES'
      WHERE NAME LIKE '%stage/%';
```

3. Ensure that `events_statements_*` and `events_stages_*` consumers are enabled. Some consumers may already be enabled by default.

```
mysql> UPDATE performance_schema.setup_consumers SET ENABLED = 'YES'
      WHERE NAME LIKE '%events_statements_%';

mysql> UPDATE performance_schema.setup_consumers SET ENABLED = 'YES'
      WHERE NAME LIKE '%events_stages_%';
```

4. Under the user account you are monitoring, run the statement that you want to profile. For example:

```
mysql> SELECT * FROM employees.employees WHERE emp_no = 10001;
+-----+-----+-----+-----+-----+-----+
| emp_no | birth_date | first_name | last_name | gender | hire_date |
+-----+-----+-----+-----+-----+-----+
| 10001 | 1953-09-02 | Georgi    | Facello   | M      | 1986-06-26 |
+-----+-----+-----+-----+-----+-----+
```

5. Identify the `EVENT_ID` of the statement by querying the `events_statements_history_long` table. This step is similar to running `SHOW PROFILES` to identify the `Query_ID`. The following query produces output similar to `SHOW PROFILES`:

```
mysql> SELECT EVENT_ID, TRUNCATE(TIMER_WAIT/1000000000000,6) as Duration, SQL_TEXT
      FROM performance_schema.events_statements_history_long WHERE SQL_TEXT like '%10001%';
+-----+-----+-----+
| event_id | duration | sql_text
+-----+-----+-----+
| 31 | 0.028310 | SELECT * FROM employees.employees WHERE emp_no = 10001
+-----+-----+-----+
```

6. Query the `events_stages_history_long` table to retrieve the statement's stage events. Stages are linked to statements using event nesting. Each stage event record has a `NESTING_EVENT_ID` column that contains the `EVENT_ID` of the parent statement.

```
mysql> SELECT event_name AS Stage, TRUNCATE(TIMER_WAIT/1000000000000,6) AS Duration
      FROM performance_schema.events_stages_history_long WHERE NESTING_EVENT_ID=31;
+-----+-----+
| Stage | Duration |
+-----+-----+
| stage/sql/starting | 0.000080 |
| stage/sql/checking permissions | 0.000005 |
| stage/sql/Opening tables | 0.027759 |
| stage/sql/init | 0.000052 |
| stage/sql/System lock | 0.000009 |
| stage/sql/optimizing | 0.000006 |
| stage/sql/statistics | 0.000082 |
| stage/sql/preparing | 0.000008 |
| stage/sql/executing | 0.000000 |
| stage/sql/Sending data | 0.000017 |
| stage/sql/end | 0.000001 |
| stage/sql/query end | 0.000004 |
| stage/sql/closing tables | 0.000006 |
| stage/sql/freeing items | 0.000272 |
+-----+-----+
```

```
| stage/sql/cleaning up | 0.000001 |
+-----+-----+
```

## 24.18 Migrating to Performance Schema System and Status Variable Tables

The `INFORMATION_SCHEMA` has tables that contain system and status variable information (see [Section 23.10](#), “The `INFORMATION_SCHEMA` `GLOBAL_VARIABLES` and `SESSION_VARIABLES` Tables”, and [Section 23.9](#), “The `INFORMATION_SCHEMA` `GLOBAL_STATUS` and `SESSION_STATUS` Tables”). As of MySQL 5.7.6, the Performance Schema also contains system and status variable tables (see [Section 24.10.13](#), “Performance Schema System Variable Tables”, and [Section 24.10.14](#), “Performance Schema Status Variable Tables”). The Performance Schema tables are intended to replace the `INFORMATION_SCHEMA` tables, which are deprecated as of MySQL 5.7.6 and will be removed in a future MySQL release.

This section describes the intended migration path away from the `INFORMATION_SCHEMA` system and status variable tables to the corresponding Performance Schema tables. Application developers should use this information as guidance regarding the changes required to access system and status variables in MySQL 5.7.6 and up as the `INFORMATION_SCHEMA` tables become deprecated and eventually are removed.

### MySQL 5.6

In MySQL 5.6, system and status variable information is available from these `SHOW` statements:

```
SHOW VARIABLES
SHOW STATUS
```

And from these `INFORMATION_SCHEMA` tables:

```
INFORMATION_SCHEMA.GLOBAL_VARIABLES
INFORMATION_SCHEMA.SESSION_VARIABLES

INFORMATION_SCHEMA.GLOBAL_STATUS
INFORMATION_SCHEMA.SESSION_STATUS
```

### MySQL 5.7

As of MySQL 5.7.6, the Performance Schema includes these tables as new sources of system and status variable information:

```
performance_schema.global_variables
performance_schema.session_variables
performance_schema.variables_by_thread

performance_schema.global_status
performance_schema.session_status
performance_schema.status_by_thread
performance_schema.status_by_account
performance_schema.status_by_host
performance_schema.status_by_user
```

MySQL 5.7.6 also adds a `show_compatibility_56` system variable to control how the server makes system and status variable information available.

When `show_compatibility_56` is `ON`, compatibility with MySQL 5.6 is enabled. The older system and status variable sources (`SHOW` statements, `INFORMATION_SCHEMA` tables) are available with semantics identical to MySQL 5.6. Applications should run as is, with no code changes, and should see the same variable names and values as in MySQL 5.6. Warnings occur under these circumstances:

- A deprecation warning is raised when selecting from the `INFORMATION_SCHEMA` tables.

- In MySQL 5.7.6 and 5.7.7, a deprecation warning is raised when using a `WHERE` clause with the `SHOW` statements. This behavior does not occur as of MySQL 5.7.8.

When `show_compatibility_56` is `OFF`, compatibility with MySQL 5.6 is disabled and several changes result. Applications must be revised as follows to run properly:

- Selecting from the `INFORMATION_SCHEMA` tables produces an error. Applications that access the `INFORMATION_SCHEMA` tables should be revised to use the corresponding Performance Schema tables instead.

Before MySQL 5.7.9, selecting from the `INFORMATION_SCHEMA` tables produces an empty result set plus a deprecation warning. This was not sufficient notice to signal the need to migrate to the corresponding Performance Schema system and status variable tables for the case that `show_compatibility_56=OFF`. Producing an error in MySQL 5.7.9 and higher makes it more evident that an application is operating under conditions that require modification, as well as where the problem lies.

In MySQL 5.7.6 and 5.7.7, the Performance Schema `session_variables` and `session_status` tables do not fully reflect all variable values in effect for the current session; they include no rows for global variables that have no session counterpart. This is corrected in MySQL 5.7.8.

- Output for the `SHOW` statements is produced using the underlying Performance Schema tables. Applications written to use these statements can still use them, but it is best to use MySQL 5.7.8 or higher. In MySQL 5.7.6 and 5.7.7, the results may differ:
  - `SHOW [SESSION] VARIABLES` output does not include global variables that have no session counterpart.
  - Using a `WHERE` clause with the `SHOW` statements produces an error.
- These `Slave_xxx` status variables become unavailable through `SHOW STATUS`:

```
Slave_heartbeat_period
Slave_last_heartbeat
Slave_received_heartbeats
Slave_retried_transactions
Slave_running
```

Applications that use these status variables should be revised to obtain this information using the replication-related Performance Schema tables. For details, see [Effect of show\\_compatibility\\_56 on Slave Status Variables](#).

## Migration and Privileges

Initially, with the introduction of Performance Schema system and status variable tables in MySQL 5.7.6, access to those tables required the `SELECT` privilege, just as for other Performance Schema tables. However, this had the consequence that when `show_compatibility_56=OFF`, the `SHOW VARIABLES` and `SHOW STATUS` statements also required the `SELECT` privilege: With compatibility disabled, output for those statements was taken from the Performance Schema `global_variables`, `session_variables`, `global_status`, and `session_status` tables.

As of MySQL 5.7.9, those Performance Schema tables are world readable and accessible without the `SELECT` privilege. Consequently, `SHOW VARIABLES` and `SHOW STATUS` do not require privileges on the underlying Performance Schema tables from which their output is produced when `show_compatibility_56=OFF`.

## Beyond MySQL 5.7

In a MySQL 8.0, the `INFORMATION_SCHEMA` variable tables and the `show_compatibility_56` system variable are removed, and output from the `SHOW` statements is always based on the underlying Performance Schema tables.

Applications that have been revised to work in MySQL 5.7 when `show_compatibility_56=OFF` should work without further changes, except that it will not be possible to test or set `show_compatibility_56` because it will not exist.

---

## Chapter 25 MySQL sys Schema

### Table of Contents

|   |      |
|---|------|
| 25.1 Prerequisites for Using the sys Schema ..... | 3711 |
| 25.2 Using the sys Schema .....                   | 3712 |
| 25.3 sys Schema Progress Reporting .....          | 3713 |
| 25.4 sys Schema Object Reference .....            | 3714 |
| 25.4.1 sys Schema Object Index .....              | 3714 |
| 25.4.2 sys Schema Tables and Triggers .....       | 3718 |
| 25.4.3 sys Schema Views .....                     | 3721 |
| 25.4.4 sys Schema Stored Procedures .....         | 3760 |
| 25.4.5 sys Schema Stored Functions .....          | 3779 |

MySQL 5.7.7 and higher includes the `sys` schema, a set of objects that helps DBAs and developers interpret data collected by the Performance Schema. `sys` schema objects can be used for typical tuning and diagnosis use cases. Objects in this schema include:

- Views that summarize Performance Schema data into more easily understandable form.
- Stored procedures that perform operations such as Performance Schema configuration and generating diagnostic reports.
- Stored functions that query Performance Schema configuration and provide formatting services.

For new installations, the `sys` schema is installed by default during data directory initialization if you use `mysqld` with the `--initialize` or `--initialize-insecure` option, or if you use `mysql_install_db`. To permit this behavior to be suppressed, `mysql_install_db` has a `--skip-sys-schema` option. `mysqld` has no such option, but if you initialize the data directory using `mysqld --initialize` (or `--initialize-insecure`) rather than `mysql_install_db`, you can drop the `sys` schema manually after initialization if it is unneeded.

For upgrades, `mysql_upgrade` installs the `sys` schema if it is not installed, and upgrades it to the current version otherwise. To permit this behavior to be suppressed, `mysql_upgrade` has a `--skip-sys-schema` option.

`mysql_upgrade` returns an error if a `sys` schema exists but has no `version` view, on the assumption that absence of this view indicates a user-created `sys` schema. To upgrade in this case, remove or rename the existing `sys` schema first.

As of MySQL 5.7.9, `sys` schema objects have a `DEFINER` of `'mysql.sys'@'localhost'`. (Before MySQL 5.7.9, the `DEFINER` is `'root'@'localhost'`.) Use of the dedicated `mysql.sys` account avoids problems that occur if a DBA renames or removes the `root` account.

### 25.1 Prerequisites for Using the sys Schema

Before using the `sys` schema, the prerequisites described in this section must be satisfied.

The `sys` schema requires MySQL 5.6 or higher.

Because the `sys` schema provides an alternative means of accessing the Performance Schema, the Performance Schema must be enabled for the `sys` schema to work. See [Section 24.2.2, “Performance Schema Startup Configuration”](#).

For full access to the `sys` schema, a user must have these privileges:

- `SELECT` on all `sys` tables and views
- `EXECUTE` on all `sys` stored procedures and functions
- `INSERT` and `UPDATE` for the `sys_config` table, if changes are to be made to it

- Additional privileges for certain `sys` schema stored procedures and functions, as noted in their descriptions; for example, the `ps_setup_save()` procedure

It is also necessary to have privileges for the objects underlying the `sys` schema objects:

- `SELECT` on any Performance Schema tables accessed by `sys` schema objects, and `UPDATE` for any tables to be updated using `sys` schema objects
- `PROCESS` for the `INFORMATION_SCHEMA INNODB_BUFFER_PAGE` table

Certain Performance Schema instruments and consumers must be enabled and (for instruments) timed to take full advantage of `sys` schema capabilities:

- All `wait` instruments
- All `stage` instruments
- All `statement` instruments
- `xxx_current` and `xxx_history_long` consumers for all events

You can use the `sys` schema itself to enable all of the additional instruments and consumers:

```
CALL sys.ps_setup_enable_instrument('wait');
CALL sys.ps_setup_enable_instrument('stage');
CALL sys.ps_setup_enable_instrument('statement');
CALL sys.ps_setup_enable_consumer('current');
CALL sys.ps_setup_enable_consumer('history_long');
```

#### Note

For many uses of the `sys` schema, the default Performance Schema is sufficient for data collection. Enabling all the instruments and consumers just mentioned has a performance impact, so it is preferable to enable only the additional configuration you need. Also, remember that if you enable additional configuration, you can easily restore the default configuration like this:

```
CALL sys.ps_setup_reset_to_default(TRUE);
```

## 25.2 Using the sys Schema

You can make the `sys` schema the default schema so that references to its objects need not be qualified with the schema name:

```
mysql> USE sys;
Database changed
mysql> SELECT * FROM version;
+-----+-----+
| sys_version | mysql_version |
+-----+-----+
| 1.5.0       | 5.7.9-debug-log |
+-----+-----+
```

(The `version` view shows the `sys` schema and MySQL server versions.)

To access `sys` schema objects while a different schema is the default (or simply to be explicit), qualify object references with the schema name:

```
mysql> SELECT * FROM sys.version;
+-----+-----+
| sys_version | mysql_version |
+-----+-----+
| 1.5.0       | 5.7.9-debug-log |
+-----+-----+
```

Examples in this chapter usually assume `sys` as the default schema.

The `sys` schema contains many views that summarize Performance Schema tables in various ways. Most of these views come in pairs, such that one member of the pair has the same name as the other member, plus a `x$` prefix. For example, the `host_summary_by_file_io` view summarizes file I/O grouped by host and displays latencies converted from picoseconds to more readable values (with units);

```
mysql> SELECT * FROM host_summary_by_file_io;
```

| host       | ios   | io_latency |
|------------|-------|------------|
| localhost  | 67570 | 5.38 s     |
| background | 3468  | 4.18 s     |

The `x$host_summary_by_file_io` view summarizes the same data but displays unformatted picosecond latencies:

```
mysql> SELECT * FROM x$host_summary_by_file_io;
```

| host       | ios   | io_latency    |
|------------|-------|---------------|
| localhost  | 67574 | 5380678125144 |
| background | 3474  | 4758696829416 |

The view without the `x$` prefix is intended to provide output that is more user friendly and easier for humans to read. The view with the `x$` prefix that displays the same values in raw form is intended more for use with other tools that perform their own processing on the data. For additional information about the differences between non-`x$` and `x$` views, see [Section 25.4.3, “sys Schema Views”](#).

To examine `sys` schema object definitions, use the appropriate `SHOW` statement or `INFORMATION_SCHEMA` query. For example, to examine the definitions of the `session` view and `format_bytes()` function, use these statements:

```
mysql> SHOW CREATE VIEW session;
mysql> SHOW CREATE FUNCTION format_bytes;
```

However, those statements display the definitions in relatively unformatted form. To view object definitions with more readable formatting, access the individual `.sql` files available from the `sys` schema development web site at <https://github.com/mysql/mysql-sys>.

Neither `mysqldump` nor `mysqlpump` dump the `sys` schema by default. To generate a dump file, name the `sys` schema explicitly on the command line using either of these commands:

```
mysqldump --databases --routines sys > sys_dump.sql
mysqlpump sys > sys_dump.sql
```

To reinstall the schema from the dump file, use this command:

```
mysql < sys_dump.sql
```

## 25.3 sys Schema Progress Reporting

As of MySQL 5.7.9, the following `sys` schema views provide progress reporting for long-running transactions:

```
processlist
session
x$processlist
x$session
```

Assuming that the required instruments and consumers are enabled, the `progress` column of these views shows the percentage of work completed for stages that support progress reporting.

Stage progress reporting requires that the `events_stages_current` consumer be enabled, as well as the instruments for which progress information is desired. Instruments for these stages currently support progress reporting:

```
stage/sql/Copying to tmp table
stage/innodb/alter table (end)
stage/innodb/alter table (flush)
stage/innodb/alter table (insert)
stage/innodb/alter table (log apply index)
stage/innodb/alter table (log apply table)
stage/innodb/alter table (merge sort)
stage/innodb/alter table (read PK and internal sort)
stage/innodb/buffer pool load
```

For stages that do not support estimated and completed work reporting, or if the required instruments or consumers are not enabled, the `progress` column is `NULL`.

## 25.4 sys Schema Object Reference

The `sys` schema includes tables and triggers, views, and stored procedures and functions. The following sections provide details for each of these objects.

### 25.4.1 sys Schema Object Index

The following tables list `sys` schema objects and provide a short description of each one.

**Table 25.1 sys Schema Tables and Triggers**

| Table or Trigger Name                   | Description                                   |
|---|---|
| <code>sys_config</code>                 | <code>sys</code> schema configuration options |
| <code>sys_config_insert_set_user</code> | <code>sys_config</code> insert trigger        |
| <code>sys_config_update_set_user</code> | <code>sys_config</code> update trigger        |

**Table 25.2 sys Schema Views**

| View Name  | Description  |
|--|--|
| <code>host_summary</code> , <code>x\$host_summary</code>   | Statement activity, file I/O, and connections, grouped by host |
| <code>host_summary_by_file_io</code> , <code>x\$host_summary_by_file_io</code>                     | File I/O, grouped by host                                      |
| <code>host_summary_by_file_io_type</code> , <code>x\$host_summary_by_file_io_type</code>           | File I/O, grouped by host and event type                       |
| <code>host_summary_by_stages</code> , <code>x\$host_summary_by_stages</code>                       | Statement stages, grouped by host                              |
| <code>host_summary_by_statement_latency</code> , <code>x\$host_summary_by_statement_latency</code> | Statement statistics, grouped by host                          |
| <code>host_summary_by_statement_type</code> , <code>x\$host_summary_by_statement_type</code>       | Statements executed, grouped by host and statement             |
| <code>innodb_buffer_stats_by_schema</code> , <code>x\$innodb_buffer_stats_by_schema</code>         | InnoDB buffer information, grouped by schema                   |
| <code>innodb_buffer_stats_by_table</code> , <code>x\$innodb_buffer_stats_by_table</code>           | InnoDB buffer information, grouped by schema and table         |
| <code>innodb_lock_waits</code> , <code>x\$innodb_lock_waits</code>                                 | InnoDB lock information  |

| View Name   | Description   |
|---|---|
| <a href="#">io_by_thread_by_latency, x</a><br><a href="#">\$io_by_thread_by_latency</a>                         | I/O consumers, grouped by thread  |
| <a href="#">io_global_by_file_by_bytes, x</a><br><a href="#">\$io_global_by_file_by_bytes</a>                   | Global I/O consumers, grouped by file and bytes                           |
| <a href="#">io_global_by_file_by_latency, x</a><br><a href="#">\$io_global_by_file_by_latency</a>               | Global I/O consumers, grouped by file and latency                         |
| <a href="#">io_global_by_wait_by_bytes, x</a><br><a href="#">\$io_global_by_wait_by_bytes</a>                   | Global I/O consumers, grouped by bytes                                    |
| <a href="#">io_global_by_wait_by_latency, x</a><br><a href="#">\$io_global_by_wait_by_latency</a>               | Global I/O consumers, grouped by latency                                  |
| <a href="#">latest_file_io, x\$latest_file_io</a>   | Most recent I/O, grouped by file and thread                               |
| <a href="#">memory_by_host_by_current_bytes, x</a><br><a href="#">\$memory_by_host_by_current_bytes</a>         | Memory use, grouped by host   |

Table 25.3 sys Schema Stored Procedures

| Procedure Name                                     | Description                               |
|--|---|
| <code>create_synonym_db()</code>                   | Create synonym for schema                 |
| <code>diagnostics()</code>                         | Collect system diagnostic information     |
| <code>execute_prepared_stmt()</code>               | Execute prepared statement                |
| <code>ps_setup_disable_background_threads()</code> | Disable background thread instrumentation |
| <code>ps_setup_disable_consumer()</code>           | Disable consumers                         |
| <code>ps_setup_disable_instrument()</code>         | Disable instruments                       |
| <code>ps_setup_disable_thread()</code>             | Disable instrumentation for thread        |

| Procedure Name                                    | Description   |
|---|---|
| <code>ps_setup_enable_background_threads()</code> | Enable background thread instrumentation            |
| <code>ps_setup_enable_consumer()</code>           | Enable consumers                                    |
| <code>ps_setup_enable_instrument()</code>         | Enable instruments                                  |
| <code>ps_setup_enable_thread()</code>             | Enable instrumentation for thread                   |
| <code>ps_setup_reload_saved()</code>              | Reload saved Performance Schema configuration       |
| <code>ps_setup_reset_to_default()</code>          | Reset saved Performance Schema configuration        |
| <code>ps_setup_save()</code>                      | Save Performance Schema configuration               |
| <code>ps_setup_show_disabled()</code>             | Display disabled Performance Schema configuration   |
| <code>ps_setup_show_disabled_consumers()</code>   | Display disabled Performance Schema consumers       |
| <code>ps_setup_show_disabled_instruments()</code> | Display disabled Performance Schema instruments     |
| <code>ps_setup_show_enabled()</code>              | Display enabled Performance Schema configuration    |
| <code>ps_setup_show_enabled_consumers()</code>    | Display enabled Performance Schema consumers        |
| <code>ps_setup_show_enabled_instruments()</code>  | Display enabled Performance Schema instruments      |
| <code>ps_statement_avg_latency_histogram()</code> | Display statement latency histogram                 |
| <code>ps_trace_statement_digest()</code>          | Trace Performance Schema instrumentation for digest |
| <code>ps_trace_thread()</code>                    | Dump Performance Schema data for thread             |
| <code>ps_truncate_all_tables()</code>             | Truncate Performance Schema summary tables          |
| <code>statement_performance_analyzer()</code>     | Report of statements running on server              |
| <code>table_exists()</code>                       | Whether a table exists                              |

**Table 25.4 sys Schema Stored Functions**

| Function Name                                | Description  |
|--|--|
| <code>extract_schema_from_file_name()</code> | Extract schema name from file path name                                  |
| <code>extract_table_from_file_name()</code>  | Extract table name from file path name                                   |
| <code>format_bytes()</code>                  | Convert byte value to value with units                                   |
| <code>format_path()</code>                   | Replace data and temp-file directories in path name with symbolic values |
| <code>format_statement()</code>              | Truncate long statement to fixed length                                  |
| <code>format_time()</code>                   | Convert picoseconds value to value with units                            |
| <code>list_add()</code>                      | Add item to list   |
| <code>list_drop()</code>                     | Remove item from list  |

| Function Name                                   | Description   |
|---|---|
| <code>ps_is_account_enabled()</code>            | Check whether account instrumentation is enabled    |
| <code>ps_is_consumer_enabled()</code>           | Check whether consumer is enabled                   |
| <code>ps_is_instrument_default_enabled()</code> | Check whether instrument is enabled                 |
| <code>ps_is_instrument_default_timed()</code>   | Check whether instrument is timed                   |
| <code>ps_is_thread_instrumented()</code>        | Check whether thread is instrumented                |
| <code>ps_thread_account()</code>                | Return account for thread ID                        |
| <code>ps_thread_id()</code>                     | Return thread ID for connection ID                  |
| <code>ps_thread_stack()</code>                  | Return event information for thread ID              |
| <code>ps_thread_trx_info()</code>               | Return transaction information for thread ID        |
| <code>quote_identifier()</code>                 | Return string as quoted identifier                  |
| <code>sys_get_config()</code>                   | Return <code>sys</code> schema configuration option |
| <code>version_major()</code>                    | MySQL server major version number                   |
| <code>version_minor()</code>                    | MySQL server minor version number                   |
| <code>version_patch()</code>                    | MySQL server patch release version number           |

## 25.4.2 sys Schema Tables and Triggers

The following sections describe `sys` schema tables and triggers.

### 25.4.2.1 The `sys_config` Table

This table contains `sys` schema configuration options, one row per option. Configuration changes made by updating this table persist across client sessions and server restarts.

The `sys_config` table has these columns:

- `variable`

The configuration option name.

- `value`

The configuration option value.

- `set_time`

The timestamp of the most recent modification to the row.

- `set_by`

The account that made the most recent modification to the row. The value is `NULL` if the row has not been changed since the `sys` schema was installed.

As an efficiency measure to minimize the number of direct reads from the `sys_config` table, `sys` schema functions that use a value from this table check for a user-defined variable with a corresponding name, which is the user-defined variable having the same name plus a `@sys.` prefix. (For example, the variable corresponding to the `diagnostics.include_raw` option is `@sys.diagnostics.include_raw`.) If the user-defined variable exists in the current session and is non-`NULL`, the function uses its value in preference to the value in the `sys_config` table. Otherwise, the function reads and uses the value from the table. In the latter case, the calling function

conventionally also sets the corresponding user-defined variable to the table value so that further references to the configuration option within the same session use the variable and need not read the table again.

For example, the `statement_truncate_len` option controls the maximum length of statements returned by the `format_statement()` function. The default is 64. To temporarily change the value to 32 for your current session, set the corresponding `@sys.statement_truncate_len` user-defined variable:

```
mysql> SET @stmt = 'SELECT variable, value, set_time, set_by FROM sys_config';
mysql> SELECT format_statement(@stmt);
+-----+
| format_statement(@stmt) |
+-----+
| SELECT variable, value, set_time, set_by FROM sys_config |
+-----+
mysql> SET @sys.statement_truncate_len = 32;
mysql> SELECT format_statement(@stmt);
+-----+
| format_statement(@stmt) |
+-----+
| SELECT variabl ... ROM sys_config |
+-----+
```

Subsequent invocations of `format_statement()` within the session continue to use the user-defined variable value (32), rather than the value stored in the table (64).

To stop using the user-defined variable and revert to using the value in the table, set the variable to `NULL` within your session:

```
mysql> SET @sys.statement_truncate_len = NULL;
mysql> SELECT format_statement(@stmt);
+-----+
| format_statement(@stmt) |
+-----+
| SELECT variable, value, set_time, set_by FROM sys_config |
+-----+
```

Alternatively, end your current session (causing the user-defined variable to no longer exist) and begin a new session.

The conventional relationship just described between options in the `sys_config` table and user-defined variables can be exploited to make temporary configuration changes that end when your session ends. However, if you set a user-defined variable and then subsequently change the corresponding table value within the same session, the changed table value will not be used in that session as long as the user-defined variable exists with a non-`NULL` value. (The changed table value *will* be used in other sessions that do not have the user-defined variable assigned.)

The following list describes the options in the `sys_config` table and the corresponding user-defined variables:

- `diagnostics.allow_i_s_tables`, `@sys.diagnostics.allow_i_s_tables`

If this option is `ON`, the `diagnostics()` procedure is permitted to perform table scans on the `INFORMATION_SCHEMA.TABLES` table. This can be expensive if there are many tables. The default is `OFF`.

This option was added in MySQL 5.7.9.

- `diagnostics.include_raw`, `@sys.diagnostics.include_raw`

If this option is `ON`, the `diagnostics()` procedure includes the raw output from querying the `metrics` view. The default is `OFF`.

This option was added in MySQL 5.7.9.

- `ps_thread_trx_info.max_length, @sys.ps_thread_trx_info.max_length`

The maximum length for JSON output produced by the `ps_thread_trx_info()` function. The default is 65535.

This option was added in MySQL 5.7.9.

- `statement_performance_analyzer.limit, @sys.statement_performance_analyzer.limit`

The maximum number of rows to return for views that have no built-in limit. (For example, the `statements_with_runtimes_in_95th_percentile` view has a built-in limit in the sense that it returns only statements with average execution time in the 95th percentile.) The default is 100.

This option was added in MySQL 5.7.9.

- `statement_performance_analyzer.view, @sys.statement_performance_analyzer.view`

The custom query or view to be used by the `statement_performance_analyzer()` procedure (which is itself invoked by the `diagnostics()` procedure). If the option value contains a space, it is interpreted as a query. Otherwise, it must be the name of an existing view that queries the Performance Schema `events_statements_summary_by_digest` table. There cannot be any `LIMIT` clause in the query or view definition if the `statement_performance_analyzer.limit` configuration option is greater than 0. The default is `NULL` (no custom view defined).

This option was added in MySQL 5.7.9.

- `statement_truncate_len, @sys.statement_truncate_len`

The maximum length of statements returned by the `format_statement()` function. Longer statements are truncated to this length. The default is 64.

Other options can be added to the `sys_config` table. For example, the `diagnostics()` and `execute_prepared_stmt()` procedures use the `debug` option if it exists, but this option is not part of the `sys_config` table by default because debug output normally is enabled only temporarily, by setting the corresponding `@sys.debug` user-defined variable. To enable debug output without having to set that variable in individual sessions, add the option to the table:

```
mysql> INSERT INTO sys_config (variable, value) VALUES('debug', 'ON');
```

To change the debug setting in the table, do two things. First, modify the value in the table itself:

```
mysql> UPDATE sys_config SET value = 'OFF' WHERE variable = 'debug';
```

Second, to also ensure that procedure invocations within the current session use the changed value from the table, set the corresponding user-defined variable to `NULL`:

```
mysql> SET @sys.debug = NULL;
```

### 25.4.2.2 The `sys_config_insert_set_user` Trigger

For rows added to the `sys_config` table by `INSERT` statements, the `sys_config_insert_set_user` trigger sets the `set_by` column to the current user.

### 25.4.2.3 The `sys_config_update_set_user` Trigger

The `sys_config_update_set_user` trigger for the `sys_config` table is similar to the `sys_config_insert_set_user` trigger, but for `UPDATE` statements.

## 25.4.3 sys Schema Views

The following sections describe `sys` schema views.

The `sys` schema contains many views that summarize Performance Schema tables in various ways. Most of these views come in pairs, such that one member of the pair has the same name as the other member, plus a `x$` prefix. For example, the `host_summary_by_file_io` view summarizes file I/O grouped by host and displays latencies converted from picoseconds to more readable values (with units);

```
mysql> SELECT * FROM host_summary_by_file_io;
+-----+-----+-----+
| host      | ios    | io_latency |
+-----+-----+-----+
| localhost | 67570  | 5.38 s     |
| background | 3468   | 4.18 s     |
+-----+-----+-----+
```

The `x$host_summary_by_file_io` view summarizes the same data but displays unformatted picosecond latencies:

```
mysql> SELECT * FROM x$host_summary_by_file_io;
+-----+-----+-----+
| host      | ios    | io_latency |
+-----+-----+-----+
| localhost | 67574  | 5380678125144 |
| background | 3474   | 4758696829416 |
+-----+-----+-----+
```

The view without the `x$` prefix is intended to provide output that is more user friendly and easier to read. The view with the `x$` prefix that displays the same values in raw form is intended more for use with other tools that perform their own processing on the data.

Views without the `x$` prefix differ from the corresponding `x$` views in these ways:

- Byte values are formatted with size units using `format_bytes()`.
- Time values are formatted with temporal units using `format_time()`.
- SQL statements are truncated to a maximum display width using `format_statement()`.
- Path names are shortened using `format_path()`.

### 25.4.3.1 The `host_summary` and `x$host_summary` Views

These views summarize statement activity, file I/O, and connections, grouped by host.

The `host_summary` and `x$host_summary` views have these columns:

- `host`

The host from which the client connected. Rows for which the `HOST` column in the underlying Performance Schema table is `NULL` are assumed to be for background threads and are reported with a host name of `background`.

- `statements`

The total number of statements for the host.

- `statement_latency`

The total wait time of timed statements for the host.

- `statement_avg_latency`

The average wait time per timed statement for the host.

- `table_scans`

The total number of table scans for the host.

- `file_ios`

The total number of file I/O events for the host.

- `file_io_latency`

The total wait time of timed file I/O events for the host.

- `current_connections`

The current number of connections for the host.

- `total_connections`

The total number of connections for the host.

- `unique_users`

The number of distinct users for the host.

- `current_memory`

The current amount of allocated memory for the host.

- `total_memory_allocated`

The total amount of allocated memory for the host.

### 25.4.3.2 The `host_summary_by_file_io` and `x$host_summary_by_file_io` Views

These views summarize file I/O, grouped by host. By default, rows are sorted by descending total file I/O latency.

The `host_summary_by_file_io` and `x$host_summary_by_file_io` views have these columns:

- `host`

The host from which the client connected. Rows for which the `HOST` column in the underlying Performance Schema table is `NULL` are assumed to be for background threads and are reported with a host name of `background`.

- `ios`

The total number of file I/O events for the host.

- `io_latency`

The total wait time of timed file I/O events for the host.

### 25.4.3.3 The `host_summary_by_file_io_type` and `x$host_summary_by_file_io_type` Views

These views summarize file I/O, grouped by host and event type. By default, rows are sorted by host and descending total I/O latency.

The `host_summary_by_file_io_type` and `x$host_summary_by_file_io_type` views have these columns:

- `host`

The host from which the client connected. Rows for which the `HOST` column in the underlying Performance Schema table is `NULL` are assumed to be for background threads and are reported with a host name of `background`.

- `event_name`

The file I/O event name.

- `total`

The total number of occurrences of the file I/O event for the host.

- `total_latency`

The total wait time of timed occurrences of the file I/O event for the host.

- `max_latency`

The maximum single wait time of timed occurrences of the file I/O event for the host.

#### 25.4.3.4 The `host_summary_by_stages` and `x$host_summary_by_stages` Views

These views summarize statement stages, grouped by host. By default, rows are sorted by host and descending total latency.

The `host_summary_by_stages` and `x$host_summary_by_stages` views have these columns:

- `host`

The host from which the client connected. Rows for which the `HOST` column in the underlying Performance Schema table is `NULL` are assumed to be for background threads and are reported with a host name of `background`.

- `event_name`

The stage event name.

- `total`

The total number of occurrences of the stage event for the host.

- `total_latency`

The total wait time of timed occurrences of the stage event for the host.

- `avg_latency`

The average wait time per timed occurrence of the stage event for the host.

#### 25.4.3.5 The `host_summary_by_statement_latency` and `x$host_summary_by_statement_latency` Views

These views summarize overall statement statistics, grouped by host. By default, rows are sorted by descending total latency.

The `host_summary_by_statement_latency` and `x$host_summary_by_statement_latency` views have these columns:

- `host`

The host from which the client connected. Rows for which the `HOST` column in the underlying Performance Schema table is `NULL` are assumed to be for background threads and are reported with a host name of `background`.

- `total`

The total number of statements for the host.

- `total_latency`

The total wait time of timed statements for the host.

- `max_latency`

The maximum single wait time of timed statements for the host.

- `lock_latency`

The total time waiting for locks by timed statements for the host.

- `rows_sent`

The total number of rows returned by statements for the host.

- `rows_examined`

The total number of rows read from storage engines by statements for the host.

- `rows_affected`

The total number of rows affected by statements for the host.

- `full_scans`

The total number of full table scans by statements for the host.

#### 25.4.3.6 The `host_summary_by_statement_type` and `x$host_summary_by_statement_type` Views

These views summarize information about statements executed, grouped by host and statement type. By default, rows are sorted by host and descending total latency.

The `host_summary_by_statement_type` and `x$host_summary_by_statement_type` views have these columns:

- `host`

The host from which the client connected. Rows for which the `HOST` column in the underlying Performance Schema table is `NULL` are assumed to be for background threads and are reported with a host name of `background`.

- `statement`

The final component of the statement event name.

- `total`

The total number of occurrences of the statement event for the host.

- `total_latency`

The total wait time of timed occurrences of the statement event for the host.

- `max_latency`

The maximum single wait time of timed occurrences of the statement event for the host.

- `lock_latency`

The total time waiting for locks by timed occurrences of the statement event for the host.

- `rows_sent`

The total number of rows returned by occurrences of the statement event for the host.

- `rows_examined`

The total number of rows read from storage engines by occurrences of the statement event for the host.

- `rows_affected`

The total number of rows affected by occurrences of the statement event for the host.

- `full_scans`

The total number of full table scans by occurrences of the statement event for the host.

### 25.4.3.7 The `innodb_buffer_stats_by_schema` and `x$innodb_buffer_stats_by_schema` Views

These views summarize the information in the `INFORMATION_SCHEMA INNODB_BUFFER_PAGE` table, grouped by schema. By default, rows are sorted by descending buffer size.

The `innodb_buffer_stats_by_schema` and `x$innodb_buffer_stats_by_schema` views have these columns:

- `object_schema`

The schema name for the object, or `InnoDB System` if the table belongs to the `InnoDB` storage engine.

- `allocated`

The total number of bytes allocated for the schema.

- `data`

The total number of data bytes allocated for the schema.

- `pages`

The total number of pages allocated for the schema.

- `pages_hashed`

The total number of hashed pages allocated for the schema.

- `pages_old`

The total number of old pages allocated for the schema.

- `rows_cached`

The total number of cached rows for the schema.

### 25.4.3.8 The `innodb_buffer_stats_by_table` and `x$innodb_buffer_stats_by_table` Views

These views summarize the information in the `INFORMATION_SCHEMA.INNODB_BUFFER_PAGE` table, grouped by schema and table. By default, rows are sorted by descending buffer size.

The `innodb_buffer_stats_by_table` and `x$innodb_buffer_stats_by_table` views have these columns:

- `object_schema`

The schema name for the object, or `InnoDB System` if the table belongs to the `InnoDB` storage engine.

- `object_name`

The table name.

- `allocated`

The total number of bytes allocated for the table.

- `data`

The number of data bytes allocated for the table.

- `pages`

The total number of pages allocated for the table.

- `pages_hashed`

The number of hashed pages allocated for the table.

- `pages_old`

The number of old pages allocated for the table.

- `rows_cached`

The number of cached rows for the table.

### 25.4.3.9 The `innodb_lock_waits` and `x$innodb_lock_waits` Views

These views summarize the `InnoDB` locks that transactions are waiting for. By default, rows are sorted by descending lock age.

The `innodb_lock_waits` and `x$innodb_lock_waits` views have these columns:

- `wait_started`

The time at which the lock wait started.

- `wait_age`

How long the lock has been waited for, as a `TIME` value.

- `wait_age_secs`

How long the lock has been waited for, in seconds.

This column was added in MySQL 5.7.9.

- `locked_table`

The name of the locked table. This column contains combined schema/table name values.

- `locked_index`

The name of the locked index.

- `locked_type`

The type of the waiting lock.

- `waiting_trx_id`

The ID of the waiting transaction.

- `waiting_trx_started`

The time at which the waiting transaction started.

- `waiting_trx_age`

How long the waiting transaction has been waiting, as a `TIME` value.

- `waiting_trx_rows_locked`

The number of rows locked by the waiting transaction.

- `waiting_trx_rows_modified`

The number of rows modified by the waiting transaction.

- `waiting_pid`

The processlist ID of the waiting transaction.

- `waiting_query`

The statement that is waiting for the lock.

- `waiting_lock_id`

The ID of the waiting lock.

- `waiting_lock_mode`

The mode of the waiting lock.

- `blocking_trx_id`

The ID of the transaction that is blocking the waiting lock.

- `blocking_pid`

The processlist ID of the blocking transaction.

- `blocking_query`

The statement the blocking transaction is executing.

- `blocking_lock_id`

The ID of the lock that is blocking the waiting lock.

- `blocking_lock_mode`

The mode of the lock that is blocking the waiting lock.

- `blocking_trx_started`

The time at which the blocking transaction started.

- `blocking_trx_age`

How long the blocking transaction has been executing, as a `TIME` value.

- `blocking_trx_rows_locked`

The number of rows locked by the blocking transaction.

- `blocking_trx_rows_modified`

The number of rows modified by the blocking transaction.

- `sql_kill_blocking_query`

The `KILL` statement to execute to kill the blocking statement.

This column was added in MySQL 5.7.9.

- `sql_kill_blocking_connection`

The `KILL` statement to execute to kill the session running the blocking statement.

This column was added in MySQL 5.7.9.

#### 25.4.3.10 The `io_by_thread_by_latency` and `x$io_by_thread_by_latency` Views

These views summarize I/O consumers to display time waiting for I/O, grouped by thread. By default, rows are sorted by descending total I/O latency.

The `io_by_thread_by_latency` and `x$io_by_thread_by_latency` views have these columns:

- `user`

For foreground threads, the account associated with the thread. For background threads, the thread name.

- `total`

The total number of I/O events for the thread.

- `total_latency`

The total wait time of timed I/O events for the thread.

- `min_latency`

The minimum single wait time of timed I/O events for the thread.

- `avg_latency`

The average wait time per timed I/O event for the thread.

- `max_latency`

The maximum single wait time of timed I/O events for the thread.

- `thread_id`

The thread ID.

- `processlist_id`

For foreground threads, the processlist ID of the thread. For background threads, `NULL`.

#### 25.4.3.11 The `io_global_by_file_by_bytes` and `x$io_global_by_file_by_bytes` Views

These views summarize global I/O consumers to display amount of I/O, grouped by file. By default, rows are sorted by descending total I/O (bytes read and written).

The `io_global_by_file_by_bytes` and `x$io_global_by_file_by_bytes` views have these columns:

- `file`

The file path name.

- `count_read`

The total number of read events for the file.

- `total_read`

The total number of bytes read from the file.

- `avg_read`

The average number of bytes per read from the file.

- `count_write`

The total number of write events for the file.

- `total_written`

The total number of bytes written to the file.

- `avg_write`

The average number of bytes per write to the file.

- `total`

The total number of bytes read and written for the file.

- `write_pct`

The percentage of total bytes of I/O that were writes.

#### 25.4.3.12 The `io_global_by_file_by_latency` and `x$io_global_by_file_by_latency` Views

These views summarize global I/O consumers to display time waiting for I/O, grouped by file. By default, rows are sorted by descending total latency.

The `io_global_by_file_by_latency` and `x$io_global_by_file_by_latency` views have these columns:

- `file`

The file path name.

- `total`

The total number of I/O events for the file.

- `total_latency`

The total wait time of timed I/O events for the file.

- `count_read`

The total number of read I/O events for the file.

- `read_latency`

The total wait time of timed read I/O events for the file.

- `count_write`

The total number of write I/O events for the file.

- `write_latency`

The total wait time of timed write I/O events for the file.

- `count_misc`

The total number of other I/O events for the file.

- `misc_latency`

The total wait time of timed other I/O events for the file.

#### 25.4.3.13 The `io_global_by_wait_by_bytes` and `x$io_global_by_wait_by_bytes` Views

These views summarize global I/O consumers to display amount of I/O and time waiting for I/O, grouped by event. By default, rows are sorted by descending total I/O (bytes read and written).

The `io_global_by_wait_by_bytes` and `x$io_global_by_wait_by_bytes` views have these columns:

- `event_name`

The I/O event name, with the `wait/io/file/` prefix stripped.

- `total`

The total number of occurrences of the I/O event.

- `total_latency`

The total wait time of timed occurrences of the I/O event.

- `min_latency`

The minimum single wait time of timed occurrences of the I/O event.

- `avg_latency`

The average wait time per timed occurrence of the I/O event.

- `max_latency`

The maximum single wait time of timed occurrences of the I/O event.

- `count_read`

The number of read requests for the I/O event.

- `total_read`

The number of bytes read for the I/O event.

- `avg_read`

The average number of bytes per read for the I/O event.

- `count_write`

The number of write requests for the I/O event.

- `total_written`

The number of bytes written for the I/O event.

- `avg_written`

The average number of bytes per write for the I/O event.

- `total_requested`

The total number of bytes read and written for the I/O event.

#### **25.4.3.14 The `io_global_by_wait_by_latency` and `x$io_global_by_wait_by_latency` Views**

These views summarize global I/O consumers to display amount of I/O and time waiting for I/O, grouped by event. By default, rows are sorted by descending total latency.

The `io_global_by_wait_by_latency` and `x$io_global_by_wait_by_latency` views have these columns:

- `event_name`

The I/O event name, with the `wait/io/file/` prefix stripped.

- `total`

The total number of occurrences of the I/O event.

- `total_latency`

The total wait time of timed occurrences of the I/O event.

- `avg_latency`

The average wait time per timed occurrence of the I/O event.

- `max_latency`

The maximum single wait time of timed occurrences of the I/O event.

- `read_latency`

The total wait time of timed read occurrences of the I/O event.

- `write_latency`

The total wait time of timed write occurrences of the I/O event.

- `misc_latency`

The total wait time of timed other occurrences of the I/O event.

- `count_read`

The number of read requests for the I/O event.

- `total_read`

The number of bytes read for the I/O event.

- `avg_read`

The average number of bytes per read for the I/O event.

- `count_write`

The number of write requests for the I/O event.

- `total_written`

The number of bytes written for the I/O event.

- `avg_written`

The average number of bytes per write for the I/O event.

#### 25.4.3.15 The `latest_file_io` and `x$latest_file_io` Views

These views summarize file I/O activity, grouped by file and thread. By default, rows are sorted with most recent I/O first.

The `latest_file_io` and `x$latest_file_io` views have these columns:

- `thread`

For foreground threads, the account associated with the thread (and port number for TCP/IP connections). For background threads, the thread name and thread ID

- `file`

The file path name.

- `latency`

The wait time of the file I/O event.

- `operation`

The type of operation.

- `requested`

The number of data bytes requested for the file I/O event.

#### 25.4.3.16 The `memory_by_host_by_current_bytes` and `x$memory_by_host_by_current_bytes` Views

These views summarize memory use, grouped by host. By default, rows are sorted by descending amount of memory used.

The `memory_by_host_by_current_bytes` and `x$memory_by_host_by_current_bytes` views have these columns:

- `host`

The host from which the client connected. Rows for which the `HOST` column in the underlying Performance Schema table is `NULL` are assumed to be for background threads and are reported with a host name of `background`.

- `current_count_used`

The current number of allocated memory blocks that have not been freed yet for the host.

- `current_allocated`

The current number of allocated bytes that have not been freed yet for the host.

- `current_avg_alloc`

The current number of allocated bytes per memory block for the host.

- `current_max_alloc`

The largest single current memory allocation in bytes for the host.

- `total_allocated`

The total memory allocation in bytes for the host.

#### **25.4.3.17 The `memory_by_thread_by_current_bytes` and `x$memory_by_thread_by_current_bytes` Views**

These views summarize memory use, grouped by thread. By default, rows are sorted by descending amount of memory used.

The `memory_by_thread_by_current_bytes` and `x$memory_by_thread_by_current_bytes` views have these columns:

- `thread_id`

The thread ID.

- `user`

The thread user or thread name.

- `current_count_used`

The current number of allocated memory blocks that have not been freed yet for the thread.

- `current_allocated`

The current number of allocated bytes that have not been freed yet for the thread.

- `current_avg_alloc`

The current number of allocated bytes per memory block for the thread.

- `current_max_alloc`

The largest single current memory allocation in bytes for the thread.

- `total_allocated`

The total memory allocation in bytes for the thread.

#### 25.4.3.18 The `memory_by_user_by_current_bytes` and `x$memory_by_user_by_current_bytes` Views

These views summarize memory use, grouped by user. By default, rows are sorted by descending amount of memory used.

The `memory_by_user_by_current_bytes` and `x$memory_by_user_by_current_bytes` views have these columns:

- `user`

The client user name. Rows for which the `USER` column in the underlying Performance Schema table is `NULL` are assumed to be for background threads and are reported with a host name of `background`.

- `current_count_used`

The current number of allocated memory blocks that have not been freed yet for the user.

- `current_allocated`

The current number of allocated bytes that have not been freed yet for the user.

- `current_avg_alloc`

The current number of allocated bytes per memory block for the user.

- `current_max_alloc`

The largest single current memory allocation in bytes for the user.

- `total_allocated`

The total memory allocation in bytes for the user.

#### 25.4.3.19 The `memory_global_by_current_bytes` and `x$memory_global_by_current_bytes` Views

These views summarize memory use, grouped by allocation type (that is, by event). By default, rows are sorted by descending amount of memory used.

The `memory_global_by_current_bytes` and `x$memory_global_by_current_bytes` views have these columns:

- `event_name`

The memory event name.

- `current_count`

The total number of occurrences of the event.

- `current_alloc`

The current number of allocated bytes that have not been freed yet for the event.

- `current_avg_alloc`

The current number of allocated bytes per memory block for the event.

- `high_count`

The high-water mark for number of memory blocks allocated for the event.

- `high_alloc`

The high-water mark for number of bytes allocated for the event.

- `high_avg_alloc`

The high-water mark for average number of bytes per memory block allocated for the event.

#### 25.4.3.20 The `memory_global_total` and `x$memory_global_total` Views

These views summarize total memory use within the server.

The `memory_global_total` and `x$memory_global_total` views have these columns:

- `total_allocated`

The total bytes of memory allocated within the server.

#### 25.4.3.21 The `metrics` View

This view summarizes MySQL server metrics to show variable names, values, types, and whether they are enabled. By default, rows are sorted by variable type and name.

This view was added in MySQL 5.7.9.

The `metrics` view includes this information:

- Global status variables from the Performance Schema `global_status` table
- InnoDB metrics from the `INFORMATION_SCHEMA INNODB_METRICS` table
- Current and total memory allocation, based on the Performance Schema memory instrumentation
- The current time (human readable and Unix timestamp formats)

There is some duplication of information between the `global_status` and `INNODB_METRICS` tables, which the `metrics` view eliminates.

The `metrics` view has these columns:

- `Variable_name`

The metric name. The metric type determines the source from which the name is taken:

- For global status variables: The `VARIABLE_NAME` column of the `global_status` table
- For InnoDB metrics: The `NAME` column of the `INNODB_METRICS` table
- For other metrics: A view-provided descriptive string

- `Variable_value`

The metric value. The metric type determines the source from which the value is taken:

- For global status variables: The `VARIABLE_VALUE` column of the `global_status` table
- For InnoDB metrics: The `COUNT` column of the `INNODB_METRICS` table
- For memory metrics: The relevant column from the Performance Schema `memory_summary_global_by_event_name` table

- For the current time: The value of `NOW(3)` or `UNIX_TIMESTAMP(NOW(3))`
- `Type`  
The metric type:
  - For global status variables: `Global Status`
  - For InnoDB metrics: `InnoDB Metrics - %`, where `%` is replaced by the value of the `SUBSYSTEM` column of the `INNODB_METRICS` table
  - For memory metrics: `Performance Schema`
  - For the current time: `System Time`
- `Enabled`  
Whether the metric is enabled:
  - For global status variables: `YES`
  - For InnoDB metrics: `YES` if the `STATUS` column of the `INNODB_METRICS` table is `enabled`, `NO` otherwise
  - For memory metrics: `NO`, `YES`, or `PARTIAL` (currently, `PARTIAL` occurs only for memory metrics and indicates that not all `memory/%` instruments are enabled; Performance Schema memory instruments are always enabled)
  - For the current time: `YES`

#### 25.4.3.22 The processlist and x\$processlist Views

These views summarize processlist information. They provide more complete information than the `SHOW PROCESSLIST` statement and the `INFORMATION_SCHEMA.PROCESSLIST` table, and are also nonblocking. By default, rows are sorted by descending process time and descending wait time.

The column descriptions here are brief. For additional information, see the description of the Performance Schema `threads` table at [Section 24.10.16.3, “The threads Table”](#).

The `processlist` and `x$processlist` views have these columns:

- `thd_id`  
The thread ID.
- `conn_id`  
The connection ID.
- `user`  
The thread user or thread name.
- `db`  
The default database for the thread, or `NULL` if there is none.
- `command`  
For foreground threads, the type of command the thread is executing on behalf of the client, or `Sleep` if the session is idle.
- `state`

An action, event, or state that indicates what the thread is doing.

- `time`

The time in seconds that the thread has been in its current state.

- `current_statement`

The statement the thread is executing, or `NULL` if it is not executing any statement.

- `statement_latency`

How long the statement has been executing.

This column was added in MySQL 5.7.9.

- `progress`

The percentage of work completed for stages that support progress reporting. See [Section 25.3, “sys Schema Progress Reporting”](#).

This column was added in MySQL 5.7.9.

- `lock_latency`

The time spent waiting for locks by the current statement.

- `rows_examined`

The number of rows read from storage engines by the current statement.

- `rows_sent`

The number of rows returned by the current statement.

- `rows_affected`

The number of rows affected by the current statement.

- `tmp_tables`

The number of internal in-memory temporary tables created by the current statement.

- `tmp_disk_tables`

The number of internal on-disk temporary tables created by the current statement.

- `full_scan`

The number of full table scans performed by the current statement.

- `last_statement`

The last statement executed by the thread, if there is no currently executing statement or wait.

- `last_statement_latency`

How long the last statement executed.

- `current_memory`

The number of bytes allocated by the thread.

- `last_wait`

The name of the most recent wait event for the thread.

- `last_wait_latency`

The wait time of the most recent wait event for the thread.

- `source`

The source file and line number containing the instrumented code that produced the event.

- `trx_latency`

The wait time of the current transaction for the thread.

This column was added in MySQL 5.7.9.

- `trx_state`

The state for the current transaction for the thread.

This column was added in MySQL 5.7.9.

- `trx_autocommit`

Whether autocommit mode was enabled when the current transaction started.

This column was added in MySQL 5.7.9.

- `pid`

The client process ID.

This column was added in MySQL 5.7.9.

- `program_name`

The client program name.

This column was added in MySQL 5.7.9.

#### 25.4.3.23 The `ps_check_lost_instrumentation` View

This view returns information about lost Performance Schema instruments, to indicate whether the Performance Schema is unable to monitor all runtime data.

The `ps_check_lost_instrumentation` view has these columns:

- `variable_name`

The Performance Schema status variable name indicating which type of instrument was lost.

- `variable_value`

The number of instruments lost.

#### 25.4.3.24 The `schema_auto_increment_columns` View

This view indicates which tables have `AUTO_INCREMENT` columns and provides information about those columns, such as the current and maximum column values and the usage ratio (ratio of used to possible values). By default, rows are sorted by descending usage ratio and maximum column value.

Tables in these schemas are excluded from view output: `mysql`, `sys`, `INFORMATION_SCHEMA`, `performance_schema`.

This view was added in MySQL 5.7.9.

The `schema_auto_increment_columns` view has these columns:

- `table_schema`

The schema that contains the table.

- `table_name`

The table that contains the `AUTO_INCREMENT` column.

- `column_name`

The name of the `AUTO_INCREMENT` column.

- `data_type`

The data type of the column.

- `column_type`

The column type of the column, which is the data type plus possibly other information. For example, for a column with a `bigint(20) unsigned` column type, the data type is just `bigint`.

- `is_signed`

Whether the column type is signed.

- `is_unsigned`

Whether the column type is unsigned.

- `max_value`

The maximum permitted value for the column.

- `auto_increment`

The current `AUTO_INCREMENT` value for the column.

- `auto_increment_ratio`

The ratio of used to permitted values for the column. This indicates how much of the sequence of values is “used up.”

### 25.4.3.25 The `schema_index_statistics` and `x$schema_index_statistics` Views

These views provide index statistics. By default, rows are sorted by descending total index latency.

The `schema_index_statistics` and `x$schema_index_statistics` views have these columns:

- `table_schema`

The schema that contains the table.

- `table_name`

The table that contains the index.

- `index_name`

The name of the index.

- `rows_selected`

The total number of rows read using the index.

- `select_latency`

The total wait time of timed reads using the index.

- `rows_inserted`

The total number of rows inserted into the index.

- `insert_latency`

The total wait time of timed inserts into the index.

- `rows_updated`

The total number of rows updated in the index.

- `update_latency`

The total wait time of timed updates in the index.

- `rows_deleted`

The total number of rows deleted from the index.

- `delete_latency`

The total wait time of timed deletes from the index.

#### 25.4.3.26 The `schema_object_overview` View

This view summarizes the types of objects within each schema. By default, rows are sorted by schema and object type.

**Note**

For MySQL instances with a large number of objects, this view might take a long time to execute.

The `schema_object_overview` view has these columns:

- `db`

The schema name.

- `object_type`

The object type: `BASE TABLE`, `INDEX (index_type)`, `EVENT`, `FUNCTION`, `PROCEDURE`, `TRIGGER`, `VIEW`.

- `count`

The number of objects in the schema of the given type.

#### 25.4.3.27 The `schema_redundant_indexes` and `x$schema_flattened_keys` Views

The `schema_redundant_indexes` view displays indexes that duplicate other indexes or are made redundant by them. The `x$schema_flattened_keys` view is a helper view for `schema_redundant_indexes`.

These views were added in MySQL 5.7.9.

In the following column descriptions, the dominant index is the one that makes the redundant index redundant.

The `schema_redundant_indexes` view has these columns:

- `table_schema`

The schema that contains the table.

- `table_name`

The table that contains the index.

- `redundant_index_name`

The name of the redundant index.

- `redundant_index_columns`

The names of the columns in the redundant index.

- `redundant_index_non_unique`

The number of nonunique columns in the redundant index.

- `dominant_index_name`

The name of the dominant index.

- `dominant_index_columns`

The names of the columns in the dominant index.

- `dominant_index_non_unique`

The number of nonunique columns in the dominant index.

- `subpart_exists`

Whether the index indexes only part of a column.

- `sql_drop_index`

The statement to execute to drop the redundant index.

The `x$schema_flattened_keys` view has these columns:

- `table_schema`

The schema that contains the table.

- `table_name`

The table that contains the index.

- `index_name`

An index name.

- `non_unique`

The number of nonunique columns in the index.

- `subpart_exists`

Whether the index indexes only part of a column.

- `index_columns`

The name of the columns in the index.

### 25.4.3.28 The `schema_table_lock_waits` and `x$schema_table_lock_waits` Views

These views display which sessions are blocked waiting on metadata locks, and what is blocking them.

These views were added in MySQL 5.7.9.

The column descriptions here are brief. For additional information, see the description of the Performance Schema `metadata_locks` table at [Section 24.10.12.1, “The metadata\\_locks Table”](#).

The `schema_table_lock_waits` and `x$schema_table_lock_waits` views have these columns:

- `object_schema`

The schema containing the object to be locked.

- `object_name`

The name of the instrumented object.

- `waiting_thread_id`

The thread ID of the thread that is waiting for the lock.

- `waiting_pid`

The processlist ID of the thread that is waiting for the lock.

- `waiting_account`

The account associated with the session that is waiting for the lock.

- `waiting_lock_type`

The type of the waiting lock.

- `waiting_lock_duration`

How long the waiting lock has been waiting.

- `waiting_query`

The statement that is waiting for the lock.

- `waiting_query_secs`

How long the statement has been waiting, in seconds.

- `waiting_query_rows_affected`

The number of rows affected by the statement.

- `waiting_query_rows_examined`

The number of rows read from storage engines by the statement.

- `blocking_thread_id`

The thread ID of the thread that is blocking the waiting lock.

- `blocking_pid`

The processlist ID of the thread that is blocking the waiting lock.

- `blocking_account`

The account associated with the thread that is blocking the waiting lock.

- `blocking_lock_type`

The type of lock that is blocking the waiting lock.

- `blocking_lock_duration`

How long the blocking lock has been held.

- `sql_kill_blocking_query`

The `KILL` statement to execute to kill the blocking statement.

- `sql_kill_blocking_connection`

The `KILL` statement to execute to kill the session running the blocking statement.

#### 25.4.3.29 The `schema_table_statistics` and `x$schema_table_statistics` Views

These views summarize table statistics. By default, rows are sorted by descending total wait time (tables with most contention first).

These views user a helper view, `x$ps_schema_table_statistics_io`.

The `schema_table_statistics` and `x$schema_table_statistics` views have these columns:

- `table_schema`

The schema that contains the table.

- `table_name`

The table name.

- `total_latency`

The total wait time of timed I/O events for the table.

- `rows_fetched`

The total number of rows read from the table.

- `fetch_latency`

The total wait time of timed read I/O events for the table.

- `rows_inserted`

The total number of rows inserted into the table.

- `insert_latency`

The total wait time of timed insert I/O events for the table.

- `rows_updated`

The total number of rows updated in the table.

- `update_latency`

The total wait time of timed update I/O events for the table.

- `rows_deleted`

The total number of rows deleted from the table.

- `delete_latency`

The total wait time of timed delete I/O events for the table.

- `io_read_requests`

The total number of read requests for the table.

- `io_read`

The total number of bytes read from the table.

- `io_read_latency`

The total wait time of reads from the table.

- `io_write_requests`

The total number of write requests for the table.

- `io_write`

The total number of bytes written to the table.

- `io_write_latency`

The total wait time of writes to the table.

- `io_misc_requests`

The total number of miscellaneous I/O requests for the table.

- `io_misc_latency`

The total wait time of miscellaneous I/O requests for the table.

### 25.4.3.30 The `schema_table_statistics_with_buffer` and `x$schema_table_statistics_with_buffer` Views

These views summarize table statistics, including `InnoDB` buffer pool statistics. By default, rows are sorted by descending total wait time (tables with most contention first).

These views use a helper view, `x$ps_schema_table_statistics_io`.

The `schema_table_statistics_with_buffer` and `x$schema_table_statistics_with_buffer` views have these columns:

- `table_schema`

The schema that contains the table.

- `table_name`

The table name.

- `rows_fetched`

The total number of rows read from the table.

- `fetch_latency`

The total wait time of timed read I/O events for the table.

- `rows_inserted`

The total number of rows inserted into the table.

- `insert_latency`

The total wait time of timed insert I/O events for the table.

- `rows_updated`

The total number of rows updated in the table.

- `update_latency`

The total wait time of timed update I/O events for the table.

- `rows_deleted`

The total number of rows deleted from the table.

- `delete_latency`

The total wait time of timed delete I/O events for the table.

- `io_read_requests`

The total number of read requests for the table.

- `io_read`

The total number of bytes read from the table.

- `io_read_latency`

The total wait time of reads from the table.

- `io_write_requests`

The total number of write requests for the table.

- `io_write`

The total number of bytes written to the table.

- `io_write_latency`

The total wait time of writes to the table.

- `io_misc_requests`

The total number of miscellaneous I/O requests for the table.

- `io_misc_latency`

The total wait time of miscellaneous I/O requests for the table.

- `innodb_buffer_allocated`

The total number of InnoDB buffer bytes allocated for the table.

- `innodb_buffer_data`

The total number of InnoDB data bytes allocated for the table.

- `innodb_buffer_free`

The total number of InnoDB nondata bytes allocated for the table (`innodb_buffer_allocated - innodb_buffer_data`).

- `innodb_buffer_pages`

The total number of InnoDB pages allocated for the table.

- `innodb_buffer_pages_hashed`

The total number of InnoDB hashed pages allocated for the table.

- `innodb_buffer_pages_old`

The total number of InnoDB old pages allocated for the table.

- `innodb_buffer_rows_cached`

The total number of InnoDB cached rows for the table.

#### **25.4.3.31 The `schema_tables_with_full_table_scans` and `x$schema_tables_with_full_table_scans` Views**

These views display which tables are being accessed with full table scans. By default, rows are sorted by descending rows scanned.

The `schema_tables_with_full_table_scans` and `x$schema_tables_with_full_table_scans` views have these columns:

- `object_schema`

The schema name.

- `object_name`

The table name.

- `rows_full_scanned`

The total number of rows scanned by full scans of the table.

- `latency`

The total wait time of full scans of the table.

#### **25.4.3.32 The `schema_unused_indexes` View**

These views display indexes for which there are no events, which indicates that they are not being used. By default, rows are sorted by schema and table.

This view is most useful when the server has been up and processing long enough that its workload is representative. Otherwise, presence of an index in this view may not be meaningful.

The `schema_unused_indexes` view has these columns:

- `object_schema`

The schema name.

- `object_name`

The table name.

- `index_name`

The unused index name.

#### 25.4.3.33 The session and x\$session Views

These views are similar to `processlist` and `x$processlist`, but they filter out background processes to display only user sessions. For descriptions of the columns, see [Section 25.4.3.22, “The processlist and x\\$processlist Views”](#).

These views were added in MySQL 5.7.9.

#### 25.4.3.34 The session\_ssl\_status View

For each connection, this view displays the SSL version, cipher, and count of reused SSL sessions.

This view was added in MySQL 5.7.9.

The `session_ssl_status` view has these columns:

- `thread_id`

The thread ID for the connection.

- `ssl_version`

The version of SSL used for the connection.

- `ssl_cipher`

The SSL cipher used for the connection.

- `ssl_sessions_reused`

The number of reused SSL sessions for the connection.

#### 25.4.3.35 The statement\_analysis and x\$statement\_analysis Views

These views list normalized statements with aggregated statistics. The content mimics the MySQL Enterprise Monitor Query Analysis view. By default, rows are sorted by descending total latency.

The `statement_analysis` and `x$statement_analysis` views have these columns:

- `query`

The normalized statement string.

- `db`

The default database for the statement, or `NULL` if there is none.

- `full_scan`

The total number of full table scans performed by occurrences of the statement.

- `exec_count`

The total number of times the statement has executed.

- `err_count`

The total number of errors produced by occurrences of the statement.

- `warn_count`

The total number of warnings produced by occurrences of the statement.

- `total_latency`

The total wait time of timed occurrences of the statement.

- `max_latency`

The maximum single wait time of timed occurrences of the statement.

- `avg_latency`

The average wait time per timed occurrence of the statement.

- `lock_latency`

The total time waiting for locks by timed occurrences of the statement.

- `rows_sent`

The total number of rows returned by occurrences of the statement.

- `rows_sent_avg`

The average number of rows returned per occurrence of the statement.

- `rows_examined`

The total number of rows read from storage engines by occurrences of the statement.

- `rows_examined_avg`

The average number of rows read from storage engines per occurrence of the statement.

- `rows_affected`

The total number of rows affected by occurrences of the statement.

- `rows_affected_avg`

The average number of rows affected per occurrence of the statement.

- `tmp_tables`

The total number of internal in-memory temporary tables created by occurrences of the statement.

- `tmp_disk_tables`

The total number of internal on-disk temporary tables created by occurrences of the statement.

- `rows_sorted`

The total number of rows sorted by occurrences of the statement.

- `sort_merge_passes`

The total number of sort merge passes by occurrences of the statement.

- `digest`

The statement digest.

- `first_seen`

The time at which the statement was first seen.

- `last_seen`

The time at which the statement was most recently seen.

### 25.4.3.36 The `statements_with_errors_or_warnings` and `x$statements_with_errors_or_warnings` Views

These views display normalized statements that have produced errors or warnings. By default, rows are sorted by descending error and warning counts.

The `statements_with_errors_or_warnings` and `x$statements_with_errors_or_warnings` views have these columns:

- `query`

The normalized statement string.

- `db`

The default database for the statement, or `NULL` if there is none.

- `exec_count`

The total number of times the statement has executed.

- `errors`

The total number of errors produced by occurrences of the statement.

- `error_pct`

The percentage of statement occurrences that produced errors.

- `warnings`

The total number of warnings produced by occurrences of the statement.

- `warning_pct`

The percentage of statement occurrences that produced warnings.

- `first_seen`

The time at which the statement was first seen.

- `last_seen`

The time at which the statement was most recently seen.

- `digest`

The statement digest.

### 25.4.3.37 The `statements_with_full_table_scans` and `x$statements_with_full_table_scans` Views

These views display normalized statements that have done full table scans. By default, rows are sorted by descending percentage of time a full scan was done and descending total latency.

The `statements_with_full_table_scans` and `x$statements_with_full_table_scans` views have these columns:

- `query`

The normalized statement string.

- `db`

The default database for the statement, or `NULL` if there is none.

- `exec_count`

The total number of times the statement has executed.

- `total_latency`

The total wait time of timed statement events for the statement.

- `no_index_used_count`

The total number of times no index was used to scan the table.

- `no_good_index_used_count`

The total number of times no good index was used to scan the table.

- `no_index_used_pct`

The percentage of the time no index was used to scan the table.

- `rows_sent`

The total number of rows returned from the table.

- `rows_examined`

The total number of rows read from the storage engine for the table.

- `rows_sent_avg`

The average number of rows returned from the table.

- `rows_examined_avg`

The average number of rows read from the storage engine for the table.

- `first_seen`

The time at which the statement was first seen.

- `last_seen`

The time at which the statement was most recently seen.

- `digest`

The statement digest.

#### 25.4.3.38 The `statements_with_runtimes_in_95th_percentile` and `x$statements_with_runtimes_in_95th_percentile` Views

These views list statements with runtimes in the 95th percentile. By default, rows are sorted by descending average latency.

Both views use two helper views, `x$ps_digest_avg_latency_distribution` and `x$ps_digest_95th_percentile_by_avg_us`.

The `statements_with_runtimes_in_95th_percentile` and `x$statements_with_runtimes_in_95th_percentile` views have these columns:

- `query`

The normalized statement string.

- `db`

The default database for the statement, or `NULL` if there is none.

- `full_scan`

The total number of full table scans performed by occurrences of the statement.

- `exec_count`

The total number of times the statement has executed.

- `err_count`

The total number of errors produced by occurrences of the statement.

- `warn_count`

The total number of warnings produced by occurrences of the statement.

- `total_latency`

The total wait time of timed occurrences of the statement.

- `max_latency`

The maximum single wait time of timed occurrences of the statement.

- `avg_latency`

The average wait time per timed occurrence of the statement.

- `rows_sent`

The total number of rows returned by occurrences of the statement.

- `rows_sent_avg`

The average number of rows returned per occurrence of the statement.

- `rows_examined`

The total number of rows read from storage engines by occurrences of the statement.

- `rows_examined_avg`

The average number of rows read from storage engines per occurrence of the statement.

- `first_seen`

The time at which the statement was first seen.

- `last_seen`

The time at which the statement was most recently seen.

- `digest`

The statement digest.

### 25.4.3.39 The `statements_with_sorting` and `x$statements_with_sorting` Views

These views list normalized statements that have performed sorts. By default, rows are sorted by descending total latency.

The `statements_with_sorting` and `x$statements_with_sorting` views have these columns:

- `query`

The normalized statement string.

- `db`

The default database for the statement, or `NULL` if there is none.

- `exec_count`

The total number of times the statement has executed.

- `total_latency`

The total wait time of timed occurrences of the statement.

- `sort_merge_passes`

The total number of sort merge passes by occurrences of the statement.

- `avg_sort_merges`

The average number of sort merge passes per occurrence of the statement.

- `sorts_using_scans`

The total number of sorts using table scans by occurrences of the statement.

- `sort_using_range`

The total number of sorts using range accesses by occurrences of the statement.

- `rows_sorted`

The total number of rows sorted by occurrences of the statement.

- `avg_rows_sorted`

The average number of rows sorted per occurrence of the statement.

- `first_seen`

The time at which the statement was first seen.

- `last_seen`

The time at which the statement was most recently seen.

- `digest`

The statement digest.

#### 25.4.3.40 The `statements_with_temp_tables` and `x$statements_with_temp_tables` Views

These views list normalized statements that have used temporary tables. By default, rows are sorted by descending number of on-disk temporary tables used and descending number of in-memory temporary tables used.

The `statements_with_temp_tables` and `x$statements_with_temp_tables` views have these columns:

- `query`

The normalized statement string.

- `db`

The default database for the statement, or `NULL` if there is none.

- `exec_count`

The total number of times the statement has executed.

- `total_latency`

The total wait time of timed occurrences of the statement.

- `memory_tmp_tables`

The total number of internal in-memory temporary tables created by occurrences of the statement.

- `disk_tmp_tables`

The total number of internal on-disk temporary tables created by occurrences of the statement.

- `avg_tmp_tables_per_query`

The average number of internal temporary tables created per occurrence of the statement.

- `tmp_tables_to_disk_pct`

The percentage of internal in-memory temporary tables that were converted to on-disk tables.

- `first_seen`

The time at which the statement was first seen.

- `last_seen`

The time at which the statement was most recently seen.

- `digest`

The statement digest.

#### 25.4.3.41 The `user_summary` and `x$user_summary` Views

These views summarize statement activity, file I/O, and connections, grouped by user. By default, rows are sorted by descending total latency.

The `user_summary` and `x$user_summary` views have these columns:

- `user`

The client user name. Rows for which the `USER` column in the underlying Performance Schema table is `NULL` are assumed to be for background threads and are reported with a host name of `background`.

- `statements`

The total number of statements for the user.

- `statement_latency`

The total wait time of timed statements for the user.

- `statement_avg_latency`

The average wait time per timed statement for the user.

- `table_scans`

The total number of table scans for the user.

- `file_ios`

The total number of file I/O events for the user.

- `file_io_latency`

The total wait time of timed file I/O events for the user.

- `current_connections`

The current number of connections for the user.

- `total_connections`

The total number of connections for the user.

- `unique_hosts`

The number of distinct hosts from which connections for the user have originated.

- `current_memory`

The current amount of allocated memory for the user.

- `total_memory_allocated`

The total amount of allocated memory for the user.

#### 25.4.3.42 The `user_summary_by_file_io` and `x$user_summary_by_file_io` Views

These views summarize file I/O, grouped by user. By default, rows are sorted by descending total file I/O latency.

The `user_summary_by_file_io` and `x$user_summary_by_file_io` views have these columns:

- `user`

The client user name. Rows for which the `USER` column in the underlying Performance Schema table is `NULL` are assumed to be for background threads and are reported with a host name of `background`.

- `ios`

The total number of file I/O events for the user.

- `io_latency`

The total wait time of timed file I/O events for the user.

#### 25.4.3.43 The `user_summary_by_file_io_type` and `x$user_summary_by_file_io_type` Views

These views summarize file I/O, grouped by user and event type. By default, rows are sorted by user and descending total latency.

The `user_summary_by_file_io_type` and `x$user_summary_by_file_io_type` views have these columns:

- `user`

The client user name. Rows for which the `USER` column in the underlying Performance Schema table is `NULL` are assumed to be for background threads and are reported with a host name of `background`.

- `event_name`

The file I/O event name.

- `total`

The total number of occurrences of the file I/O event for the user.

- `latency`

The total wait time of timed occurrences of the file I/O event for the user.

- `max_latency`

The maximum single wait time of timed occurrences of the file I/O event for the user.

#### 25.4.3.44 The `user_summary_by_stages` and `x$user_summary_by_stages` Views

These views summarize stages, grouped by user. By default, rows are sorted by user and descending total stage latency.

The `user_summary_by_stages` and `x$user_summary_by_stages` views have these columns:

- `user`

The client user name. Rows for which the `USER` column in the underlying Performance Schema table is `NULL` are assumed to be for background threads and are reported with a host name of `background`.

- `event_name`

The stage event name.

- `total`

The total number of occurrences of the stage event for the user.

- `total_latency`

The total wait time of timed occurrences of the stage event for the user.

- `avg_latency`

The average wait time per timed occurrence of the stage event for the user.

#### **25.4.3.45 The `user_summary_by_statement_latency` and `x$user_summary_by_statement_latency` Views**

These views summarize overall statement statistics, grouped by user. By default, rows are sorted by descending total latency.

The `user_summary_by_statement_latency` and `x$user_summary_by_statement_latency` views have these columns:

- `user`

The client user name. Rows for which the `USER` column in the underlying Performance Schema table is `NULL` are assumed to be for background threads and are reported with a host name of `background`.

- `total`

The total number of statements for the user.

- `total_latency`

The total wait time of timed statements for the user.

- `max_latency`

The maximum single wait time of timed statements for the user.

- `lock_latency`

The total time waiting for locks by timed statements for the user.

- `rows_sent`

The total number of rows returned by statements for the user.

- `rows_examined`

The total number of rows read from storage engines by statements for the user.

- `rows_affected`

The total number of rows affected by statements for the user.

- `full_scans`

The total number of full table scans by statements for the user.

#### **25.4.3.46 The `user_summary_by_statement_type` and `x$user_summary_by_statement_type` Views**

These views summarize information about statements executed, grouped by user and statement type. By default, rows are sorted by user and descending total latency.

The `user_summary_by_statement_type` and `x$user_summary_by_statement_type` views have these columns:

- `user`

The client user name. Rows for which the `USER` column in the underlying Performance Schema table is `NULL` are assumed to be for background threads and are reported with a host name of `background`.

- `statement`

The final component of the statement event name.

- `total`

The total number of occurrences of the statement event for the user.

- `total_latency`

The total wait time of timed occurrences of the statement event for the user.

- `max_latency`

The maximum single wait time of timed occurrences of the statement event for the user.

- `lock_latency`

The total time waiting for locks by timed occurrences of the statement event for the user.

- `rows_sent`

The total number of rows returned by occurrences of the statement event for the user.

- `rows_examined`

The total number of rows read from storage engines by occurrences of the statement event for the user.

- `rows_affected`

The total number of rows affected by occurrences of the statement event for the user.

- `full_scans`

The total number of full table scans by occurrences of the statement event for the user.

#### 25.4.3.47 The version View

This view provides the current `sys` schema and MySQL server versions.

The `version` view has these columns:

- `sys_version`

The `sys` schema version.

- `mysql_version`

The MySQL server version.

#### 25.4.3.48 The `wait_classes_global_by_avg_latency` and `x$wait_classes_global_by_avg_latency` Views

These views summarize wait class average latencies, grouped by event class. By default, rows are sorted by descending average latency. Idle events are ignored.

An event class is determined by stripping from the event name everything after the first three components. For example, the class for `wait/io/file/sql/slow_log` is `wait/io/file`.

The `wait_classes_global_by_avg_latency` and `x$wait_classes_global_by_avg_latency` views have these columns:

- `event_class`  
The event class.
- `total`  
The total number of occurrences of events in the class.
- `total_latency`  
The total wait time of timed occurrences of events in the class.
- `min_latency`  
The minimum single wait time of timed occurrences of events in the class.
- `avg_latency`  
The average wait time per timed occurrence of events in the class.
- `max_latency`  
The maximum single wait time of timed occurrences of events in the class.

#### 25.4.3.49 The `wait_classes_global_by_latency` and `x$wait_classes_global_by_latency` Views

These views summarize wait class total latencies, grouped by event class. By default, rows are sorted by descending total latency. Idle events are ignored.

An event class is determined by stripping from the event name everything after the first three components. For example, the class for `wait/io/file/sql/slow_log` is `wait/io/file`.

The `wait_classes_global_by_latency` and `x$wait_classes_global_by_latency` views have these columns:

- `event_class`  
The event class.
- `total`  
The total number of occurrences of events in the class.
- `total_latency`  
The total wait time of timed occurrences of events in the class.
- `min_latency`  
The minimum single wait time of timed occurrences of events in the class.
- `avg_latency`

The average wait time per timed occurrence of events in the class.

- `max_latency`

The maximum single wait time of timed occurrences of events in the class.

#### 25.4.3.50 The `waits_by_host_by_latency` and `x$waits_by_host_by_latency` Views

These views summarize wait events, grouped by host and event. By default, rows are sorted by host and descending total latency. Idle events are ignored.

The `waits_by_host_by_latency` and `x$waits_by_host_by_latency` views have these columns:

- `host`

The host from which the connection originated.

- `event`

The event name.

- `total`

The total number of occurrences of the event for the host.

- `total_latency`

The total wait time of timed occurrences of the event for the host.

- `avg_latency`

The average wait time per timed occurrence of the event for the host.

- `max_latency`

The maximum single wait time of timed occurrences of the event for the host.

#### 25.4.3.51 The `waits_by_user_by_latency` and `x$waits_by_user_by_latency` Views

These views summarize wait events, grouped by user and event. By default, rows are sorted by user and descending total latency. Idle events are ignored.

The `waits_by_user_by_latency` and `x$waits_by_user_by_latency` views have these columns:

- `user`

The user associated with the connection.

- `event`

The event name.

- `total`

The total number of occurrences of the event for the user.

- `total_latency`

The total wait time of timed occurrences of the event for the user.

- `avg_latency`

The average wait time per timed occurrence of the event for the user.

- `max_latency`

The maximum single wait time of timed occurrences of the event for the user.

### 25.4.3.52 The `waits_global_by_latency` and `x$waits_global_by_latency` Views

These views summarize wait events, grouped by event. By default, rows are sorted by descending total latency. Idle events are ignored.

The `waits_global_by_latency` and `x$waits_global_by_latency` views have these columns:

- `events`

The event name.

- `total`

The total number of occurrences of the event.

- `total_latency`

The total wait time of timed occurrences of the event.

- `avg_latency`

The average wait time per timed occurrence of the event.

- `max_latency`

The maximum single wait time of timed occurrences of the event.

## 25.4.4 sys Schema Stored Procedures

The following sections describe `sys` schema stored procedures.

### 25.4.4.1 The `create_synonym_db()` Procedure

Given a schema name, this procedure creates a synonym schema containing views that refer to all the tables and views in the original schema. This can be used, for example, to create a shorter name by which to refer to a schema with a long name (such as `info` rather than `INFORMATION_SCHEMA`).

#### Parameters

- `in_db_name VARCHAR(64)`: The name of the schema for which to create the synonym.
- `in_synonym VARCHAR(64)`: The name to use for the synonym schema. This schema must not already exist.

#### Example

```
mysql> SHOW DATABASES;
+-----+
| Database |
+-----+
| information_schema |
| mysql |
| performance_schema |
| sys |
| world |
+-----+
mysql> CALL create_synonym_db('INFORMATION_SCHEMA', 'info');
```

```

+-----+
| summary |
+-----+
| Created 63 views in the info database |
+-----+
mysql> SHOW DATABASES;
+-----+
| Database |
+-----+
| information_schema |
| info |
| mysql |
| performance_schema |
| sys |
| world |
+-----+
mysql> SHOW FULL TABLES FROM info;
+-----+
| Tables_in_info | Table_type |
+-----+
| character_sets | VIEW |
| collation_character_set_applicability | VIEW |
| collations | VIEW |
| column_privileges | VIEW |
| columns | VIEW |
...

```

#### 25.4.4.2 The diagnostics() Procedure

Creates a report of the current server status for diagnostic purposes.

This procedure requires the [SUPER](#) privilege because it manipulates the session `sql_log_bin` system variable to disable binary logging during its execution.

This procedure was added in MySQL 5.7.9. For MySQL 5.6, it requires MySQL 5.6.10 or higher. For MySQL 5.7, it requires MySQL 5.7.9 or higher.

Data collected for `diagnostics()` includes this information:

- Information from the `metrics` view (see [Section 25.4.3.21, “The metrics View”](#))
- Information from other relevant `sys` schema views, such as the one that determines queries in the 95th percentile
- Information from the `ndbinfo` schema, if the MySQL server is part of MySQL Cluster
- Replication status (both master and slave)

Some of the `sys` schema views are calculated as initial (optional), overall, and delta values:

- The initial view is the content of the view at the start of the `diagnostics()` procedure. This output is the same as the start values used for the delta view. The initial view is included if the `diagnostics.include_raw` configuration option is `ON`.
- The overall view is the content of the view at the end of the `diagnostics()` procedure. This output is the same as the end values used for the delta view. The overall view is always included.
- The delta view is the difference from the beginning to the end of procedure execution. The minimum and maximum values are the minimum and maximum values from the end view, respectively. They do not necessarily reflect the minimum and maximum values in the monitored period. Except for the `metrics` view, the delta is calculated only between the first and last outputs.

#### Parameters

- `in_max_runtime` `INT UNSIGNED`: The maximum data collection time in seconds. Use `NULL` to collect data for the default of 60 seconds. Otherwise, use a value greater than 0.

- `in_interval` `INT UNSIGNED`: The sleep time between data collections in seconds. Use `NULL` to sleep for the default of 30 seconds. Otherwise, use a value greater than 0.
- `in_auto_config` `ENUM('current', 'medium', 'full')`: The Performance Schema configuration to use. Permitted values are:
  - `current`: Use the current instrument and consumer settings.
  - `medium`: Enable some instruments and consumers.
  - `full`: Enable all instruments and consumers.

**Note**

The more instruments and consumers enabled, the more impact on MySQL server performance. Be careful with the `medium` setting and especially the `full` setting, which has a large performance impact.

Use of the `medium` or `full` setting requires the `SUPER` privilege.

If a setting other than `current` is chosen, the current settings are restored at the end of the procedure.

## Configuration Options

`diagnostics()` operation can be modified using the following configuration options or their corresponding user-defined variables (see [Section 25.4.2.1, “The sys\\_config Table”](#)):

- `debug`, `@sys.debug`

If this option is `ON`, produce debugging output. The default is `OFF`.

- `diagnostics.allow_i_s_tables`, `@sys.diagnostics.allow_i_s_tables`

If this option is `ON`, the `diagnostics()` procedure is permitted to perform table scans on the `INFORMATION_SCHEMA.TABLES` table. This can be expensive if there are many tables. The default is `OFF`.

- `diagnostics.include_raw`, `@sys.diagnostics.include_raw`

If this option is `ON`, the `diagnostics()` procedure output includes the raw output from querying the `metrics` view. The default is `OFF`.

- `statement_truncate_len`, `@sys.statement_truncate_len`

The maximum length of statements returned by the `format_statement()` function. Longer statements are truncated to this length. The default is 64.

## Example

Create a diagnostics report that starts an iteration every 30 seconds and runs for at most 120 seconds using the current Performance Schema settings:

```
mysql> CALL diagnostics(120, 30, 'current');
```

To capture the output from the `diagnostics()` procedure in a file as it runs, use the `mysql` client `tee filename` and `notee` commands (see [Section 5.5.1.2, “mysql Commands”](#)):

```
mysql> tee diag.out;
mysql> CALL diagnostics(120, 30, 'current');
mysql> notee;
```

### 25.4.4.3 The `execute_prepared_stmt()` Procedure

Given an SQL statement as a string, executes it as a prepared statement. The prepared statement is deallocated after execution, so it is not subject to reuse. Thus, this procedure is useful primarily for executing dynamic statements on a one-time basis.

This procedure uses `sys_execute_prepared_stmt` as the prepared statement name. If that statement name exists when the procedure is called, its previous content is destroyed.

This procedure was added in MySQL 5.7.9.

#### Parameters

- `in_query` `LONGTEXT CHARACTER SET utf8`: The statement string to execute.

#### Configuration Options

`execute_prepared_stmt()` operation can be modified using the following configuration options or their corresponding user-defined variables (see [Section 25.4.2.1, “The `sys\_config` Table](#)”):

- `debug`, `@sys.debug`

If this option is `ON`, produce debugging output. The default is `OFF`.

#### Example

```
mysql> CALL execute_prepared_stmt('SELECT COUNT(*) FROM mysql.user');
+-----+
| COUNT(*) |
+-----+
|      15  |
+-----+
```

### 25.4.4.4 The `ps_setup_disable_background_threads()` Procedure

Disables Performance Schema instrumentation for all background threads. Produces a result set indicating how many background threads were disabled. Already disabled threads do not count.

#### Parameters

None.

#### Example

```
mysql> CALL ps_setup_disable_background_threads();
+-----+
| summary |
+-----+
| Disabled 24 background threads |
+-----+
```

### 25.4.4.5 The `ps_setup_disable_consumer()` Procedure

Disables Performance Schema consumers with names that contain the argument. Produces a result set indicating how many consumers were disabled. Already disabled consumers do not count.

#### Parameters

- `consumer` `VARCHAR(128)`: The value used to match consumer names, which are identified by using `%consumer%` as an operand for a `LIKE` pattern match.

A value of `' '` matches all consumers.

## Example

Disable all statement consumers:

```
mysql> CALL ps_setup_disable_consumer('statement');
+-----+
| summary |
+-----+
| Disabled 4 consumers |
+-----+
```

### 25.4.4.6 The ps\_setup\_disable\_instrument() Procedure

Disables Performance Schema instruments with names that contain the argument. Produces a result set indicating how many instruments were disabled. Already disabled instruments do not count.

#### Parameters

- `in_pattern VARCHAR(128)`: The value used to match instrument names, which are identified by using `%in_pattern%` as an operand for a `LIKE` pattern match.

A value of `' '` matches all instruments.

## Example

Disable a specific instrument:

```
mysql> CALL ps_setup_disable_instrument('wait/lock/metadata/sql/mdl');
+-----+
| summary |
+-----+
| Disabled 1 instrument |
+-----+
```

Disable all mutex instruments:

```
mysql> CALL ps_setup_disable_instrument('mutex');
+-----+
| summary |
+-----+
| Disabled 177 instruments |
+-----+
```

### 25.4.4.7 The ps\_setup\_disable\_thread() Procedure

Given a connection ID, disables Performance Schema instrumentation for the thread. Produces a result set indicating how many threads were disabled. Already disabled threads do not count.

#### Parameters

- `in_connection_id BIGINT`: The connection ID. This is a connection ID as given in the `PROCESSLIST_ID` column of the Performance Schema `threads` table or the `Id` column of `SHOW PROCESSLIST` output.

## Example

Disable a specific connection by its connection ID:

```
mysql> CALL ps_setup_disable_thread(225);
+-----+
| summary |
+-----+
```

```
| Disabled 1 thread |
+-----+
```

Disable the current connection:

```
mysql> CALL ps_setup_disable_thread(CONNECTION_ID());
+-----+
| summary |
+-----+
| Disabled 1 thread |
+-----+
```

#### 25.4.4.8 The `ps_setup_enable_background_threads()` Procedure

Enables Performance Schema instrumentation for all background threads. Produces a result set indicating how many background threads were enabled. Already enabled threads do not count.

##### Parameters

None.

##### Example

```
mysql> CALL ps_setup_enable_background_threads();
+-----+
| summary |
+-----+
| Enabled 24 background threads |
+-----+
```

#### 25.4.4.9 The `ps_setup_enable_consumer()` Procedure

Enables Performance Schema consumers with names that contain the argument. Produces a result set indicating how many consumers were enabled. Already enabled consumers do not count.

##### Parameters

- `consumer VARCHAR(128)`: The value used to match consumer names, which are identified by using `%consumer%` as an operand for a `LIKE` pattern match.

A value of `' '` matches all consumers.

##### Example

Enable all statement consumers:

```
mysql> CALL ps_setup_enable_consumer('statement');
+-----+
| summary |
+-----+
| Enabled 4 consumers |
+-----+
```

#### 25.4.4.10 The `ps_setup_enable_instrument()` Procedure

Enables Performance Schema instruments with names that contain the argument. Produces a result set indicating how many instruments were enabled. Already enabled instruments do not count.

##### Parameters

- `in_pattern VARCHAR(128)`: The value used to match instrument names, which are identified by using `%in_pattern%` as an operand for a `LIKE` pattern match.

A value of '' matches all instruments.

### Example

Enable a specific instrument:

```
mysql> CALL ps_setup_enable_instrument('wait/lock/metadata/sql/mdl');
+-----+
| summary                |
+-----+
| Enabled 1 instrument   |
+-----+
```

Enable all mutex instruments:

```
mysql> CALL ps_setup_enable_instrument('mutex');
+-----+
| summary                |
+-----+
| Enabled 177 instruments |
+-----+
```

#### 25.4.4.11 The `ps_setup_enable_thread()` Procedure

Given a connection ID, enables Performance Schema instrumentation for the thread. Produces a result set indicating how many threads were enabled. Already enabled threads do not count.

### Parameters

- `in_connection_id` `BIGINT`: The connection ID. This is a connection ID as given in the `PROCESSLIST_ID` column of the Performance Schema `threads` table or the `Id` column of `SHOW PROCESSLIST` output.

### Example

Enable a specific connection by its connection ID:

```
mysql> CALL ps_setup_enable_thread(225);
+-----+
| summary                |
+-----+
| Enabled 1 thread       |
+-----+
```

Enable the current connection:

```
mysql> CALL ps_setup_enable_thread(CONNECTION_ID());
+-----+
| summary                |
+-----+
| Enabled 1 thread       |
+-----+
```

#### 25.4.4.12 The `ps_setup_reload_saved()` Procedure

Reloads a Performance Schema configuration saved earlier within the same session using `ps_setup_save()`. For more information, see the description of `ps_setup_save()`.

This procedure requires the `SUPER` privilege because it manipulates the session `sql_log_bin` system variable to disable binary logging during its execution.

## Parameters

None.

### 25.4.4.13 The `ps_setup_reset_to_default()` Procedure

Resets the Performance Schema configuration to its default settings.

## Parameters

- `in_verbose` `BOOLEAN`: Whether to display information about each setup stage during procedure execution. This includes the SQL statements executed.

## Example

```
mysql> CALL ps_setup_reset_to_default(TRUE)\G
***** 1. row *****
status: Resetting: setup_actors
DELETE
FROM performance_schema.setup_actors
WHERE NOT (HOST = '%' AND USER = '%' AND ROLE = '%')

***** 1. row *****
status: Resetting: setup_actors
INSERT IGNORE INTO performance_schema.setup_actors
VALUES ('%', '%', '%')
...
```

### 25.4.4.14 The `ps_setup_save()` Procedure

Saves the current Performance Schema configuration. This enables you to alter the configuration temporarily for debugging or other purposes, then restore it to the previous state by invoking the `ps_setup_reload_saved()` procedure.

To prevent other simultaneous calls to save the configuration, `ps_setup_save()` acquires an advisory lock named `sys.ps_setup_save` by calling the `GET_LOCK()` function. `ps_setup_save()` takes a timeout parameter to indicate how many seconds to wait if the lock already exists (which indicates that some other session has a saved configuration outstanding). If the timeout expires without obtaining the lock, `ps_setup_save()` fails.

It is intended you call `ps_setup_reload_saved()` later within the *same* session as `ps_setup_save()` because the configuration is saved in `TEMPORARY` tables. `ps_setup_save()` drops the temporary tables and releases the lock. If you end your session without invoking `ps_setup_save()`, the tables and lock disappear automatically.

This procedure requires the `SUPER` privilege because it manipulates the session `sql_log_bin` system variable to disable binary logging during its execution.

## Parameters

- `in_timeout` `INT`: How many seconds to wait to obtain the `sys.ps_setup_save` lock. A negative timeout value means infinite timeout.

## Example

```
mysql> CALL ps_setup_save(10);

... make Performance Schema configuration changes ...

mysql> CALL ps_setup_reload_saved();
```

### 25.4.4.15 The `ps_setup_show_disabled()` Procedure

Displays all currently disabled Performance Schema configuration.

#### Parameters

- `in_show_instruments` `BOOLEAN`: Whether to display disabled instruments. This might be a long list.
- `in_show_threads` `BOOLEAN`: Whether to display disabled threads.

#### Example

```
mysql> CALL ps_setup_show_disabled(TRUE, TRUE);
+-----+
| performance_schema_enabled |
+-----+
| 1 |
+-----+

+-----+
| enabled_users |
+-----+
| '%@%' |
+-----+

+-----+-----+-----+-----+
| object_type | objects | enabled | timed |
+-----+-----+-----+-----+
| EVENT | mysql.% | NO | NO |
| EVENT | performance_schema.% | NO | NO |
| EVENT | information_schema.% | NO | NO |
| FUNCTION | mysql.% | NO | NO |
| FUNCTION | performance_schema.% | NO | NO |
| FUNCTION | information_schema.% | NO | NO |
| PROCEDURE | mysql.% | NO | NO |
| PROCEDURE | performance_schema.% | NO | NO |
| PROCEDURE | information_schema.% | NO | NO |
| TABLE | mysql.% | NO | NO |
| TABLE | performance_schema.% | NO | NO |
| TABLE | information_schema.% | NO | NO |
| TRIGGER | mysql.% | NO | NO |
| TRIGGER | performance_schema.% | NO | NO |
| TRIGGER | information_schema.% | NO | NO |
+-----+-----+-----+-----+
...
```

### 25.4.4.16 The `ps_setup_show_disabled_consumers()` Procedure

Displays all currently disabled Performance Schema consumers.

#### Parameters

None.

#### Example

```
mysql> CALL ps_setup_show_disabled_consumers();
+-----+
| disabled_consumers |
+-----+
| events_stages_current |
| events_stages_history |
| events_stages_history_long |
| events_statements_history |
+-----+
```

```

| events_statements_history_long |
| events_transactions_history   |
| events_transactions_history_long |
| events_waits_current          |
| events_waits_history          |
| events_waits_history_long     |
+-----+

```

#### 25.4.4.17 The `ps_setup_show_disabled_instruments()` Procedure

Displays all currently disabled Performance Schema instruments. This might be a long list.

##### Parameters

None.

##### Example

```

mysql> CALL ps_setup_show_disabled_instruments()\G
***** 1. row *****
disabled_instruments: wait/synch/mutex/sql/TC_LOG_MMAP::LOCK_tc
                    timed: NO
***** 2. row *****
disabled_instruments: wait/synch/mutex/sql/LOCK_des_key_file
                    timed: NO
***** 3. row *****
disabled_instruments: wait/synch/mutex/sql/MYSQL_BIN_LOG::LOCK_commit
                    timed: NO
...

```

#### 25.4.4.18 The `ps_setup_show_enabled()` Procedure

Displays all currently enabled Performance Schema configuration.

##### Parameters

- `in_show_instruments` `BOOLEAN`: Whether to display enabled instruments. This might be a long list.
- `in_show_threads` `BOOLEAN`: Whether to display enabled threads.

##### Example

```

mysql> CALL ps_setup_show_enabled(FALSE, FALSE);
+-----+
| performance_schema_enabled |
+-----+
| 1 |
+-----+
1 row in set (0.00 sec)

+-----+
| enabled_users |
+-----+
| '%'@'%' |
+-----+
1 row in set (0.00 sec)

+-----+-----+-----+-----+
| object_type | objects | enabled | timed |
+-----+-----+-----+-----+
| EVENT       | %.%    | YES    | YES   |
| FUNCTION    | %.%    | YES    | YES   |
| PROCEDURE   | %.%    | YES    | YES   |
| TABLE      | %.%    | YES    | YES   |

```

```

| TRIGGER | %.% | YES | YES |
+-----+-----+-----+-----+
5 rows in set (0.01 sec)

+-----+
| enabled_consumers |
+-----+
| events_statements_current |
| events_transactions_current |
| global_instrumentation |
| thread_instrumentation |
| statements_digest |
+-----+

```

#### 25.4.4.19 The `ps_setup_show_enabled_consumers()` Procedure

Displays all currently enabled Performance Schema consumers.

##### Parameters

None.

##### Example

```

mysql> CALL ps_setup_show_enabled_consumers();
+-----+
| enabled_consumers |
+-----+
| events_statements_current |
| events_transactions_current |
| global_instrumentation |
| thread_instrumentation |
| statements_digest |
+-----+

```

#### 25.4.4.20 The `ps_setup_show_enabled_instruments()` Procedure

Displays all currently enabled Performance Schema instruments. This might be a long list.

##### Parameters

None.

##### Example

```

mysql> CALL ps_setup_show_enabled_instruments()\G
***** 1. row *****
enabled_instruments: wait/io/file/sql/map
      timed: YES
***** 2. row *****
enabled_instruments: wait/io/file/sql/binlog
      timed: YES
***** 3. row *****
enabled_instruments: wait/io/file/sql/binlog_cache
      timed: YES
...

```

#### 25.4.4.21 The `ps_statement_avg_latency_histogram()` Procedure

Displays a textual histogram graph of the average latency values across all normalized statements tracked within the Performance Schema `events_statements_summary_by_digest` table.

This procedure can be used to display a very high-level picture of the latency distribution of statements running within this MySQL instance.

## Parameters

None.

## Example

The histogram output in statement units. For example, `* = 2 units` in the histogram legend means that each `*` character represents 2 statements.

```
mysql> CALL ps_statement_avg_latency_histogram()\G
***** 1. row *****
Performance Schema Statement Digest Average Latency Histogram:

. = 1 unit
* = 2 units
# = 3 units

(0 - 66ms)      88 | #####
(66 - 133ms)    14 | .....
(133 - 199ms)    4 | ....
(199 - 265ms)    5 | **
(265 - 332ms)    1 | .
(332 - 398ms)    0 |
(398 - 464ms)    1 | .
(464 - 531ms)    0 |
(531 - 597ms)    0 |
(597 - 663ms)    0 |
(663 - 730ms)    0 |
(730 - 796ms)    0 |
(796 - 863ms)    0 |
(863 - 929ms)    0 |
(929 - 995ms)    0 |
(995 - 1062ms)  0 |

Total Statements: 114; Buckets: 16; Bucket Size: 66 ms;
```

### 25.4.4.22 The `ps_trace_statement_digest()` Procedure

Traces all Performance Schema instrumentation for a specific statement digest.

If you find a statement of interest within the Performance Schema `events_statements_summary_by_digest` table, specify its `DIGEST` column MD5 value to this procedure and indicate the polling duration and interval. The result is a report of all statistics tracked within Performance Schema for that digest for the interval.

The procedure also attempts to execute `EXPLAIN` for the longest running example of the digest during the interval. This attempt might fail because the Performance Schema truncates long `SQL_TEXT` values. Consequently, `EXPLAIN` will fail due to parse errors.

This procedure requires the `SUPER` privilege because it manipulates the session `sql_log_bin` system variable to disable binary logging during its execution.

## Parameters

- `in_digest` `VARCHAR(32)`: The statement digest identifier to analyze.
- `in_runtime` `INT`: How long to run the analysis in seconds.
- `in_interval` `DECIMAL(2,2)`: The analysis interval in seconds (which can be fractional) at which to try to take snapshots.
- `in_start_fresh` `BOOLEAN`: Whether to truncate the Performance Schema `events_statements_history_long` and `events_stages_history_long` tables before starting.

- `in_auto_enable` `BOOLEAN`: Whether to automatically enable required consumers.

## Example

```
mysql> CALL ps_trace_statement_digest('891ec6860f98ba46d89dd20b0c03652c', 10, 0.1, TRUE, TRUE);
```

### 25.4.4.23 The `ps_trace_thread()` Procedure

Dumps all Performance Schema data for an instrumented thread to a `.dot` formatted graph file (for the DOT graph description language). Each result set returned from the procedure should be used for a complete graph.

This procedure requires the `SUPER` privilege because it manipulates the session `sql_log_bin` system variable to disable binary logging during its execution.

#### Parameters

- `in_thread_id` `INT`: The thread to trace.
- `in_outfile` `VARCHAR(255)`: The name to use for the `.dot` output file.
- `in_max_runtime` `DECIMAL(20,2)`: The maximum number of seconds (which can be fractional) to collect data. Use `NULL` to collect data for the default of 60 seconds.
- `in_interval` `DECIMAL(20,2)`: The number of seconds (which can be fractional) to sleep between data collections. Use `NULL` to sleep for the default of 1 second.
- `in_start_fresh` `BOOLEAN`: Whether to reset all Performance Schema data before tracing.
- `in_auto_setup` `BOOLEAN`: Whether to disable all other threads and enable all instruments and consumers. This also resets the settings at the end of the run.
- `in_debug` `BOOLEAN`: Whether to include `file:lineno` information in the graph.

#### Example

```

mysql> CALL ps_trace_thread(25, CONCAT('/tmp/stack-', REPLACE(NOW(), ' ', '-'), '.dot'), NULL, NULL, TR
+-----+-----+
| summary |
+-----+-----+
| Disabled 1 thread |

+-----+
| summary |
+-----+
| Enabled 1 thread |
+-----+
1 row in set (60.32 sec)

```

#### 25.4.4.24 The `ps_truncate_all_tables()` Procedure

Truncates all Performance Schema summary tables, resetting all aggregated instrumentation as a snapshot. Produces a result set indicating how many tables were truncated.

##### Parameters

- `in_verbose` **BOOLEAN**: Whether to display each `TRUNCATE TABLE` statement before executing it.

##### Example

```

mysql> CALL ps_truncate_all_tables(FALSE);
+-----+
| summary |
+-----+
| Truncated 44 tables |
+-----+

```

#### 25.4.4.25 The `statement_performance_analyzer()` Procedure

Creates a report of the statements running on the server. The views are calculated based on the overall and/or delta activity.

This procedure requires the `SUPER` privilege because it manipulates the session `sql_log_bin` system variable to disable binary logging during its execution.

This procedure was added in MySQL 5.7.9.

##### Parameters

- `in_action` **ENUM**('snapshot', 'overall', 'delta', 'create\_tmp', 'create\_table', 'save', 'cleanup'): The action to take. These values are permitted:
  - snapshot**: Store a snapshot. The default is to make a snapshot of the current content of the Performance Schema `events_statements_summary_by_digest` table. By setting `in_table`, this can be overwritten to copy the content of the specified table. The snapshot is stored in the `sys` schema `tmp_digests` temporary table.
  - overall**: Generate an analysis based on the content of the table specified by `in_table`. For the overall analysis, `in_table` can be `NOW()` to use a fresh snapshot. This overwrites an existing snapshot. Use `NULL` for `in_table` to use the existing snapshot. If `in_table` is `NULL` and no snapshot exists, a new snapshot is created. The `in_views` parameter and the `statement_performance_analyzer.limit` configuration option affect the operation of this procedure.
  - delta**: Generate a delta analysis. The delta is calculated between the reference table specified by `in_table` and the snapshot, which must exist. This action uses the `sys` schema `tmp_digests_delta` temporary table. The `in_views` parameter and the `statement_performance_analyzer.limit` configuration option affect the operation of this procedure.

- `create_table`: Create a regular table suitable for storing the snapshot for later use (for example, for calculating deltas).
- `create_tmp`: Create a temporary table suitable for storing the snapshot for later use (for example, for calculating deltas).
- `save`: Save the snapshot in the table specified by `in_table`. The table must exist and have the correct structure. If no snapshot exists, a new snapshot is created.
- `cleanup`: Remove the temporary tables used for the snapshot and delta.
- `in_table VARCHAR(129)`: The table parameter used for some of the actions specified by the `in_action` parameter. Use the format `db_name.tbl_name` or `tbl_name` without using any backtick (``) identifier-quoting characters. Periods (.) are not supported in database and table names.

The meaning of the `in_table` value for each `in_action` value is detailed in the individual `in_action` value descriptions.

- `in_views SET ('with_runtimes_in_95th_percentile', 'analysis', 'with_errors_or_warnings', 'with_full_table_scans', 'with_sorting', 'with_temp_tables', 'custom')`: Which views to include. This parameter is a `SET` value, so it can contain multiple view names, separated by commas. The default is to include all views except `custom`. The following values are permitted:
  - `with_runtimes_in_95th_percentile`: Use the `statements_with_runtimes_in_95th_percentile` view.
  - `analysis`: Use the `statement_analysis` view.
  - `with_errors_or_warnings`: Use the `statements_with_errors_or_warnings` view.
  - `with_full_table_scans`: Use the `statements_with_full_table_scans` view.
  - `with_sorting`: Use the `statements_with_sorting` view.
  - `with_temp_tables`: Use the `statements_with_temp_tables` view.
  - `custom`: Use a custom view. This view must be specified using the `statement_performance_analyzer.view` configuration option to name a query or an existing view.

## Configuration Options

`statement_performance_analyzer()` operation can be modified using the following configuration options or their corresponding user-defined variables (see [Section 25.4.2.1, “The sys\\_config Table”](#)):

- `debug`, `@sys.debug`

If this option is `ON`, produce debugging output. The default is `OFF`.

- `statement_performance_analyzer.limit`,  
`@sys.statement_performance_analyzer.limit`

The maximum number of rows to return for views that have no built-in limit. The default is 100.

- `statement_performance_analyzer.view`,  
`@sys.statement_performance_analyzer.view`

The custom query or view to be used. If the option value contains a space, it is interpreted as a query. Otherwise, it must be the name of an existing view that queries the Performance Schema

`events_statements_summary_by_digest` table. There cannot be any `LIMIT` clause in the query or view definition if the `statement_performance_analyzer.limit` configuration option is greater than 0. If specifying a view, use the same format as for the `in_table` parameter. The default is `NULL` (no custom view defined).

This option was added in MySQL 5.7.9.

## Example

To create a report with the queries in the 95th percentile since the last truncation of `events_statements_summary_by_digest` and with a one-minute delta period:

1. Create a temporary table to store the initial snapshot.
2. Create the initial snapshot.
3. Save the initial snapshot in the temporary table.
4. Wait one minute.
5. Create a new snapshot.
6. Perform analysis based on the new snapshot.
7. Perform analysis based on the delta between the initial and new snapshots.

```
mysql> CALL statement_performance_analyzer('create_tmp', 'mydb.tmp_digests_ini', NULL);
Query OK, 0 rows affected (0.08 sec)

mysql> CALL statement_performance_analyzer('snapshot', NULL, NULL);
Query OK, 0 rows affected (0.02 sec)

mysql> CALL statement_performance_analyzer('save', 'mydb.tmp_digests_ini', NULL);
Query OK, 0 rows affected (0.00 sec)

mysql> DO SLEEP(60);
Query OK, 0 rows affected (1 min 0.00 sec)

mysql> CALL statement_performance_analyzer('snapshot', NULL, NULL);
Query OK, 0 rows affected (0.02 sec)

mysql> CALL statement_performance_analyzer('overall', NULL, 'with_runtimes_in_95th_percentile');
+-----+
| Next Output |
+-----+
| Queries with Runtime in 95th Percentile |
+-----+
1 row in set (0.05 sec)

...

mysql> CALL statement_performance_analyzer('delta', 'mydb.tmp_digests_ini', 'with_runtimes_in_95th_percentile');
+-----+
| Next Output |
+-----+
| Queries with Runtime in 95th Percentile |
+-----+
1 row in set (0.03 sec)

...
```

Create an overall report of the 95th percentile queries and the top 10 queries with full table scans:

```
mysql> CALL statement_performance_analyzer('snapshot', NULL, NULL);
Query OK, 0 rows affected (0.01 sec)
```

```
mysql> SET @sys.statement_performance_analyzer.limit = 10;
Query OK, 0 rows affected (0.00 sec)

mysql> CALL statement_performance_analyzer('overall', NULL, 'with_runtimes_in_95th_percentile,with_full
+-----+
| Next Output |
+-----+
| Queries with Runtime in 95th Percentile |
+-----+
1 row in set (0.01 sec)

...

+-----+
| Next Output |
+-----+
| Top 10 Queries with Full Table Scan |
+-----+
1 row in set (0.09 sec)

...
```

Use a custom view showing the top 10 queries sorted by total execution time, refreshing the view every minute using the `watch` command in Linux:

```
mysql> CREATE OR REPLACE VIEW mydb.my_statements AS
-> SELECT sys.format_statement(DIGEST_TEXT) AS query,
->        SCHEMA_NAME AS db,
->        COUNT_STAR AS exec_count,
->        sys.format_time(SUM_TIMER_WAIT) AS total_latency,
->        sys.format_time(AVG_TIMER_WAIT) AS avg_latency,
->        ROUND(IFNULL(SUM_ROWS_SENT / NULLIF(COUNT_STAR, 0), 0)) AS rows_sent_avg,
->        ROUND(IFNULL(SUM_ROWS_EXAMINED / NULLIF(COUNT_STAR, 0), 0)) AS rows_examined_avg,
->        ROUND(IFNULL(SUM_ROWS_AFFECTED / NULLIF(COUNT_STAR, 0), 0)) AS rows_affected_avg,
->        DIGEST AS digest
-> FROM performance_schema.events_statements_summary_by_digest
-> ORDER BY SUM_TIMER_WAIT DESC;
Query OK, 0 rows affected (0.01 sec)

mysql> CALL statement_performance_analyzer('create_table', 'mydb.digests_prev', NULL);
Query OK, 0 rows affected (0.10 sec)

shell> watch -n 60 "mysql sys --table -e \"
> SET @sys.statement_performance_analyzer.view = 'mydb.my_statements';
> SET @sys.statement_performance_analyzer.limit = 10;
> CALL statement_performance_analyzer('snapshot', NULL, NULL);
> CALL statement_performance_analyzer('delta', 'mydb.digests_prev', 'custom');
> CALL statement_performance_analyzer('save', 'mydb.digests_prev', NULL);
> \""

Every 60.0s: mysql sys --table -e "          ... Mon Dec 22 10:58:51 2014

+-----+
| Next Output |
+-----+
| Top 10 Queries Using Custom View |
+-----+

+-----+-----+-----+-----+-----+-----+
| query          | db    | exec_count | total_latency | avg_latency | rows_sent_avg | rows_examined_avg |
+-----+-----+-----+-----+-----+-----+
...
```

#### 25.4.4.26 The `table_exists()` Procedure

Tests whether a given table exists as a regular table, a `TEMPORARY` table, or a view. The procedure returns the table type in an `OUT` parameter. If both a temporary and a permanent table exist with the given name, `TEMPORARY` is returned.

This procedure was added in MySQL 5.7.9.

## Parameters

- `in_db VARCHAR(64)`: The name of the database in which to check for table existence.
- `in_table VARCHAR(64)`: The name of the table to check the existence of.
- `out_exists ENUM('', 'BASE TABLE', 'VIEW', 'TEMPORARY')`: The return value. This is an `OUT` parameter, so it must be a variable into which the table type can be stored. When the procedure returns, the variable has one of the following values to indicate whether the table exists:
  - `''`: The table name does not exist as a base table, `TEMPORARY` table, or view.
  - `BASE TABLE`: The table name exists as a base (permanent) table.
  - `VIEW`: The table name exists as a view.
  - `TEMPORARY`: The table name exists as a `TEMPORARY` table.

## Example

```
mysql> CREATE DATABASE db1;
Query OK, 1 row affected (0.01 sec)

mysql> USE db1;
Database changed
mysql> CREATE TABLE t1 (id INT PRIMARY KEY);
Query OK, 0 rows affected (0.03 sec)

mysql> CREATE TABLE t2 (id INT PRIMARY KEY);
Query OK, 0 rows affected (0.20 sec)

mysql> CREATE view v_t1 AS SELECT * FROM t1;
Query OK, 0 rows affected (0.02 sec)

mysql> CREATE TEMPORARY TABLE t1 (id INT PRIMARY KEY);
Query OK, 0 rows affected (0.00 sec)

mysql> CALL sys.table_exists('db1', 't1', @exists); SELECT @exists;
Query OK, 0 rows affected (0.01 sec)

+-----+
| @exists |
+-----+
| TEMPORARY |
+-----+
1 row in set (0.00 sec)

mysql> CALL sys.table_exists('db1', 't2', @exists); SELECT @exists;
Query OK, 0 rows affected (0.02 sec)

+-----+
| @exists |
+-----+
| BASE TABLE |
+-----+
1 row in set (0.00 sec)

mysql> CALL sys.table_exists('db1', 'v_t1', @exists); SELECT @exists;
Query OK, 0 rows affected (0.02 sec)

+-----+
| @exists |
+-----+
| VIEW |
+-----+
1 row in set (0.00 sec)

mysql> CALL sys.table_exists('db1', 't3', @exists); SELECT @exists;
Query OK, 0 rows affected (0.00 sec)
```

```

+-----+
| @exists |
+-----+
|         |
+-----+
1 row in set (0.00 sec)

```

## 25.4.5 sys Schema Stored Functions

The following sections describe `sys` schema stored functions.

### 25.4.5.1 The `extract_schema_from_file_name()` Function

Given a file path name, returns the path component that represents the schema name. This function assumes that the file name lies within the schema directory. For this reason, it will not work with partitions or tables defined using their own `DATA_DIRECTORY` table option.

This function is useful when extracting file I/O information from the Performance Schema that includes file path names. It provides a convenient way to display schema names, which can be more easily understood than full path names, and can be used in joins against object schema names.

#### Parameters

- `path VARCHAR(512)`: The full path to a data file from which to extract the schema name.

#### Return Value

A `VARCHAR(64)` value.

#### Example

```

mysql> SELECT extract_schema_from_file_name('/usr/local/mysql/data/world/City.ibd');
+-----+
| extract_schema_from_file_name('/usr/local/mysql/data/world/City.ibd') |
+-----+
| world |
+-----+

```

### 25.4.5.2 The `extract_table_from_file_name()` Function

Given a file path name, returns the path component that represents the table name.

This function is useful when extracting file I/O information from the Performance Schema that includes file path names. It provides a convenient way to display table names, which can be more easily understood than full path names, and can be used in joins against object table names.

#### Parameters

- `path VARCHAR(512)`: The full path to a data file from which to extract the table name.

#### Return Value

A `VARCHAR(64)` value.

#### Example

```

mysql> SELECT extract_table_from_file_name('/usr/local/mysql/data/world/City.ibd');
+-----+
| extract_table_from_file_name('/usr/local/mysql/data/world/City.ibd') |
+-----+

```

|         |         |
|---------|---------|
| City    |         |
| +-----+ | +-----+ |

### 25.4.5.3 The format\_bytes() Function

Given a value in bytes, converts it to human-readable format and returns a string consisting of a value and a units indicator. Depending on the size of the value, the units part is `bytes`, `KiB` (kibibytes), `MiB` (mebibytes), `GiB` (gibibytes), `TiB` (tebibytes), or `PiB` (pebibytes).

#### Parameters

- `bytes TEXT`: The bytes value to format.

#### Return Value

A `TEXT` value.

#### Example

```
mysql> SELECT format_bytes(512), format_bytes(18446644073709551615);
+-----+-----+
| format_bytes(512) | format_bytes(18446644073709551615) |
+-----+-----+
| 512 bytes        | 16383.91 PiB                        |
+-----+-----+
```

### 25.4.5.4 The format\_path() Function

Given a path name, returns the modified path name after replacing subpaths that match the values of the following system variables, in order:

```
datadir
tmpdir
slave_load_tmpdir
innodb_data_home_dir
innodb_log_group_home_dir
innodb_undo_directory
basedir
```

A value that matches the value of system variable `sysvar` is replaced with the string `@@global.sysvar`.

Prior to MySQL 5.7.14, backslashes in Windows path names are converted to forward slashes in the result.

#### Parameters

- `path VARCHAR(512)`: The path name to format.

#### Return Value

A `VARCHAR(512) CHARACTER SET utf8` value.

#### Example

```
mysql> SELECT format_path('/usr/local/mysql/data/world/City.ibd');
+-----+
| format_path('/usr/local/mysql/data/world/City.ibd') |
+-----+
| @@datadir/world/City.ibd                            |
+-----+
```

### 25.4.5.5 The `format_statement()` Function

Given a string (normally representing an SQL statement), reduces it to the length given by the `statement_truncate_len` configuration option, and returns the result. No truncation occurs if the string is shorter than `statement_truncate_len`. Otherwise, the middle part of the string is replaced by an ellipsis (...).

This function is useful for formatting possibly lengthy statements retrieved from Performance Schema tables to a known fixed maximum length.

#### Parameters

- `statement` `LONGTEXT`: The statement to format.

#### Configuration Options

`format_statement()` operation can be modified using the following configuration options or their corresponding user-defined variables (see [Section 25.4.2.1, “The sys\\_config Table”](#)):

- `statement_truncate_len`, `@sys.statement_truncate_len`

The maximum length of statements returned by the `format_statement()` function. Longer statements are truncated to this length. The default is 64.

#### Return Value

A `LONGTEXT` value.

#### Example

By default, `format_statement()` truncates statements to be no more than 64 characters. Setting `@sys.statement_truncate_len` changes the truncation length for the current session:

```
mysql> SET @stmt = 'SELECT variable, value, set_time, set_by FROM sys_config';
mysql> SELECT format_statement(@stmt);
+-----+
| format_statement(@stmt) |
+-----+
| SELECT variable, value, set_time, set_by FROM sys_config |
+-----+
mysql> SET @sys.statement_truncate_len = 32;
mysql> SELECT format_statement(@stmt);
+-----+
| format_statement(@stmt) |
+-----+
| SELECT variabl ... ROM sys_config |
+-----+
```

### 25.4.5.6 The `format_time()` Function

Given a Performance Schema latency or wait time in picoseconds, converts it to human-readable format and returns a string consisting of a value and a units indicator. Depending on the size of the value, the units part is `ns` (nanoseconds), `us` (microseconds), `ms` (milliseconds), `s` (seconds), `m` (minutes), `h` (hours), `d` (days), or `w` (weeks).

#### Parameters

- `picoseconds` `TEXT`: The picoseconds value to format.

#### Return Value

A `TEXT` value.

## Example

```
mysql> SELECT format_time(3501), format_time(188732396662000);
+-----+-----+
| format_time(3501) | format_time(188732396662000) |
+-----+-----+
| 3.50 ns          | 3.15 m                        |
+-----+-----+
```

### 25.4.5.7 The list\_add() Function

Adds a value to a comma-separated list of values and returns the result.

This function and `list_drop()` can be useful for manipulating the value of system variables such as `sql_mode` and `optimizer_switch` that take a comma-separated list of values.

This function was added in MySQL 5.7.9.

#### Parameters

- `in_list TEXT`: The list to be modified.
- `in_add_value TEXT`: The value to add to the list.

#### Return Value

A `TEXT` value.

## Example

```
mysql> SELECT @@sql_mode;
+-----+
| @@sql_mode |
+-----+
| ONLY_FULL_GROUP_BY,STRICT_TRANS_TABLES |
+-----+
mysql> SET @@sql_mode = list_add(@@sql_mode, 'NO_ENGINE_SUBSTITUTION');
mysql> SELECT @@sql_mode;
+-----+
| @@sql_mode |
+-----+
| ONLY_FULL_GROUP_BY,STRICT_TRANS_TABLES,NO_ENGINE_SUBSTITUTION |
+-----+
mysql> SET @@sql_mode = list_drop(@@sql_mode, 'ONLY_FULL_GROUP_BY');
mysql> SELECT @@sql_mode;
+-----+
| @@sql_mode |
+-----+
| STRICT_TRANS_TABLES,NO_ENGINE_SUBSTITUTION |
+-----+
```

### 25.4.5.8 The list\_drop() Function

Removes a value from a comma-separated list of values and returns the result. For more information, see the description of `list_add()`

This function was added in MySQL 5.7.9.

#### Parameters

- `in_list TEXT`: The list to be modified.
- `in_drop_value TEXT`: The value to drop from the list.

## Return Value

A `TEXT` value.

### 25.4.5.9 The `ps_is_account_enabled()` Function

Returns `YES` or `NO` to indicate whether Performance Schema instrumentation for a given account is enabled.

## Parameters

- `in_host VARCHAR(60)`: The host name of the account to check.
- `in_user VARCHAR(32)`: The user name of the account to check.

## Return Value

An `ENUM('YES', 'NO')` value.

## Example

```
mysql> SELECT ps_is_account_enabled('localhost', 'root');
+-----+
| ps_is_account_enabled('localhost', 'root') |
+-----+
| YES                                         |
+-----+
```

### 25.4.5.10 The `ps_is_consumer_enabled()` Function

Returns `YES` or `NO` to indicate whether a given Performance Schema consumer is enabled, or `NULL` if the argument is not a valid consumer name.

This function accounts for the consumer hierarchy, so a consumer is not considered enabled unless all consumers on which depends are also enabled. For information about the consumer hierarchy, see [Section 24.3.7, “Pre-Filtering by Consumer”](#).

## Parameters

- `in_consumer VARCHAR(64)`: The name of the consumer to check.

## Return Value

An `ENUM('YES', 'NO')` value.

## Example

```
mysql> SELECT ps_is_consumer_enabled('thread_instrumentation');
+-----+
| ps_is_consumer_enabled('thread_instrumentation') |
+-----+
| YES                                         |
+-----+
```

### 25.4.5.11 The `ps_is_instrument_default_enabled()` Function

Returns `YES` or `NO` to indicate whether a given Performance Schema instrument is enabled by default.

## Parameters

- `in_instrument VARCHAR(128)`: The name of the instrument to check.

## Return Value

An `ENUM('YES', 'NO')` value.

## Example

```
mysql> SELECT ps_is_instrument_default_enabled('memory/innodb/row_log_buf');
+-----+
| ps_is_instrument_default_enabled('memory/innodb/row_log_buf') |
+-----+
| NO                                                                |
+-----+
mysql> SELECT ps_is_instrument_default_enabled('statement/sql/alter_user');
+-----+
| ps_is_instrument_default_enabled('statement/sql/alter_user') |
+-----+
| YES                                                            |
+-----+
```

### 25.4.5.12 The `ps_is_instrument_default_timed()` Function

Returns `YES` or `NO` to indicate whether a given Performance Schema instrument is timed by default.

## Parameters

- `in_instrument` `VARCHAR(128)`: The name of the instrument to check.

## Return Value

An `ENUM('YES', 'NO')` value.

## Example

```
mysql> SELECT ps_is_instrument_default_timed('memory/innodb/row_log_buf');
+-----+
| ps_is_instrument_default_timed('memory/innodb/row_log_buf') |
+-----+
| NO                                                                |
+-----+
mysql> SELECT ps_is_instrument_default_timed('statement/sql/alter_user');
+-----+
| ps_is_instrument_default_timed('statement/sql/alter_user') |
+-----+
| YES                                                            |
+-----+
```

### 25.4.5.13 The `ps_is_thread_instrumented()` Function

Returns `YES` or `NO` to indicate whether Performance Schema instrumentation for a given connection ID is enabled, `UNKNOWN` if the ID is unknown, or `NULL` if the ID is `NULL`.

## Parameters

- `in_connection_id` `BIGINT UNSIGNED`: The connection ID. This is a connection ID as given in the `PROCESSLIST_ID` column of the Performance Schema `threads` table or the `Id` column of `SHOW PROCESSLIST` output.

## Return Value

An `ENUM('YES', 'NO', 'UNKNOWN')` value.

## Example

```
mysql> SELECT ps_is_thread_instrumented(43);
+-----+
| ps_is_thread_instrumented(43) |
+-----+
| UNKNOWN                        |
+-----+
mysql> SELECT ps_is_thread_instrumented(CONNECTION_ID());
+-----+
| ps_is_thread_instrumented(CONNECTION_ID()) |
+-----+
| YES                                         |
+-----+
```

#### 25.4.5.14 The `ps_thread_account()` Function

Given a Performance Schema thread ID, returns the `user_name@host_name` account associated with the thread.

This function was added in MySQL 5.7.9.

##### Parameters

- `in_thread_id` **BIGINT UNSIGNED**: The thread ID for which to return the account. The value should match the `THREAD_ID` column from some Performance Schema `threads` table row.

##### Return Value

A **TEXT** value.

##### Example

```
mysql> SELECT ps_thread_account(ps_thread_id(CONNECTION_ID()));
+-----+
| ps_thread_account(ps_thread_id(CONNECTION_ID())) |
+-----+
| root@localhost                                   |
+-----+
```

#### 25.4.5.15 The `ps_thread_id()` Function

Returns the Performance Schema thread ID for a given connection ID, or the thread ID for the current connection if the connection ID is **NULL**.

##### Parameters

- `in_connection_id` **BIGINT UNSIGNED**: The ID of the connection for which to return the thread ID. This is a connection ID as given in the `PROCESSLIST_ID` column of the Performance Schema `threads` table or the `Id` column of `SHOW PROCESSLIST` output.

##### Return Value

A **BIGINT UNSIGNED** value.

##### Example

```
mysql> SELECT ps_thread_id(260);
+-----+
| ps_thread_id(260) |
+-----+
| 285               |
+-----+
```

#### 25.4.5.16 The `ps_thread_stack()` Function

Returns a JSON formatted stack of all statements, stages, and events within the Performance Schema for a given thread ID.

### Parameters

- `in_thread_id` **BIGINT**: The ID of the thread to trace. The value should match the `THREAD_ID` column from some Performance Schema `threads` table row.
- `in_verbose` **BOOLEAN**: Whether to include `file:lineno` information in the events.

### Return Value

A **LONGTEXT CHARACTER SET latin1** value.

### Example

```
mysql> SELECT ps_thread_stack(37, FALSE) AS thread_stack\G
***** 1. row *****
thread_stack: {"rankdir": "LR", "nodesep": "0.10",
"stack_created": "2014-02-19 13:39:03", "mysql_version": "5.7.3-m13",
"mysql_user": "root@localhost", "events": [{"nesting_event_id": "0",
"event_id": "10", "timer_wait": 256.35, "event_info": "sql/select",
"wait_info": "select @@version_comment limit 1\nerrors: 0\nwarnings: 0\nlock time:
...

```

## 25.4.5.17 The `ps_thread_trx_info()` Function

Returns a JSON object containing information about a given thread. The information includes the current transaction, and the statements it has already executed, derived from the Performance Schema `events_transactions_current` and `events_statements_history` tables. (The consumers for those tables must be enabled to obtain full data in the JSON object.)

If the output exceeds the truncation length (65535 by default), a JSON error object is returned, such as:

```
{ "error": "Trx info truncated: Row 6 was cut by GROUP_CONCAT()" }
```

Similar error objects are returned for other warnings and exceptions raised during function execution.

This function was added in MySQL 5.7.9.

### Parameters

- `in_thread_id` **BIGINT UNSIGNED**: The thread ID for which to return transaction information. The value should match the `THREAD_ID` column from some Performance Schema `threads` table row.

### Configuration Options

`ps_thread_trx_info()` operation can be modified using the following configuration options or their corresponding user-defined variables (see [Section 25.4.2.1, “The sys\\_config Table”](#)):

- `ps_thread_trx_info.max_length`, `@sys.ps_thread_trx_info.max_length`

The maximum length of the output. The default is 65535.

### Return Value

A **LONGTEXT** value.

### Example

```
mysql> SELECT ps_thread_trx_info(48)\G
***** 1. row *****

```

```

ps_thread_trx_info(48): [
{
  "time": "790.70 us",
  "state": "COMMITTED",
  "mode": "READ WRITE",
  "autocommitted": "NO",
  "gtid": "AUTOMATIC",
  "isolation": "REPEATABLE READ",
  "statements_executed": [
    {
      "sql_text": "INSERT INTO info VALUES (1, \'foo\')",
      "time": "471.02 us",
      "schema": "trx",
      "rows_examined": 0,
      "rows_affected": 1,
      "rows_sent": 0,
      "tmp_tables": 0,
      "tmp_disk_tables": 0,
      "sort_rows": 0,
      "sort_merge_passes": 0
    },
    {
      "sql_text": "COMMIT",
      "time": "254.42 us",
      "schema": "trx",
      "rows_examined": 0,
      "rows_affected": 0,
      "rows_sent": 0,
      "tmp_tables": 0,
      "tmp_disk_tables": 0,
      "sort_rows": 0,
      "sort_merge_passes": 0
    }
  ]
},
{
  "time": "426.20 us",
  "state": "COMMITTED",
  "mode": "READ WRITE",
  "autocommitted": "NO",
  "gtid": "AUTOMATIC",
  "isolation": "REPEATABLE READ",
  "statements_executed": [
    {
      "sql_text": "INSERT INTO info VALUES (2, \'bar\')",
      "time": "107.33 us",
      "schema": "trx",
      "rows_examined": 0,
      "rows_affected": 1,
      "rows_sent": 0,
      "tmp_tables": 0,
      "tmp_disk_tables": 0,
      "sort_rows": 0,
      "sort_merge_passes": 0
    },
    {
      "sql_text": "COMMIT",
      "time": "213.23 us",
      "schema": "trx",
      "rows_examined": 0,
      "rows_affected": 0,
      "rows_sent": 0,
      "tmp_tables": 0,
      "tmp_disk_tables": 0,
      "sort_rows": 0,
      "sort_merge_passes": 0
    }
  ]
}
]

```

#### 25.4.5.18 The quote\_identifier() Function

Given a string argument, this function produces a quoted identifier suitable for inclusion in SQL statements. This is useful when a value to be used as an identifier is a reserved word or contains backtick ( ``` ) characters. It was added in MySQL 5.7.14.

### Parameters

`in_identifier TEXT`: The identifier to quote.

### Return Value

A `TEXT` value.

### Example

```
mysql> SELECT quote_identifier('plain');
+-----+
| quote_identifier('plain') |
+-----+
| `plain`                  |
+-----+
mysql> SELECT quote_identifier('trick`ier');
+-----+
| quote_identifier('trick`ier') |
+-----+
| `trick`ier`                  |
+-----+
mysql> SELECT quote_identifier('integer');
+-----+
| quote_identifier('integer') |
+-----+
| `integer`                  |
+-----+
```

## 25.4.5.19 The sys\_get\_config() Function

Given a configuration option name, returns the option value from the `sys_config` table, or the provided default value (which may be `NULL`) if the option does not exist in the table.

If `sys_get_config()` returns the default value and that value is `NULL`, it is expected that the caller is able to handle `NULL` for the given configuration option.

By convention, routines that call `sys_get_config()` first check whether the corresponding user-defined variable exists and is non-`NULL`. If so, the routine uses the variable value without reading the `sys_config` table. If the variable does not exist or is `NULL`, the routine reads the option value from the table and sets the user-defined variable to that value. For more information about the relationship between configuration options and their corresponding user-defined variables, see [Section 25.4.2.1](#), “The `sys_config` Table”.

If you want to check whether the configuration option has already been set and, if not, use the return value of `sys_get_config()`, you can use `IFNULL(...)` (see example later). However, this should not be done inside a loop (for example, for each row in a result set) because for repeated calls where the assignment is needed only in the first iteration, using `IFNULL(...)` is expected to be significantly slower than using an `IF (...) THEN ... END IF;` block (see example later).

### Parameters

- `in_variable_name VARCHAR(128)`: The name of the configuration option for which to return the value.
- `in_default_value VARCHAR(128)`: The default value to return if the configuration option is not found in the `sys_config` table.

## Return Value

A `VARCHAR(128)` value.

## Example

Get a configuration value from the `sys_config` table, falling back to 128 as the default if the option is not present in the table:

```
mysql> SELECT sys.sys_get_config('statement_truncate_len', 128) AS Value;
+-----+
| Value |
+-----+
| 64    |
+-----+
```

One-liner example: Check whether the option is already set; if not, assign the `IFNULL(...)` result (using the value from the `sys_config` table):

```
mysql> SET @sys.statement_truncate_len =
-> IFNULL(@sys.statement_truncate_len,
-> sys.sys_get_config('statement_truncate_len', 64));
```

`IF (...) THEN ... END IF;` block example: Check whether the option is already set; if not, assign the value from the `sys_config` table:

```
IF (@sys.statement_truncate_len IS NULL) THEN
  SET @sys.statement_truncate_len = sys.sys_get_config('statement_truncate_len', 64);
END IF;
```

### 25.4.5.20 The version\_major() Function

This function returns the major version of the MySQL server. It was added in MySQL 5.7.9.

## Parameters

None.

## Return Value

A `TINYINT UNSIGNED` value.

## Example

```
mysql> SELECT VERSION(), version_major();
+-----+-----+
| VERSION() | version_major() |
+-----+-----+
| 5.7.9-debug-log | 5 |
+-----+-----+
```

### 25.4.5.21 The version\_minor() Function

This function returns the minor version of the MySQL server. It was added in MySQL 5.7.9.

## Parameters

None.

## Return Value

A `TINYINT UNSIGNED` value.

## Example

```
mysql> SELECT VERSION(), version_minor();
+-----+-----+
| VERSION() | version_minor() |
+-----+-----+
| 5.7.9-debug-log | 7 |
+-----+-----+
```

### 25.4.5.22 The version\_patch() Function

This function returns the patch release version of the MySQL server. It was added in MySQL 5.7.9.

#### Parameters

None.

#### Return Value

A `TINYINT UNSIGNED` value.

## Example

```
mysql> SELECT VERSION(), version_patch();
+-----+-----+
| VERSION() | version_patch() |
+-----+-----+
| 5.7.9-debug-log | 9 |
+-----+-----+
```

---

MySQL Connectors provide connectivity to the MySQL server for client programs. APIs provide low-level access to the MySQL protocol and MySQL resources. Both Connectors and the APIs enable you to connect and execute MySQL statements from another language or environment, including ODBC, Java (JDBC), Perl, Python, PHP, Ruby, and native C and embedded MySQL instances.

#### Note

Connector version numbers do not correlate with MySQL Server version numbers. See [Table 26.2, “MySQL Connector Versions and MySQL Server Versions”](#).

## MySQL Connectors

Oracle develops a number of connectors:

- [Connector/ODBC](#) provides driver support for connecting to MySQL using the Open Database Connectivity (ODBC) API. Support is available for ODBC connectivity from Windows, Unix, and OS X platforms.
- [Connector/Net](#) enables developers to create .NET applications that connect to MySQL. Connector/Net implements a fully functional ADO.NET interface and provides support for use with ADO.NET aware tools. Applications that use Connector/Net can be written in any supported .NET language.

The MySQL [Visual Studio Plugin](#) works with Connector/Net and Visual Studio 2005. The plugin is a MySQL DDEX Provider, which means that you can use the schema and data manipulation tools available in Visual Studio to create and edit objects within a MySQL database.

- [Connector/J](#) provides driver support for connecting to MySQL from Java applications using the standard Java Database Connectivity (JDBC) API.
- [Connector/Python](#) provides driver support for connecting to MySQL from Python applications using an API that is compliant with the [Python DB API version 2.0](#). No additional Python modules or MySQL client libraries are required.
- [Connector/C++](#) enables C++ applications to connect to MySQL.
- [Connector/C](#) is a standalone replacement for the MySQL Client Library ([libmysqlclient](#)), to be used for C applications.

## The MySQL C API

For direct access to using MySQL natively within a C application, there are two methods:

- The [C API](#) provides low-level access to the MySQL client/server protocol through the [libmysqlclient](#) client library. This is the primary method used to connect to an instance of the MySQL server, and is used both by MySQL command-line clients and many of the MySQL Connectors and third-party APIs detailed here.

[libmysqlclient](#) is included in MySQL distributions and in Connector/C distributions.

- [libmysqld](#) is an embedded MySQL server library that enables you to embed an instance of the MySQL server into your C applications.

[libmysqld](#) is included in MySQL distributions, but not in Connector/C distributions.

### Note

The [libmysqld](#) embedded server library is deprecated as of MySQL 5.7.17 and will be removed in MySQL 8.0.

See also [Section 26.8.1, “MySQL C API Implementations”](#).

To access MySQL from a C application, or to build an interface to MySQL for a language not supported by the Connectors or APIs in this chapter, the [C API](#) is where to start. A number of programmer's utilities are available to help with the process; see [Section 5.7, “MySQL Program Development Utilities”](#).

## Third-Party MySQL APIs

The remaining APIs described in this chapter provide an interface to MySQL from specific application languages. These third-party solutions are not developed or supported by Oracle. Basic information on their usage and abilities is provided here for reference purposes only.

All the third-party language APIs are developed using one of two methods, using `libmysqlclient` or by implementing a *native driver*. The two solutions offer different benefits:

- Using `libmysqlclient` offers complete compatibility with MySQL because it uses the same libraries as the MySQL client applications. However, the feature set is limited to the implementation and interfaces exposed through `libmysqlclient` and the performance may be lower as data is copied between the native language, and the MySQL API components.
- *Native drivers* are an implementation of the MySQL network protocol entirely within the host language or environment. Native drivers are fast, as there is less copying of data between components, and they can offer advanced functionality not available through the standard MySQL API. Native drivers are also easier for end users to build and deploy because no copy of the MySQL client libraries is needed to build the native driver components.

Table 26.1, “MySQL APIs and Interfaces” lists many of the libraries and interfaces available for MySQL. Table 26.2, “MySQL Connector Versions and MySQL Server Versions” shows which MySQL Server versions each connector supports.

**Table 26.1 MySQL APIs and Interfaces**

| Environment    | API                              | Type  | Notes  |
|----------------|----------------------------------|---|--|

Table 26.2 MySQL Connector Versions and MySQL Server Versions

| Connector        | Connector version            | MySQL Server version       |
|------------------|------------------------------|----------------------------|
| Connector/C      | 6.1.0 GA                     | 5.6, 5.5, 5.1, 5.0, 4.1    |
| Connector/C++    | 1.0.5 GA                     | 5.6, 5.5, 5.1              |
| Connector/J      | 5.1.8                        | 5.6, 5.5, 5.1, 5.0, 4.1    |
| Connector/Net    | 6.5                          | 5.6, 5.5, 5.1, 5.0         |
| Connector/Net    | 6.4                          | 5.6, 5.5, 5.1, 5.0         |
| Connector/Net    | 6.3                          | 5.6, 5.5, 5.1, 5.0         |
| Connector/Net    | 6.2 (No longer supported)    | 5.6, 5.5, 5.1, 5.0         |
| Connector/Net    | 6.1 (No longer supported)    | 5.6, 5.5, 5.1, 5.0         |
| Connector/Net    | 6.0 (No longer supported)    | 5.6, 5.5, 5.1, 5.0         |
| Connector/Net    | 5.2 (No longer supported)    | 5.6, 5.5, 5.1, 5.0         |
| Connector/Net    | 1.0 (No longer supported)    | 5.0, 4.0                   |
| Connector/ODBC   | 5.1                          | 5.6, 5.5, 5.1, 5.0, 4.1.1+ |
| Connector/ODBC   | 3.51 (Unicode not supported) | 5.6, 5.5, 5.1, 5.0, 4.1    |
| Connector/Python | 2.0                          | 5.7, 5.6, 5.5              |
| Connector/Python | 1.2                          | 5.7, 5.6, 5.5              |

## 26.1 MySQL Connector/ODBC

The MySQL Connector/ODBC manual is published in standalone form, not as part of the MySQL Reference Manual. For information, see these documents:

- Main manual: [MySQL Connector/ODBC Developer Guide](#)
- Release notes: [MySQL Connector/ODBC Release Notes](#)

## 26.2 MySQL Connector/Net

The MySQL Connector/Net manual is published in standalone form, not as part of the MySQL Reference Manual. For information, see these documents:

- Main manual: [MySQL Connector/Net Developer Guide](#)
- Release notes: [MySQL Connector/Net Release Notes](#)

## 26.3 MySQL Connector/J

The MySQL Connector/J manual is published in standalone form, not as part of the MySQL Reference Manual. For information, see these documents:

- Main manual: [MySQL Connector/J 5.1 Developer Guide](#)
- Release notes: [MySQL Connector/J Release Notes](#)

## 26.4 MySQL Connector/C++

The MySQL Connector/C++ manual is published in standalone form, not as part of the MySQL Reference Manual. For information, see these documents:

- Main manual: [MySQL Connector/C++ Developer Guide](#)
- Release notes: [MySQL Connector/C++ Release Notes](#)

## 26.5 MySQL Connector/C

The MySQL Connector/C manual is published in standalone form, not as part of the MySQL Reference Manual. For information, see these documents:

- Main manual: [MySQL Connector/C Developer Guide](#)
- Release notes: [MySQL Connector/C Release Notes](#)

## 26.6 MySQL Connector/Python

The MySQL Connector/Python manual is published in standalone form, not as part of the MySQL Reference Manual. For information, see these documents:

- Main manual: [MySQL Connector/Python Developer Guide](#)
- Release notes: [MySQL Connector/Python Release Notes](#)

## 26.7 libmysqld, the Embedded MySQL Server Library

The embedded MySQL server library makes it possible to run a full-featured MySQL server inside a client application. The main benefits are increased speed and more simple management for embedded applications.

**Note**

The `libmysqld` embedded server library is deprecated as of MySQL 5.7.17 and will be removed in MySQL 8.0.

The embedded server library is based on the client/server version of MySQL, which is written in C/C++. Consequently, the embedded server also is written in C/C++. There is no embedded server available in other languages.

The API is identical for the embedded MySQL version and the client/server version. To change a threaded application to use the embedded library, you normally only have to add calls to the following functions.

**Table 26.3 MySQL Embedded Server Library Functions**

| Function                          | When to Call   |
|-----------------------------------|--|
| <code>mysql_library_init()</code> | Call it before any other MySQL function is called, preferably early in the <code>main()</code> function. |
| <code>mysql_library_end()</code>  | Call it before your program exits.   |
| <code>mysql_thread_init()</code>  | Call it in each thread you create that accesses MySQL.   |
| <code>mysql_thread_end()</code>   | Call it before calling <code>pthread_exit()</code> .   |

Then, link your code with `libmysqld.a` instead of `libmysqlclient.a`. To ensure binary compatibility between your application and the server library, always compile your application against headers for the same series of MySQL that was used to compile the server library. For example, if `libmysqld` was compiled against MySQL 5.6 headers, do not compile your application against MySQL 5.7 headers, or vice versa.

Because the `mysql_library_xxx()` functions are also included in `libmysqlclient.a`, you can change between the embedded and the client/server version by just linking your application with the right library. See [Section 26.8.7.41](#), “`mysql_library_init()`”.

One difference between the embedded server and the standalone server is that for the embedded server, authentication for connections is disabled by default.

## 26.7.1 Compiling Programs with libmysqld

In precompiled binary MySQL distributions that include `libmysqld`, the embedded server library, MySQL builds the library using the appropriate vendor compiler if there is one.

To get a `libmysqld` library if you build MySQL from source yourself, you should configure MySQL with the `-DWITH_EMBEDDED_SERVER=1` option. See [Section 2.9.4](#), “MySQL Source-Configuration Options”.

When you link your program with `libmysqld`, you must also include the system-specific `pthread` libraries and some libraries that the MySQL server uses. You can get the full list of libraries by executing `mysql_config --libmysqld-libs`.

The correct flags for compiling and linking a threaded program must be used, even if you do not directly call any thread functions in your code.

To compile a C program to include the necessary files to embed the MySQL server library into an executable version of a program, the compiler will need to know where to find various files and need instructions on how to compile the program. The following example shows how a program could be compiled from the command line, assuming that you are using `gcc`, use the GNU C compiler:

```
gcc mysql_test.c -o mysql_test \
  `~/usr/local/mysql/bin/mysql_config --include --libmysqld-libs`
```

Immediately following the `gcc` command is the name of the C program source file. After it, the `-o` option is given to indicate that the file name that follows is the name that the compiler is to give to

the output file, the compiled program. The next line of code tells the compiler to obtain the location of the include files and libraries and other settings for the system on which it is compiled. The `mysql_config` command is contained in backticks, not single quotation marks.

On some non-`gcc` platforms, the embedded library depends on C++ runtime libraries and linking against the embedded library might result in missing-symbol errors. To solve this, link using a C++ compiler or explicitly list the required libraries on the link command line.

## 26.7.2 Restrictions When Using the Embedded MySQL Server

The embedded server has the following limitations:

- No user-defined functions (UDFs).
- No stack trace on core dump.
- You cannot set this up as a master or a slave (no replication).
- Very large result sets may be unusable on low memory systems.
- You cannot connect to an embedded server from an outside process with sockets or TCP/IP. However, you can connect to an intermediate application, which in turn can connect to an embedded server on the behalf of a remote client or outside process.
- `InnoDB` is not reentrant in the embedded server and cannot be used for multiple connections, either successively or simultaneously.
- The Event Scheduler is not available. Because of this, the `event_scheduler` system variable is disabled.
- The Performance Schema is not available.
- The embedded server cannot share the same `secure_file_priv` directory with another server. As of MySQL 5.7.8, the default value for this directory can be set at build time with the `INSTALL_SECURE_FILE_PRIV_EMBEDDED` CMake option.

Some of these limitations can be changed by editing the `mysql_embed.h` include file and recompiling MySQL.

## 26.7.3 Options with the Embedded Server

Any options that may be given with the `mysqld` server daemon, may be used with an embedded server library. Server options may be given in an array as an argument to the `mysql_library_init()`, which initializes the server. They also may be given in an option file like `my.cnf`. To specify an option file for a C program, use the `--defaults-file` option as one of the elements of the second argument of the `mysql_library_init()` function. See [Section 26.8.7.41](#), “`mysql_library_init()`”, for more information on the `mysql_library_init()` function.

Using option files can make it easier to switch between a client/server application and one where MySQL is embedded. Put common options under the `[server]` group. These are read by both MySQL versions. Client/server-specific options should go under the `[mysqld]` section. Put options specific to the embedded MySQL server library in the `[embedded]` section. Options specific to applications go under section labeled `[ApplicationName_SERVER]`. See [Section 5.2.6](#), “Using Option Files”.

## 26.7.4 Embedded Server Examples

These two example programs should work without any changes on a Linux or FreeBSD system. For other operating systems, minor changes are needed, mostly with file paths. These examples are designed to give enough details for you to understand the problem, without the clutter that is a necessary part of a real application. The first example is very straightforward. The second example is a little more advanced with some error checking. The first is followed by a command-line entry for

compiling the program. The second is followed by a GNUmake file that may be used for compiling instead.

### Example 1

`test1_libmysqld.c`

```
#include <stdio.h>
#include <stdlib.h>
#include <stdarg.h>
#include "mysql.h"

MYSQL *mysql;
MYSQL_RES *results;
MYSQL_ROW record;

static char *server_options[] = \
    { "mysql_test", "--defaults-file=my.cnf", NULL };
int num_elements = (sizeof(server_options) / sizeof(char *)) - 1;

static char *server_groups[] = { "libmysqld_server",
    "libmysqld_client", NULL };

int main(void)
{
    mysql_library_init(num_elements, server_options, server_groups);
    mysql = mysql_init(NULL);
    mysql_options(mysql, MYSQL_READ_DEFAULT_GROUP, "libmysqld_client");
    mysql_options(mysql, MYSQL_OPT_USE_EMBEDDED_CONNECTION, NULL);

    mysql_real_connect(mysql, NULL, NULL, NULL, "database1", 0, NULL, 0);

    mysql_query(mysql, "SELECT column1, column2 FROM table1");

    results = mysql_store_result(mysql);

    while((record = mysql_fetch_row(results))) {
        printf("%s - %s\n", record[0], record[1]);
    }

    mysql_free_result(results);
    mysql_close(mysql);
    mysql_library_end();

    return 0;
}
```

Here is the command line for compiling the above program:

```
gcc test1_libmysqld.c -o test1_libmysqld \
    `./usr/local/mysql/bin/mysql_config --include --libmysqld-libs`
```

### Example 2

To try the example, create an `test2_libmysqld` directory at the same level as the MySQL source directory. Save the `test2_libmysqld.c` source and the `GNUmakefile` in the directory, and run GNU `make` from inside the `test2_libmysqld` directory.

`test2_libmysqld.c`

```
/*
 * A simple example client, using the embedded MySQL server library
 */

#include <mysql.h>
#include <stdarg.h>
#include <stdio.h>
#include <stdlib.h>
```

```

MYSQL *db_connect(const char *dbname);
void db_disconnect(MYSQL *db);
void db_do_query(MYSQL *db, const char *query);

const char *server_groups[] = {
    "test2_libmysqld_SERVER", "embedded", "server", NULL
};

int
main(int argc, char **argv)
{
    MYSQL *one, *two;

    /* mysql_library_init() must be called before any other mysql
     * functions.
     *
     * You can use mysql_library_init(0, NULL, NULL), and it
     * initializes the server using groups = {
     *     "server", "embedded", NULL
     * }.
     *
     * In your $HOME/.my.cnf file, you probably want to put:
     [test2_libmysqld_SERVER]
     language = /path/to/source/of/mysql/sql/share/english
     *
     * You could, of course, modify argc and argv before passing
     * them to this function. Or you could create new ones in any
     * way you like. But all of the arguments in argv (except for
     * argv[0], which is the program name) should be valid options
     * for the MySQL server.
     *
     * If you link this client against the normal mysqlclient
     * library, this function is just a stub that does nothing.
     */
    mysql_library_init(argc, argv, (char **)server_groups);

    one = db_connect("test");
    two = db_connect(NULL);

    db_do_query(one, "SHOW TABLE STATUS");
    db_do_query(two, "SHOW DATABASES");

    mysql_close(two);
    mysql_close(one);

    /* This must be called after all other mysql functions */
    mysql_library_end();

    exit(EXIT_SUCCESS);
}

static void
die(MYSQL *db, char *fmt, ...)
{
    va_list ap;
    va_start(ap, fmt);
    vfprintf(stderr, fmt, ap);
    va_end(ap);
    (void)putc('\n', stderr);
    if (db)
        db_disconnect(db);
    exit(EXIT_FAILURE);
}

MYSQL *
db_connect(const char *dbname)
{
    MYSQL *db = mysql_init(NULL);
    if (!db)
        die(db, "mysql_init failed: no memory");

```

```

/*
 * Notice that the client and server use separate group names.
 * This is critical, because the server does not accept the
 * client's options, and vice versa.
 */
mysql_options(db, MYSQL_READ_DEFAULT_GROUP, "test2_libmysqld_CLIENT");
if (!mysql_real_connect(db, NULL, NULL, NULL, dbname, 0, NULL, 0))
    die(db, "mysql_real_connect failed: %s", mysql_error(db));

return db;
}

void
db_disconnect(MYSQL *db)
{
    mysql_close(db);
}

void
db_do_query(MYSQL *db, const char *query)
{
    if (mysql_query(db, query) != 0)
        goto err;

    if (mysql_field_count(db) > 0)
    {
        MYSQL_RES *res;
        MYSQL_ROW row, end_row;
        int num_fields;

        if (!(res = mysql_store_result(db)))
            goto err;
        num_fields = mysql_num_fields(res);
        while ((row = mysql_fetch_row(res)))
        {
            (void)fputs(">> ", stdout);
            for (end_row = row + num_fields; row < end_row; ++row)
                (void)printf("%s\t", row ? (char*)*row : "NULL");
            (void)fputc('\n', stdout);
        }
        (void)fputc('\n', stdout);
        mysql_free_result(res);
    }
    else
        (void)printf("Affected rows: %lld\n", mysql_affected_rows(db));

    return;
err:
    die(db, "db_do_query failed: %s [%s]", mysql_error(db), query);
}

```

## GNUMakefile

```

# This assumes the MySQL software is installed in /usr/local/mysql
inc      := /usr/local/mysql/include/mysql
lib      := /usr/local/mysql/lib

# If you have not installed the MySQL software yet, try this instead
#inc     := $(HOME)/mysql-5.7/include
#lib     := $(HOME)/mysql-5.7/libmysqld

CC       := gcc

## 26.8 MySQL C API

The C API provides low-level access to the MySQL client/server protocol and enables C programs to access database contents. The C API code is distributed with MySQL and implemented in the `libmysqlclient` library. See [Section 26.8.1, “MySQL C API Implementations”](#).

Most other client APIs use the `libmysqlclient` library to communicate with the MySQL server. (Exceptions are except Connector/J and Connector/Net.) This means that, for example, you can take advantage of many of the same environment variables that are used by other client programs because they are referenced from the library. For a list of these variables, see [Section 5.1, “Overview of MySQL Programs”](#).

For instructions on building client programs using the C API, see [Section 26.8.4.1, “Building C API Client Programs”](#). For programming with threads, see [Section 26.8.4.3, “Writing C API Threaded Client Programs”](#). To create a standalone application which includes the "server" and "client" in the same program (and does not communicate with an external MySQL server), see [Section 26.7, “libmysqld, the Embedded MySQL Server Library”](#).

### Note

If, after an upgrade, you experience problems with compiled client programs, such as `Commands out of sync` or unexpected core dumps, the programs were probably compiled using old header or library files. In this case, check the date of the `mysql.h` file and `libmysqlclient.a` library used for compilation to verify that they are from the new MySQL distribution. If not, recompile the programs with the new headers and libraries. Recompilation might also be necessary for programs compiled against the shared client library if the library major version number has changed (for example, from `libmysqlclient.so.17` to `libmysqlclient.so.18`). For additional compatibility information, see [Section 26.8.4.4, “Running C API Client Programs”](#).

Clients have a maximum communication buffer size. The size of the buffer that is allocated initially (16KB) is automatically increased up to the maximum size (16MB by default). Because buffer sizes are increased only as demand warrants, simply increasing the maximum limit does not in itself cause more resources to be used. This size check is mostly a precaution against erroneous statements and communication packets.

The communication buffer must be large enough to contain a single SQL statement (for client-to-server traffic) and one row of returned data (for server-to-client traffic). Each session's communication buffer is dynamically enlarged to handle any query or row up to the maximum limit. For example, if you have `BLOB` values that contain up to 16MB of data, you must have a communication buffer limit of at least 16MB (in both server and client). The default maximum built into the client library is 1GB, but the default maximum in the server is 1MB. You can increase this by changing the value of the `max_allowed_packet` parameter at server startup. See [Section 6.1.1, “Configuring the Server”](#).

The MySQL server shrinks each communication buffer to `net_buffer_length` bytes after each query. For clients, the size of the buffer associated with a connection is not decreased until the connection is closed, at which time client memory is reclaimed.

## 26.8.1 MySQL C API Implementations

The MySQL C API is a C-based API that client applications written in C can use to communicate with MySQL Server. Client programs refer to C API header files at compile time and link to a C API library file at link time. The library comes in two versions, depending on how the application is intended to communicate with the server:

- `libmysqlclient`: The client version of the library, used for applications that communicate over a network connection as a client of a standalone server process.
- `libmysqld`: The embedded server version of the library, used for applications intended to include an embedded MySQL server within the application itself. The application communicates with its own private server instance.

### Note

The `libmysqld` embedded server library is deprecated as of MySQL 5.7.17 and will be removed in MySQL 8.0.

Both libraries have the same interface. In terms of C API calls, an application communicates with a standalone server the same way it communicates with an embedded server. A given client can be built to communicate with a standalone or embedded server, depending on whether it is linked against `libmysqlclient` or `libmysqld` at build time.

There are two ways to obtain the C API header and library files required to build C API client programs:

- Install a MySQL Server distribution. Server distributions include both `libmysqlclient` and `libmysqld`.
- Install a Connector/C distribution. Connector/C distributions include only `libmysqlclient`. They do not include `libmysqld`.

For both MySQL Server and Connector/C, you can install a binary distribution that contains the C API files pre-built, or you can use a source distribution and build the C API files yourself.

Normally, you install either a MySQL Server distribution or a Connector/C distribution, but not both. For information about issues involved with simultaneous MySQL Server and Connector/C installations, see [Section 26.8.2, “Simultaneous MySQL Server and Connector/C Installations”](#).

The names of the library files to use when linking C API client applications depend on the library type and platform for which a distribution is built:

- On Unix (and Unix-like) systems, the static library is `libmysqlclient.a`. The dynamic library is `libmysqlclient.so` on most Unix systems and `libmysqlclient.dylib` on OS X.

For distributions that include embedded server libraries, the corresponding library names begin with `libmysqld` rather than `libmysqlclient`.

- On Windows, the static library is `mysqlclient.lib` and the dynamic library is `libmysql.dll`. Windows distributions also include `libmysql.lib`, a static import library needed for using the dynamic library.

For distributions that include embedded server libraries, the corresponding library names are `mysqlserver.lib`, `libmysqld.dll`, and `libmysqld.lib`.

Windows distributions also include a set of debug libraries. These have the same names as the nondebug libraries, but are located in the `lib/debug` library. You must use the debug libraries when compiling clients built using the debug C runtime.

On Unix, you may also see libraries that include `_r` in the names. Before MySQL 5.5, these were built as thread-safe (re-entrant) libraries separately from the non-`_r` libraries. As of 5.5, both libraries are the same and the `_r` names are symbolic links to the corresponding non-`_r` names. There is no need to use the `_r` libraries. For example, if you use `mysql_config` to obtain linker flags, you can use `mysql_config --libs` in all cases, even for threaded clients. There is no need to use `mysql_config --libs_r`.

## 26.8.2 Simultaneous MySQL Server and Connector/C Installations

MySQL Server and Connector/C installation packages both provide the files needed to build and run MySQL C API client programs. This section discusses when it is possible to install both products on the same system. For some packaging formats, this is possible without conflict. For others, both products cannot be installed at the same time.

This discussion assumes the use of similar package types for both products (for example, RPM packages for both products). It does not try to describe coexistence between packaging types (for example, use of RPM packages for one product and a `tar` file package for the other). Nor does it describe coexistence of packages provided by Oracle and those provided by third-party vendors.

If you install both products, it may be necessary to adjust your development tools or runtime environment to choose one set of header files and libraries over the other. See [Section 26.8.4.1, “Building C API Client Programs”](#), and [Section 26.8.4.4, “Running C API Client Programs”](#).

`tar` and Zip file packages install under the directory into which you unpack them. For example, you can unpack MySQL Server and Connector/C `tar` packages under `/usr/local` and they will unpack into distinct directory names without conflict.

Windows MSI installers use their own installation directory, so MySQL Server and Connector/C installers do not conflict.

OS X DMG packages install under the same parent directory but in a different subdirectory, so there is no conflict. For example:

```
/usr/local/mysql-5.6.11-osx10.7-x86_64/  
/usr/local/mysql-connector-c-6.1.0-osx10.7-x86/
```

Solaris PKG packages install under the same parent directory but in a different subdirectory, so there is no conflict. For example:

```
/opt/mysql/mysql  
/opt/mysql/connector-c
```

The Solaris Connector/C installer does not create any symlinks from system directories such as `/usr/bin` or `/usr/lib` into the installation directory. That must be done manually if desired after installation.

For RPM installations, there are several types of RPM packages. MySQL Server `shared` and `devel` RPM packages are similar to the corresponding Connector/C RPM packages. These RPM package types cannot coexist because the MySQL Server and Connector/C RPM packages use the same installation locations for the client library-related files. This means the following conditions hold:

- If MySQL Server `shared` and `devel` RPM packages are installed, they provide the C API headers and libraries, and there is no need to install the Connector/C RPM packages. To install the Connector/C packages anyway, you must first remove the corresponding MySQL Server packages.
- To install MySQL Server RPM packages if you already have Connector/C RPM packages installed, you must first remove the Connector/C RPM packages.

MySQL Server RPM packages other than `shared` and `devel` do not conflict with Connector/C packages and can be installed if Connector/C is installed. This includes the main server RPM that includes the `mysqld` server itself.

## 26.8.3 Example C API Client Programs

Many of the clients in MySQL source distributions are written in C, such as `mysql`, `mysqladmin`, and `mysqlshow`. If you are looking for examples that demonstrate how to use the C API, take a look at these clients: Obtain a source distribution and look in its `client` directory. See [Section 2.1.2, “How to Get MySQL”](#).

## 26.8.4 Building and Running C API Client Programs

The following sections provide information on building client programs that use the C API. Topics include compiling and linking clients, writing threaded clients, and troubleshooting runtime problems.

### 26.8.4.1 Building C API Client Programs

This section provides guidelines for compiling C programs that use the MySQL C API.

#### Compiling MySQL Clients on Unix

The examples here use `gcc` as the compiler. A different compiler might be appropriate on some systems (for example, `clang` on OS X or FreeBSD, or Sun Studio on Solaris). Adjust the examples as necessary.

You may need to specify an `-I` option when you compile client programs that use MySQL header files, so that the compiler can find them. For example, if the header files are installed in `/usr/local/mysql/include`, use this option in the compile command:

```
-I/usr/local/mysql/include
```

MySQL clients must be linked using the `-lmysqlclient` option in the link command. You may also need to specify a `-L` option to tell the linker where to find the library. For example, if the library is installed in `/usr/local/mysql/lib`, use these options in the link command:

```
-L/usr/local/mysql/lib -lmysqlclient
```

The path names may differ on your system. Adjust the `-I` and `-L` options as necessary.

To make it simpler to compile MySQL programs on Unix, use the `mysql_config` script. See [Section 5.7.1, “mysql\\_config — Display Options for Compiling Clients”](#).

`mysql_config` displays the options needed for compiling or linking:

```
shell> mysql_config --cflags
shell> mysql_config --libs
```

You can run those commands to get the proper options and add them manually to compilation or link commands. Alternatively, include the output from `mysql_config` directly within command lines using backticks:

```
shell> gcc -c `mysql_config --cflags` progname.c
shell> gcc -o progname progname.o `mysql_config --libs`
```

On Unix, linking uses dynamic libraries by default. To link to the static client library instead, add its path name to the link command. For example, if the library is located in `/usr/local/mysql/lib`, link like this:

```
shell> gcc -o progname progname.o /usr/local/mysql/lib/libmysqlclient.a
```

Or use `mysql_config` to provide the library name:

```
shell> gcc -o progname progname.o `mysql_config --variable=pkglibdir`/libmysqlclient.a
```

`mysql_config` does not currently provide a way to list all libraries needed for static linking, so it might be necessary to name additional libraries on the link command (for example, `-lnsl -lsocket` on Solaris). To get an idea which libraries to add, use `mysql_config --libs` and `ldd libmysqlclient.so` (or `otool -L libmysqlclient.dylib` on OS X).

As of MySQL 5.7.9, `pkg-config` can be used as an alternative to `mysql_config` for obtaining information such as compiler flags or link libraries required to compile MySQL applications. For example, the following pairs of commands are equivalent:

```
mysql_config --cflags
pkg-config --cflags mysqlclient

mysql_config --libs
pkg-config --libs mysqlclient
```

To produce flags for static linking, use this command:

```
pkg-config --static --libs mysqlclient
```

For more information, see [Section 26.8.4.2, “Building C API Client Programs Using pkg-config”](#).

## Compiling MySQL Clients on Microsoft Windows

To specify header and library file locations, use the facilities provided by your development environment.

To build C API clients on Windows, you must link in the C client library, as well as the Windows `ws2_32` sockets library and Secur32 security library.

On Windows, you can link your code with either the dynamic or static C client library. The static library is named `mysqlclient.lib` and the dynamic library is named `libmysql.dll`. In addition, the `libmysql.lib` static import library is needed for using the dynamic library.

If you link with the static library, failure can occur unless these conditions are satisfied:

- The client application must be compiled with the same version of Visual Studio used to compile the library.
- The client application should link the C runtime statically by using the `/MT` compiler option.

If the client application is built in debug mode and uses the static debug C runtime (`/MTd` compiler option), it can link to the `mysqlclient.lib` static library if that library was built using the same option. If the client application uses the dynamic C runtime (`/MD` option, or `/MDd` option in debug mode), it must be linked to the `libmysql.dll` dynamic library. It cannot link to the static client library.

The MSDN page describing the link options can be found here: <http://msdn.microsoft.com/en-us/library/2kzt1wy3.aspx>

## Troubleshooting Problems Linking to the MySQL Client Library

The MySQL client library includes SSL support built in. It is unnecessary to specify either `-lssl` or `-lcrypto` at link time. Doing so may in fact result in problems at runtime.

If the linker cannot find the MySQL client library, you might get undefined-reference errors for symbols that start with `mysql_`, such as those shown here:

```
/tmp/ccFKsdPa.o: In function `main':
/tmp/ccFKsdPa.o(.text+0xb): undefined reference to `mysql_init'
/tmp/ccFKsdPa.o(.text+0x31): undefined reference to `mysql_real_connect'
/tmp/ccFKsdPa.o(.text+0x69): undefined reference to `mysql_error'
/tmp/ccFKsdPa.o(.text+0x9a): undefined reference to `mysql_close'
```

You should be able to solve this problem by adding `-Ldir_path -lmysqlclient` at the end of your link command, where `dir_path` represents the path name of the directory where the client library is located. To determine the correct directory, try this command:

```
shell> mysql_config --libs
```

The output from `mysql_config` might indicate other libraries that should be specified on the link command as well. You can include `mysql_config` output directly in your compile or link command using backticks. For example:

```
shell> gcc -o progname progname.o `mysql_config --libs`
```

If an error occurs at link time that the `floor` symbol is undefined, link to the math library by adding `-lm` to the end of the compile/link line. Similarly, if you get undefined-reference errors for other functions that should exist on your system, such as `connect()`, check the manual page for the function in question to determine which libraries you should add to the link command.

If you get undefined-reference errors such as the following for functions that do not exist on your system, it usually means that your MySQL client library was compiled on a system that is not 100% compatible with yours:

```
mf_format.o(.text+0x201): undefined reference to `__lxstat'
```

In this case, you should download the latest MySQL or Connector/C source distribution and compile the MySQL client library yourself. See [Section 2.9, “Installing MySQL from Source”](#), and [MySQL Connector/C Developer Guide](#).

### 26.8.4.2 Building C API Client Programs Using pkg-config

As of MySQL 5.7.9, MySQL distributions contain a `mysqlclient.pc` file that provides information about MySQL configuration for use by the `pkg-config` command. This enables `pkg-config` to be used as an alternative to `mysql_config` for obtaining information such as compiler flags or link libraries required to compile MySQL applications. For example, the following pairs of commands are equivalent:

```
mysql_config --cflags
pkg-config --cflags mysqlclient

mysql_config --libs
pkg-config --libs mysqlclient
```

The last `pkg-config` command produces flags for dynamic linking. To produce flags for static linking, use this command:

```
pkg-config --static --libs mysqlclient
```

On some platforms, the output with and without `--static` might be the same.

#### Note

If `pkg-config` does not find MySQL information, it might be necessary to set the `PKG_CONFIG_PATH` environment variable to the directory in which the `mysqlclient.pc` file is located, which by default is usually the `pkgconfig`

directory under the MySQL library directory. For example (adjust the location appropriately):

```
export PKG_CONFIG_PATH=/usr/local/mysql/lib/pkgconfig # sh, bash, ...
setenv PKG_CONFIG_PATH /usr/local/mysql/lib/pkgconfig # csh, tcsh, ...
```

The `mysqlconfig.pc` installation location can be controlled using the `INSTALL_PKGCONFIGDIR` CMake option. See [Section 2.9.4, “MySQL Source-Configuration Options”](#).

The `--variable` option takes a configuration variable name and displays the variable value:

```
pkg-config --variable=prefix mysqlclient      # installation prefix directory
pkg-config --variable=includedir mysqlclient  # header file directory
pkg-config --variable=libdir mysqlclient      # library directory
```

To see which variable values `pkg-config` can display using the `--variable` option, use this command:

```
pkg-config --print-variables mysqlclient
```

You can use `pkg-config` within a command line using backticks to include the output that it produces for particular options. For example, to compile and link a MySQL client program, use `pkg-config` as follows:

```
gcc -c `pkg-config --cflags mysqlclient` progname.c
gcc -o progname progname.o `pkg-config --libs mysqlclient`
```

### 26.8.4.3 Writing C API Threaded Client Programs

The client library is almost thread-safe. The biggest problem is that the subroutines in `sql/net_serv.cc` that read from sockets are not interrupt-safe. This was done with the thought that you might want to have your own alarm that can break a long read to a server. If you install interrupt handlers for the `SIGPIPE` interrupt, socket handling should be thread-safe.

To avoid aborting the program when a connection terminates, MySQL blocks `SIGPIPE` on the first call to `mysql_library_init()`, `mysql_init()`, or `mysql_connect()`. To use your own `SIGPIPE` handler, first call `mysql_library_init()`, then install your handler.

If “undefined symbol” errors occur when linking against the `libmysqlclient` client library, in most cases this is because you have not included the thread libraries on the link/compile command.

The client library is thread-safe per connection. You can let two threads share the same connection with the following caveats:

- Multiple threads cannot send a query to the MySQL server at the same time on the same connection. In particular, you must ensure that between calls to `mysql_query()` and `mysql_store_result()` in one thread, no other thread uses the same connection. You must have a mutex lock around your pair of `mysql_query()` and `mysql_store_result()` calls. After `mysql_store_result()` returns, the lock can be released and other threads may query the same connection.

If you use POSIX threads, you can use `pthread_mutex_lock()` and `pthread_mutex_unlock()` to establish and release a mutex lock.

- Many threads can access different result sets that are retrieved with `mysql_store_result()`.
- To use `mysql_use_result()`, you must ensure that no other thread is using the same connection until the result set is closed. However, it really is best for threaded clients that share the same connection to use `mysql_store_result()`.

You need to know the following if you have a thread that did not create the connection to the MySQL database but is calling MySQL functions:

When you call `mysql_init()`, MySQL creates a thread-specific variable for the thread that is used by the debug library (among other things). If you call a MySQL function before the thread has called `mysql_init()`, the thread does not have the necessary thread-specific variables in place and you are likely to end up with a core dump sooner or later. To avoid problems, you must do the following:

1. Call `mysql_library_init()` before any other MySQL functions. It is not thread-safe, so call it before threads are created, or protect the call with a mutex.
2. Arrange for `mysql_thread_init()` to be called early in the thread handler before calling any MySQL function. If you call `mysql_init()`, it will call `mysql_thread_init()` for you.
3. In the thread, call `mysql_thread_end()` before calling `pthread_exit()`. This frees the memory used by MySQL thread-specific variables.

The preceding notes regarding `mysql_init()` also apply to `mysql_connect()`, which calls `mysql_init()`.

#### 26.8.4.4 Running C API Client Programs

If, after an upgrade, you experience problems with compiled client programs, such as `Commands out of sync` or unexpected core dumps, the programs were probably compiled using old header or library files. In this case, check the date of the `mysql.h` file and `libmysqlclient.a` library used for compilation to verify that they are from the new MySQL distribution. If not, recompile the programs with the new headers and libraries. Recompilation might also be necessary for programs compiled against the shared client library if the library major version number has changed (for example, from `libmysqlclient.so.17` to `libmysqlclient.so.18`).

The major client library version determines compatibility. (For example, for `libmysqlclient.so.18.1.0`, the major version is 18.) For this reason, the libraries shipped with newer versions of MySQL are drop-in replacements for older versions that have the same major number. As long as the major library version is the same, you can upgrade the library and old applications should continue to work with it.

Undefined-reference errors might occur at runtime when you try to execute a MySQL program. If these errors specify symbols that start with `mysql_` or indicate that the `libmysqlclient` library cannot be found, it means that your system cannot find the shared `libmysqlclient.so` library. The solution to this problem is to tell your system to search for shared libraries in the directory where that library is located. Use whichever of the following methods is appropriate for your system:

- Add the path of the directory where `libmysqlclient.so` is located to the `LD_LIBRARY_PATH` or `LD_LIBRARY` environment variable.
- On OS X, add the path of the directory where `libmysqlclient.dylib` is located to the `DYLD_LIBRARY_PATH` environment variable.
- Copy the shared-library files (such as `libmysqlclient.so`) to some directory that is searched by your system, such as `/lib`, and update the shared library information by executing `ldconfig`. Be sure to copy all related files. A shared library might exist under several names, using symlinks to provide the alternate names.

If the application is linked to the embedded server library, runtime error messages will indicate the `libmysqld` rather than `libmysqlclient` library, but the solution to the problem is the same as just described.

#### 26.8.4.5 C API Server and Client Library Versions

The string and numeric forms of the MySQL server version are available at compile time as the values of the `MYSQL_SERVER_VERSION` and `MYSQL_VERSION_ID` macros, and at runtime as the values of the `mysql_get_server_info()` and `mysql_get_server_version()` functions.

As of MySQL 5.7.4 and Connector/C 6.1.3, the MySQL client library version depends on the type of distribution that provides the library:

- For MySQL distributions, the client library version is the MySQL version. The string and numeric forms of this version are available at compile time as the values of the `MYSQL_SERVER_VERSION` and `MYSQL_VERSION_ID` macros, and at runtime as the values of the `mysql_get_client_info()` and `mysql_get_client_version()` functions.

The `LIBMYSQL_VERSION` and `LIBMYSQL_VERSION_ID` macros have the same values as `MYSQL_SERVER_VERSION` and `MYSQL_VERSION_ID` and the two sets of macros can be used interchangeably.

- For Connector/C distributions, the client library version is the Connector/C version. The string and numeric forms of this version are available at compile time as the values of the `LIBMYSQL_VERSION` and `LIBMYSQL_VERSION_ID` macros, and at runtime as the values of the `mysql_get_client_info()` and `mysql_get_client_version()` functions.

The `MYSQL_SERVER_VERSION` and `MYSQL_VERSION_ID` macros indicate the string and numeric forms of the MySQL version on which the Connector/C distribution is based.

Prior to MySQL 5.7.4 and Connector/C 6.1.3, the client library version is the MySQL version. For Connector/C, this is the MySQL version on which the Connector/C distribution is based. The string and numeric forms of this version are available at compile time as the values of the `MYSQL_SERVER_VERSION` and `MYSQL_VERSION_ID` macros, and at runtime as the values of the `mysql_get_client_info()` and `mysql_get_client_version()` functions.

The `LIBMYSQL_VERSION` and `LIBMYSQL_VERSION_ID` macros are not defined before MySQL 5.7.4 and Connector/C 6.1.3.

## 26.8.5 C API Data Structures

This section describes C API data structures other than those used for prepared statements. For information about the latter, see [Section 26.8.9, “C API Prepared Statement Data Structures”](#).

- `MYSQL`

This structure represents a handle to one database connection. It is used for almost all MySQL functions. Do not try to make a copy of a `MYSQL` structure. There is no guarantee that such a copy will be usable.

- `MYSQL_RES`

This structure represents the result of a query that returns rows (`SELECT`, `SHOW`, `DESCRIBE`, `EXPLAIN`). The information returned from a query is called the *result set* in the remainder of this section.

- `MYSQL_ROW`

This is a type-safe representation of one row of data. It is currently implemented as an array of counted byte strings. (You cannot treat these as null-terminated strings if field values may contain binary data, because such values may contain null bytes internally.) Rows are obtained by calling `mysql_fetch_row()`.

- `MYSQL_FIELD`

This structure contains metadata: information about a field, such as the field's name, type, and size. Its members are described in more detail later in this section. You may obtain the `MYSQL_FIELD` structures for each field by calling `mysql_fetch_field()` repeatedly. Field values are not part of this structure; they are contained in a `MYSQL_ROW` structure.

- `MYSQL_FIELD_OFFSET`

This is a type-safe representation of an offset into a MySQL field list. (Used by `mysql_field_seek()`.) Offsets are field numbers within a row, beginning at zero.

- `my_ulonglong`

The type used for the number of rows and for `mysql_affected_rows()`, `mysql_num_rows()`, and `mysql_insert_id()`. This type provides a range of 0 to 1.84e19.

Some functions that return a row count using this type return -1 as an unsigned value to indicate an error or exceptional condition. You can check for -1 by comparing the return value to `(my_ulonglong)-1` (or to `(my_ulonglong)~0`, which is equivalent).

On some systems, attempting to print a value of type `my_ulonglong` does not work. To print such a value, convert it to `unsigned long` and use a `%lu` print format. Example:

```
printf ("Number of rows: %lu\n",
        (unsigned long) mysql_num_rows(result));
```

- `my_bool`

A boolean type, for values that are true (nonzero) or false (zero).

The `MYSQL_FIELD` structure contains the members described in the following list. The definitions apply primarily for columns of result sets such as those produced by `SELECT` statements. `MYSQL_FIELD` structures are also used to provide metadata for `OUT` and `INOUT` parameters returned from stored procedures executed using prepared `CALL` statements. For such parameters, some of the structure members have a meaning different from the meaning for column values.

- `char * name`

The name of the field, as a null-terminated string. If the field was given an alias with an `AS` clause, the value of `name` is the alias. For a procedure parameter, the parameter name.

- `char * org_name`

The name of the field, as a null-terminated string. Aliases are ignored. For expressions, the value is an empty string. For a procedure parameter, the parameter name.

- `char * table`

The name of the table containing this field, if it is not a calculated field. For calculated fields, the `table` value is an empty string. If the column is selected from a view, `table` names the view. If the table or view was given an alias with an `AS` clause, the value of `table` is the alias. For a `UNION`, the value is the empty string. For a procedure parameter, the procedure name.

- `char * org_table`

The name of the table, as a null-terminated string. Aliases are ignored. If the column is selected from a view, `org_table` names the view. If the column is selected from a derived table, `org_table` names the base table. If a derived table wraps a view, `org_table` still names the base table. If the column is an expression, `org_table` is the empty string. For a `UNION`, the value is the empty string. For a procedure parameter, the value is the procedure name.

- `char * db`

The name of the database that the field comes from, as a null-terminated string. If the field is a calculated field, `db` is an empty string. For a `UNION`, the value is the empty string. For a procedure parameter, the name of the database containing the procedure.

- `char * catalog`

The catalog name. This value is always `"def"`.

- `char * def`

The default value of this field, as a null-terminated string. This is set only if you use `mysql_list_fields()`.

- `unsigned long length`

The width of the field. This corresponds to the display length, in bytes.

The server determines the `length` value before it generates the result set, so this is the minimum length required for a data type capable of holding the largest possible value from the result column, without knowing in advance the actual values that will be produced by the query for the result set.

- `unsigned long max_length`

The maximum width of the field for the result set (the length in bytes of the longest field value for the rows actually in the result set). If you use `mysql_store_result()` or `mysql_list_fields()`, this contains the maximum length for the field. If you use `mysql_use_result()`, the value of this variable is zero.

The value of `max_length` is the length of the string representation of the values in the result set. For example, if you retrieve a `FLOAT` column and the “widest” value is `-12.345`, `max_length` is 7 (the length of `'-12.345'`).

If you are using prepared statements, `max_length` is not set by default because for the binary protocol the lengths of the values depend on the types of the values in the result set. (See [Section 26.8.9, “C API Prepared Statement Data Structures”](#).) If you want the `max_length` values anyway, enable the `STMT_ATTR_UPDATE_MAX_LENGTH` option with `mysql_stmt_attr_set()` and the lengths will be set when you call `mysql_stmt_store_result()`. (See [Section 26.8.11.3, “mysql\\_stmt\\_attr\\_set\(\)”](#), and [Section 26.8.11.28, “mysql\\_stmt\\_store\\_result\(\)”](#).)

- `unsigned int name_length`

The length of `name`.

- `unsigned int org_name_length`

The length of `org_name`.

- `unsigned int table_length`

The length of `table`.

- `unsigned int org_table_length`

The length of `org_table`.

- `unsigned int db_length`

The length of `db`.

- `unsigned int catalog_length`

The length of `catalog`.

- `unsigned int def_length`

The length of `def`.

- `unsigned int flags`

Bit-flags that describe the field. The `flags` value may have zero or more of the bits set that are shown in the following table.

| Flag Value                         | Flag Description   |
|------------------------------------|--|
| <code>NOT_NULL_FLAG</code>         | Field cannot be <code>NULL</code>                                |
| <code>PRI_KEY_FLAG</code>          | Field is part of a primary key                                   |
| <code>UNIQUE_KEY_FLAG</code>       | Field is part of a unique key                                    |
| <code>MULTIPLE_KEY_FLAG</code>     | Field is part of a nonunique key                                 |
| <code>UNSIGNED_FLAG</code>         | Field has the <code>UNSIGNED</code> attribute                    |
| <code>ZEROFILL_FLAG</code>         | Field has the <code>ZEROFILL</code> attribute                    |
| <code>BINARY_FLAG</code>           | Field has the <code>BINARY</code> attribute                      |
| <code>AUTO_INCREMENT_FLAG</code>   | Field has the <code>AUTO_INCREMENT</code> attribute              |
| <code>ENUM_FLAG</code>             | Field is an <code>ENUM</code>                                    |
| <code>SET_FLAG</code>              | Field is a <code>SET</code>                                      |
| <code>BLOB_FLAG</code>             | Field is a <code>BLOB</code> or <code>TEXT</code> (deprecated)   |
| <code>TIMESTAMP_FLAG</code>        | Field is a <code>TIMESTAMP</code> (deprecated)                   |
| <code>NUM_FLAG</code>              | Field is numeric; see additional notes following table           |
| <code>NO_DEFAULT_VALUE_FLAG</code> | Field has no default value; see additional notes following table |

Some of these flags indicate data type information and are superseded by or used in conjunction with the `MYSQL_TYPE_xxx` value in the `field->type` member described later:

- To check for `BLOB` or `TIMESTAMP` values, check whether `type` is `MYSQL_TYPE_BLOB` or `MYSQL_TYPE_TIMESTAMP`. (The `BLOB_FLAG` and `TIMESTAMP_FLAG` flags are unneeded.)
- `ENUM` and `SET` values are returned as strings. For these, check that the `type` value is `MYSQL_TYPE_STRING` and that the `ENUM_FLAG` or `SET_FLAG` flag is set in the `flags` value.

`NUM_FLAG` indicates that a column is numeric. This includes columns with a type of `MYSQL_TYPE_DECIMAL`, `MYSQL_TYPE_NEWDECIMAL`, `MYSQL_TYPE_TINY`, `MYSQL_TYPE_SHORT`, `MYSQL_TYPE_LONG`, `MYSQL_TYPE_FLOAT`, `MYSQL_TYPE_DOUBLE`, `MYSQL_TYPE_NULL`, `MYSQL_TYPE_LONGLONG`, `MYSQL_TYPE_INT24`, and `MYSQL_TYPE_YEAR`.

`NO_DEFAULT_VALUE_FLAG` indicates that a column has no `DEFAULT` clause in its definition. This does not apply to `NULL` columns (because such columns have a default of `NULL`), or to `AUTO_INCREMENT` columns (which have an implied default value).

The following example illustrates a typical use of the `flags` value:

```
if (field->flags & NOT_NULL_FLAG)
    printf("Field cannot be null\n");
```

You may use the convenience macros shown in the following table to determine the boolean status of the `flags` value.

| Flag Status                     | Description   |
|---------------------------------|---|
| <code>IS_NOT_NULL(flags)</code> | True if this field is defined as <code>NOT NULL</code>  |
| <code>IS_PRI_KEY(flags)</code>  | True if this field is a primary key   |
| <code>IS_BLOB(flags)</code>     | True if this field is a <code>BLOB</code> or <code>TEXT</code> (deprecated; test <code>field-&gt;type</code> instead) |

- `unsigned int decimals`

The number of decimals for numeric fields, and the fractional seconds precision for temporal fields.

- `unsigned int charsetnr`

An ID number that indicates the character set/collation pair for the field.

Normally, character values in result sets are converted to the character set indicated by the `character_set_results` system variable. In this case, `charsetnr` corresponds to the character set indicated by that variable. Character set conversion can be suppressed by setting `character_set_results` to `NULL`. In this case, `charsetnr` corresponds to the character set of the original table column or expression. See also [Section 11.1.4, “Connection Character Sets and Collations”](#).

To distinguish between binary and nonbinary data for string data types, check whether the `charsetnr` value is 63. If so, the character set is `binary`, which indicates binary rather than nonbinary data. This enables you to distinguish `BINARY` from `CHAR`, `VARBINARY` from `VARCHAR`, and the `BLOB` types from the `TEXT` types.

`charsetnr` values are the same as those displayed in the `Id` column of the `SHOW COLLATION` statement or the `ID` column of the `INFORMATION_SCHEMA.COLLATIONS` table. You can use those information sources to see which character set and collation specific `charsetnr` values indicate:

```
mysql> SHOW COLLATION WHERE Id = 63;
+-----+-----+-----+-----+-----+-----+
| Collation | Charset | Id | Default | Compiled | Sortlen |
+-----+-----+-----+-----+-----+-----+
| binary    | binary  | 63 | Yes      | Yes      | 1        |
+-----+-----+-----+-----+-----+-----+

mysql> SELECT COLLATION_NAME, CHARACTER_SET_NAME
-> FROM INFORMATION_SCHEMA.COLLATIONS WHERE ID = 33;
+-----+-----+
| COLLATION_NAME | CHARACTER_SET_NAME |
+-----+-----+
| utf8_general_ci | utf8                |
+-----+-----+
```

- `enum enum_field_types type`

The type of the field. The `type` value may be one of the `MYSQL_TYPE_` symbols shown in the following table.

| Type Value                         | Type Description  |
|------------------------------------|---|
| <code>MYSQL_TYPE_TINY</code>       | <code>TINYINT</code> field                                  |
| <code>MYSQL_TYPE_SHORT</code>      | <code>SMALLINT</code> field                                 |
| <code>MYSQL_TYPE_LONG</code>       | <code>INTEGER</code> field                                  |
| <code>MYSQL_TYPE_INT24</code>      | <code>MEDIUMINT</code> field                                |
| <code>MYSQL_TYPE_LONGLONG</code>   | <code>BIGINT</code> field                                   |
| <code>MYSQL_TYPE_DECIMAL</code>    | <code>DECIMAL</code> or <code>NUMERIC</code> field          |
| <code>MYSQL_TYPE_NEWDECIMAL</code> | Precision math <code>DECIMAL</code> or <code>NUMERIC</code> |
| <code>MYSQL_TYPE_FLOAT</code>      | <code>FLOAT</code> field                                    |
| <code>MYSQL_TYPE_DOUBLE</code>     | <code>DOUBLE</code> or <code>REAL</code> field              |
| <code>MYSQL_TYPE_BIT</code>        | <code>BIT</code> field                                      |
| <code>MYSQL_TYPE_TIMESTAMP</code>  | <code>TIMESTAMP</code> field                                |
| <code>MYSQL_TYPE_DATE</code>       | <code>DATE</code> field                                     |

| Type Value                         | Type Description   |
|------------------------------------|--|
| <code>MYSQL_TYPE_TIME</code>       | <code>TIME</code> field  |
| <code>MYSQL_TYPE_DATETIME</code>   | <code>DATETIME</code> field  |
| <code>MYSQL_TYPE_YEAR</code>       | <code>YEAR</code> field  |
| <code>MYSQL_TYPE_STRING</code>     | <code>CHAR</code> or <code>BINARY</code> field   |
| <code>MYSQL_TYPE_VAR_STRING</code> | <code>VARCHAR</code> or <code>VARBINARY</code> field   |
| <code>MYSQL_TYPE_BLOB</code>       | <code>BLOB</code> or <code>TEXT</code> field (use <code>max_length</code> to determine the maximum length) |
| <code>MYSQL_TYPE_SET</code>        | <code>SET</code> field   |
| <code>MYSQL_TYPE_ENUM</code>       | <code>ENUM</code> field  |
| <code>MYSQL_TYPE_GEOMETRY</code>   | Spatial field  |
| <code>MYSQL_TYPE_NULL</code>       | <code>NULL</code> -type field  |

The `MYSQL_TYPE_TIME2`, `MYSQL_TYPE_DATETIME2`, and `MYSQL_TYPE_TIMESTAMP2` type codes are used only on the server side. Clients see the `MYSQL_TYPE_TIME`, `MYSQL_TYPE_DATETIME`, and `MYSQL_TYPE_TIMESTAMP` codes.

You can use the `IS_NUM()` macro to test whether a field has a numeric type. Pass the `type` value to `IS_NUM()` and it evaluates to `TRUE` if the field is numeric:

```
if (IS_NUM(field->type))
    printf("Field is numeric\n");
```

`ENUM` and `SET` values are returned as strings. For these, check that the `type` value is `MYSQL_TYPE_STRING` and that the `ENUM_FLAG` or `SET_FLAG` flag is set in the `flags` value.

## 26.8.6 C API Function Overview

The functions available in the C API are summarized here and described in greater detail in a later section. See [Section 26.8.7, “C API Function Descriptions”](#).

**Table 26.4 C API Function Names and Descriptions**

| Function                                    | Description  |
|---|--|
| <code>my_init()</code>                      | Initialize global variables, and thread handler in thread-safe programs  |
| <code>mysql_affected_rows()</code>          | Returns the number of rows changed/deleted/inserted by the last <code>UPDATE</code> , <code>DELETE</code> , or <code>INSERT</code> query |
| <code>mysql_autocommit()</code>             | Toggles autocommit mode on/off   |
| <code>mysql_change_user()</code>            | Changes user and database on an open connection  |
| <code>mysql_character_set_name()</code>     | Return default character set name for current connection   |
| <code>mysql_client_find_plugin()</code>     | Return pointer to plugin   |
| <code>mysql_client_register_plugin()</code> | Register a plugin  |
| <code>mysql_close()</code>                  | Closes a server connection   |
| <code>mysql_commit()</code>                 | Commits the transaction  |
| <code>mysql_connect()</code>                | Connects to a MySQL server (this function is deprecated; use <code>mysql_real_connect()</code> instead)                                  |
| <code>mysql_create_db()</code>              | Creates a database (this function is deprecated; use the SQL statement <code>CREATE DATABASE</code> instead)                             |
| <code>mysql_data_seek()</code>              | Seeks to an arbitrary row number in a query result set   |

| Function                                    | Description   |
|---|---|
| <code>mysql_debug()</code>                  | Does a <code>DEBUG_PUSH</code> with the given string  |
| <code>mysql_drop_db()</code>                | Drops a database (this function is deprecated; use the SQL statement <code>DROP DATABASE</code> instead)  |
| <code>mysql_dump_debug_info()</code>        | Makes the server write debug information to the log   |
| <code>mysql_eof()</code>                    | Determines whether the last row of a result set has been read (this function is deprecated; <code>mysql_errno()</code> or <code>mysql_error()</code> may be used instead) |
| <code>mysql_errno()</code>                  | Returns the error number for the most recently invoked MySQL function   |
| <code>mysql_error()</code>                  | Returns the error message for the most recently invoked MySQL function  |
| <code>mysql_escape_string()</code>          | Escapes special characters in a string for use in an SQL statement  |
| <code>mysql_fetch_field()</code>            | Returns the type of the next table field  |
| <code>mysql_fetch_field_direct()</code>     | Returns the type of a table field, given a field number   |
| <code>mysql_fetch_fields()</code>           | Returns an array of all field structures  |
| <code>mysql_fetch_lengths()</code>          | Returns the lengths of all columns in the current row   |
| <code>mysql_fetch_row()</code>              | Fetches the next row from the result set  |
| <code>mysql_field_count()</code>            | Returns the number of result columns for the most recent statement  |
| <code>mysql_field_seek()</code>             | Puts the column cursor on a specified column  |
| <code>mysql_field_tell()</code>             | Returns the position of the field cursor used for the last <code>mysql_fetch_field()</code>   |
| <code>mysql_free_result()</code>            | Frees memory used by a result set   |
| <code>mysql_get_character_set_name()</code> | Returns information about default character set   |
| <code>mysql_get_client_info()</code>        | Returns client version information as a string  |
| <code>mysql_get_client_version()</code>     | Returns client version information as an integer  |
| <code>mysql_get_host_info()</code>          | Returns a string describing the connection  |
| <code>mysql_get_option()</code>             | Returns the value of a <code>mysql_options()</code> option  |
| <code>mysql_get_proto_info()</code>         | Returns the protocol version used by the connection   |
| <code>mysql_get_server_info()</code>        | Returns the server version number   |
| <code>mysql_get_server_version()</code>     | Returns version number of server as an integer  |
| <code>mysql_get_ssl_cipher()</code>         | Return current SSL cipher   |
| <code>mysql_hex_string()</code>             | Encode string in hexadecimal format   |
| <code>mysql_info()</code>                   | Returns information about the most recently executed query  |
| <code>mysql_init()</code>                   | Gets or initializes a <code>MYSQL</code> structure  |
| <code>mysql_insert_id()</code>              | Returns the ID generated for an <code>AUTO_INCREMENT</code> column by the previous query  |
| <code>mysql_kill()</code>                   | Kills a given thread  |
| <code>mysql_library_end()</code>            | Finalize the MySQL C API library  |
| <code>mysql_library_init()</code>           | Initialize the MySQL C API library  |
| <code>mysql_list_dbs()</code>               | Returns database names matching a simple regular expression   |
| <code>mysql_list_fields()</code>            | Returns field names matching a simple regular expression  |
| <code>mysql_list_processes()</code>         | Returns a list of the current server threads  |
| <code>mysql_list_tables()</code>            | Returns table names matching a simple regular expression  |

| Function                                       | Description   |
|--|---|
| <code>mysql_load_plugin()</code>               | Load a plugin   |
| <code>mysql_load_plugin_v()</code>             | Load a plugin   |
| <code>mysql_more_results()</code>              | Checks whether any more results exist   |
| <code>mysql_next_result()</code>               | Returns/initiates the next result in multiple-result executions   |
| <code>mysql_num_fields()</code>                | Returns the number of columns in a result set   |
| <code>mysql_num_rows()</code>                  | Returns the number of rows in a result set  |
| <code>mysql_options()</code>                   | Sets connect options for <code>mysql_real_connect()</code>  |
| <code>mysql_options4()</code>                  | Sets connect options for <code>mysql_real_connect()</code>  |
| <code>mysql_ping()</code>                      | Checks whether the connection to the server is working, reconnecting as necessary   |
| <code>mysql_plugin_options()</code>            | Set a plugin option   |
| <code>mysql_query()</code>                     | Executes an SQL query specified as a null-terminated string   |
| <code>mysql_real_connect()</code>              | Connects to a MySQL server  |
| <code>mysql_real_escape_string()</code>        | Escapes special characters in a string for use in an SQL statement, taking into account the current character set of the connection                         |
| <code>mysql_real_escape_string_utf8()</code>   | Escapes special characters in a string for use in an SQL statement, taking into account the current character set of the connection and the quoting context |
| <code>mysql_real_query()</code>                | Executes an SQL query specified as a counted string   |
| <code>mysql_refresh()</code>                   | Flush or reset tables and caches  |
| <code>mysql_reload()</code>                    | Tells the server to reload the grant tables   |
| <code>mysql_reset_connection()</code>          | Reset connection to clear session state   |
| <code>mysql_rollback()</code>                  | Rolls back the transaction  |
| <code>mysql_row_seek()</code>                  | Seeks to a row offset in a result set, using value returned from <code>mysql_row_tell()</code>  |
| <code>mysql_row_tell()</code>                  | Returns the row cursor position   |
| <code>mysql_select_db()</code>                 | Selects a database  |
| <code>mysql_server_end()</code>                | Finalize the MySQL C API library  |
| <code>mysql_server_init()</code>               | Initialize the MySQL C API library  |
| <code>mysql_session_track_get_first()</code>   | Get first part of session state-change information  |
| <code>mysql_session_track_get_next()</code>    | Get next part of session state-change information   |
| <code>mysql_set_character_set()</code>         | Set default character set for current connection  |
| <code>mysql_set_local_infile_defaults()</code> | Set the <code>LOAD DATA LOCAL INFILE</code> handler callbacks to their default values   |
| <code>mysql_set_local_infile_handler()</code>  | Install application-specific <code>LOAD DATA LOCAL INFILE</code> handler callbacks  |
| <code>mysql_set_server_option()</code>         | Sets an option for the connection (like <code>multi-statements</code> )   |
| <code>mysql_sqlstate()</code>                  | Returns the SQLSTATE error code for the last error  |
| <code>mysql_shutdown()</code>                  | Shuts down the database server  |
| <code>mysql_ssl_set()</code>                   | Prepare to establish SSL connection to server   |
| <code>mysql_stat()</code>                      | Returns the server status as a string   |
| <code>mysql_store_result()</code>              | Retrieves a complete result set to the client   |
| <code>mysql_thread_end()</code>                | Finalize thread handler   |

| Function                           | Description  |
|------------------------------------|--|
| <code>mysql_thread_id()</code>     | Returns the current thread ID                            |
| <code>mysql_thread_init()</code>   | Initialize thread handler                                |
| <code>mysql_thread_safe()</code>   | Returns 1 if the clients are compiled as thread-safe     |
| <code>mysql_use_result()</code>    | Initiates a row-by-row result set retrieval              |
| <code>mysql_warning_count()</code> | Returns the warning count for the previous SQL statement |

Application programs should use this general outline for interacting with MySQL:

1. Initialize the MySQL library by calling `mysql_library_init()`. This function exists in both the `libmysqlclient` C client library and the `libmysqld` embedded server library, so it is used whether you build a regular client program by linking with the `-libmysqlclient` flag, or an embedded server application by linking with the `-libmysqld` flag.
2. Initialize a connection handler by calling `mysql_init()` and connect to the server by calling `mysql_real_connect()`.
3. Issue SQL statements and process their results. (The following discussion provides more information about how to do this.)
4. Close the connection to the MySQL server by calling `mysql_close()`.
5. End use of the MySQL library by calling `mysql_library_end()`.

The purpose of calling `mysql_library_init()` and `mysql_library_end()` is to provide proper initialization and finalization of the MySQL library. For applications that are linked with the client library, they provide improved memory management. If you do not call `mysql_library_end()`, a block of memory remains allocated. (This does not increase the amount of memory used by the application, but some memory leak detectors will complain about it.) For applications that are linked with the embedded server, these calls start and stop the server.

In a nonmulti-threaded environment, the call to `mysql_library_init()` may be omitted, because `mysql_init()` will invoke it automatically as necessary. However, `mysql_library_init()` is not thread-safe in a multi-threaded environment, and thus neither is `mysql_init()`, which calls `mysql_library_init()`. You must either call `mysql_library_init()` prior to spawning any threads, or else use a mutex to protect the call, whether you invoke `mysql_library_init()` or indirectly through `mysql_init()`. This should be done prior to any other client library call.

To connect to the server, call `mysql_init()` to initialize a connection handler, then call `mysql_real_connect()` with that handler (along with other information such as the host name, user name, and password). Upon connection, `mysql_real_connect()` sets the `reconnect` flag (part of the `MYSQL` structure) to a value of `1` in versions of the API older than 5.0.3, or `0` in newer versions. A value of `1` for this flag indicates that if a statement cannot be performed because of a lost connection, to try reconnecting to the server before giving up. You can use the `MYSQL_OPT_RECONNECT` option to `mysql_options()` to control reconnection behavior. When you are done with the connection, call `mysql_close()` to terminate it.

While a connection is active, the client may send SQL statements to the server using `mysql_query()` or `mysql_real_query()`. The difference between the two is that `mysql_query()` expects the query to be specified as a null-terminated string whereas `mysql_real_query()` expects a counted string. If the string contains binary data (which may include null bytes), you must use `mysql_real_query()`.

For each non-`SELECT` query (for example, `INSERT`, `UPDATE`, `DELETE`), you can find out how many rows were changed (affected) by calling `mysql_affected_rows()`.

For `SELECT` queries, you retrieve the selected rows as a result set. (Note that some statements are `SELECT`-like in that they return rows. These include `SHOW`, `DESCRIBE`, and `EXPLAIN`. Treat these statements the same way as `SELECT` statements.)

There are two ways for a client to process result sets. One way is to retrieve the entire result set all at once by calling `mysql_store_result()`. This function acquires from the server all the rows returned by the query and stores them in the client. The second way is for the client to initiate a row-by-row result set retrieval by calling `mysql_use_result()`. This function initializes the retrieval, but does not actually get any rows from the server.

In both cases, you access rows by calling `mysql_fetch_row()`. With `mysql_store_result()`, `mysql_fetch_row()` accesses rows that have previously been fetched from the server. With `mysql_use_result()`, `mysql_fetch_row()` actually retrieves the row from the server. Information about the size of the data in each row is available by calling `mysql_fetch_lengths()`.

After you are done with a result set, call `mysql_free_result()` to free the memory used for it.

The two retrieval mechanisms are complementary. Choose the approach that is most appropriate for each client application. In practice, clients tend to use `mysql_store_result()` more commonly.

An advantage of `mysql_store_result()` is that because the rows have all been fetched to the client, you not only can access rows sequentially, you can move back and forth in the result set using `mysql_data_seek()` or `mysql_row_seek()` to change the current row position within the result set. You can also find out how many rows there are by calling `mysql_num_rows()`. On the other hand, the memory requirements for `mysql_store_result()` may be very high for large result sets and you are more likely to encounter out-of-memory conditions.

An advantage of `mysql_use_result()` is that the client requires less memory for the result set because it maintains only one row at a time (and because there is less allocation overhead, `mysql_use_result()` can be faster). Disadvantages are that you must process each row quickly to avoid tying up the server, you do not have random access to rows within the result set (you can only access rows sequentially), and the number of rows in the result set is unknown until you have retrieved them all. Furthermore, you *must* retrieve all the rows even if you determine in mid-retrieval that you've found the information you were looking for.

The API makes it possible for clients to respond appropriately to statements (retrieving rows only as necessary) without knowing whether the statement is a `SELECT`. You can do this by calling `mysql_store_result()` after each `mysql_query()` (or `mysql_real_query()`). If the result set call succeeds, the statement was a `SELECT` and you can read the rows. If the result set call fails, call `mysql_field_count()` to determine whether a result was actually to be expected. If `mysql_field_count()` returns zero, the statement returned no data (indicating that it was an `INSERT`, `UPDATE`, `DELETE`, and so forth), and was not expected to return rows. If `mysql_field_count()` is nonzero, the statement should have returned rows, but did not. This indicates that the statement was a `SELECT` that failed. See the description for `mysql_field_count()` for an example of how this can be done.

Both `mysql_store_result()` and `mysql_use_result()` enable you to obtain information about the fields that make up the result set (the number of fields, their names and types, and so forth). You can access field information sequentially within the row by calling `mysql_fetch_field()` repeatedly, or by field number within the row by calling `mysql_fetch_field_direct()`. The current field cursor position may be changed by calling `mysql_field_seek()`. Setting the field cursor affects subsequent calls to `mysql_fetch_field()`. You can also get information for fields all at once by calling `mysql_fetch_fields()`.

For detecting and reporting errors, MySQL provides access to error information by means of the `mysql_errno()` and `mysql_error()` functions. These return the error code or error message for the most recently invoked function that can succeed or fail, enabling you to determine when an error occurred and what it was.

## 26.8.7 C API Function Descriptions

In the descriptions here, a parameter or return value of `NULL` means `NULL` in the sense of the C programming language, not a MySQL `NULL` value.

Functions that return a value generally return a pointer or an integer. Unless specified otherwise, functions returning a pointer return a non-`NULL` value to indicate success or a `NULL` value to indicate an error, and functions returning an integer return zero to indicate success or nonzero to indicate an error. Note that “nonzero” means just that. Unless the function description says otherwise, do not test against a value other than zero:

```
if (result)                /* correct */
    ... error ...

if (result < 0)             /* incorrect */
    ... error ...

if (result == -1)          /* incorrect */
    ... error ...
```

When a function returns an error, the **Errors** subsection of the function description lists the possible types of errors. You can find out which of these occurred by calling `mysql_errno()`. A string representation of the error may be obtained by calling `mysql_error()`.

### 26.8.7.1 `mysql_affected_rows()`

```
my_ulonglong mysql_affected_rows(MYSQL *mysql)
```

#### Description

`mysql_affected_rows()` may be called immediately after executing a statement with `mysql_query()` or `mysql_real_query()`. It returns the number of rows changed, deleted, or inserted by the last statement if it was an `UPDATE`, `DELETE`, or `INSERT`. For `SELECT` statements, `mysql_affected_rows()` works like `mysql_num_rows()`.

For `UPDATE` statements, the affected-rows value by default is the number of rows actually changed. If you specify the `CLIENT_FOUND_ROWS` flag to `mysql_real_connect()` when connecting to `mysqld`, the affected-rows value is the number of rows “found”; that is, matched by the `WHERE` clause.

For `REPLACE` statements, the affected-rows value is 2 if the new row replaced an old row, because in this case, one row was inserted after the duplicate was deleted.

For `INSERT ... ON DUPLICATE KEY UPDATE` statements, the affected-rows value per row is 1 if the row is inserted as a new row, 2 if an existing row is updated, and 0 if an existing row is set to its current values. If you specify the `CLIENT_FOUND_ROWS` flag, the affected-rows value is 1 (not 0) if an existing row is set to its current values.

Following a `CALL` statement for a stored procedure, `mysql_affected_rows()` returns the value that it would return for the last statement executed within the procedure, or 0 if that statement would return -1. Within the procedure, you can use `ROW_COUNT()` at the SQL level to obtain the affected-rows value for individual statements.

In MySQL 5.7, `mysql_affected_rows()` returns a meaningful value for a wider range of statements. For details, see the description for `ROW_COUNT()` in [Section 13.14, “Information Functions”](#).

#### Return Values

An integer greater than zero indicates the number of rows affected or retrieved. Zero indicates that no records were updated for an `UPDATE` statement, no rows matched the `WHERE` clause in the query or that no query has yet been executed. -1 indicates that the query returned an error or that, for a `SELECT` query, `mysql_affected_rows()` was called prior to calling `mysql_store_result()`.

Because `mysql_affected_rows()` returns an unsigned value, you can check for -1 by comparing the return value to `(my_ulonglong)-1` (or to `(my_ulonglong)~0`, which is equivalent).

#### Errors

None.

## Example

```
char *stmt = "UPDATE products SET cost=cost*1.25
              WHERE group=10";
mysql_query(&mysql,stmt);
printf("%ld products updated",
       (long) mysql_affected_rows(&mysql));
```

### 26.8.7.2 `mysql_autocommit()`

```
my_bool mysql_autocommit(MYSQL *mysql, my_bool mode)
```

#### Description

Sets autocommit mode on if `mode` is 1, off if `mode` is 0.

#### Return Values

Zero for success. Nonzero if an error occurred.

#### Errors

None.

### 26.8.7.3 `mysql_change_user()`

```
my_bool mysql_change_user(MYSQL *mysql, const char *user, const char
*password, const char *db)
```

#### Description

Changes the user and causes the database specified by `db` to become the default (current) database on the connection specified by `mysql`. In subsequent queries, this database is the default for table references that include no explicit database specifier.

`mysql_change_user()` fails if the connected user cannot be authenticated or does not have permission to use the database. In this case, the user and database are not changed.

Pass a `db` parameter of `NULL` if you do not want to have a default database.

This function resets the session state as if one had done a new connect and reauthenticated. (See [Section 26.8.16, “Controlling Automatic Reconnection Behavior”](#).) It always performs a `ROLLBACK` of any active transactions, closes and drops all temporary tables, and unlocks all locked tables. Session system variables are reset to the values of the corresponding global system variables. Prepared statements are released and `HANDLER` variables are closed. Locks acquired with `GET_LOCK()` are released. These effects occur even if the user did not change.

To reset the connection state in a more lightweight manner without changing the user, use `mysql_reset_connection()`.

#### Return Values

Zero for success. Nonzero if an error occurred.

#### Errors

The same that you can get from `mysql_real_connect()`, plus:

- `CR_COMMANDS_OUT_OF_SYNC`  
Commands were executed in an improper order.
- `CR_SERVER_GONE_ERROR`

The MySQL server has gone away.

- [CR\\_SERVER\\_LOST](#)

The connection to the server was lost during the query.

- [CR\\_UNKNOWN\\_ERROR](#)

An unknown error occurred.

- [ER\\_UNKNOWN\\_COM\\_ERROR](#)

The MySQL server does not implement this command (probably an old server).

- [ER\\_ACCESS\\_DENIED\\_ERROR](#)

The user or password was wrong.

- [ER\\_BAD\\_DB\\_ERROR](#)

The database did not exist.

- [ER\\_DBACCESS\\_DENIED\\_ERROR](#)

The user did not have access rights to the database.

- [ER\\_WRONG\\_DB\\_NAME](#)

The database name was too long.

### Example

```
if (mysql_change_user(&mysql, "user", "password", "new_database"))
{
    fprintf(stderr, "Failed to change user. Error: %s\n",
            mysql_error(&mysql));
}
```

#### 26.8.7.4 `mysql_character_set_name()`

```
const char *mysql_character_set_name(MYSQL *mysql)
```

### Description

Returns the default character set name for the current connection.

### Return Values

The default character set name

### Errors

None.

#### 26.8.7.5 `mysql_close()`

```
void mysql_close(MYSQL *mysql)
```

### Description

Closes a previously opened connection. `mysql_close()` also deallocates the connection handle pointed to by `mysql` if the handle was allocated automatically by `mysql_init()` or `mysql_connect()`.

**Return Values**

None.

**Errors**

None.

**26.8.7.6 mysql\_commit()**

```
my_bool mysql_commit(MYSQL *mysql)
```

**Description**

Commits the current transaction.

The action of this function is subject to the value of the `completion_type` system variable. In particular, if the value of `completion_type` is `RELEASE` (or 2), the server performs a release after terminating a transaction and closes the client connection. Call `mysql_close()` from the client program to close the connection from the client side.

**Return Values**

Zero for success. Nonzero if an error occurred.

**Errors**

None.

**26.8.7.7 mysql\_connect()**

```
MYSQL *mysql_connect(MYSQL *mysql, const char *host, const char *user, const char *passwd)
```

**Description**

This function is deprecated. Use `mysql_real_connect()` instead.

`mysql_connect()` attempts to establish a connection to a MySQL database engine running on `host`. `mysql_connect()` must complete successfully before you can execute any of the other API functions, with the exception of `mysql_get_client_info()`.

The meanings of the parameters are the same as for the corresponding parameters for `mysql_real_connect()` with the difference that the connection parameter may be `NULL`. In this case, the C API allocates memory for the connection structure automatically and frees it when you call `mysql_close()`. The disadvantage of this approach is that you cannot retrieve an error message if the connection fails. (To get error information from `mysql_errno()` or `mysql_error()`, you must provide a valid `MYSQL` pointer.)

**Return Values**

Same as for `mysql_real_connect()`.

**Errors**

Same as for `mysql_real_connect()`.

**26.8.7.8 mysql\_create\_db()**

```
int mysql_create_db(MYSQL *mysql, const char *db)
```

## Description

Creates the database named by the `db` parameter.

This function is deprecated. It is preferable to use `mysql_query()` to issue an SQL `CREATE DATABASE` statement instead.

## Return Values

Zero for success. Nonzero if an error occurred.

## Errors

- `CR_COMMANDS_OUT_OF_SYNC`

Commands were executed in an improper order.

- `CR_SERVER_GONE_ERROR`

The MySQL server has gone away.

- `CR_SERVER_LOST`

The connection to the server was lost during the query.

- `CR_UNKNOWN_ERROR`

An unknown error occurred.

## Example

```
if(mysql_create_db(&mysql, "my_database"))
{
    fprintf(stderr, "Failed to create new database.  Error: %s\n",
            mysql_error(&mysql));
}
```

### 26.8.7.9 `mysql_data_seek()`

```
void mysql_data_seek(MYSQL_RES *result, my_ulonglong offset)
```

## Description

Seeks to an arbitrary row in a query result set. The `offset` value is a row number. Specify a value in the range from 0 to `mysql_num_rows(result)-1`.

This function requires that the result set structure contains the entire result of the query, so `mysql_data_seek()` may be used only in conjunction with `mysql_store_result()`, not with `mysql_use_result()`.

## Return Values

None.

## Errors

None.

### 26.8.7.10 `mysql_debug()`

```
void mysql_debug(const char *debug)
```

## Description

Does a `DEBUG_PUSH` with the given string. `mysql_debug()` uses the Fred Fish debug library. To use this function, you must compile the client library to support debugging. See [Section 27.5.3, “The DEBUG Package”](#).

## Return Values

None.

## Errors

None.

## Example

The call shown here causes the client library to generate a trace file in `/tmp/client.trace` on the client machine:

```
mysql_debug("d:t:O,/tmp/client.trace");
```

### 26.8.7.11 `mysql_drop_db()`

```
int mysql_drop_db(MYSQL *mysql, const char *db)
```

## Description

Drops the database named by the `db` parameter.

This function is deprecated. It is preferable to use `mysql_query()` to issue an SQL `DROP DATABASE` statement instead.

## Return Values

Zero for success. Nonzero if an error occurred.

## Errors

- `CR_COMMANDS_OUT_OF_SYNC`  
Commands were executed in an improper order.
- `CR_SERVER_GONE_ERROR`  
The MySQL server has gone away.
- `CR_SERVER_LOST`  
The connection to the server was lost during the query.
- `CR_UNKNOWN_ERROR`  
An unknown error occurred.

## Example

```
if(mysql_drop_db(&mysql, "my_database"))  
    fprintf(stderr, "Failed to drop the database: Error: %s\n",  
            mysql_error(&mysql));
```

### 26.8.7.12 `mysql_dump_debug_info()`

```
int mysql_dump_debug_info(MYSQL *mysql)
```

## Description

Instructs the server to write debugging information to the error log. The connected user must have the `SUPER` privilege.

## Return Values

Zero for success. Nonzero if an error occurred.

## Errors

- `CR_COMMANDS_OUT_OF_SYNC`  
Commands were executed in an improper order.
- `CR_SERVER_GONE_ERROR`  
The MySQL server has gone away.
- `CR_SERVER_LOST`  
The connection to the server was lost during the query.
- `CR_UNKNOWN_ERROR`  
An unknown error occurred.

### 26.8.7.13 `mysql_eof()`

```
my_bool mysql_eof(MYSQL_RES *result)
```

## Description

This function is deprecated. `mysql_errno()` or `mysql_error()` may be used instead.

`mysql_eof()` determines whether the last row of a result set has been read.

If you acquire a result set from a successful call to `mysql_store_result()`, the client receives the entire set in one operation. In this case, a `NULL` return from `mysql_fetch_row()` always means the end of the result set has been reached and it is unnecessary to call `mysql_eof()`. When used with `mysql_store_result()`, `mysql_eof()` always returns true.

On the other hand, if you use `mysql_use_result()` to initiate a result set retrieval, the rows of the set are obtained from the server one by one as you call `mysql_fetch_row()` repeatedly. Because an error may occur on the connection during this process, a `NULL` return value from `mysql_fetch_row()` does not necessarily mean the end of the result set was reached normally. In this case, you can use `mysql_eof()` to determine what happened. `mysql_eof()` returns a nonzero value if the end of the result set was reached and zero if an error occurred.

Historically, `mysql_eof()` predates the standard MySQL error functions `mysql_errno()` and `mysql_error()`. Because those error functions provide the same information, their use is preferred over `mysql_eof()`, which is deprecated. (In fact, they provide more information, because `mysql_eof()` returns only a boolean value whereas the error functions indicate a reason for the error when one occurs.)

## Return Values

Zero for success. Nonzero if the end of the result set has been reached.

## Errors

None.

## Example

The following example shows how you might use `mysql_eof()`:

```
mysql_query(&mysql, "SELECT * FROM some_table");
result = mysql_use_result(&mysql);
while((row = mysql_fetch_row(result)))
{
    // do something with data
}
if(!mysql_eof(result)) // mysql_fetch_row() failed due to an error
{
    fprintf(stderr, "Error: %s\n", mysql_error(&mysql));
}
```

However, you can achieve the same effect with the standard MySQL error functions:

```
mysql_query(&mysql, "SELECT * FROM some_table");
result = mysql_use_result(&mysql);
while((row = mysql_fetch_row(result)))
{
    // do something with data
}
if(mysql_errno(&mysql)) // mysql_fetch_row() failed due to an error
{
    fprintf(stderr, "Error: %s\n", mysql_error(&mysql));
}
```

### 26.8.7.14 mysql\_errno()

```
unsigned int mysql_errno(MYSQL *mysql)
```

#### Description

For the connection specified by `mysql`, `mysql_errno()` returns the error code for the most recently invoked API function that can succeed or fail. A return value of zero means that no error occurred. Client error message numbers are listed in the MySQL `errmsg.h` header file. Server error message numbers are listed in `mysqld_error.h`. Errors also are listed at [Appendix B, Errors, Error Codes, and Common Problems](#).

#### Note

Some functions such as `mysql_fetch_row()` do not set `mysql_errno()` if they succeed. A rule of thumb is that all functions that have to ask the server for information reset `mysql_errno()` if they succeed.

MySQL-specific error numbers returned by `mysql_errno()` differ from `SQLSTATE` values returned by `mysql_sqlstate()`. For example, the `mysql` client program displays errors using the following format, where 1146 is the `mysql_errno()` value and '42S02' is the corresponding `mysql_sqlstate()` value:

```
shell> SELECT * FROM no_such_table;
ERROR 1146 (42S02): Table 'test.no_such_table' doesn't exist
```

#### Return Values

An error code value for the last `mysql_xxx()` call, if it failed. zero means no error occurred.

#### Errors

None.

### 26.8.7.15 mysql\_error()

```
const char *mysql_error(MYSQL *mysql)
```

## Description

For the connection specified by `mysql`, `mysql_error()` returns a null-terminated string containing the error message for the most recently invoked API function that failed. If a function did not fail, the return value of `mysql_error()` may be the previous error or an empty string to indicate no error.

A rule of thumb is that all functions that have to ask the server for information reset `mysql_error()` if they succeed.

For functions that reset `mysql_error()`, either of these two tests can be used to check for an error:

```
if(*mysql_error(&mysql))
{
    // an error occurred
}

if(mysql_error(&mysql)[0])
{
    // an error occurred
}
```

The language of the client error messages may be changed by recompiling the MySQL client library. You can choose error messages in several different languages. See [Section 11.2, “Setting the Error Message Language”](#).

## Return Values

A null-terminated character string that describes the error. An empty string if no error occurred.

## Errors

None.

### 26.8.7.16 `mysql_escape_string()`

#### Note

Do not use this function. `mysql_escape_string()` does not have arguments that enable it to respect the current character set or the quoting context. Use `mysql_real_escape_string_quote()` instead.

### 26.8.7.17 `mysql_fetch_field()`

```
MYSQL_FIELD *mysql_fetch_field(MYSQL_RES *result)
```

## Description

Returns the definition of one column of a result set as a `MYSQL_FIELD` structure. Call this function repeatedly to retrieve information about all columns in the result set. `mysql_fetch_field()` returns `NULL` when no more fields are left.

`mysql_fetch_field()` is reset to return information about the first field each time you execute a new `SELECT` query. The field returned by `mysql_fetch_field()` is also affected by calls to `mysql_field_seek()`.

If you've called `mysql_query()` to perform a `SELECT` on a table but have not called `mysql_store_result()`, MySQL returns the default blob length (8KB) if you call `mysql_fetch_field()` to ask for the length of a `BLOB` field. (The 8KB size is chosen because MySQL does not know the maximum length for the `BLOB`. This should be made configurable sometime.) Once you've retrieved the result set, `field->max_length` contains the length of the largest value for this column in the specific query.

## Return Values

The `MYSQL_FIELD` structure for the current column. `NULL` if no columns are left.

## Errors

None.

## Example

```
MYSQL_FIELD *field;

while((field = mysql_fetch_field(result)))
{
    printf("field name %s\n", field->name);
}
```

### 26.8.7.18 `mysql_fetch_field_direct()`

```
MYSQL_FIELD *mysql_fetch_field_direct(MYSQL_RES *result, unsigned int
fieldnr)
```

## Description

Given a field number `fieldnr` for a column within a result set, returns that column's field definition as a `MYSQL_FIELD` structure. Use this function to retrieve the definition for an arbitrary column. Specify a value for `fieldnr` in the range from 0 to `mysql_num_fields(result)-1`.

## Return Values

The `MYSQL_FIELD` structure for the specified column.

## Errors

None.

## Example

```
unsigned int num_fields;
unsigned int i;
MYSQL_FIELD *field;

num_fields = mysql_num_fields(result);
for(i = 0; i < num_fields; i++)
{
    field = mysql_fetch_field_direct(result, i);
    printf("Field %u is %s\n", i, field->name);
}
```

### 26.8.7.19 `mysql_fetch_fields()`

```
MYSQL_FIELD *mysql_fetch_fields(MYSQL_RES *result)
```

## Description

Returns an array of all `MYSQL_FIELD` structures for a result set. Each structure provides the field definition for one column of the result set.

## Return Values

An array of `MYSQL_FIELD` structures for all columns of a result set.

## Errors

None.

## Example

```
unsigned int num_fields;
unsigned int i;
MYSQL_FIELD *fields;

num_fields = mysql_num_fields(result);
fields = mysql_fetch_fields(result);
for(i = 0; i < num_fields; i++)
{
    printf("Field %u is %s\n", i, fields[i].name);
}
```

### 26.8.7.20 `mysql_fetch_lengths()`

```
unsigned long *mysql_fetch_lengths(MYSQL_RES *result)
```

## Description

Returns the lengths of the columns of the current row within a result set. If you plan to copy field values, this length information is also useful for optimization, because you can avoid calling `strlen()`. In addition, if the result set contains binary data, you **must** use this function to determine the size of the data, because `strlen()` returns incorrect results for any field containing null characters.

The length for empty columns and for columns containing `NULL` values is zero. To see how to distinguish these two cases, see the description for `mysql_fetch_row()`.

## Return Values

An array of unsigned long integers representing the size of each column (not including any terminating null bytes). `NULL` if an error occurred.

## Errors

`mysql_fetch_lengths()` is valid only for the current row of the result set. It returns `NULL` if you call it before calling `mysql_fetch_row()` or after retrieving all rows in the result.

## Example

```
MYSQL_ROW row;
unsigned long *lengths;
unsigned int num_fields;
unsigned int i;

row = mysql_fetch_row(result);
if (row)
{
    num_fields = mysql_num_fields(result);
    lengths = mysql_fetch_lengths(result);
    for(i = 0; i < num_fields; i++)
    {
        printf("Column %u is %lu bytes in length.\n",
            i, lengths[i]);
    }
}
```

### 26.8.7.21 `mysql_fetch_row()`

```
MYSQL_ROW mysql_fetch_row(MYSQL_RES *result)
```

## Description

Retrieves the next row of a result set. When used after `mysql_store_result()`, `mysql_fetch_row()` returns `NULL` when there are no more rows to retrieve. When used after `mysql_use_result()`, `mysql_fetch_row()` returns `NULL` when there are no more rows to retrieve or if an error occurred.

The number of values in the row is given by `mysql_num_fields(result)`. If `row` holds the return value from a call to `mysql_fetch_row()`, pointers to the values are accessed as `row[0]` to `row[mysql_num_fields(result)-1]`. `NULL` values in the row are indicated by `NULL` pointers.

The lengths of the field values in the row may be obtained by calling `mysql_fetch_lengths()`. Empty fields and fields containing `NULL` both have length 0; you can distinguish these by checking the pointer for the field value. If the pointer is `NULL`, the field is `NULL`; otherwise, the field is empty.

## Return Values

A `MYSQL_ROW` structure for the next row. `NULL` if there are no more rows to retrieve or if an error occurred.

## Errors

Errors are not reset between calls to `mysql_fetch_row()`

- `CR_SERVER_LOST`

The connection to the server was lost during the query.

- `CR_UNKNOWN_ERROR`

An unknown error occurred.

## Example

```
MYSQL_ROW row;
unsigned int num_fields;
unsigned int i;

num_fields = mysql_num_fields(result);
while ((row = mysql_fetch_row(result)))
{
    unsigned long *lengths;
    lengths = mysql_fetch_lengths(result);
    for(i = 0; i < num_fields; i++)
    {
        printf("[%.*s] ", (int) lengths[i],
            row[i] ? row[i] : "NULL");
    }
    printf("\n");
}
```

### 26.8.7.22 `mysql_field_count()`

```
unsigned int mysql_field_count(MYSQL *mysql)
```

## Description

Returns the number of columns for the most recent query on the connection.

The normal use of this function is when `mysql_store_result()` returned `NULL` (and thus you have no result set pointer). In this case, you can call `mysql_field_count()` to determine whether `mysql_store_result()` should have produced a nonempty result. This enables the client program

to take proper action without knowing whether the query was a [SELECT](#) (or [SELECT-like](#)) statement. The example shown here illustrates how this may be done.

See [Section 26.8.15.1, “Why mysql\\_store\\_result\(\) Sometimes Returns NULL After mysql\\_query\(\) Returns Success”](#).

## Return Values

An unsigned integer representing the number of columns in a result set.

## Errors

None.

## Example

```
MYSQL_RES *result;
unsigned int num_fields;
unsigned int num_rows;

if (mysql_query(&mysql, query_string))
{
    // error
}
else // query succeeded, process any data returned by it
{
    result = mysql_store_result(&mysql);
    if (result) // there are rows
    {
        num_fields = mysql_num_fields(result);
        // retrieve rows, then call mysql_free_result(result)
    }
    else // mysql_store_result() returned nothing; should it have?
    {
        if(mysql_field_count(&mysql) == 0)
        {
            // query does not return data
            // (it was not a SELECT)
            num_rows = mysql_affected_rows(&mysql);
        }
        else // mysql_store_result() should have returned data
        {
            fprintf(stderr, "Error: %s\n", mysql_error(&mysql));
        }
    }
}
```

An alternative is to replace the `mysql_field_count(&mysql)` call with `mysql_errno(&mysql)`. In this case, you are checking directly for an error from `mysql_store_result()` rather than inferring from the value of `mysql_field_count()` whether the statement was a [SELECT](#).

### 26.8.7.23 mysql\_field\_seek()

```
MYSQL_FIELD_OFFSET mysql_field_seek(MYSQL_RES *result, MYSQL_FIELD_OFFSET
offset)
```

## Description

Sets the field cursor to the given offset. The next call to `mysql_fetch_field()` retrieves the field definition of the column associated with that offset.

To seek to the beginning of a row, pass an `offset` value of zero.

## Return Values

The previous value of the field cursor.

## Errors

None.

### 26.8.7.24 `mysql_field_tell()`

```
MYSQL_FIELD_OFFSET mysql_field_tell(MYSQL_RES *result)
```

#### Description

Returns the position of the field cursor used for the last `mysql_fetch_field()`. This value can be used as an argument to `mysql_field_seek()`.

#### Return Values

The current offset of the field cursor.

## Errors

None.

### 26.8.7.25 `mysql_free_result()`

```
void mysql_free_result(MYSQL_RES *result)
```

#### Description

Frees the memory allocated for a result set by `mysql_store_result()`, `mysql_use_result()`, `mysql_list_dbs()`, and so forth. When you are done with a result set, you must free the memory it uses by calling `mysql_free_result()`.

Do not attempt to access a result set after freeing it.

#### Return Values

None.

## Errors

None.

### 26.8.7.26 `mysql_get_character_set_info()`

```
void mysql_get_character_set_info(MYSQL *mysql, MY_CHARSET_INFO *cs)
```

#### Description

This function provides information about the default client character set. The default character set may be changed with the `mysql_set_character_set()` function.

#### Example

This example shows the fields that are available in the `MY_CHARSET_INFO` structure:

```
if (!mysql_set_character_set(&mysql, "utf8"))
{
    MY_CHARSET_INFO cs;
    mysql_get_character_set_info(&mysql, &cs);
    printf("character set information:\n");
    printf("character set+collation number: %d\n", cs.number);
    printf("character set name: %s\n", cs.name);
    printf("collation name: %s\n", cs.csname);
}
```

```
printf("comment: %s\n", cs.comment);
printf("directory: %s\n", cs.dir);
printf("multi byte character min. length: %d\n", cs.mbminlen);
printf("multi byte character max. length: %d\n", cs.mbmaxlen);
}
```

### 26.8.7.27 `mysql_get_client_info()`

```
const char *mysql_get_client_info(void)
```

#### Description

Returns a string that represents the MySQL client library version; for example, "5.7.18".

As of MySQL 5.7.4 and Connector/C 6.1.3, the function value is the version of MySQL or Connector/C that provides the client library. Before MySQL 5.7.4 and Connector/C 6.1.3, the function value is the MySQL version. For Connector/C, this is the MySQL version on which the Connector/C distribution is based. For more information, see [Section 26.8.4.5, "C API Server and Client Library Versions"](#).

#### Return Values

A character string that represents the MySQL client library version.

#### Errors

None.

### 26.8.7.28 `mysql_get_client_version()`

```
unsigned long mysql_get_client_version(void)
```

#### Description

Returns an integer that represents the MySQL client library version. The value has the format `XYZZZ` where `X` is the major version, `YY` is the release level (or minor version), and `ZZ` is the sub-version within the release level:

```
major_version*10000 + release_level*100 + sub_version
```

For example, "5.7.18" is returned as 50718.

As of MySQL 5.7.4 and Connector/C 6.1.3, the function value is the version of MySQL or Connector/C that provides the client library. Before MySQL 5.7.4 and Connector/C 6.1.3, the function value is the MySQL version. For Connector/C, this is the MySQL version on which the Connector/C distribution is based. For more information, see [Section 26.8.4.5, "C API Server and Client Library Versions"](#).

#### Return Values

An integer that represents the MySQL client library version.

#### Errors

None.

### 26.8.7.29 `mysql_get_host_info()`

```
const char *mysql_get_host_info(MYSQL *mysql)
```

#### Description

Returns a string describing the type of connection in use, including the server host name.

## Return Values

A character string representing the server host name and the connection type.

## Errors

None.

### 26.8.7.30 `mysql_get_option()`

```
int mysql_get_option(MYSQL *mysql, enum mysql_option option, const void *arg)
```

## Description

Returns the current value of an option settable using `mysql_options()`. The value should be treated as read only. This function was added in MySQL 5.7.3.

The `option` argument is the option for which you want its value. The `arg` argument is a pointer to a variable in which to store the option value. `arg` must be a pointer to a variable of the type appropriate for the `option` argument. The following table shows which variable type to use for each `option` value.

| arg Type                              | Applicable option Values  |
|---------------------------------------|---|
| unsigned int                          | MYSQL_OPT_CONNECT_TIMEOUT, MYSQL_OPT_PROTOCOL, MYSQL_OPT_READ_TIMEOUT, MYSQL_OPT_RETRY_COUNT, MYSQL_OPT_WRITE_TIMEOUT   |
| unsigned long                         | MYSQL_OPT_MAX_ALLOWED_PACKET (added in MySQL 5.7.9), MYSQL_OPT_NET_BUFFER_LENGTH (added in MySQL 5.7.9)   |
| my_bool                               | MYSQL_ENABLE_CLEARTEXT_PLUGIN, MYSQL_OPT_CAN_HANDLE_EXPIRED_PASSWORDS, MYSQL_OPT_COMPRESS, MYSQL_OPT_GUESS_CONNECTION, MYSQL_OPT_LOCAL_INFILE, MYSQL_OPT_RECONNECT, MYSQL_OPT_SSL_ENFORCE, MYSQL_OPT_SSL_VERIFY_SERVER_CERT, MYSQL_OPT_USE_EMBEDDED_CONNECTION, MYSQL_OPT_USE_REMOTE_CONNECTION, MYSQL_REPORT_DATA_TRUNCATION, MYSQL_SECURE_AUTH  |
| const char *                          | MYSQL_DEFAULT_AUTH, MYSQL_OPT_BIND, MYSQL_OPT_SSL_CA, MYSQL_OPT_SSL_CAPATH, MYSQL_OPT_SSL_CERT, MYSQL_OPT_SSL_CIPHER, MYSQL_OPT_SSL_CRL, MYSQL_OPT_SSL_CRLPATH, MYSQL_OPT_SSL_KEY, MYSQL_OPT_SSL_MODE, MYSQL_OPT_TLS_VERSION, MYSQL_PLUGIN_DIR, MYSQL_READ_DEFAULT_FILE, MYSQL_READ_DEFAULT_GROUP, MYSQL_SERVER_PUBLIC_KEY, MYSQL_SET_CHARSET_DIR, MYSQL_SET_CHARSET_NAME, MYSQL_SET_CLIENT_IP, MYSQL_SHARED_MEMORY_BASE_NAME |
| cannot be queried (error is returned) | MYSQL_INIT_COMMAND, MYSQL_OPT_CONNECT_ATTR_DELETE, MYSQL_OPT_CONNECT_ATTR_RESET, MYSQL_OPT_NAMED_PIPE   |

## Return Values

Zero for success. Nonzero if an error occurred; this occurs for `option` values that cannot be queried.

## Example

The following call tests the `MYSQL_OPT_RECONNECT` option. After the call returns successfully, the value of `reconnect` is true or false to indicate whether automatic reconnection is enabled.

```
my_bool reconnect;  
  
if (mysql_get_option(mysql, MYSQL_OPT_RECONNECT, &reconnect))  
    fprintf(stderr, "mysql_get_options() failed\n");
```

### 26.8.7.31 `mysql_get_proto_info()`

```
unsigned int mysql_get_proto_info(MYSQL *mysql)
```

#### Description

Returns the protocol version used by current connection.

#### Return Values

An unsigned integer representing the protocol version used by the current connection.

#### Errors

None.

### 26.8.7.32 `mysql_get_server_info()`

```
const char *mysql_get_server_info(MYSQL *mysql)
```

#### Description

Returns a string that represents the MySQL server version; for example, "5.7.18".

#### Return Values

A character string that represents the MySQL server version.

#### Errors

None.

### 26.8.7.33 `mysql_get_server_version()`

```
unsigned long mysql_get_server_version(MYSQL *mysql)
```

#### Description

Returns an integer that represents the MySQL server version. The value has the format `XYZZ` where `X` is the major version, `YY` is the release level (or minor version), and `ZZ` is the sub-version within the release level:

```
major_version*10000 + release_level*100 + sub_version
```

For example, "5.7.18" is returned as 50718.

This function is useful in client programs for determining whether some version-specific server capability exists.

#### Return Values

An integer that represents the MySQL server version.

#### Errors

None.

### 26.8.7.34 `mysql_get_ssl_cipher()`

```
const char *mysql_get_ssl_cipher(MYSQL *mysql)
```

## Description

`mysql_get_ssl_cipher()` returns the encryption cipher used for the given connection to the server. `mysql` is the connection handler returned from `mysql_init()`.

## Return Values

A string naming the encryption cipher used for the connection, or `NULL` if no cipher is being used.

### 26.8.7.35 `mysql_hex_string()`

```
unsigned long mysql_hex_string(char *to, const char *from, unsigned long length)
```

## Description

This function creates a legal SQL string for use in an SQL statement. See [Section 10.1.1, “String Literals”](#).

The string in the `from` argument is encoded in hexadecimal format, with each character encoded as two hexadecimal digits. The result is placed in the `to` argument, followed by a terminating null byte.

The string pointed to by `from` must be `length` bytes long. You must allocate the `to` buffer to be at least `length*2+1` bytes long. When `mysql_hex_string()` returns, the contents of `to` is a null-terminated string. The return value is the length of the encoded string, not including the terminating null byte.

The return value can be placed into an SQL statement using either `X'value` or `0xvalue` format. However, the return value does not include the `X'...` or `0x`. The caller must supply whichever of those is desired.

## Example

```
char query[1000],*end;

end = strmov(query,"INSERT INTO test_table values(");
end = strmov(end,"X'");
end += mysql_hex_string(end,"What is this",12);
end = strmov(end,"',X'");
end += mysql_hex_string(end,"binary data: \0\r\n",16);
end = strmov(end,"')");

if (mysql_real_query(&mysql,query,(unsigned int) (end - query)))
{
    fprintf(stderr, "Failed to insert row, Error: %s\n",
            mysql_error(&mysql));
}
```

The `strmov()` function used in the example is included in the `libmysqlclient` library and works like `strcpy()` but returns a pointer to the terminating null of the first parameter.

## Return Values

The length of the encoded string that is placed into `to`, not including the terminating null character.

## Errors

None.

### 26.8.7.36 `mysql_info()`

```
const char *mysql_info(MYSQL *mysql)
```

## Description

Retrieves a string providing information about the most recently executed statement, but only for the statements listed here. For other statements, `mysql_info()` returns `NULL`. The format of the string varies depending on the type of statement, as described here. The numbers are illustrative only; the string contains values appropriate for the statement.

- `INSERT INTO ... SELECT ...`

String format: `Records: 100 Duplicates: 0 Warnings: 0`

- `INSERT INTO ... VALUES (...),(...),(...)...`

String format: `Records: 3 Duplicates: 0 Warnings: 0`

- `LOAD DATA INFILE ...`

String format: `Records: 1 Deleted: 0 Skipped: 0 Warnings: 0`

- `ALTER TABLE`

String format: `Records: 3 Duplicates: 0 Warnings: 0`

- `UPDATE`

String format: `Rows matched: 40 Changed: 40 Warnings: 0`

`mysql_info()` returns a non-`NULL` value for `INSERT ... VALUES` only for the multiple-row form of the statement (that is, only if multiple value lists are specified).

## Return Values

A character string representing additional information about the most recently executed statement. `NULL` if no information is available for the statement.

## Errors

None.

### 26.8.7.37 `mysql_init()`

```
MYSQL *mysql_init(MYSQL *mysql)
```

## Description

Allocates or initializes a `MYSQL` object suitable for `mysql_real_connect()`. If `mysql` is a `NULL` pointer, the function allocates, initializes, and returns a new object. Otherwise, the object is initialized and the address of the object is returned. If `mysql_init()` allocates a new object, it is freed when `mysql_close()` is called to close the connection.

In a nonmulti-threaded environment, `mysql_init()` invokes `mysql_library_init()` automatically as necessary. However, `mysql_library_init()` is not thread-safe in a multi-threaded environment, and thus neither is `mysql_init()`. Before calling `mysql_init()`, either call `mysql_library_init()` prior to spawning any threads, or use a mutex to protect the `mysql_library_init()` call. This should be done prior to any other client library call.

## Return Values

An initialized `MYSQL*` handle. `NULL` if there was insufficient memory to allocate a new object.

## Errors

In case of insufficient memory, `NULL` is returned.

### 26.8.7.38 `mysql_insert_id()`

```
my_ulonglong mysql_insert_id(MYSQL *mysql)
```

#### Description

Returns the value generated for an `AUTO_INCREMENT` column by the previous `INSERT` or `UPDATE` statement. Use this function after you have performed an `INSERT` statement into a table that contains an `AUTO_INCREMENT` field, or have used `INSERT` or `UPDATE` to set a column value with `LAST_INSERT_ID(expr)`.

The return value of `mysql_insert_id()` is always zero unless explicitly updated under one of the following conditions:

- `INSERT` statements that store a value into an `AUTO_INCREMENT` column. This is true whether the value is automatically generated by storing the special values `NULL` or `0` into the column, or is an explicit nonspecial value.
- In the case of a multiple-row `INSERT` statement, `mysql_insert_id()` returns the first automatically generated `AUTO_INCREMENT` value that was successfully inserted.

If no rows are successfully inserted, `mysql_insert_id()` returns 0.

- If an `INSERT ... SELECT` statement is executed, and no automatically generated value is successfully inserted, `mysql_insert_id()` returns the ID of the last inserted row.
- If an `INSERT ... SELECT` statement uses `LAST_INSERT_ID(expr)`, `mysql_insert_id()` returns `expr`.
- `INSERT` statements that generate an `AUTO_INCREMENT` value by inserting `LAST_INSERT_ID(expr)` into any column or by updating any column to `LAST_INSERT_ID(expr)`.
- If the previous statement returned an error, the value of `mysql_insert_id()` is undefined.

The return value of `mysql_insert_id()` can be simplified to the following sequence:

1. If there is an `AUTO_INCREMENT` column, and an automatically generated value was successfully inserted, return the first such value.
2. If `LAST_INSERT_ID(expr)` occurred in the statement, return `expr`, even if there was an `AUTO_INCREMENT` column in the affected table.
3. The return value varies depending on the statement used. When called after an `INSERT` statement:
  - If there is an `AUTO_INCREMENT` column in the table, and there were some explicit values for this column that were successfully inserted into the table, return the last of the explicit values.

When called after an `INSERT ... ON DUPLICATE KEY UPDATE` statement:

- If there is an `AUTO_INCREMENT` column in the table and there were some explicit successfully inserted values or some updated values, return the last of the inserted or updated values.

`mysql_insert_id()` returns 0 if the previous statement does not use an `AUTO_INCREMENT` value. If you need to save the value for later, be sure to call `mysql_insert_id()` immediately after the statement that generates the value.

The value of `mysql_insert_id()` is affected only by statements issued within the current client connection. It is not affected by statements issued by other clients.

The `LAST_INSERT_ID()` SQL function will contain the value of the first automatically generated value that was successfully inserted. `LAST_INSERT_ID()` is not reset between statements because the

value of that function is maintained in the server. Another difference from `mysql_insert_id()` is that `LAST_INSERT_ID()` is not updated if you set an `AUTO_INCREMENT` column to a specific nonspecial value. See [Section 13.14, “Information Functions”](#).

`mysql_insert_id()` returns 0 following a `CALL` statement for a stored procedure that generates an `AUTO_INCREMENT` value because in this case `mysql_insert_id()` applies to `CALL` and not the statement within the procedure. Within the procedure, you can use `LAST_INSERT_ID()` at the SQL level to obtain the `AUTO_INCREMENT` value.

The reason for the differences between `LAST_INSERT_ID()` and `mysql_insert_id()` is that `LAST_INSERT_ID()` is made easy to use in scripts while `mysql_insert_id()` tries to provide more exact information about what happens to the `AUTO_INCREMENT` column.

## Return Values

Described in the preceding discussion.

## Errors

- `ER_AUTO_INCREMENT_CONFLICT`

A user-specified `AUTO_INCREMENT` value in a multi `INSERT` statement falls within the range between the current `AUTO_INCREMENT` value and the sum of the current and number of rows affected values.

### 26.8.7.39 `mysql_kill()`

```
int mysql_kill(MYSQL *mysql, unsigned long pid)
```

## Description

### Note

As of MySQL 5.7.11, `mysql_kill()` is deprecated and will be removed in a future version of MySQL. Instead, use `mysql_query()` to execute a `KILL` statement.

Asks the server to kill the thread specified by `pid`.

This function is deprecated. It is preferable to use `mysql_query()` to issue an SQL `KILL` statement instead.

`mysql_kill()` cannot handle values larger than 32 bits, but to guard against killing the wrong thread returns an error in these cases:

- If given an ID larger than 32 bits, `mysql_kill()` returns a `CR_INVALID_CONN_HANDLE` error.
- After the server's internal thread ID counter reaches a value larger than 32 bits, it returns an `ER_DATA_OUT_OF_RANGE` error for any `mysql_kill()` invocation and `mysql_kill()` fails.

## Return Values

Zero for success. Nonzero if an error occurred.

## Errors

- `CR_COMMANDS_OUT_OF_SYNC`

Commands were executed in an improper order.

- `CR_INVALID_CONN_HANDLE`

The `pid` was larger than 32 bits.

- [CR\\_SERVER\\_GONE\\_ERROR](#)

The MySQL server has gone away.

- [CR\\_SERVER\\_LOST](#)

The connection to the server was lost during the query.

- [CR\\_UNKNOWN\\_ERROR](#)

An unknown error occurred.

- [ER\\_DATA\\_OUT\\_OF\\_RANGE](#)

The server's internal thread ID counter has reached a value larger than 32 bits, at which point it rejects all `mysql_kill()` invocations.

#### 26.8.7.40 `mysql_library_end()`

```
void mysql_library_end(void)
```

##### Description

This function finalizes the MySQL library. Call it when you are done using the library (for example, after disconnecting from the server). The action taken by the call depends on whether your application is linked to the MySQL client library or the MySQL embedded server library. For a client program linked against the `libmysqlclient` library by using the `-lmysqlclient` flag, `mysql_library_end()` performs some memory management to clean up. For an embedded server application linked against the `libmysqld` library by using the `-lmysqld` flag, `mysql_library_end()` shuts down the embedded server and then cleans up.

For usage information, see [Section 26.8.6, “C API Function Overview”](#), and [Section 26.8.7.41, “mysql\\_library\\_init\(\)”](#).

#### 26.8.7.41 `mysql_library_init()`

```
int mysql_library_init(int argc, char **argv, char **groups)
```

##### Description

Call this function to initialize the MySQL library before you call any other MySQL function, whether your application is a regular client program or uses the embedded server. If the application uses the embedded server, this call starts the server and initializes any subsystems (`mysys`, `InnoDB`, and so forth) that the server uses.

After your application is done using the MySQL library, call `mysql_library_end()` to clean up. See [Section 26.8.7.40, “mysql\\_library\\_end\(\)”](#).

The choice of whether the application operates as a regular client or uses the embedded server depends on whether you use the `libmysqlclient` or `libmysqld` library at link time to produce the final executable. For additional information, see [Section 26.8.6, “C API Function Overview”](#).

In a nonmulti-threaded environment, the call to `mysql_library_init()` may be omitted, because `mysql_init()` will invoke it automatically as necessary. However, `mysql_library_init()` is not thread-safe in a multi-threaded environment, and thus neither is `mysql_init()`, which calls `mysql_library_init()`. You must either call `mysql_library_init()` prior to spawning any threads, or else use a mutex to protect the call, whether you invoke `mysql_library_init()` or indirectly through `mysql_init()`. Do this prior to any other client library call.

The `argc` and `argv` arguments are analogous to the arguments to `main()`, and enable passing of options to the embedded server. For convenience, `argc` may be 0 (zero) if there are no command-

line arguments for the server. This is the usual case for applications intended for use only as regular (nonembedded) clients, and the call typically is written as `mysql_library_init(0, NULL, NULL)`.

```
#include <mysql.h>
#include <stdlib.h>

int main(void) {
    if (mysql_library_init(0, NULL, NULL)) {
        fprintf(stderr, "could not initialize MySQL library\n");
        exit(1);
    }

    /* Use any MySQL API functions here */

    mysql_library_end();

    return EXIT_SUCCESS;
}
```

When arguments are to be passed (`argc` is greater than 0), the first element of `argv` is ignored (it typically contains the program name). `mysql_library_init()` makes a copy of the arguments so it is safe to destroy `argv` or `groups` after the call.

For embedded applications, if you want to connect to an external server without starting the embedded server, you have to specify a negative value for `argc`.

The `groups` argument is an array of strings that indicate the groups in option files from which to read options. See [Section 5.2.6, “Using Option Files”](#). Make the final entry in the array `NULL`. For convenience, if the `groups` argument itself is `NULL`, the `[server]` and `[embedded]` groups are used by default.

```
#include <mysql.h>
#include <stdlib.h>

static char *server_args[] = {
    "this_program", /* this string is not used */
    "--datadir=",
    "--key_buffer_size=32M"
};

static char *server_groups[] = {
    "embedded",
    "server",
    "this_program_SERVER",
    (char *)NULL
};

int main(void) {
    if (mysql_library_init(sizeof(server_args) / sizeof(char *),
                          server_args, server_groups)) {
        fprintf(stderr, "could not initialize MySQL library\n");
        exit(1);
    }

    /* Use any MySQL API functions here */

    mysql_library_end();

    return EXIT_SUCCESS;
}
```

## Return Values

Zero for success. Nonzero if an error occurred.

### 26.8.7.42 `mysql_list_dbs()`

```
MYSQL_RES *mysql_list_dbs(MYSQL *mysql, const char *wild)
```

## Description

Returns a result set consisting of database names on the server that match the simple regular expression specified by the `wild` parameter. `wild` may contain the wildcard characters `%` or `_`, or may be a `NULL` pointer to match all databases. Calling `mysql_list_dbs()` is similar to executing the query `SHOW DATABASES [LIKE wild]`.

You must free the result set with `mysql_free_result()`.

## Return Values

A `MYSQL_RES` result set for success. `NULL` if an error occurred.

## Errors

- `CR_COMMANDS_OUT_OF_SYNC`

Commands were executed in an improper order.

- `CR_OUT_OF_MEMORY`

Out of memory.

- `CR_SERVER_GONE_ERROR`

The MySQL server has gone away.

- `CR_SERVER_LOST`

The connection to the server was lost during the query.

- `CR_UNKNOWN_ERROR`

An unknown error occurred.

### 26.8.7.43 `mysql_list_fields()`

```
MYSQL_RES *mysql_list_fields(MYSQL *mysql, const char *table, const char *wild)
```

## Description

### Note

As of MySQL 5.7.11, `mysql_list_fields()` is deprecated and will be removed in a future version of MySQL. Instead, use `mysql_query()` to execute a `SHOW COLUMNS` statement.

Returns an empty result set for which the metadata provides information about the columns in the given table that match the simple regular expression specified by the `wild` parameter. `wild` may contain the wildcard characters `%` or `_`, or may be a `NULL` pointer to match all fields. Calling `mysql_list_fields()` is similar to executing the query `SHOW COLUMNS FROM tbl_name [LIKE wild]`.

It is preferable to use `SHOW COLUMNS FROM tbl_name` instead of `mysql_list_fields()`.

You must free the result set with `mysql_free_result()`.

## Return Values

A `MYSQL_RES` result set for success. `NULL` if an error occurred.

## Errors

- [CR\\_COMMANDS\\_OUT\\_OF\\_SYNC](#)

Commands were executed in an improper order.

- [CR\\_SERVER\\_GONE\\_ERROR](#)

The MySQL server has gone away.

- [CR\\_SERVER\\_LOST](#)

The connection to the server was lost during the query.

- [CR\\_UNKNOWN\\_ERROR](#)

An unknown error occurred.

## Example

```
int i;
MYSQL_RES *tbl_cols = mysql_list_fields(mysql, "mytbl", "f%");

unsigned int field_cnt = mysql_num_fields(tbl_cols);
printf("Number of columns: %d\n", field_cnt);

for (i=0; i < field_cnt; ++i)
{
    /* col describes i-th column of the table */
    MYSQL_FIELD *col = mysql_fetch_field_direct(tbl_cols, i);
    printf("Column %d: %s\n", i, col->name);
}
mysql_free_result(tbl_cols);
```

### 26.8.7.44 `mysql_list_processes()`

```
MYSQL_RES *mysql_list_processes(MYSQL *mysql)
```

#### Description

##### Note

As of MySQL 5.7.11, `mysql_list_processes()` is deprecated and will be removed in a future version of MySQL. Instead, use `mysql_query()` to execute a [SHOW PROCESSLIST](#) statement.

Returns a result set describing the current server threads. This is the same kind of information as that reported by `mysqladmin processlist` or a [SHOW PROCESSLIST](#) query.

You must free the result set with `mysql_free_result()`.

#### Return Values

A [MYSQL\\_RES](#) result set for success. [NULL](#) if an error occurred.

## Errors

- [CR\\_COMMANDS\\_OUT\\_OF\\_SYNC](#)

Commands were executed in an improper order.

- [CR\\_SERVER\\_GONE\\_ERROR](#)

The MySQL server has gone away.

- `CR_SERVER_LOST`

The connection to the server was lost during the query.

- `CR_UNKNOWN_ERROR`

An unknown error occurred.

#### 26.8.7.45 `mysql_list_tables()`

```
MYSQL_RES *mysql_list_tables(MYSQL *mysql, const char *wild)
```

##### Description

Returns a result set consisting of table names in the current database that match the simple regular expression specified by the `wild` parameter. `wild` may contain the wildcard characters `%` or `_`, or may be a `NULL` pointer to match all tables. Calling `mysql_list_tables()` is similar to executing the query `SHOW TABLES [LIKE wild]`.

You must free the result set with `mysql_free_result()`.

##### Return Values

A `MYSQL_RES` result set for success. `NULL` if an error occurred.

##### Errors

- `CR_COMMANDS_OUT_OF_SYNC`

Commands were executed in an improper order.

- `CR_SERVER_GONE_ERROR`

The MySQL server has gone away.

- `CR_SERVER_LOST`

The connection to the server was lost during the query.

- `CR_UNKNOWN_ERROR`

An unknown error occurred.

#### 26.8.7.46 `mysql_more_results()`

```
my_bool mysql_more_results(MYSQL *mysql)
```

##### Description

This function is used when you execute multiple statements specified as a single statement string, or when you execute `CALL` statements, which can return multiple result sets.

`mysql_more_results()` true if more results exist from the currently executed statement, in which case the application must call `mysql_next_result()` to fetch the results.

##### Return Values

`TRUE` (1) if more results exist. `FALSE` (0) if no more results exist.

In most cases, you can call `mysql_next_result()` instead to test whether more results exist and initiate retrieval if so.

See [Section 26.8.17, “C API Support for Multiple Statement Execution”](#), and [Section 26.8.7.47, “mysql\\_next\\_result\(\)”](#).

## Errors

None.

### 26.8.7.47 mysql\_next\_result()

```
int mysql_next_result(MYSQL *mysql)
```

#### Description

This function is used when you execute multiple statements specified as a single statement string, or when you use `CALL` statements to execute stored procedures, which can return multiple result sets.

`mysql_next_result()` reads the next statement result and returns a status to indicate whether more results exist. If `mysql_next_result()` returns an error, there are no more results.

Before each call to `mysql_next_result()`, you must call `mysql_free_result()` for the current statement if it is a statement that returned a result set (rather than just a result status).

After calling `mysql_next_result()` the state of the connection is as if you had called `mysql_real_query()` or `mysql_query()` for the next statement. This means that you can call `mysql_store_result()`, `mysql_warning_count()`, `mysql_affected_rows()`, and so forth.

If your program uses `CALL` statements to execute stored procedures, the `CLIENT_MULTI_RESULTS` flag must be enabled. This is because each `CALL` returns a result to indicate the call status, in addition to any result sets that might be returned by statements executed within the procedure. Because `CALL` can return multiple results, process them using a loop that calls `mysql_next_result()` to determine whether there are more results.

`CLIENT_MULTI_RESULTS` can be enabled when you call `mysql_real_connect()`, either explicitly by passing the `CLIENT_MULTI_RESULTS` flag itself, or implicitly by passing `CLIENT_MULTI_STATEMENTS` (which also enables `CLIENT_MULTI_RESULTS`). In MySQL 5.7, `CLIENT_MULTI_RESULTS` is enabled by default.

It is also possible to test whether there are more results by calling `mysql_more_results()`. However, this function does not change the connection state, so if it returns true, you must still call `mysql_next_result()` to advance to the next result.

For an example that shows how to use `mysql_next_result()`, see [Section 26.8.17, “C API Support for Multiple Statement Execution”](#).

## Return Values

| Return Value | Description                              |
|--------------|--|
| 0            | Successful and there are more results    |
| -1           | Successful and there are no more results |
| >0           | An error occurred                        |

## Errors

- `CR_COMMANDS_OUT_OF_SYNC`

Commands were executed in an improper order. For example, if you did not call `mysql_use_result()` for a previous result set.

- `CR_SERVER_GONE_ERROR`

The MySQL server has gone away.

- `CR_SERVER_LOST`

The connection to the server was lost during the query.

- `CR_UNKNOWN_ERROR`

An unknown error occurred.

### 26.8.7.48 `mysql_num_fields()`

```
unsigned int mysql_num_fields(MYSQL_RES *result)
```

To pass a `MYSQL*` argument instead, use `unsigned int mysql_field_count(MYSQL *mysql)`.

#### Description

Returns the number of columns in a result set.

You can get the number of columns either from a pointer to a result set or to a connection handle. You would use the connection handle if `mysql_store_result()` or `mysql_use_result()` returned `NULL` (and thus you have no result set pointer). In this case, you can call `mysql_field_count()` to determine whether `mysql_store_result()` should have produced a nonempty result. This enables the client program to take proper action without knowing whether the query was a `SELECT` (or `SELECT-like`) statement. The example shown here illustrates how this may be done.

See [Section 26.8.15.1, “Why `mysql\_store\_result\(\)` Sometimes Returns `NULL` After `mysql\_query\(\)` Returns Success”](#).

#### Return Values

An unsigned integer representing the number of columns in a result set.

#### Errors

None.

#### Example

```
MYSQL_RES *result;
unsigned int num_fields;
unsigned int num_rows;

if (mysql_query(&mysql, query_string))
{
    // error
}
else // query succeeded, process any data returned by it
{
    result = mysql_store_result(&mysql);
    if (result) // there are rows
    {
        num_fields = mysql_num_fields(result);
        // retrieve rows, then call mysql_free_result(result)
    }
    else // mysql_store_result() returned nothing; should it have?
    {
        if (mysql_errno(&mysql))
        {
            fprintf(stderr, "Error: %s\n", mysql_error(&mysql));
        }
        else if (mysql_field_count(&mysql) == 0)
        {
            // ...
        }
    }
}
```

```
        // query does not return data
        // (it was not a SELECT)
        num_rows = mysql_affected_rows(&mysql);
    }
}
```

An alternative (if you know that your query should have returned a result set) is to replace the `mysql_errno(&mysql)` call with a check whether `mysql_field_count(&mysql)` returns 0. This happens only if something went wrong.

### 26.8.7.49 `mysql_num_rows()`

```
my_ulonglong mysql_num_rows(MYSQL_RES *result)
```

#### Description

Returns the number of rows in the result set.

The use of `mysql_num_rows()` depends on whether you use `mysql_store_result()` or `mysql_use_result()` to return the result set. If you use `mysql_store_result()`, `mysql_num_rows()` may be called immediately. If you use `mysql_use_result()`, `mysql_num_rows()` does not return the correct value until all the rows in the result set have been retrieved.

`mysql_num_rows()` is intended for use with statements that return a result set, such as `SELECT`. For statements such as `INSERT`, `UPDATE`, or `DELETE`, the number of affected rows can be obtained with `mysql_affected_rows()`.

#### Return Values

The number of rows in the result set.

#### Errors

None.

### 26.8.7.50 `mysql_options()`

```
int mysql_options(MYSQL *mysql, enum mysql_option option, const void *arg)
```

#### Description

Can be used to set extra connect options and affect behavior for a connection. This function may be called multiple times to set several options. (To retrieve option values, use `mysql_get_option()`.)

Call `mysql_options()` after `mysql_init()` and before `mysql_connect()` or `mysql_real_connect()`.

The `option` argument is the option that you want to set; the `arg` argument is the value for the option. If the option is an integer, specify a pointer to the value of the integer as the `arg` argument.

The following list describes the possible options, their effect, and how `arg` is used for each option. For option descriptions that indicate `arg` is unused, its value is irrelevant; it is conventional to pass 0. Several of the options apply only when the application is linked against the `libmysqld` embedded server library and are unused for applications linked against the `libmysqlclient` client library.

- `MYSQL_DEFAULT_AUTH` (argument type: `char *`)

The name of the authentication plugin to use.

- `MYSQL_ENABLE_CLEARTEXT_PLUGIN` (argument type: `my_bool *`)

Enable the `mysql_clear_password` cleartext authentication plugin. (See [Section 7.5.1.8](#), “The Cleartext Client-Side Authentication Plugin”.)

- `MYSQL_INIT_COMMAND` (argument type: `char *`)

SQL statement to execute when connecting to the MySQL server. Automatically re-executed if reconnection occurs.

- `MYSQL_OPT_BIND` (argument: `char *`)

The network interface from which to connect to the server. This is used when the client host has multiple network interfaces. The argument is a host name or IP address (specified as a string).

- `MYSQL_OPT_CAN_HANDLE_EXPIRED_PASSWORDS` (argument type: `my_bool *`)

Indicate whether the client can handle expired passwords. For more information, see [Section 7.3.7](#), “Password Expiration and Sandbox Mode”.

- `MYSQL_OPT_COMPRESS` (argument: not used)

Use the compressed client/server protocol.

- `MYSQL_OPT_CONNECT_ATTR_DELETE` (argument type: `char *`)

Given a key name, this option deletes a key/value pair from the current set of connection attributes to pass to the server at connect time. The argument is a pointer to a null-terminated string naming the key. Comparison of the key name with existing keys is case sensitive.

See also the description for the `MYSQL_OPT_CONNECT_ATTR_RESET` option, as well as the description for the `MYSQL_OPT_CONNECT_ATTR_ADD` option in the description of the `mysql_options4()` function. That function description also includes a usage example.

The Performance Schema exposes connection attributes through the `session_connect_attrs` and `session_account_connect_attrs` tables. See [Section 24.10.9](#), “Performance Schema Connection Attribute Tables”.

- `MYSQL_OPT_CONNECT_ATTR_RESET` (argument not used)

This option resets (clears) the current set of connection attributes to pass to the server at connect time.

See also the description for the `MYSQL_OPT_CONNECT_ATTR_DELETE` option, as well as the description for the `MYSQL_OPT_CONNECT_ATTR_ADD` option in the description of the `mysql_options4()` function. That function description also includes a usage example.

The Performance Schema exposes connection attributes through the `session_connect_attrs` and `session_account_connect_attrs` tables. See [Section 24.10.9](#), “Performance Schema Connection Attribute Tables”.

- `MYSQL_OPT_CONNECT_TIMEOUT` (argument type: `unsigned int *`)

The connect timeout in seconds.

- `MYSQL_OPT_GUESS_CONNECTION` (argument: not used)

For an application linked against the `libmysqld` embedded server library, this enables the library to guess whether to use the embedded server or a remote server. “Guess” means that if the host name is set and is not `localhost`, it uses a remote server. This behavior is the default. `MYSQL_OPT_USE_EMBEDDED_CONNECTION` and `MYSQL_OPT_USE_REMOTE_CONNECTION` can be used to override it. This option is ignored for applications linked against the `libmysqlclient` client library.

- `MYSQL_OPT_LOCAL_INFILE` (argument type: optional pointer to `unsigned int`)

If no pointer is given or if pointer points to an `unsigned int` that has a nonzero value, the `LOAD DATA LOCAL INFILE` statement is enabled.

- `MYSQL_OPT_MAX_ALLOWED_PACKET` (argument: `unsigned long *`)

This option sets the `max_allowed_packet` system variable. If the `mysql` argument is non-`NULL`, the call sets the session system variable value for that session. If `mysql` is `NULL`, the call sets the global system variable value. This option was added in MySQL 5.7.9.

- `MYSQL_OPT_NAMED_PIPE` (argument: not used)

Use a named pipe to connect to the MySQL server on Windows, if the server permits named-pipe connections.

- `MYSQL_OPT_NET_BUFFER_LENGTH` (argument: `unsigned long *`)

This option sets the `net_buffer_length` system variable. If the `mysql` argument is non-`NULL`, the call sets the session system variable value for that session. If `mysql` is `NULL`, the call sets the global system variable value. This option was added in MySQL 5.7.9.

- `MYSQL_OPT_PROTOCOL` (argument type: `unsigned int *`)

Type of protocol to use. Specify one of the enum values of `mysql_protocol_type` defined in `mysql.h`.

- `MYSQL_OPT_READ_TIMEOUT` (argument type: `unsigned int *`)

The timeout in seconds for each attempt to read from the server. There are retries if necessary, so the total effective timeout value is three times the option value. You can set the value so that a lost connection can be detected earlier than the TCP/IP `Close_Wait_Timeout` value of 10 minutes.

- `MYSQL_OPT_RECONNECT` (argument type: `my_bool *`)

Enable or disable automatic reconnection to the server if the connection is found to have been lost. Reconnect is off by default; this option provides a way to set reconnection behavior explicitly.

- `MYSQL_OPT_RETRY_COUNT` (argument type: `unsigned int *`)

The retry count for I/O-related system calls that are interrupted while connecting to the server or communicating with it. The default value is 1 (1 retry if the initial call is interrupted for 2 tries total).

This option can be used only by clients that link against a C client library compiled with MySQL Cluster support. It is available as of MySQL Cluster 7.5.1.

- `MYSQL_OPT_SSL_CA` (argument type: `char *`)

The path to a file in PEM format that contains a list of trusted SSL CAs.

- `MYSQL_OPT_SSL_CAPATH` (argument type: `char *`)

The path to a directory that contains trusted SSL CA certificates in PEM format.

- `MYSQL_OPT_SSL_CERT` (argument type: `char *`)

The name of an SSL certificate file in PEM format to use for establishing a secure connection.

- `MYSQL_OPT_SSL_CIPHER` (argument type: `char *`)

A list of permissible ciphers to use for SSL encryption.

- `MYSQL_OPT_SSL_CRL` (argument type: `char *`)

The path to a file containing certificate revocation lists in PEM format.

- `MYSQL_OPT_SSL_CRLPATH` (argument type: `char *`)

The path to a directory that contains files containing certificate revocation lists in PEM format.

- `MYSQL_OPT_SSL_ENFORCE` (argument type: `my_bool *`)

Whether to require the connection to use SSL. If enabled and an encrypted connection cannot be established, the connection attempt fails. This option was added in MySQL 5.7.3.

This option is deprecated as of MySQL 5.7.11 and is removed in MySQL 8.0. It is preferable to use `MYSQL_OPT_SSL_MODE` with a value of `SSL_MODE_REQUIRED`.

- `MYSQL_OPT_SSL_KEY` (argument type: `char *`)

The name of an SSL key file in PEM format to use for establishing a secure connection.

- `MYSQL_OPT_SSL_MODE` (argument type: `unsigned int *`)

The security state to use for the connection to the server: `SSL_MODE_DISABLED`, `SSL_MODE_PREFERRED`, `SSL_MODE_REQUIRED`, `SSL_MODE_VERIFY_CA`, `SSL_MODE_VERIFY_IDENTITY`. The default is `SSL_MODE_PREFERRED`. These modes are the permitted values of the `mysql_ssl_mode` enumeration defined in `mysql.h`. For more information about the security modes, see the description of `--ssl-mode` in [Section 7.4.5, “Command Options for Secure Connections”](#).

This option was added in MySQL 5.7.11.

- `MYSQL_OPT_SSL_VERIFY_SERVER_CERT` (argument type: `my_bool *`)

Enable or disable verification of the server's Common Name value in its certificate against the host name used when connecting to the server. The connection is rejected if there is a mismatch. For encrypted connections, this feature can be used to prevent man-in-the-middle attacks. Verification is disabled by default.

This option is deprecated as of MySQL 5.7.11 and is removed in MySQL 8.0. It is preferable to use `MYSQL_OPT_SSL_MODE` with a value of `SSL_MODE_VERIFY_IDENTITY`.

- `MYSQL_OPT_TLS_VERSION` (argument type: `char *`)

The protocols permitted by the client for encrypted connections. The value is a comma-separated list containing one or more protocol names. The protocols that can be named for this option depend on the SSL library used to compile MySQL. For details, see [Section 7.4.3, “Secure Connection Protocols and Ciphers”](#).

This option was added in MySQL 5.7.10.

- `MYSQL_OPT_USE_EMBEDDED_CONNECTION` (argument: not used)

For an application linked against the `libmysqld` embedded server library, this forces the use of the embedded server for the connection. This option is ignored for applications linked against the `libmysqlclient` client library.

- `MYSQL_OPT_USE_REMOTE_CONNECTION` (argument: not used)

For an application linked against the `libmysqld` embedded server library, this forces the use of a remote server for the connection. This option is ignored for applications linked against the `libmysqlclient` client library.

- `MYSQL_OPT_USE_RESULT` (argument: not used)

This option is unused.

- `MYSQL_OPT_WRITE_TIMEOUT` (argument type: `unsigned int *`)

The timeout in seconds for each attempt to write to the server. There is a retry if necessary, so the total effective timeout value is two times the option value.

- `MYSQL_PLUGIN_DIR` (argument type: `char *`)

The directory in which to look for client plugins.

- `MYSQL_READ_DEFAULT_FILE` (argument type: `char *`)

Read options from the named option file instead of from `my.cnf`.

- `MYSQL_READ_DEFAULT_GROUP` (argument type: `char *`)

Read options from the named group from `my.cnf` or the file specified with `MYSQL_READ_DEFAULT_FILE`.

- `MYSQL_REPORT_DATA_TRUNCATION` (argument type: `my_bool *`)

Enable or disable reporting of data truncation errors for prepared statements using the `error` member of `MYSQL_BIND` structures. (Default: enabled.)

- `MYSQL_SECURE_AUTH` (argument type: `my_bool *`)

Whether to connect to a server that does not support the password hashing used in MySQL 4.1.1 and later. This option is enabled by default.

- `MYSQL_SERVER_PUBLIC_KEY` (argument type: `char *`)

The path name to a file containing the server RSA public key. The file must be in PEM format. The public key is used for RSA encryption of the client password for connections to the server made using accounts that authenticate with the `sha256_password` plugin. This option is ignored for client accounts that do not authenticate with that plugin. It is also ignored if password encryption is not needed, as is the case when the client connects to the server using an SSL connection.

The server sends the public key to the client as needed, so it is not necessary to use this option for RSA password encryption to occur. It is more efficient to do so because then the server need not send the key.

For additional discussion regarding use of the `sha256_password` plugin, including how to get the RSA public key, see [Section 7.5.1.4, “The SHA-256 Authentication Plugin”](#).

- `MYSQL_SET_CHARSET_DIR` (argument type: `char *`)

The path name to the directory that contains character set definition files.

- `MYSQL_SET_CHARSET_NAME` (argument type: `char *`)

The name of the character set to use as the default character set. The argument can be `MYSQL_AUTODETECT_CHARSET_NAME` to cause the character set to be autodetected based on the operating system setting (see [Section 11.1.4, “Connection Character Sets and Collations”](#)).

- `MYSQL_SET_CLIENT_IP` (argument type: `char *`)

For an application linked against the `libmysqld` embedded server library (when `libmysqld` is compiled with authentication support), this means that the user is considered to have connected from the specified IP address (specified as a string) for authentication purposes. This option is ignored for applications linked against the `libmysqlclient` client library.

- `MYSQL_SHARED_MEMORY_BASE_NAME` (argument type: `char *`)

The name of the shared-memory object for communication to the server on Windows, if the server supports shared-memory connections. Specify the same value as the `--shared-memory-base-name` option used for the `mysqld` server you want to connect to.

The `client` group is always read if you use `MYSQL_READ_DEFAULT_FILE` or `MYSQL_READ_DEFAULT_GROUP`.

The specified group in the option file may contain the following options.

| Option  | Description  |
|---|--|
| <code>character-sets-dir=dir_name</code>        | The directory where character sets are installed.  |
| <code>compress</code>                           | Use the compressed client/server protocol.   |
| <code>connect-timeout=seconds</code>            | The connect timeout in seconds. On Linux this timeout is also used for waiting for the first answer from the server.   |
| <code>database=db_name</code>                   | Connect to this database if no database was specified in the connect command.  |
| <code>debug</code>                              | Debug options.   |
| <code>default-character-set=charset_name</code> | The default character set to use.  |
| <code>disable-local-infile</code>               | Disable use of <code>LOAD DATA LOCAL INFILE</code> .   |
| <code>enable-cleartext-plugin</code>            | Enable the <code>mysql_clear_password</code> cleartext authentication plugin.  |
| <code>host=host_name</code>                     | Default host name.   |
| <code>init-command=stmt</code>                  | Statement to execute when connecting to MySQL server. Automatically re-executed if reconnection occurs.  |
| <code>interactive-timeout=seconds</code>        | Same as specifying <code>CLIENT_INTERACTIVE</code> to <code>mysql_real_connect()</code> . See <a href="#">Section 26.8.7.54</a> , “ <code>mysql_real_connect()</code> ”. |
| <code>local-infile[={0 1}]</code>               | If no argument or nonzero argument, enable use of <code>LOAD DATA LOCAL</code> ; otherwise disable.  |
| <code>max_allowed_packet=bytes</code>           | Maximum size of packet that client can read from server.   |
| <code>multi-queries, multi-results</code>       | Enable multiple result sets from multiple-statement executions or stored procedures.   |
| <code>multi-statements</code>                   | Enable the client to send multiple statements in a single string (separated by <code>;</code> characters).   |
| <code>password=password</code>                  | Default password.  |
| <code>pipe</code>                               | Use named pipes to connect to a MySQL server on Windows.   |
| <code>port=port_num</code>                      | Default port number.   |
| <code>protocol={TCP SOCKET PIPE MEMORY}</code>  | The protocol to use when connecting to the server.   |
| <code>return-found-rows</code>                  | Tell <code>mysql_info()</code> to return found rows instead of updated rows when using <code>UPDATE</code> .   |
| <code>shared-memory-base-name=name</code>       | Shared-memory name to use to connect to server.  |
| <code>socket={file_name pipe_name}</code>       | Default socket file.   |
| <code>ssl-ca=file_name</code>                   | Certificate Authority file.  |
| <code>ssl-capath=dir_name</code>                | Certificate Authority directory.   |

| Option                                      | Description                         |
|---|-------------------------------------|
| <code>ssl-cert=</code> <i>file_name</i>     | Certificate file.                   |
| <code>ssl-cipher=</code> <i>cipher_list</i> | Permissible SSL ciphers.            |
| <code>ssl-key=</code> <i>file_name</i>      | Key file.                           |
| <code>timeout=</code> <i>seconds</i>        | Like <code>connect-timeout</code> . |
| <code>user</code>                           | Default user.                       |

`timeout` has been replaced by `connect-timeout`, but `timeout` is still supported for backward compatibility.

For more information about option files used by MySQL programs, see [Section 5.2.6, “Using Option Files”](#).

## Return Values

Zero for success. Nonzero if you specify an unknown option.

## Example

The following `mysql_options()` calls request the use of compression in the client/server protocol, cause options to be read from the `[odbc]` group of option files, and disable transaction autocommit mode:

```
MYSQL mysql;

mysql_init(&mysql);
mysql_options(&mysql, MYSQL_OPT_COMPRESS, 0);
mysql_options(&mysql, MYSQL_READ_DEFAULT_GROUP, "odbc");
mysql_options(&mysql, MYSQL_INIT_COMMAND, "SET autocommit=0");
if (!mysql_real_connect(&mysql, "host", "user", "passwd", "database", 0, NULL, 0))
{
    fprintf(stderr, "Failed to connect to database: Error: %s\n",
            mysql_error(&mysql));
}
```

This code requests that the client use the compressed client/server protocol and read the additional options from the `odbc` section in the `my.cnf` file.

### 26.8.7.51 `mysql_options4()`

```
int mysql_options4(MYSQL *mysql, enum mysql_option option, const void *arg1,
const void *arg2)
```

## Description

`mysql_options4()` is similar to `mysql_options()` but has an extra fourth argument so that two values can be passed for the option specified in the second argument.

The following list describes the permitted options, their effect, and how `arg1` and `arg2` are used.

- `MYSQL_OPT_CONNECT_ATTR_ADD` (argument types: `char *`, `char *`)

This option adds an attribute key/value pair to the current set of connection attributes to pass to the server at connect time. Both arguments are pointers to null-terminated strings. The first and second strings indicate the key and value, respectively. If the key is empty or already exists in the current set of connection attributes, an error occurs. Comparison of the key name with existing keys is case sensitive.

Key names that begin with an underscore (`_`) are reserved for internal use and should not be created by application programs. This convention permits new attributes to be introduced by MySQL without colliding with application attributes.

`mysql_options4()` imposes a limit of 64KB on the aggregate size of connection attribute data it will accept. For calls that cause this limit to be exceeded, a `CR_INVALID_PARAMETER_NO` error occurs. Attribute size-limit checks also occur on the server side. For details, see [Section 24.10.9, “Performance Schema Connection Attribute Tables”](#), which also describes how the Performance Schema exposes connection attributes through the `session_connect_attrs` and `session_account_connect_attrs` tables.

See also the descriptions for the `MYSQL_OPT_CONNECT_ATTR_RESET` and `MYSQL_OPT_CONNECT_ATTR_DELETE` options in the description of the `mysql_options()` function.

## Return Values

Zero for success. Nonzero if you specify an unknown option.

## Errors

- `CR_DUPLICATE_CONNECTION_ATTR`

A duplicate attribute name was specified.

- `CR_INVALID_PARAMETER_NO`

A key name was empty or the amount of key/value connection attribute data exceeds 64KB limit.

- `CR_OUT_OF_MEMORY`

Out of memory.

## Example

This example demonstrates the calls that specify connection attributes:

```
MYSQL mysql;

mysql_init(&mysql);
mysql_options(&mysql,MYSQL_OPT_CONNECT_ATTR_RESET, 0);
mysql_options4(&mysql,MYSQL_OPT_CONNECT_ATTR_ADD, "key1", "value1");
mysql_options4(&mysql,MYSQL_OPT_CONNECT_ATTR_ADD, "key2", "value2");
mysql_options4(&mysql,MYSQL_OPT_CONNECT_ATTR_ADD, "key3", "value3");
mysql_options(&mysql,MYSQL_OPT_CONNECT_ATTR_DELETE, "key1");
if (!mysql_real_connect(&mysql,"host","user","passwd","database",0,NULL,0))
{
    fprintf(stderr, "Failed to connect to database: Error: %s\n",
        mysql_error(&mysql));
}
```

### 26.8.7.52 `mysql_ping()`

```
int mysql_ping(MYSQL *mysql)
```

## Description

Checks whether the connection to the server is working. If the connection has gone down and auto-reconnect is enabled an attempt to reconnect is made. If the connection is down and auto-reconnect is disabled, `mysql_ping()` returns an error.

Auto-reconnect is disabled by default. To enable it, call `mysql_options()` with the `MYSQL_OPT_RECONNECT` option. For details, see [Section 26.8.7.50, “mysql\\_options\(\)”](#).

`mysql_ping()` can be used by clients that remain idle for a long while, to check whether the server has closed the connection and reconnect if necessary.

If `mysql_ping()` does cause a reconnect, there is no explicit indication of it. To determine whether a reconnect occurs, call `mysql_thread_id()` to get the original connection identifier before calling `mysql_ping()`, then call `mysql_thread_id()` again to see whether the identifier has changed.

If reconnect occurs, some characteristics of the connection will have been reset. For details about these characteristics, see [Section 26.8.16, “Controlling Automatic Reconnection Behavior”](#).

## Return Values

Zero if the connection to the server is active. Nonzero if an error occurred. A nonzero return does not indicate whether the MySQL server itself is down; the connection might be broken for other reasons such as network problems.

## Errors

- `CR_COMMANDS_OUT_OF_SYNC`

Commands were executed in an improper order.

- `CR_SERVER_GONE_ERROR`

The MySQL server has gone away.

- `CR_UNKNOWN_ERROR`

An unknown error occurred.

### 26.8.7.53 `mysql_query()`

```
int mysql_query(MYSQL *mysql, const char *stmt_str)
```

## Description

Executes the SQL statement pointed to by the null-terminated string `stmt_str`. Normally, the string must consist of a single SQL statement without a terminating semicolon (;) or \g. If multiple-statement execution has been enabled, the string can contain several statements separated by semicolons. See [Section 26.8.17, “C API Support for Multiple Statement Execution”](#).

`mysql_query()` cannot be used for statements that contain binary data; you must use `mysql_real_query()` instead. (Binary data may contain the `\0` character, which `mysql_query()` interprets as the end of the statement string.)

If you want to know whether the statement returns a result set, you can use `mysql_field_count()` to check for this. See [Section 26.8.7.22, “mysql\\_field\\_count\(\)”](#).

## Return Values

Zero for success. Nonzero if an error occurred.

## Errors

- `CR_COMMANDS_OUT_OF_SYNC`

Commands were executed in an improper order.

- `CR_SERVER_GONE_ERROR`

The MySQL server has gone away.

- `CR_SERVER_LOST`

The connection to the server was lost during the query.

- `CR_UNKNOWN_ERROR`

An unknown error occurred.

### 26.8.7.54 `mysql_real_connect()`

```
MYSQL *mysql_real_connect(MYSQL *mysql, const char *host, const char
*user, const char *passwd, const char *db, unsigned int port, const char
*unix_socket, unsigned long client_flag)
```

#### Description

`mysql_real_connect()` attempts to establish a connection to a MySQL database engine running on `host`. `mysql_real_connect()` must complete successfully before you can execute any other API functions that require a valid `MYSQL` connection handle structure.

The parameters are specified as follows:

- For the first parameter, specify the address of an existing `MYSQL` structure. Before calling `mysql_real_connect()`, call `mysql_init()` to initialize the `MYSQL` structure. You can change a lot of connect options with the `mysql_options()` call. See [Section 26.8.7.50, “mysql\\_options\(\)”](#).
- The value of `host` may be either a host name or an IP address. If `host` is `NULL` or the string `"localhost"`, a connection to the local host is assumed. For Windows, the client connects using a shared-memory connection, if the server has shared-memory connections enabled. Otherwise, TCP/IP is used. For Unix, the client connects using a Unix socket file. For local connections, you can also influence the type of connection to use with the `MYSQL_OPT_PROTOCOL` or `MYSQL_OPT_NAMED_PIPE` options to `mysql_options()`. The type of connection must be supported by the server. For a `host` value of `"."` on Windows, the client connects using a named pipe, if the server has named-pipe connections enabled. If named-pipe connections are not enabled, an error occurs.
- The `user` parameter contains the user's MySQL login ID. If `user` is `NULL` or the empty string `" "`, the current user is assumed. Under Unix, this is the current login name. Under Windows ODBC, the current user name must be specified explicitly. See the Connector/ODBC section of [Chapter 26, Connectors and APIs](#).
- The `passwd` parameter contains the password for `user`. If `passwd` is `NULL`, only entries in the `user` table for the user that have a blank (empty) password field are checked for a match. This enables the database administrator to set up the MySQL privilege system in such a way that users get different privileges depending on whether they have specified a password.

#### Note

Do not attempt to encrypt the password before calling `mysql_real_connect()`; password encryption is handled automatically by the client API.

- The `user` and `passwd` parameters use whatever character set has been configured for the `MYSQL` object. By default, this is `latin1`, but can be changed by calling `mysql_options(mysql, MYSQL_SET_CHARSET_NAME, "charset_name")` prior to connecting.
- `db` is the database name. If `db` is not `NULL`, the connection sets the default database to this value.
- If `port` is not 0, the value is used as the port number for the TCP/IP connection. Note that the `host` parameter determines the type of the connection.
- If `unix_socket` is not `NULL`, the string specifies the socket or named pipe to use. Note that the `host` parameter determines the type of the connection.
- The value of `client_flag` is usually 0, but can be set to a combination of the following flags to enable certain features.

| Flag Name                                 | Flag Description   |
|---|--|
| <code>CAN_HANDLE_EXPIRED_PASSWORDS</code> | The client can handle expired passwords. For more information, see <a href="#">Section 7.3.7, “Password Expiration and Sandbox Mode”</a> .   |
| <code>CLIENT_COMPRESS</code>              | Use compression in the client/server protocol.   |
| <code>CLIENT_FOUND_ROWS</code>            | Return the number of found (matched) rows, not the number of changed rows.   |
| <code>CLIENT_IGNORE_SIGPIPE</code>        | Prevents the client library from installing a <code>SIGPIPE</code> signal handler. This can be used to avoid conflicts with a handler that the application has already installed.  |
| <code>CLIENT_IGNORE_SPACE</code>          | Permit spaces after function names. Makes all functions names reserved words.  |
| <code>CLIENT_INTERACTIVE</code>           | Permit <code>interactive_timeout</code> seconds of inactivity (rather than <code>wait_timeout</code> seconds) before closing the connection. The client's session <code>wait_timeout</code> variable is set to the value of the session <code>interactive_timeout</code> variable.                           |
| <code>CLIENT_LOCAL_FILES</code>           | Enable <code>LOAD DATA LOCAL</code> handling.  |
| <code>CLIENT_MULTI_RESULTS</code>         | Tell the server that the client can handle multiple result sets from multiple-statement executions or stored procedures. This flag is automatically enabled if <code>CLIENT_MULTI_STATEMENTS</code> is enabled. See the note following this table for more information about this flag.                      |
| <code>CLIENT_MULTI_STATEMENTS</code>      | Tell the server that the client may send multiple statements in a single string (separated by <code>;</code> characters). If this flag is not set, multiple-statement execution is disabled. See the note following this table for more information about this flag.   |
| <code>CLIENT_NO_SCHEMA</code>             | Do not permit <code>db_name.tbl_name.col_name</code> syntax. This is for ODBC. It causes the parser to generate an error if you use that syntax, which is useful for trapping bugs in some ODBC programs.  |
| <code>CLIENT_ODBC</code>                  | Unused.  |
| <code>CLIENT_SSL</code>                   | Use SSL (encrypted protocol). Do not set this option within an application program; it is set internally in the client library. Instead, use <code>mysql_ssl_set()</code> before calling <code>mysql_real_connect()</code> .   |
| <code>CLIENT_REMEMBER_OPTIONS</code>      | Remember options specified by calls to <code>mysql_options()</code> . Without this option, if <code>mysql_real_connect()</code> fails, you must repeat the <code>mysql_options()</code> calls before trying to connect again. With this option, the <code>mysql_options()</code> calls need not be repeated. |

If your program uses `CALL` statements to execute stored procedures, the `CLIENT_MULTI_RESULTS` flag must be enabled. This is because each `CALL` returns a result to indicate the call status, in addition to any result sets that might be returned by statements executed within the procedure. Because `CALL` can return multiple results, process them using a loop that calls `mysql_next_result()` to determine whether there are more results.

`CLIENT_MULTI_RESULTS` can be enabled when you call `mysql_real_connect()`, either explicitly by passing the `CLIENT_MULTI_RESULTS` flag itself, or implicitly by passing `CLIENT_MULTI_STATEMENTS` (which also enables `CLIENT_MULTI_RESULTS`). In MySQL 5.7, `CLIENT_MULTI_RESULTS` is enabled by default.

If you enable `CLIENT_MULTI_STATEMENTS` or `CLIENT_MULTI_RESULTS`, process the result for every call to `mysql_query()` or `mysql_real_query()` by using a loop that calls

`mysql_next_result()` to determine whether there are more results. For an example, see [Section 26.8.17, “C API Support for Multiple Statement Execution”](#).

For some parameters, it is possible to have the value taken from an option file rather than from an explicit value in the `mysql_real_connect()` call. To do this, call `mysql_options()` with the `MYSQL_READ_DEFAULT_FILE` or `MYSQL_READ_DEFAULT_GROUP` option before calling `mysql_real_connect()`. Then, in the `mysql_real_connect()` call, specify the “no-value” value for each parameter to be read from an option file:

- For `host`, specify a value of `NULL` or the empty string (`" "`).
- For `user`, specify a value of `NULL` or the empty string.
- For `passwd`, specify a value of `NULL`. (For the password, a value of the empty string in the `mysql_real_connect()` call cannot be overridden in an option file, because the empty string indicates explicitly that the MySQL account must have an empty password.)
- For `db`, specify a value of `NULL` or the empty string.
- For `port`, specify a value of 0.
- For `unix_socket`, specify a value of `NULL`.

If no value is found in an option file for a parameter, its default value is used as indicated in the descriptions given earlier in this section.

## Return Values

A `MYSQL*` connection handle if the connection was successful, `NULL` if the connection was unsuccessful. For a successful connection, the return value is the same as the value of the first parameter.

## Errors

- `CR_CONN_HOST_ERROR`

Failed to connect to the MySQL server.

- `CR_CONNECTION_ERROR`

Failed to connect to the local MySQL server.

- `CR_IPSOCK_ERROR`

Failed to create an IP socket.

- `CR_OUT_OF_MEMORY`

Out of memory.

- `CR_SOCKET_CREATE_ERROR`

Failed to create a Unix socket.

- `CR_UNKNOWN_HOST`

Failed to find the IP address for the host name.

- `CR_VERSION_ERROR`

A protocol mismatch resulted from attempting to connect to a server with a client library that uses a different protocol version.

- [CR\\_NAMEDPIPEOPEN\\_ERROR](#)

Failed to create a named pipe on Windows.

- [CR\\_NAMEDPIPEWAIT\\_ERROR](#)

Failed to wait for a named pipe on Windows.

- [CR\\_NAMEDPIPESETSTATE\\_ERROR](#)

Failed to get a pipe handler on Windows.

- [CR\\_SERVER\\_LOST](#)

If `connect_timeout > 0` and it took longer than `connect_timeout` seconds to connect to the server or if the server died while executing the `init-command`.

- [CR\\_ALREADY\\_CONNECTED](#)

The `MYSQL` connection handle is already connected.

## Example

```
MYSQL mysql;

mysql_init(&mysql);
mysql_options(&mysql, MYSQL_READ_DEFAULT_GROUP, "your_prog_name");
if (!mysql_real_connect(&mysql, "host", "user", "passwd", "database", 0, NULL, 0))
{
    fprintf(stderr, "Failed to connect to database: Error: %s\n",
            mysql_error(&mysql));
}
```

By using `mysql_options()` the MySQL library reads the `[client]` and `[your_prog_name]` sections in the `my.cnf` file which ensures that your program works, even if someone has set up MySQL in some nonstandard way.

Upon connection, `mysql_real_connect()` sets the `reconnect` flag (part of the `MYSQL` structure) to a value of `1` in versions of the API older than 5.0.3, or `0` in newer versions. A value of `1` for this flag indicates that if a statement cannot be performed because of a lost connection, to try reconnecting to the server before giving up. You can use the `MYSQL_OPT_RECONNECT` option to `mysql_options()` to control reconnection behavior.

### 26.8.7.55 `mysql_real_escape_string()`

```
unsigned long mysql_real_escape_string(MYSQL *mysql, char *to, const char
*from, unsigned long length)
```

#### Description

This function creates a legal SQL string for use in an SQL statement. See [Section 10.1.1, “String Literals”](#).

#### Note

As of MySQL 5.7.6, `mysql_real_escape_string()` fails and produces an `CR_INSECURE_API_ERR` error if the `NO_BACKSLASH_ESCAPES` SQL mode is enabled. In this case, the function cannot escape quote characters except by doubling them, and to do this properly, it must know more information about the quoting context than is available. Instead, use `mysql_real_escape_string_quote()`, which takes an extra argument for specifying the quoting context.

The `mysql` argument must be a valid, open connection because character escaping depends on the character set in use by the server.

The string in the `from` argument is encoded to produce an escaped SQL string, taking into account the current character set of the connection. The result is placed in the `to` argument, followed by a terminating null byte.

Characters encoded are `\`, `'`, `"`, `NUL` (ASCII 0), `\n`, `\r`, and `Control+Z`. Strictly speaking, MySQL requires only that backslash and the quote character used to quote the string in the query be escaped. `mysql_real_escape_string()` quotes the other characters to make them easier to read in log files. For comparison, see the quoting rules for literal strings and the `QUOTE()` SQL function in [Section 10.1.1, “String Literals”](#), and [Section 13.5, “String Functions”](#).

The string pointed to by `from` must be `length` bytes long. You must allocate the `to` buffer to be at least `length*2+1` bytes long. (In the worst case, each character may need to be encoded as using two bytes, and there must be room for the terminating null byte.) When `mysql_real_escape_string()` returns, the contents of `to` is a null-terminated string. The return value is the length of the encoded string, not including the terminating null byte.

If you must change the character set of the connection, use the `mysql_set_character_set()` function rather than executing a `SET NAMES` (or `SET CHARACTER SET`) statement. `mysql_set_character_set()` works like `SET NAMES` but also affects the character set used by `mysql_real_escape_string()`, which `SET NAMES` does not.

## Example

The following example inserts two escaped strings into an `INSERT` statement, each within single quote characters:

```
char query[1000],*end;

end = my_stpcpy(query,"INSERT INTO test_table VALUES('");
end += mysql_real_escape_string(&mysql,end,"What is this",12);
end = my_stpcpy(end,"','");
end += mysql_real_escape_string(&mysql,end,"binary data: \0\r\n",16);
end = my_stpcpy(end,"')");

if (mysql_real_query(&mysql,query,(unsigned int) (end - query)))
{
    fprintf(stderr, "Failed to insert row, Error: %s\n",
            mysql_error(&mysql));
}
```

The `my_stpcpy()` function used in the example is included in the `libmysqlclient` library and works like `strcpy()` but returns a pointer to the terminating null of the first parameter.

## Return Values

The length of the encoded string that is placed into the `to` argument, not including the terminating null byte, or -1 if an error occurs.

Because `mysql_real_escape_string()` returns an unsigned value, you can check for -1 by comparing the return value to `(unsigned long)-1` (or to `(unsigned long)~0`, which is equivalent).

## Errors

- `CR_INSECURE_API_ERR`

This error occurs as of MySQL 5.7.6 if the `NO_BACKSLASH_ESCAPES` SQL mode is enabled because, in that case, `mysql_real_escape_string()` cannot be guaranteed to produce a properly encoded result. To avoid this error, use `mysql_real_escape_string_quote()` instead.

### 26.8.7.56 `mysql_real_escape_string_quote()`

```
unsigned long mysql_real_escape_string_quote(MYSQL *mysql, char *to, const
char *from, unsigned long length, char quote)
```

#### Description

This function creates a legal SQL string for use in an SQL statement. See [Section 10.1.1, “String Literals”](#).

The `mysql` argument must be a valid, open connection because character escaping depends on the character set in use by the server.

The string in the `from` argument is encoded to produce an escaped SQL string, taking into account the current character set of the connection. The result is placed in the `to` argument, followed by a terminating null byte.

Characters encoded are `\`, `'`, `"`, `NUL` (ASCII 0), `\n`, `\r`, Control+Z, and (as of MySQL 5.7.8) ```. Strictly speaking, MySQL requires only that backslash and the quote character used to quote the string in the query be escaped. `mysql_real_escape_string_quote()` quotes the other characters to make them easier to read in log files. For comparison, see the quoting rules for literal strings and the `QUOTE()` SQL function in [Section 10.1.1, “String Literals”](#), and [Section 13.5, “String Functions”](#).

#### Note

If the `ANSI_QUOTES` SQL mode is enabled, `mysql_real_escape_string_quote()` cannot be used to escape double quote characters for use within double-quoted identifiers. (The function cannot tell whether the mode is enabled to determine the proper escaping character.)

The string pointed to by `from` must be `length` bytes long. You must allocate the `to` buffer to be at least `length*2+1` bytes long. (In the worst case, each character may need to be encoded as using two bytes, and there must be room for the terminating null byte.) When `mysql_real_escape_string_quote()` returns, the contents of `to` is a null-terminated string. The return value is the length of the encoded string, not including the terminating null byte.

The `quote` argument indicates the context in which the escaped string is to be placed. Suppose that you intend to escape the `from` argument and insert the escaped string (designated here by `str`) into one of the following statements:

```
1) SELECT * FROM table WHERE name = 'str'
2) SELECT * FROM table WHERE name = "str"
3) SELECT * FROM `str` WHERE id = 103
```

To perform escaping properly for each statement, call `mysql_real_escape_string_quote()` as follows, where the final argument indicates the quoting context:

```
1) len = mysql_real_escape_string_quote(&mysql,to,from,from_len,'');
2) len = mysql_real_escape_string_quote(&mysql,to,from,from_len,'"');
3) len = mysql_real_escape_string_quote(&mysql,to,from,from_len,'`');
```

If you must change the character set of the connection, use the `mysql_set_character_set()` function rather than executing a `SET NAMES` (or `SET CHARACTER SET`) statement. `mysql_set_character_set()` works like `SET NAMES` but also affects the character set used by `mysql_real_escape_string_quote()`, which `SET NAMES` does not.

This function was added in MySQL 5.7.6.

#### Example

The following example inserts two escaped strings into an `INSERT` statement, each within single quote characters:

```
char query[1000],*end;

end = my_stpcpy(query,"INSERT INTO test_table VALUES('');
end += mysql_real_escape_string_quote(&mysql,end,"What is this",12,'');
end = my_stpcpy(end,"','");
end += mysql_real_escape_string_quote(&mysql,end,"binary data: \0\r\n",16,'');
end = my_stpcpy(end,"')");

if (mysql_real_query(&mysql,query,(unsigned int) (end - query)))
{
    fprintf(stderr, "Failed to insert row, Error: %s\n",
            mysql_error(&mysql));
}
```

The `my_stpcpy()` function used in the example is included in the `libmysqlclient` library and works like `strcpy()` but returns a pointer to the terminating null of the first parameter.

## Return Values

The length of the encoded string that is placed into the `to` argument, not including the terminating null byte.

## Errors

None.

### 26.8.7.57 `mysql_real_query()`

```
int mysql_real_query(MYSQL *mysql, const char *stmt_str, unsigned long
length)
```

## Description

Executes the SQL statement pointed to by `stmt_str`, a string `length` bytes long. Normally, the string must consist of a single SQL statement without a terminating semicolon (;) or \g. If multiple-statement execution has been enabled, the string can contain several statements separated by semicolons. See [Section 26.8.17, “C API Support for Multiple Statement Execution”](#).

`mysql_query()` cannot be used for statements that contain binary data; you must use `mysql_real_query()` instead. (Binary data may contain the `\0` character, which `mysql_query()` interprets as the end of the statement string.) In addition, `mysql_real_query()` is faster than `mysql_query()` because it does not call `strlen()` on the statement string.

If you want to know whether the statement returns a result set, you can use `mysql_field_count()` to check for this. See [Section 26.8.7.22, “mysql\\_field\\_count\(\)”](#).

## Return Values

Zero for success. Nonzero if an error occurred.

## Errors

- `CR_COMMANDS_OUT_OF_SYNC`

Commands were executed in an improper order.

- `CR_SERVER_GONE_ERROR`

The MySQL server has gone away.

- `CR_SERVER_LOST`

The connection to the server was lost during the query.

- [CR\\_UNKNOWN\\_ERROR](#)

An unknown error occurred.

### 26.8.7.58 `mysql_refresh()`

```
int mysql_refresh(MYSQL *mysql, unsigned int options)
```

#### Description

##### Note

As of MySQL 5.7.11, `mysql_refresh()` is deprecated and will be removed in a future version of MySQL. Instead, use `mysql_query()` to execute a [FLUSH](#) statement.

This function flushes tables or caches, or resets replication server information. The connected user must have the [RELOAD](#) privilege.

The `options` argument is a bit mask composed from any combination of the following values. Multiple values can be OR'ed together to perform multiple operations with a single call.

- [REFRESH\\_GRANT](#)

Refresh the grant tables, like [FLUSH PRIVILEGES](#).

- [REFRESH\\_LOG](#)

Flush the logs, like [FLUSH LOGS](#).

- [REFRESH\\_TABLES](#)

Flush the table cache, like [FLUSH TABLES](#).

- [REFRESH\\_HOSTS](#)

Flush the host cache, like [FLUSH HOSTS](#).

- [REFRESH\\_STATUS](#)

Reset status variables, like [FLUSH STATUS](#).

- [REFRESH\\_THREADS](#)

Flush the thread cache.

- [REFRESH\\_SLAVE](#)

On a slave replication server, reset the master server information and restart the slave, like [RESET SLAVE](#).

- [REFRESH\\_MASTER](#)

On a master replication server, remove the binary log files listed in the binary log index and truncate the index file, like [RESET MASTER](#).

#### Return Values

Zero for success. Nonzero if an error occurred.

#### Errors

- [CR\\_COMMANDS\\_OUT\\_OF\\_SYNC](#)

Commands were executed in an improper order.

- [CR\\_SERVER\\_GONE\\_ERROR](#)

The MySQL server has gone away.

- [CR\\_SERVER\\_LOST](#)

The connection to the server was lost during the query.

- [CR\\_UNKNOWN\\_ERROR](#)

An unknown error occurred.

### 26.8.7.59 `mysql_reload()`

```
int mysql_reload(MYSQL *mysql)
```

#### Description

Asks the MySQL server to reload the grant tables. The connected user must have the [RELOAD](#) privilege.

This function is deprecated. It is preferable to use `mysql_query()` to issue an SQL [FLUSH PRIVILEGES](#) statement instead.

#### Return Values

Zero for success. Nonzero if an error occurred.

#### Errors

- [CR\\_COMMANDS\\_OUT\\_OF\\_SYNC](#)

Commands were executed in an improper order.

- [CR\\_SERVER\\_GONE\\_ERROR](#)

The MySQL server has gone away.

- [CR\\_SERVER\\_LOST](#)

The connection to the server was lost during the query.

- [CR\\_UNKNOWN\\_ERROR](#)

An unknown error occurred.

### 26.8.7.60 `mysql_reset_connection()`

```
int mysql_reset_connection(MYSQL *mysql)
```

#### Description

Resets the connection to clear the session state. This function was added in MySQL 5.7.3.

`mysql_reset_connection()` has effects similar to `mysql_change_user()` or an auto-reconnect except that the connection is not closed and reopened, and reauthentication is not done. See [Section 26.8.7.3, “mysql\\_change\\_user\(\)”](#) and see [Section 26.8.16, “Controlling Automatic Reconnection Behavior”](#).

The connection-related state is affected as follows:

- Any active transactions are rolled back and autocommit mode is reset.
- All table locks are released.
- All `TEMPORARY` tables are closed (and dropped).
- Session system variables are reinitialized to the values of the corresponding global system variables, including system variables that are set implicitly by statements such as `SET NAMES`.
- User variable settings are lost.
- Prepared statements are released.
- `HANDLER` variables are closed.
- The value of `LAST_INSERT_ID()` is reset to 0.
- Locks acquired with `GET_LOCK()` are released.

### Return Values

Zero for success. Nonzero if an error occurred.

#### 26.8.7.61 `mysql_rollback()`

```
my_bool mysql_rollback(MYSQL *mysql)
```

### Description

Rolls back the current transaction.

The action of this function is subject to the value of the `completion_type` system variable. In particular, if the value of `completion_type` is `RELEASE` (or 2), the server performs a release after terminating a transaction and closes the client connection. Call `mysql_close()` from the client program to close the connection from the client side.

### Return Values

Zero for success. Nonzero if an error occurred.

### Errors

None.

#### 26.8.7.62 `mysql_row_seek()`

```
MYSQL_ROW_OFFSET mysql_row_seek(MYSQL_RES *result, MYSQL_ROW_OFFSET offset)
```

### Description

Sets the row cursor to an arbitrary row in a query result set. The `offset` value is a row offset, typically a value returned from `mysql_row_tell()` or from `mysql_row_seek()`. This value is not a row number; to seek to a row within a result set by number, use `mysql_data_seek()` instead.

This function requires that the result set structure contains the entire result of the query, so `mysql_row_seek()` may be used only in conjunction with `mysql_store_result()`, not with `mysql_use_result()`.

### Return Values

The previous value of the row cursor. This value may be passed to a subsequent call to `mysql_row_seek()`.

## Errors

None.

### 26.8.7.63 `mysql_row_tell()`

```
MYSQL_ROW_OFFSET mysql_row_tell(MYSQL_RES *result)
```

#### Description

Returns the current position of the row cursor for the last `mysql_fetch_row()`. This value can be used as an argument to `mysql_row_seek()`.

Use `mysql_row_tell()` only after `mysql_store_result()`, not after `mysql_use_result()`.

#### Return Values

The current offset of the row cursor.

## Errors

None.

### 26.8.7.64 `mysql_select_db()`

```
int mysql_select_db(MYSQL *mysql, const char *db)
```

#### Description

Causes the database specified by `db` to become the default (current) database on the connection specified by `mysql`. In subsequent queries, this database is the default for table references that include no explicit database specifier.

`mysql_select_db()` fails unless the connected user can be authenticated as having permission to use the database.

#### Return Values

Zero for success. Nonzero if an error occurred.

## Errors

- `CR_COMMANDS_OUT_OF_SYNC`

Commands were executed in an improper order.

- `CR_SERVER_GONE_ERROR`

The MySQL server has gone away.

- `CR_SERVER_LOST`

The connection to the server was lost during the query.

- `CR_UNKNOWN_ERROR`

An unknown error occurred.

### 26.8.7.65 `mysql_session_track_get_first()`

```
int mysql_session_track_get_first(MYSQL *mysql, enum enum_session_state_type  
type, const char **data, size_t *length)
```

## Description

This function fetches the first session state-change information received from the server. It was added in MySQL 5.7.4.

To control notification for changes to session state, use the `session_track_state_change`, `session_track_schema`, `session_track_system_variables`, and `session_track_gtids` system variables (see [Section 6.1.5, “Server System Variables”](#)).

The function parameters are used as follows. These descriptions also apply to `mysql_session_track_get_first()`, which takes the same parameters.

- `mysql`: The connection handle.
- `type`: The type of information to retrieve. Permitted values for this parameter are the members of the `enum_session_state_type` enumeration defined in `mysql_com.h`:

```
enum enum_session_state_type
{
    SESSION_TRACK_SYSTEM_VARIABLES, /* Session system variables */
    SESSION_TRACK_SCHEMA,           /* Current schema */
    SESSION_TRACK_STATE_CHANGE      /* track session state changes */
    SESSION_TRACK_GTIDS,            /* track GTIDs */
};
```

To make it easy to loop over all possible types of session information, the `SESSION_TRACK_BEGIN` and `SESSION_TRACK_END` macros are defined to be equal to the first and last members of the `enum_session_state_type` enumeration. The example code shown later in this section demonstrates this technique.

- `data`: The address of a `const char *` variable. Following a successful call, this variable points to the returned data, which should be considered read only.
- `length`: The address of a `size_t` variable. Following a successful call, this variable contains the length of the data pointed to by the `data` parameter.

Following a successful call, interpret the `data` and `length` values according to the `type` value, as follows:

- `SESSION_TRACK_SCHEMA`: `data` is the new default schema name and `length` is the name length.
- `SESSION_TRACK_SYSTEM_VARIABLES`: When a session system variable changes, two values per variable are returned (in separate calls). For the first call, `data` is the variable name and `length` is the name length. For the second call, `data` is the variable value and `length` is the value length. Both data values are represented as strings.
- `SESSION_TRACK_STATE_CHANGE`: `data` is a byte containing a boolean flag that indicates whether session state changes occurred and `length` should be 1. The flag is represented as an ASCII value, not a binary (for example, `'1'`, not `0x01`).

## Return Values

Zero for success. Nonzero if an error occurred.

## Errors

None.

## Example

The following example shows how to call `mysql_session_track_get_first()` and `mysql_session_track_get_next()` to retrieve and display all available session state-change information following successful execution of an SQL statement string (represented by `stmt_str`).

```

printf("Execute: %s\n", stmt_str);

if (mysql_query(mysql, stmt_str) != 0)
{
    fprintf(stderr, "Error %u: %s\n",
            mysql_errno(mysql), mysql_error(mysql));
    return;
}

MYSQL_RES *result = mysql_store_result(mysql);
if (result) /* there is a result set to fetch */
{
    /* ... process rows here ... */
    printf("Number of rows returned: %lu\n",
            (unsigned long) mysql_num_rows(result));
    mysql_free_result(result);
}
else /* there is no result set */
{
    if (mysql_field_count(mysql) == 0)
    {
        printf("Number of rows affected: %lu\n",
                (unsigned long) mysql_affected_rows(mysql));
    }
    else /* an error occurred */
    {
        fprintf(stderr, "Error %u: %s\n",
                mysql_errno(mysql), mysql_error(mysql));
    }
}

/* extract any available session state-change information */
enum enum_session_state_type type;
for (type = SESSION_TRACK_BEGIN; type <= SESSION_TRACK_END; type++)
{
    const char *data;
    size_t length;

    if (mysql_session_track_get_first(mysql, type, &data, &length) == 0)
    {
        printf("Type=%d:\n", type);
        printf("mysql_session_track_get_first() returns: %*.s\n",
                (int) length, (int) length, data);

        /* check for more data */
        while (mysql_session_track_get_next(mysql, type, &data, &length) == 0)
        {
            printf("mysql_session_track_get_next() returns: %*.s\n",
                    (int) length, (int) length, data);
        }
    }
}

```

### 26.8.7.66 `mysql_session_track_get_next()`

```
int mysql_session_track_get_next(MYSQL *mysql, enum enum_session_state_type
type, const char **data, size_t *length)
```

#### Description

This function fetches session state-change information received from the server, following that retrieved by `mysql_session_track_get_first()`. It was added in MySQL 5.7.4.

Following a successful call to `mysql_session_track_get_first()`, call `mysql_session_track_get_next()` repeatedly until it returns nonzero to indicate no more information is available. The calling sequence for `mysql_session_track_get_next()` is similar to that for `mysql_session_track_get_first()`. For more information and an example that demonstrates both functions, see [Section 26.8.7.65, “mysql\\_session\\_track\\_get\\_first\(\)”](#).

## Return Values

Zero for success. Nonzero if an error occurred.

## Errors

None.

### 26.8.7.67 `mysql_set_character_set()`

```
int mysql_set_character_set(MYSQL *mysql, const char *csname)
```

## Description

This function is used to set the default character set for the current connection. The string `csname` specifies a valid character set name. The connection collation becomes the default collation of the character set. This function works like the `SET NAMES` statement, but also sets the value of `mysql->charset`, and thus affects the character set used by `mysql_real_escape_string()`

## Return Values

Zero for success. Nonzero if an error occurred.

## Example

```
MYSQL mysql;

mysql_init(&mysql);
if (!mysql_real_connect(&mysql, "host", "user", "passwd", "database", 0, NULL, 0))
{
    fprintf(stderr, "Failed to connect to database: Error: %s\n",
            mysql_error(&mysql));
}

if (!mysql_set_character_set(&mysql, "utf8"))
{
    printf("New client character set: %s\n",
            mysql_character_set_name(&mysql));
}
```

### 26.8.7.68 `mysql_set_local_infile_default()`

```
void mysql_set_local_infile_default(MYSQL *mysql);
```

## Description

Sets the `LOAD DATA LOCAL INFILE` callback functions to the defaults used internally by the C client library. The library calls this function automatically if `mysql_set_local_infile_handler()` has not been called or does not supply valid functions for each of its callbacks.

## Return Values

None.

## Errors

None.

### 26.8.7.69 `mysql_set_local_infile_handler()`

```
void mysql_set_local_infile_handler(MYSQL *mysql, int (*local_infile_init)
(void **, const char *, void *), int (*local_infile_read)(void *, char *,
```

```
unsigned int), void (*local_infile_end)(void *), int (*local_infile_error)
(void *, char*, unsigned int), void *userdata);
```

## Description

This function installs callbacks to be used during the execution of `LOAD DATA LOCAL INFILE` statements. It enables application programs to exert control over local (client-side) data file reading. The arguments are the connection handler, a set of pointers to callback functions, and a pointer to a data area that the callbacks can use to share information.

To use `mysql_set_local_infile_handler()`, you must write the following callback functions:

```
int
local_infile_init(void **ptr, const char *filename, void *userdata);
```

The initialization function. This is called once to do any setup necessary, open the data file, allocate data structures, and so forth. The first `void**` argument is a pointer to a pointer. You can set the pointer (that is, `*ptr`) to a value that will be passed to each of the other callbacks (as a `void*`). The callbacks can use this pointed-to value to maintain state information. The `userdata` argument is the same value that is passed to `mysql_set_local_infile_handler()`.

Make the initialization function return zero for success, nonzero for an error.

```
int
local_infile_read(void *ptr, char *buf, unsigned int buf_len);
```

The data-reading function. This is called repeatedly to read the data file. `buf` points to the buffer where the read data is stored, and `buf_len` is the maximum number of bytes that the callback can read and store in the buffer. (It can read fewer bytes, but should not read more.)

The return value is the number of bytes read, or zero when no more data could be read (this indicates EOF). Return a value less than zero if an error occurs.

```
void
local_infile_end(void *ptr)
```

The termination function. This is called once after `local_infile_read()` has returned zero (EOF) or an error. Within this function, deallocate any memory allocated by `local_infile_init()` and perform any other cleanup necessary. It is invoked even if the initialization function returns an error.

```
int
local_infile_error(void *ptr,
                  char *error_msg,
                  unsigned int error_msg_len);
```

The error-handling function. This is called to get a textual error message to return to the user in case any of your other functions returns an error. `error_msg` points to the buffer into which the message is written, and `error_msg_len` is the length of the buffer. Write the message as a null-terminated string, at most `error_msg_len-1` bytes long.

The return value is the error number.

Typically, the other callbacks store the error message in the data structure pointed to by `ptr`, so that `local_infile_error()` can copy the message from there into `error_msg`.

After calling `mysql_set_local_infile_handler()` in your C code and passing pointers to your callback functions, you can then issue a `LOAD DATA LOCAL INFILE` statement (for example, by using `mysql_query()`). The client library automatically invokes your callbacks. The file name specified in `LOAD DATA LOCAL INFILE` will be passed as the second parameter to the `local_infile_init()` callback.

## Return Values

None.

## Errors

None.

### 26.8.7.70 `mysql_set_server_option()`

```
int mysql_set_server_option(MYSQL *mysql, enum enum_mysql_set_option option)
```

## Description

Enables or disables an option for the connection. `option` can have one of the following values.

| Option   | Description                        |
|--|------------------------------------|
| <code>MYSQL_OPTION_MULTI_STATEMENTS_ON</code>  | Enable multiple-statement support  |
| <code>MYSQL_OPTION_MULTI_STATEMENTS_OFF</code> | Disable multiple-statement support |

If you enable multiple-statement support, you should retrieve results from calls to `mysql_query()` or `mysql_real_query()` by using a loop that calls `mysql_next_result()` to determine whether there are more results. For an example, see [Section 26.8.17, “C API Support for Multiple Statement Execution”](#).

Enabling multiple-statement support with `MYSQL_OPTION_MULTI_STATEMENTS_ON` does not have quite the same effect as enabling it by passing the `CLIENT_MULTI_STATEMENTS` flag to `mysql_real_connect()`: `CLIENT_MULTI_STATEMENTS` also enables `CLIENT_MULTI_RESULTS`. If you are using the `CALL` SQL statement in your programs, multiple-result support must be enabled; this means that `MYSQL_OPTION_MULTI_STATEMENTS_ON` by itself is insufficient to permit the use of `CALL`.

## Return Values

Zero for success. Nonzero if an error occurred.

## Errors

- `CR_COMMANDS_OUT_OF_SYNC`

Commands were executed in an improper order.

- `CR_SERVER_GONE_ERROR`

The MySQL server has gone away.

- `CR_SERVER_LOST`

The connection to the server was lost during the query.

- `ER_UNKNOWN_COM_ERROR`

The server did not support `mysql_set_server_option()` (which is the case that the server is older than 4.1.1) or the server did not support the option one tried to set.

### 26.8.7.71 `mysql_shutdown()`

```
int mysql_shutdown(MYSQL *mysql, enum mysql_enum_shutdown_level shutdown_level)
```

## Description

### Note

As of MySQL 5.7.9, `mysql_shutdown()` is deprecated and will be removed in a future version of MySQL. Instead, use `mysql_query()` to execute a `SHUTDOWN` statement.

Asks the database server to shut down. The connected user must have the `SHUTDOWN` privilege. MySQL servers support only one type of shutdown; `shutdown_level` must be equal to `SHUTDOWN_DEFAULT`. Dynamically linked executables which have been compiled with older versions of the `libmysqlclient` headers and call `mysql_shutdown()` need to be used with the old `libmysqlclient` dynamic library.

As of MySQL 5.7.9, an alternative to `mysql_shutdown()` is to use the `SHUTDOWN` SQL statement.

The shutdown process is described in [Section 6.1.12, “The Server Shutdown Process”](#).

## Return Values

Zero for success. Nonzero if an error occurred.

## Errors

- `CR_COMMANDS_OUT_OF_SYNC`  
Commands were executed in an improper order.
- `CR_SERVER_GONE_ERROR`  
The MySQL server has gone away.
- `CR_SERVER_LOST`  
The connection to the server was lost during the query.
- `CR_UNKNOWN_ERROR`  
An unknown error occurred.

### 26.8.7.72 `mysql_sqlstate()`

```
const char *mysql_sqlstate(MYSQL *mysql)
```

## Description

Returns a null-terminated string containing the SQLSTATE error code for the most recently executed SQL statement. The error code consists of five characters. `'00000'` means “no error.” The values are specified by ANSI SQL and ODBC. For a list of possible values, see [Appendix B, Errors, Error Codes, and Common Problems](#).

SQLSTATE values returned by `mysql_sqlstate()` differ from MySQL-specific error numbers returned by `mysql_errno()`. For example, the `mysql` client program displays errors using the following format, where 1146 is the `mysql_errno()` value and `'42S02'` is the corresponding `mysql_sqlstate()` value:

```
shell> SELECT * FROM no_such_table;
ERROR 1146 (42S02): Table 'test.no_such_table' doesn't exist
```

Not all MySQL error numbers are mapped to SQLSTATE error codes. The value `'HY000'` (general error) is used for unmapped error numbers.

If you call `mysql_sqlstate()` after `mysql_real_connect()` fails, `mysql_sqlstate()` might not return a useful value. For example, this happens if a host is blocked by the server and the connection is closed without any SQLSTATE value being sent to the client.

## Return Values

A null-terminated character string containing the SQLSTATE error code.

## See Also

See [Section 26.8.7.14](#), “`mysql_errno()`”, [Section 26.8.7.15](#), “`mysql_error()`”, and [Section 26.8.11.27](#), “`mysql_stmt_sqlstate()`”.

### 26.8.7.73 `mysql_ssl_set()`

```
my_bool mysql_ssl_set(MYSQL *mysql, const char *key, const char *cert, const
char *ca, const char *capath, const char *cipher)
```

## Description

`mysql_ssl_set()` is used for establishing secure connections using SSL. It must be called before `mysql_real_connect()`.

`mysql_ssl_set()` does nothing unless SSL support is enabled in the client library.

`mysql` is the connection handler returned from `mysql_init()`. Specify the other parameters as follows:

- `key`: The path name to the key file
- `cert`: The path name to the certificate file
- `ca`: The path name to the certificate authority file
- `capath`: The path name to a directory that contains trusted SSL CA certificates in PEM format
- `cipher`: A list of permissible ciphers to use for SSL encryption

Any unused SSL parameters may be given as `NULL`.

## Return Values

This function always returns 0. If SSL setup is incorrect, `mysql_real_connect()` returns an error when you attempt to connect.

## Enforcing an Encrypted Connection

`mysql_ssl_set()` provides information for establishing a secure connection, but does not require that the connection established actually be encrypted. To require a secure connection prior to calling `mysql_real_connect()`, call `mysql_options()`, passing the `MYSQL_OPT_SSL_MODE` option with a value of `SSL_MODE_REQUIRED`.

### 26.8.7.74 `mysql_stat()`

```
const char *mysql_stat(MYSQL *mysql)
```

## Description

Returns a character string containing information similar to that provided by the `mysqladmin status` command. This includes uptime in seconds and the number of running threads, questions, reloads, and open tables.

## Return Values

A character string describing the server status. `NULL` if an error occurred.

## Errors

- `CR_COMMANDS_OUT_OF_SYNC`

Commands were executed in an improper order.

- `CR_SERVER_GONE_ERROR`

The MySQL server has gone away.

- `CR_SERVER_LOST`

The connection to the server was lost during the query.

- `CR_UNKNOWN_ERROR`

An unknown error occurred.

### 26.8.7.75 `mysql_store_result()`

```
MYSQL_RES *mysql_store_result(MYSQL *mysql)
```

## Description

After invoking `mysql_query()` or `mysql_real_query()`, you must call `mysql_store_result()` or `mysql_use_result()` for every statement that successfully produces a result set (`SELECT`, `SHOW`, `DESCRIBE`, `EXPLAIN`, `CHECK TABLE`, and so forth). You must also call `mysql_free_result()` after you are done with the result set.

You need not call `mysql_store_result()` or `mysql_use_result()` for other statements, but it does not do any harm or cause any notable performance degradation if you call `mysql_store_result()` in all cases. You can detect whether the statement has a result set by checking whether `mysql_store_result()` returns a nonzero value (more about this later).

If you enable multiple-statement support, you should retrieve results from calls to `mysql_query()` or `mysql_real_query()` by using a loop that calls `mysql_next_result()` to determine whether there are more results. For an example, see [Section 26.8.17, “C API Support for Multiple Statement Execution”](#).

If you want to know whether a statement should return a result set, you can use `mysql_field_count()` to check for this. See [Section 26.8.7.22, “mysql\\_field\\_count\(\)”](#).

`mysql_store_result()` reads the entire result of a query to the client, allocates a `MYSQL_RES` structure, and places the result into this structure.

`mysql_store_result()` returns a null pointer if the statement did not return a result set (for example, if it was an `INSERT` statement).

`mysql_store_result()` also returns a null pointer if reading of the result set failed. You can check whether an error occurred by checking whether `mysql_error()` returns a nonempty string, `mysql_errno()` returns nonzero, or `mysql_field_count()` returns zero.

An empty result set is returned if there are no rows returned. (An empty result set differs from a null pointer as a return value.)

After you have called `mysql_store_result()` and gotten back a result that is not a null pointer, you can call `mysql_num_rows()` to find out how many rows are in the result set.

You can call `mysql_fetch_row()` to fetch rows from the result set, or `mysql_row_seek()` and `mysql_row_tell()` to obtain or set the current row position within the result set.

See [Section 26.8.15.1, “Why mysql\\_store\\_result\(\) Sometimes Returns NULL After mysql\\_query\(\) Returns Success”](#).

## Return Values

A `MYSQL_RES` result structure with the results. `NULL` (0) if an error occurred.

## Errors

`mysql_store_result()` resets `mysql_error()` and `mysql_errno()` if it succeeds.

- `CR_COMMANDS_OUT_OF_SYNC`

Commands were executed in an improper order.

- `CR_OUT_OF_MEMORY`

Out of memory.

- `CR_SERVER_GONE_ERROR`

The MySQL server has gone away.

- `CR_SERVER_LOST`

The connection to the server was lost during the query.

- `CR_UNKNOWN_ERROR`

An unknown error occurred.

### 26.8.7.76 mysql\_thread\_id()

```
unsigned long mysql_thread_id(MYSQL *mysql)
```

## Description

Returns the thread ID of the current connection. This value can be used as an argument to `mysql_kill()` to kill the thread.

If the connection is lost and you reconnect with `mysql_ping()`, the thread ID changes. This means you should not get the thread ID and store it for later. You should get it when you need it.

### Note

This function does not work correctly if thread IDs become larger than 32 bits, which can occur on some systems. To avoid problems with `mysql_thread_id()`, do not use it. To get the connection ID, execute a `SELECT CONNECTION_ID()` query and retrieve the result.

## Return Values

The thread ID of the current connection.

## Errors

None.

### 26.8.7.77 mysql\_use\_result()

```
MYSQL_RES *mysql_use_result(MYSQL *mysql)
```

## Description

After invoking `mysql_query()` or `mysql_real_query()`, you must call `mysql_store_result()` or `mysql_use_result()` for every statement that successfully produces a result set (`SELECT`, `SHOW`, `DESCRIBE`, `EXPLAIN`, `CHECK TABLE`, and so forth). You must also call `mysql_free_result()` after you are done with the result set.

`mysql_use_result()` initiates a result set retrieval but does not actually read the result set into the client like `mysql_store_result()` does. Instead, each row must be retrieved individually by making calls to `mysql_fetch_row()`. This reads the result of a query directly from the server without storing it in a temporary table or local buffer, which is somewhat faster and uses much less memory than `mysql_store_result()`. The client allocates memory only for the current row and a communication buffer that may grow up to `max_allowed_packet` bytes.

On the other hand, you should not use `mysql_use_result()` for locking reads if you are doing a lot of processing for each row on the client side, or if the output is sent to a screen on which the user may type a `^S` (stop scroll). This ties up the server and prevent other threads from updating any tables from which the data is being fetched.

When using `mysql_use_result()`, you must execute `mysql_fetch_row()` until a `NULL` value is returned, otherwise, the unfetched rows are returned as part of the result set for your next query. The C API gives the error `Commands out of sync; you can't run this command now` if you forget to do this!

You may not use `mysql_data_seek()`, `mysql_row_seek()`, `mysql_row_tell()`, `mysql_num_rows()`, or `mysql_affected_rows()` with a result returned from `mysql_use_result()`, nor may you issue other queries until `mysql_use_result()` has finished. (However, after you have fetched all the rows, `mysql_num_rows()` accurately returns the number of rows fetched.)

You must call `mysql_free_result()` once you are done with the result set.

When using the `libmysqld` embedded server, the memory benefits are essentially lost because memory usage incrementally increases with each row retrieved until `mysql_free_result()` is called.

## Return Values

A `MYSQL_RES` result structure. `NULL` if an error occurred.

## Errors

`mysql_use_result()` resets `mysql_error()` and `mysql_errno()` if it succeeds.

- `CR_COMMANDS_OUT_OF_SYNC`

Commands were executed in an improper order.

- `CR_OUT_OF_MEMORY`

Out of memory.

- `CR_SERVER_GONE_ERROR`

The MySQL server has gone away.

- `CR_SERVER_LOST`

The connection to the server was lost during the query.

- [CR\\_UNKNOWN\\_ERROR](#)

An unknown error occurred.

### 26.8.7.78 `mysql_warning_count()`

```
unsigned int mysql_warning_count(MYSQL *mysql)
```

#### Description

Returns the number of errors, warnings, and notes generated during execution of the previous SQL statement.

#### Return Values

The warning count.

#### Errors

None.

## 26.8.8 C API Prepared Statements

The MySQL client/server protocol provides for the use of prepared statements. This capability uses the `MYSQL_STMT` statement handler data structure returned by the `mysql_stmt_init()` initialization function. Prepared execution is an efficient way to execute a statement more than once. The statement is first parsed to prepare it for execution. Then it is executed one or more times at a later time, using the statement handle returned by the initialization function.

Prepared execution is faster than direct execution for statements executed more than once, primarily because the query is parsed only once. In the case of direct execution, the query is parsed every time it is executed. Prepared execution also can provide a reduction of network traffic because for each execution of the prepared statement, it is necessary only to send the data for the parameters.

Prepared statements might not provide a performance increase in some situations. For best results, test your application both with prepared and nonprepared statements and choose whichever yields best performance.

Another advantage of prepared statements is that it uses a binary protocol that makes data transfer between client and server more efficient.

For a list of SQL statements that can be used as prepared statements, see [Section 14.5, “Prepared SQL Statement Syntax”](#).

Metadata changes to tables or views referred to by prepared statements are detected and cause automatic reparation of the statement when it is next executed. For more information, see [Section 9.10.4, “Caching of Prepared Statements and Stored Programs”](#).

## 26.8.9 C API Prepared Statement Data Structures

Prepared statements use several data structures:

- To obtain a statement handle, pass a `MYSQL` connection handler to `mysql_stmt_init()`, which returns a pointer to a `MYSQL_STMT` data structure. This structure is used for further operations with the statement. To specify the statement to prepare, pass the `MYSQL_STMT` pointer and the statement string to `mysql_stmt_prepare()`.
- To provide input parameters for a prepared statement, set up `MYSQL_BIND` structures and pass them to `mysql_stmt_bind_param()`. To receive output column values, set up `MYSQL_BIND` structures and pass them to `mysql_stmt_bind_result()`.

- The `MYSQL_TIME` structure is used to transfer temporal data in both directions.

The following discussion describes the prepared statement data types in detail. For examples that show how to use them, see [Section 26.8.11.10, “mysql\\_stmt\\_execute\(\)”](#), and [Section 26.8.11.11, “mysql\\_stmt\\_fetch\(\)”](#).

- `MYSQL_STMT`

This structure is a handle for a prepared statement. A handle is created by calling `mysql_stmt_init()`, which returns a pointer to a `MYSQL_STMT`. The handle is used for all subsequent operations with the statement until you close it with `mysql_stmt_close()`, at which point the handle becomes invalid.

The `MYSQL_STMT` structure has no members intended for application use. Applications should not try to copy a `MYSQL_STMT` structure. There is no guarantee that such a copy will be usable.

Multiple statement handles can be associated with a single connection. The limit on the number of handles depends on the available system resources.

- `MYSQL_BIND`

This structure is used both for statement input (data values sent to the server) and output (result values returned from the server):

- For input, use `MYSQL_BIND` structures with `mysql_stmt_bind_param()` to bind parameter data values to buffers for use by `mysql_stmt_execute()`.
- For output, use `MYSQL_BIND` structures with `mysql_stmt_bind_result()` to bind buffers to result set columns, for use in fetching rows with `mysql_stmt_fetch()`.

To use a `MYSQL_BIND` structure, zero its contents to initialize it, then set its members appropriately. For example, to declare and initialize an array of three `MYSQL_BIND` structures, use this code:

```
MYSQL_BIND bind[3];
memset(bind, 0, sizeof(bind));
```

The `MYSQL_BIND` structure contains the following members for use by application programs. For several of the members, the manner of use depends on whether the structure is used for input or output.

- `enum enum_field_types buffer_type`

The type of the buffer. This member indicates the data type of the C language variable bound to a statement parameter or result set column. For input, `buffer_type` indicates the type of the variable containing the value to be sent to the server. For output, it indicates the type of the variable into which a value received from the server should be stored. For permissible `buffer_type` values, see [Section 26.8.9.1, “C API Prepared Statement Type Codes”](#).

- `void *buffer`

A pointer to the buffer to be used for data transfer. This is the address of a C language variable.

For input, `buffer` is a pointer to the variable in which you store the data value for a statement parameter. When you call `mysql_stmt_execute()`, MySQL use the value stored in the variable in place of the corresponding parameter marker in the statement (specified with `?` in the statement string).

For output, `buffer` is a pointer to the variable in which to return a result set column value. When you call `mysql_stmt_fetch()`, MySQL stores a column value from the current row of the result set in this variable. You can access the value when the call returns.

To minimize the need for MySQL to perform type conversions between C language values on the client side and SQL values on the server side, use C variables that have types similar to those of the corresponding SQL values:

- For numeric data types, `buffer` should point to a variable of the proper numeric C type. For integer variables (which can be `char` for single-byte values or an integer type for larger values), you should also indicate whether the variable has the `unsigned` attribute by setting the `is_unsigned` member, described later.
- For character (nonbinary) and binary string data types, `buffer` should point to a character buffer.
- For date and time data types, `buffer` should point to a `MYSQL_TIME` structure.

For guidelines about mapping between C types and SQL types and notes about type conversions, see [Section 26.8.9.1, “C API Prepared Statement Type Codes”](#), and [Section 26.8.9.2, “C API Prepared Statement Type Conversions”](#).

- `unsigned long buffer_length`

The actual size of `*buffer` in bytes. This indicates the maximum amount of data that can be stored in the buffer. For character and binary C data, the `buffer_length` value specifies the length of `*buffer` when used with `mysql_stmt_bind_param()` to specify input values, or the maximum number of output data bytes that can be fetched into the buffer when used with `mysql_stmt_bind_result()`.

- `unsigned long *length`

A pointer to an `unsigned long` variable that indicates the actual number of bytes of data stored in `*buffer`. `length` is used for character or binary C data.

For input parameter data binding, set `*length` to indicate the actual length of the parameter value stored in `*buffer`. This is used by `mysql_stmt_execute()`.

For output value binding, MySQL sets `*length` when you call `mysql_stmt_fetch()`. The `mysql_stmt_fetch()` return value determines how to interpret the length:

- If the return value is 0, `*length` indicates the actual length of the parameter value.
- If the return value is `MYSQL_DATA_TRUNCATED`, `*length` indicates the nontruncated length of the parameter value. In this case, the minimum of `*length` and `buffer_length` indicates the actual length of the value.

`length` is ignored for numeric and temporal data types because the `buffer_type` value determines the length of the data value.

If you must determine the length of a returned value before fetching it, see [Section 26.8.11.11, “mysql\\_stmt\\_fetch\(\)”](#), for some strategies.

- `my_bool *is_null`

This member points to a `my_bool` variable that is true if a value is `NULL`, false if it is not `NULL`. For input, set `*is_null` to true to indicate that you are passing a `NULL` value as a statement parameter.

`is_null` is a *pointer* to a boolean scalar, not a boolean scalar, to provide flexibility in how you specify `NULL` values:

- If your data values are always `NULL`, use `MYSQL_TYPE_NULL` as the `buffer_type` value when you bind the column. The other `MYSQL_BIND` members, including `is_null`, do not matter.

- If your data values are always `NOT NULL`, set `is_null = (my_bool*) 0`, and set the other members appropriately for the variable you are binding.
- In all other cases, set the other members appropriately and set `is_null` to the address of a `my_bool` variable. Set that variable's value to true or false appropriately between executions to indicate whether the corresponding data value is `NULL` or `NOT NULL`, respectively.

For output, when you fetch a row, MySQL sets the value pointed to by `is_null` to true or false according to whether the result set column value returned from the statement is or is not `NULL`.

- `my_bool is_unsigned`

This member applies for C variables with data types that can be `unsigned` (`char`, `short int`, `int`, `long long int`). Set `is_unsigned` to true if the variable pointed to by `buffer` is `unsigned` and false otherwise. For example, if you bind a `signed char` variable to `buffer`, specify a type code of `MYSQL_TYPE_TINY` and set `is_unsigned` to false. If you bind an `unsigned char` instead, the type code is the same but `is_unsigned` should be true. (For `char`, it is not defined whether it is signed or unsigned, so it is best to be explicit about signedness by using `signed char` or `unsigned char`.)

`is_unsigned` applies only to the C language variable on the client side. It indicates nothing about the signedness of the corresponding SQL value on the server side. For example, if you use an `int` variable to supply a value for a `BIGINT UNSIGNED` column, `is_unsigned` should be false because `int` is a signed type. If you use an `unsigned int` variable to supply a value for a `BIGINT` column, `is_unsigned` should be true because `unsigned int` is an unsigned type. MySQL performs the proper conversion between signed and unsigned values in both directions, although a warning occurs if truncation results.

- `my_bool *error`

For output, set this member to point to a `my_bool` variable to have truncation information for the parameter stored there after a row fetching operation. When truncation reporting is enabled, `mysql_stmt_fetch()` returns `MYSQL_DATA_TRUNCATED` and `*error` is true in the `MYSQL_BIND` structures for parameters in which truncation occurred. Truncation indicates loss of sign or significant digits, or that a string was too long to fit in a column. Truncation reporting is enabled by default, but can be controlled by calling `mysql_options()` with the `MYSQL_REPORT_DATA_TRUNCATION` option.

- `MYSQL_TIME`

This structure is used to send and receive `DATE`, `TIME`, `DATETIME`, and `TIMESTAMP` data directly to and from the server. Set the `buffer` member to point to a `MYSQL_TIME` structure, and set the `buffer_type` member of a `MYSQL_BIND` structure to one of the temporal types (`MYSQL_TYPE_TIME`, `MYSQL_TYPE_DATE`, `MYSQL_TYPE_DATETIME`, `MYSQL_TYPE_TIMESTAMP`).

The `MYSQL_TIME` structure contains the members listed in the following table.

| Member                           | Description  |
|----------------------------------|--|
| <code>unsigned int year</code>   | The year   |
| <code>unsigned int month</code>  | The month of the year                                  |
| <code>unsigned int day</code>    | The day of the month                                   |
| <code>unsigned int hour</code>   | The hour of the day                                    |
| <code>unsigned int minute</code> | The minute of the hour                                 |
| <code>unsigned int second</code> | The second of the minute                               |
| <code>my_bool neg</code>         | A boolean flag indicating whether the time is negative |

| Member                                 | Description                                       |
|--|---|
| <code>unsigned long second_part</code> | The fractional part of the second in microseconds |

Only those parts of a `MYSQL_TIME` structure that apply to a given type of temporal value are used. The `year`, `month`, and `day` elements are used for `DATE`, `DATETIME`, and `TIMESTAMP` values. The `hour`, `minute`, and `second` elements are used for `TIME`, `DATETIME`, and `TIMESTAMP` values. See [Section 26.8.19, “C API Prepared Statement Handling of Date and Time Values”](#).

### 26.8.9.1 C API Prepared Statement Type Codes

The `buffer_type` member of `MYSQL_BIND` structures indicates the data type of the C language variable bound to a statement parameter or result set column. For input, `buffer_type` indicates the type of the variable containing the value to be sent to the server. For output, it indicates the type of the variable into which a value received from the server should be stored.

The following table shows the permissible values for the `buffer_type` member of `MYSQL_BIND` structures for input values sent to the server. The table shows the C variable types that you can use, the corresponding type codes, and the SQL data types for which the supplied value can be used without conversion. Choose the `buffer_type` value according to the data type of the C language variable that you are binding. For the integer types, you should also set the `is_unsigned` member to indicate whether the variable is signed or unsigned.

| Input Variable C Type      | <code>buffer_type</code> Value    | SQL Type of Destination Value                                    |
|----------------------------|-----------------------------------|--|
| <code>signed char</code>   | <code>MYSQL_TYPE_TINY</code>      | <code>TINYINT</code>   |
| <code>short int</code>     | <code>MYSQL_TYPE_SHORT</code>     | <code>SMALLINT</code>  |
| <code>int</code>           | <code>MYSQL_TYPE_LONG</code>      | <code>INT</code>   |
| <code>long long int</code> | <code>MYSQL_TYPE_LONGLONG</code>  | <code>BIGINT</code>  |
| <code>float</code>         | <code>MYSQL_TYPE_FLOAT</code>     | <code>FLOAT</code>   |
| <code>double</code>        | <code>MYSQL_TYPE_DOUBLE</code>    | <code>DOUBLE</code>  |
| <code>MYSQL_TIME</code>    | <code>MYSQL_TYPE_TIME</code>      | <code>TIME</code>  |
| <code>MYSQL_TIME</code>    | <code>MYSQL_TYPE_DATE</code>      | <code>DATE</code>  |
| <code>MYSQL_TIME</code>    | <code>MYSQL_TYPE_DATETIME</code>  | <code>DATETIME</code>  |
| <code>MYSQL_TIME</code>    | <code>MYSQL_TYPE_TIMESTAMP</code> | <code>TIMESTAMP</code>   |
| <code>char[ ]</code>       | <code>MYSQL_TYPE_STRING</code>    | <code>TEXT</code> , <code>CHAR</code> , <code>VARCHAR</code>     |
| <code>char[ ]</code>       | <code>MYSQL_TYPE_BLOB</code>      | <code>BLOB</code> , <code>BINARY</code> , <code>VARBINARY</code> |
|                            | <code>MYSQL_TYPE_NULL</code>      | <code>NULL</code>  |

Use `MYSQL_TYPE_NULL` as indicated in the description for the `is_null` member in [Section 26.8.9, “C API Prepared Statement Data Structures”](#).

For input string data, use `MYSQL_TYPE_STRING` or `MYSQL_TYPE_BLOB` depending on whether the value is a character (nonbinary) or binary string:

- `MYSQL_TYPE_STRING` indicates character input string data. The value is assumed to be in the character set indicated by the `character_set_client` system variable. If the server stores the value into a column with a different character set, it converts the value to that character set.
- `MYSQL_TYPE_BLOB` indicates binary input string data. The value is treated as having the `binary` character set. That is, it is treated as a byte string and no conversion occurs.

The following table shows the permissible values for the `buffer_type` member of `MYSQL_BIND` structures for output values received from the server. The table shows the SQL types of received values, the corresponding type codes that such values have in result set metadata, and the recommended C language data types to bind to the `MYSQL_BIND` structure to receive the SQL values without conversion. Choose the `buffer_type` value according to the data type of the C language

variable that you are binding. For the integer types, you should also set the `is_unsigned` member to indicate whether the variable is signed or unsigned.

| SQL Type of Received Value | <code>buffer_type</code> Value      | Output Variable C Type  |
|----------------------------|-------------------------------------|-------------------------|
| TINYINT                    | <code>MYSQL_TYPE_TINY</code>        | signed char             |
| SMALLINT                   | <code>MYSQL_TYPE_SHORT</code>       | short int               |
| MEDIUMINT                  | <code>MYSQL_TYPE_INT24</code>       | int                     |
| INT                        | <code>MYSQL_TYPE_LONG</code>        | int                     |
| BIGINT                     | <code>MYSQL_TYPE_LONGLONG</code>    | long long int           |
| FLOAT                      | <code>MYSQL_TYPE_FLOAT</code>       | float                   |
| DOUBLE                     | <code>MYSQL_TYPE_DOUBLE</code>      | double                  |
| DECIMAL                    | <code>MYSQL_TYPE_NEWDECIMAL</code>  | char[ ]                 |
| YEAR                       | <code>MYSQL_TYPE_SHORT</code>       | short int               |
| TIME                       | <code>MYSQL_TYPE_TIME</code>        | <code>MYSQL_TIME</code> |
| DATE                       | <code>MYSQL_TYPE_DATE</code>        | <code>MYSQL_TIME</code> |
| DATETIME                   | <code>MYSQL_TYPE_DATETIME</code>    | <code>MYSQL_TIME</code> |
| TIMESTAMP                  | <code>MYSQL_TYPE_TIMESTAMP</code>   | <code>MYSQL_TIME</code> |
| CHAR, BINARY               | <code>MYSQL_TYPE_STRING</code>      | char[ ]                 |
| VARCHAR, VARBINARY         | <code>MYSQL_TYPE_VAR_STRING</code>  | char[ ]                 |
| TINYBLOB, TINYTEXT         | <code>MYSQL_TYPE_TINY_BLOB</code>   | char[ ]                 |
| BLOB, TEXT                 | <code>MYSQL_TYPE_BLOB</code>        | char[ ]                 |
| MEDIUMBLOB, MEDIUMTEXT     | <code>MYSQL_TYPE_MEDIUM_BLOB</code> | char[ ]                 |
| LONGBLOB, LONGTEXT         | <code>MYSQL_TYPE_LONG_BLOB</code>   | char[ ]                 |
| BIT                        | <code>MYSQL_TYPE_BIT</code>         | char[ ]                 |

### 26.8.9.2 C API Prepared Statement Type Conversions

Prepared statements transmit data between the client and server using C language variables on the client side that correspond to SQL values on the server side. If there is a mismatch between the C variable type on the client side and the corresponding SQL value type on the server side, MySQL performs implicit type conversions in both directions.

MySQL knows the type code for the SQL value on the server side. The `buffer_type` value in the `MYSQL_BIND` structure indicates the type code of the C variable that holds the value on the client side. The two codes together tell MySQL what conversion must be performed, if any. Here are some examples:

- If you use `MYSQL_TYPE_LONG` with an `int` variable to pass an integer value to the server that is to be stored into a `FLOAT` column, MySQL converts the value to floating-point format before storing it.
- If you fetch an SQL `MEDIUMINT` column value, but specify a `buffer_type` value of `MYSQL_TYPE_LONGLONG` and use a C variable of type `long long int` as the destination buffer, MySQL converts the `MEDIUMINT` value (which requires less than 8 bytes) for storage into the `long long int` (an 8-byte variable).
- If you fetch a numeric column with a value of 255 into a `char[4]` character array and specify a `buffer_type` value of `MYSQL_TYPE_STRING`, the resulting value in the array is a 4-byte string `'255\0'`.
- MySQL returns `DECIMAL` values as the string representation of the original server-side value, which is why the corresponding C type is `char[ ]`. For example, `12.345` is returned to the client as

'12.345'. If you specify `MYSQL_TYPE_NEWDECIMAL` and bind a string buffer to the `MYSQL_BIND` structure, `mysql_stmt_fetch()` stores the value in the buffer as a string without conversion. If instead you specify a numeric variable and type code, `mysql_stmt_fetch()` converts the string-format `DECIMAL` value to numeric form.

- For the `MYSQL_TYPE_BIT` type code, `BIT` values are returned into a string buffer, which is why the corresponding C type is `char[]`. The value represents a bit string that requires interpretation on the client side. To return the value as a type that is easier to deal with, you can cause the value to be cast to integer using either of the following types of expressions:

```
SELECT bit_col + 0 FROM t
SELECT CAST(bit_col AS UNSIGNED) FROM t
```

To retrieve the value, bind an integer variable large enough to hold the value and specify the appropriate corresponding integer type code.

Before binding variables to the `MYSQL_BIND` structures that are to be used for fetching column values, you can check the type codes for each column of the result set. This might be desirable if you want to determine which variable types would be best to use to avoid type conversions. To get the type codes, call `mysql_stmt_result_metadata()` after executing the prepared statement with `mysql_stmt_execute()`. The metadata provides access to the type codes for the result set as described in [Section 26.8.11.23, “mysql\\_stmt\\_result\\_metadata\(\)”](#), and [Section 26.8.5, “C API Data Structures”](#).

To determine whether output string values in a result set returned from the server contain binary or nonbinary data, check whether the `charsetnr` value of the result set metadata is 63 (see [Section 26.8.5, “C API Data Structures”](#)). If so, the character set is `binary`, which indicates binary rather than nonbinary data. This enables you to distinguish `BINARY` from `CHAR`, `VARBINARY` from `VARCHAR`, and the `BLOB` types from the `TEXT` types.

If you cause the `max_length` member of the `MYSQL_FIELD` column metadata structures to be set (by calling `mysql_stmt_attr_set()`), be aware that the `max_length` values for the result set indicate the lengths of the longest string representation of the result values, not the lengths of the binary representation. That is, `max_length` does not necessarily correspond to the size of the buffers needed to fetch the values with the binary protocol used for prepared statements. Choose the size of the buffers according to the types of the variables into which you fetch the values. For example, a `TINYINT` column containing the value -128 might have a `max_length` value of 4. But the binary representation of any `TINYINT` value requires only 1 byte for storage, so you can supply a `signed char` variable in which to store the value and set `is_unsigned` to indicate that values are signed.

Metadata changes to tables or views referred to by prepared statements are detected and cause automatic reparation of the statement when it is next executed. For more information, see [Section 9.10.4, “Caching of Prepared Statements and Stored Programs”](#).

## 26.8.10 C API Prepared Statement Function Overview

The functions available for prepared statement processing are summarized here and described in greater detail in a later section. See [Section 26.8.11, “C API Prepared Statement Function Descriptions”](#).

| Function                              | Description   |
|---------------------------------------|---|
| <code>mysql_stmt_affected_rows</code> | Returns the number of rows changed, deleted, or inserted by prepared <code>UPDATE</code> , <code>DELETE</code> , or <code>INSERT</code> statement |
| <code>mysql_stmt_attr_get()</code>    | Gets value of an attribute for a prepared statement   |
| <code>mysql_stmt_attr_set()</code>    | Sets an attribute for a prepared statement  |
| <code>mysql_stmt_bind_param()</code>  | Associates application data buffers with the parameter markers in a prepared SQL statement  |
| <code>mysql_stmt_bind_result()</code> | Associates application data buffers with columns in a result set  |

| Function                                  | Description   |
|---|---|
| <code>mysql_stmt_close()</code>           | Frees memory used by a prepared statement   |
| <code>mysql_stmt_data_seek()</code>       | Seeks to an arbitrary row number in a statement result set  |
| <code>mysql_stmt_errno()</code>           | Returns the error number for the last statement execution   |
| <code>mysql_stmt_error()</code>           | Returns the error message for the last statement execution  |
| <code>mysql_stmt_execute()</code>         | Executes a prepared statement   |
| <code>mysql_stmt_fetch()</code>           | Fetches the next row of data from a result set and returns data for all bound columns                         |
| <code>mysql_stmt_fetch_column()</code>    | Fetch data for one column of the current row of a result set  |
| <code>mysql_stmt_field_count()</code>     | Returns the number of result columns for the most recent statement  |
| <code>mysql_stmt_free_result()</code>     | Free the resources allocated to a statement handle  |
| <code>mysql_stmt_init()</code>            | Allocates memory for a <code>MYSQL_STMT</code> structure and initializes it                                   |
| <code>mysql_stmt_insert_id()</code>       | Returns the ID generated for an <code>AUTO_INCREMENT</code> column by a prepared statement                    |
| <code>mysql_stmt_next_result()</code>     | Returns/initiates the next result in a multiple-result execution  |
| <code>mysql_stmt_num_rows()</code>        | Returns the row count from a buffered statement result set  |
| <code>mysql_stmt_param_count()</code>     | Returns the number of parameters in a prepared statement  |
| <code>mysql_stmt_param_metadata()</code>  | (Return parameter metadata in the form of a result set) This function does nothing                            |
| <code>mysql_stmt_prepare()</code>         | Prepares an SQL statement string for execution  |
| <code>mysql_stmt_reset()</code>           | Resets the statement buffers in the server  |
| <code>mysql_stmt_result_metadata()</code> | Returns prepared statement metadata in the form of a result set   |
| <code>mysql_stmt_row_seek()</code>        | Seeks to a row offset in a statement result set, using value returned from <code>mysql_stmt_row_tell()</code> |
| <code>mysql_stmt_row_tell()</code>        | Returns the statement row cursor position   |
| <code>mysql_stmt_send_long_data()</code>  | Sends long data in chunks to server   |
| <code>mysql_stmt_sqlstate()</code>        | Returns the <code>SQLSTATE</code> error code for the last statement execution                                 |
| <code>mysql_stmt_store_result()</code>    | Retrieves a complete result set to the client   |

Call `mysql_stmt_init()` to create a statement handle, then `mysql_stmt_prepare()` to prepare the statement string, `mysql_stmt_bind_param()` to supply the parameter data, and `mysql_stmt_execute()` to execute the statement. You can repeat the `mysql_stmt_execute()` by changing parameter values in the respective buffers supplied through `mysql_stmt_bind_param()`.

You can send text or binary data in chunks to server using `mysql_stmt_send_long_data()`. See [Section 26.8.11.26, “mysql\\_stmt\\_send\\_long\\_data\(\)”](#).

If the statement is a `SELECT` or any other statement that produces a result set, `mysql_stmt_prepare()` also returns the result set metadata information in the form of a `MYSQL_RES` result set through `mysql_stmt_result_metadata()`.

You can supply the result buffers using `mysql_stmt_bind_result()`, so that the `mysql_stmt_fetch()` automatically returns data to these buffers. This is row-by-row fetching.

When statement execution has been completed, close the statement handle using `mysql_stmt_close()` so that all resources associated with it can be freed.

If you obtained a `SELECT` statement's result set metadata by calling `mysql_stmt_result_metadata()`, you should also free the metadata using `mysql_free_result()`.

## Execution Steps

To prepare and execute a statement, an application follows these steps:

1. Create a prepared statement handle with `mysql_stmt_init()`. To prepare the statement on the server, call `mysql_stmt_prepare()` and pass it a string containing the SQL statement.
2. If the statement will produce a result set, call `mysql_stmt_result_metadata()` to obtain the result set metadata. This metadata is itself in the form of result set, albeit a separate one from the one that contains the rows returned by the query. The metadata result set indicates how many columns are in the result and contains information about each column.
3. Set the values of any parameters using `mysql_stmt_bind_param()`. All parameters must be set. Otherwise, statement execution returns an error or produces unexpected results.
4. Call `mysql_stmt_execute()` to execute the statement.
5. If the statement produces a result set, bind the data buffers to use for retrieving the row values by calling `mysql_stmt_bind_result()`.
6. Fetch the data into the buffers row by row by calling `mysql_stmt_fetch()` repeatedly until no more rows are found.
7. Repeat steps 3 through 6 as necessary, by changing the parameter values and re-executing the statement.

When `mysql_stmt_prepare()` is called, the MySQL client/server protocol performs these actions:

- The server parses the statement and sends the okay status back to the client by assigning a statement ID. It also sends total number of parameters, a column count, and its metadata if it is a result set oriented statement. All syntax and semantics of the statement are checked by the server during this call.
- The client uses this statement ID for the further operations, so that the server can identify the statement from among its pool of statements.

When `mysql_stmt_execute()` is called, the MySQL client/server protocol performs these actions:

- The client uses the statement handle and sends the parameter data to the server.
- The server identifies the statement using the ID provided by the client, replaces the parameter markers with the newly supplied data, and executes the statement. If the statement produces a result set, the server sends the data back to the client. Otherwise, it sends an okay status and the number of rows changed, deleted, or inserted.

When `mysql_stmt_fetch()` is called, the MySQL client/server protocol performs these actions:

- The client reads the data from the current row of the result set and places it into the application data buffers by doing the necessary conversions. If the application buffer type is same as that of the field type returned from the server, the conversions are straightforward.

If an error occurs, you can get the statement error number, error message, and SQLSTATE code using `mysql_stmt_errno()`, `mysql_stmt_error()`, and `mysql_stmt_sqlstate()`, respectively.

## Prepared Statement Logging

For prepared statements that are executed with the `mysql_stmt_prepare()` and `mysql_stmt_execute()` C API functions, the server writes `Prepare` and `Execute` lines to the general query log so that you can tell when statements are prepared and executed.

Suppose that you prepare and execute a statement as follows:

1. Call `mysql_stmt_prepare()` to prepare the statement string `"SELECT ?"`.
2. Call `mysql_stmt_bind_param()` to bind the value `3` to the parameter in the prepared statement.

3. Call `mysql_stmt_execute()` to execute the prepared statement.

As a result of the preceding calls, the server writes the following lines to the general query log:

```
Prepare  [1] SELECT ?
Execute  [1] SELECT 3
```

Each `Prepare` and `Execute` line in the log is tagged with a `[N]` statement identifier so that you can keep track of which prepared statement is being logged. `N` is a positive integer. If there are multiple prepared statements active simultaneously for the client, `N` may be greater than 1. Each `Execute` line shows a prepared statement after substitution of data values for `?` parameters.

## 26.8.11 C API Prepared Statement Function Descriptions

To prepare and execute queries, use the functions described in detail in the following sections.

All functions that operate with a `MYSQL_STMT` structure begin with the prefix `mysql_stmt_`.

To create a `MYSQL_STMT` handle, use the `mysql_stmt_init()` function.

### 26.8.11.1 `mysql_stmt_affected_rows()`

```
my_ulonglong mysql_stmt_affected_rows(MYSQL_STMT *stmt)
```

#### Description

`mysql_stmt_affected_rows()` may be called immediately after executing a statement with `mysql_stmt_execute()`. It is like `mysql_affected_rows()` but for prepared statements. For a description of what the affected-rows value returned by this function means, See [Section 26.8.7.1](#), “`mysql_affected_rows()`”.

#### Errors

None.

#### Example

See the Example in [Section 26.8.11.10](#), “`mysql_stmt_execute()`”.

### 26.8.11.2 `mysql_stmt_attr_get()`

```
my_bool mysql_stmt_attr_get(MYSQL_STMT *stmt, enum enum_stmt_attr_type
option, void *arg)
```

#### Description

Can be used to get the current value for a statement attribute.

The `option` argument is the option that you want to get; the `arg` should point to a variable that should contain the option value. If the option is an integer, `arg` should point to the value of the integer.

See [Section 26.8.11.3](#), “`mysql_stmt_attr_set()`”, for a list of options and option types.

#### Return Values

Zero for success. Nonzero if `option` is unknown.

#### Errors

None.

### 26.8.11.3 `mysql_stmt_attr_set()`

```
my_bool mysql_stmt_attr_set(MYSQL_STMT *stmt, enum enum_stmt_attr_type
option, const void *arg)
```

## Description

Can be used to affect behavior for a prepared statement. This function may be called multiple times to set several options.

The `option` argument is the option that you want to set. The `arg` argument is the value for the option. `arg` should point to a variable that is set to the desired attribute value. The variable type is as indicated in the following table.

The following table shows the possible `option` values.

| Option                                   | Argument Type                | Function  |
|--|------------------------------|---|
| <code>STMT_ATTR_UPDATE_MAX_LENGTH</code> | <code>my_bool *</code>       | If set to 1, causes <code>mysql_stmt_store_result()</code> to update the metadata <code>MYSQL_FIELD-&gt;max_length</code> value.  |
| <code>STMT_ATTR_CURSOR_TYPE</code>       | <code>unsigned long *</code> | Type of cursor to open for statement when <code>mysql_stmt_execute()</code> is invoked. <code>*arg</code> can be <code>CURSOR_TYPE_NO_CURSOR</code> (the default) or <code>CURSOR_TYPE_READ_ONLY</code> . |
| <code>STMT_ATTR_PREFETCH_ROWS</code>     | <code>unsigned long *</code> | Number of rows to fetch from server at a time when using a cursor. <code>*arg</code> can be in the range from 1 to the maximum value of <code>unsigned long</code> . The default is 1.                    |

If you use the `STMT_ATTR_CURSOR_TYPE` option with `CURSOR_TYPE_READ_ONLY`, a cursor is opened for the statement when you invoke `mysql_stmt_execute()`. If there is already an open cursor from a previous `mysql_stmt_execute()` call, it closes the cursor before opening a new one. `mysql_stmt_reset()` also closes any open cursor before preparing the statement for re-execution. `mysql_stmt_free_result()` closes any open cursor.

If you open a cursor for a prepared statement, `mysql_stmt_store_result()` is unnecessary, because that function causes the result set to be buffered on the client side.

## Return Values

Zero for success. Nonzero if `option` is unknown.

## Errors

None.

## Example

The following example opens a cursor for a prepared statement and sets the number of rows to fetch at a time to 5:

```
MYSQL_STMT *stmt;
int rc;
unsigned long type;
unsigned long prefetch_rows = 5;

stmt = mysql_stmt_init(mysql);
type = (unsigned long) CURSOR_TYPE_READ_ONLY;
rc = mysql_stmt_attr_set(stmt, STMT_ATTR_CURSOR_TYPE, (void*) &type);
/* ... check return value ... */
rc = mysql_stmt_attr_set(stmt, STMT_ATTR_PREFETCH_ROWS,
                        (void*) &prefetch_rows);
```

```
/* ... check return value ... */
```

#### 26.8.11.4 `mysql_stmt_bind_param()`

```
my_bool mysql_stmt_bind_param(MYSQL_STMT *stmt, MYSQL_BIND *bind)
```

##### Description

`mysql_stmt_bind_param()` is used to bind input data for the parameter markers in the SQL statement that was passed to `mysql_stmt_prepare()`. It uses `MYSQL_BIND` structures to supply the data. `bind` is the address of an array of `MYSQL_BIND` structures. The client library expects the array to contain one element for each `?` parameter marker that is present in the query.

Suppose that you prepare the following statement:

```
INSERT INTO mytbl VALUES(?,?,?)
```

When you bind the parameters, the array of `MYSQL_BIND` structures must contain three elements, and can be declared like this:

```
MYSQL_BIND bind[3];
```

[Section 26.8.9, “C API Prepared Statement Data Structures”](#), describes the members of each `MYSQL_BIND` element and how they should be set to provide input values.

##### Return Values

Zero for success. Nonzero if an error occurred.

##### Errors

- `CR_UNSUPPORTED_PARAM_TYPE`

The conversion is not supported. Possibly the `buffer_type` value is invalid or is not one of the supported types.

- `CR_OUT_OF_MEMORY`

Out of memory.

- `CR_UNKNOWN_ERROR`

An unknown error occurred.

##### Example

See the Example in [Section 26.8.11.10, “`mysql\_stmt\_execute\(\)`”](#).

#### 26.8.11.5 `mysql_stmt_bind_result()`

```
my_bool mysql_stmt_bind_result(MYSQL_STMT *stmt, MYSQL_BIND *bind)
```

##### Description

`mysql_stmt_bind_result()` is used to associate (that is, bind) output columns in the result set to data buffers and length buffers. When `mysql_stmt_fetch()` is called to fetch data, the MySQL client/server protocol places the data for the bound columns into the specified buffers.

All columns must be bound to buffers prior to calling `mysql_stmt_fetch()`. `bind` is the address of an array of `MYSQL_BIND` structures. The client library expects the array to contain one element for each column of the result set. If you do not bind columns to `MYSQL_BIND` structures, `mysql_stmt_fetch()` simply ignores the data fetch. The buffers should be large enough to hold the data values, because the protocol does not return data values in chunks.

A column can be bound or rebound at any time, even after a result set has been partially retrieved. The new binding takes effect the next time `mysql_stmt_fetch()` is called. Suppose that an application binds the columns in a result set and calls `mysql_stmt_fetch()`. The client/server protocol returns data in the bound buffers. Then suppose that the application binds the columns to a different set of buffers. The protocol places data into the newly bound buffers when the next call to `mysql_stmt_fetch()` occurs.

To bind a column, an application calls `mysql_stmt_bind_result()` and passes the type, address, and length of the output buffer into which the value should be stored. [Section 26.8.9, “C API Prepared Statement Data Structures”](#), describes the members of each `MYSQL_BIND` element and how they should be set to receive output values.

## Return Values

Zero for success. Nonzero if an error occurred.

## Errors

- `CR_UNSUPPORTED_PARAM_TYPE`

The conversion is not supported. Possibly the `buffer_type` value is invalid or is not one of the supported types.

- `CR_OUT_OF_MEMORY`

Out of memory.

- `CR_UNKNOWN_ERROR`

An unknown error occurred.

## Example

See the Example in [Section 26.8.11.11, “mysql\\_stmt\\_fetch\(\)”](#).

### 26.8.11.6 `mysql_stmt_close()`

```
my_bool mysql_stmt_close(MYSQL_STMT *)
```

## Description

Closes the prepared statement. `mysql_stmt_close()` also deallocates the statement handle pointed to by `stmt`.

If the current statement has pending or unread results, this function cancels them so that the next query can be executed.

## Return Values

Zero for success. Nonzero if an error occurred.

## Errors

- `CR_SERVER_GONE_ERROR`

The MySQL server has gone away.

- `CR_UNKNOWN_ERROR`

An unknown error occurred.

## Example

See the Example in [Section 26.8.11.10, “mysql\\_stmt\\_execute\(\)”](#).

### 26.8.11.7 `mysql_stmt_data_seek()`

```
void mysql_stmt_data_seek(MYSQL_STMT *stmt, my_ulonglong offset)
```

#### Description

Seeks to an arbitrary row in a statement result set. The `offset` value is a row number and should be in the range from 0 to `mysql_stmt_num_rows(stmt)-1`.

This function requires that the statement result set structure contains the entire result of the last executed query, so `mysql_stmt_data_seek()` may be used only in conjunction with `mysql_stmt_store_result()`.

#### Return Values

None.

#### Errors

None.

### 26.8.11.8 `mysql_stmt_errno()`

```
unsigned int mysql_stmt_errno(MYSQL_STMT *stmt)
```

#### Description

For the statement specified by `stmt`, `mysql_stmt_errno()` returns the error code for the most recently invoked statement API function that can succeed or fail. A return value of zero means that no error occurred. Client error message numbers are listed in the MySQL `errmsg.h` header file. Server error message numbers are listed in `mysqld_error.h`. Errors also are listed at [Appendix B, Errors, Error Codes, and Common Problems](#).

#### Return Values

An error code value. Zero if no error occurred.

#### Errors

None.

### 26.8.11.9 `mysql_stmt_error()`

```
const char *mysql_stmt_error(MYSQL_STMT *stmt)
```

#### Description

For the statement specified by `stmt`, `mysql_stmt_error()` returns a null-terminated string containing the error message for the most recently invoked statement API function that can succeed or fail. An empty string ("" ) is returned if no error occurred. Either of these two tests can be used to check for an error:

```
if(*mysql_stmt_errno(stmt))
{
    // an error occurred
}

if (mysql_stmt_error(stmt)[0])
{
    // an error occurred
}
```

The language of the client error messages may be changed by recompiling the MySQL client library. You can choose error messages in several different languages.

## Return Values

A character string that describes the error. An empty string if no error occurred.

## Errors

None.

### 26.8.11.10 `mysql_stmt_execute()`

```
int mysql_stmt_execute(MYSQL_STMT *stmt)
```

## Description

`mysql_stmt_execute()` executes the prepared query associated with the statement handle. The currently bound parameter marker values are sent to server during this call, and the server replaces the markers with this newly supplied data.

Statement processing following `mysql_stmt_execute()` depends on the type of statement:

- For an `UPDATE`, `DELETE`, or `INSERT`, the number of changed, deleted, or inserted rows can be found by calling `mysql_stmt_affected_rows()`.
- For a statement such as `SELECT` that generates a result set, you must call `mysql_stmt_fetch()` to fetch the data prior to calling any other functions that result in query processing. For more information on how to fetch the results, refer to [Section 26.8.11.11, “mysql\\_stmt\\_fetch\(\)”](#).

Do not following invocation of `mysql_stmt_execute()` with a call to `mysql_store_result()` or `mysql_use_result()`. Those functions are not intended for processing results from prepared statements.

For statements that generate a result set, you can request that `mysql_stmt_execute()` open a cursor for the statement by calling `mysql_stmt_attr_set()` before executing the statement. If you execute a statement multiple times, `mysql_stmt_execute()` closes any open cursor before opening a new one.

Metadata changes to tables or views referred to by prepared statements are detected and cause automatic reparation of the statement when it is next executed. For more information, see [Section 9.10.4, “Caching of Prepared Statements and Stored Programs”](#).

## Return Values

Zero for success. Nonzero if an error occurred.

## Errors

- `CR_COMMANDS_OUT_OF_SYNC`  
Commands were executed in an improper order.
- `CR_OUT_OF_MEMORY`  
Out of memory.
- `CR_SERVER_GONE_ERROR`  
The MySQL server has gone away.
- `CR_SERVER_LOST`  
The connection to the server was lost during the query.
- `CR_UNKNOWN_ERROR`  
An unknown error occurred.

## Example

The following example demonstrates how to create and populate a table using `mysql_stmt_init()`, `mysql_stmt_prepare()`, `mysql_stmt_param_count()`, `mysql_stmt_bind_param()`, `mysql_stmt_execute()`, and `mysql_stmt_affected_rows()`. The `mysql` variable is assumed to be a valid connection handle. For an example that shows how to retrieve data, see [Section 26.8.11.11](#), “`mysql_stmt_fetch()`”.

```
#define STRING_SIZE 50

#define DROP_SAMPLE_TABLE "DROP TABLE IF EXISTS test_table"
#define CREATE_SAMPLE_TABLE "CREATE TABLE test_table(col1 INT,\
                                         col2 VARCHAR(40),\
                                         col3 SMALLINT,\
                                         col4 TIMESTAMP)"

#define INSERT_SAMPLE "INSERT INTO \
test_table(col1,col2,col3) \
VALUES(?,?,?)"

MYSQL_STMT      *stmt;
MYSQL_BIND      bind[3];
my_ulonglong    affected_rows;
int             param_count;

    fprintf(stderr, " mysql_stmt_execute(), 1 failed\n");
    fprintf(stderr, " %s\n", mysql_stmt_error(stmt));
    exit(0);
}

/* Get the number of affected rows */
affected_rows= mysql_stmt_affected_rows(stmt);
fprintf(stdout, " total affected rows(insert 1): %lu\n",
        (unsigned long) affected_rows);

if (affected_rows != 1) /* validate affected rows */
{
    fprintf(stderr, " invalid affected rows by MySQL\n");
    exit(0);
}

/* Specify data values for second row,
   then re-execute the statement */
int_data= 1000;
strncpy(str_data, "
        The most popular Open Source database",
        STRING_SIZE);
str_length= strlen(str_data);
small_data= 1000;           /* smallint */
is_null= 0;                 /* reset */

/* Execute the INSERT statement - 2*/
if (mysql_stmt_execute(stmt))

```

```

{
    fprintf(stderr, " mysql_stmt_execute, 2 failed\n");
    fprintf(stderr, " %s\n", mysql_stmt_error(stmt));
    exit(0);
}

/* Get the total rows affected */
affected_rows= mysql_stmt_affected_rows(stmt);
fprintf(stdout, " total affected rows(insert 2): %lu\n",
        (unsigned long) affected_rows);

if (affected_rows != 1) /* validate affected rows */
{
    fprintf(stderr, " invalid affected rows by MySQL\n");
    exit(0);
}

/* Close the statement */
if (mysql_stmt_close(stmt))
{
    fprintf(stderr, " failed while closing the statement\n");
    fprintf(stderr, " %s\n", mysql_stmt_error(stmt));
    exit(0);
}

```

### Note

For complete examples on the use of prepared statement functions, refer to the file `tests/mysql_client_test.c`. This file can be obtained from a MySQL source distribution or from the source repository (see [Section 2.9, “Installing MySQL from Source”](#)).

## 26.8.11.11 mysql\_stmt\_fetch()

```
int mysql_stmt_fetch(MYSQL_STMT *stmt)
```

### Description

`mysql_stmt_fetch()` returns the next row in the result set. It can be called only while the result set exists; that is, after a call to `mysql_stmt_execute()` for a statement such as `SELECT` that produces a result set.

`mysql_stmt_fetch()` returns row data using the buffers bound by `mysql_stmt_bind_result()`. It returns the data in those buffers for all the columns in the current row set and the lengths are returned to the `length` pointer. All columns must be bound by the application before it calls `mysql_stmt_fetch()`.

By default, result sets are fetched unbuffered a row at a time from the server. To buffer the entire result set on the client, call `mysql_stmt_store_result()` after binding the data buffers and before calling `mysql_stmt_fetch()`.

If a fetched data value is a `NULL` value, the `*is_null` value of the corresponding `MYSQL_BIND` structure contains `TRUE` (1). Otherwise, the data and its length are returned in the `*buffer` and `*length` elements based on the buffer type specified by the application. Each numeric and temporal type has a fixed length, as listed in the following table. The length of the string types depends on the length of the actual data value, as indicated by `data_length`.

| Type                             | Length |
|----------------------------------|--------|
| <code>MYSQL_TYPE_TINY</code>     | 1      |
| <code>MYSQL_TYPE_SHORT</code>    | 2      |
| <code>MYSQL_TYPE_LONG</code>     | 4      |
| <code>MYSQL_TYPE_LONGLONG</code> | 8      |
| <code>MYSQL_TYPE_FLOAT</code>    | 4      |

| Type                             | Length                          |
|----------------------------------|---------------------------------|
| <code>MYSQL_TYPE_DOUBLE</code>   | 8                               |
| <code>MYSQL_TYPE_TIME</code>     | <code>sizeof(MYSQL_TIME)</code> |
| <code>MYSQL_TYPE_DATE</code>     | <code>sizeof(MYSQL_TIME)</code> |
| <code>MYSQL_TYPE_DATETIME</code> | <code>sizeof(MYSQL_TIME)</code> |
| <code>MYSQL_TYPE_STRING</code>   | data length                     |
| <code>MYSQL_TYPE_BLOB</code>     | data_length                     |

In some cases you might want to determine the length of a column value before fetching it with `mysql_stmt_fetch()`. For example, the value might be a long string or `BLOB` value for which you want to know how much space must be allocated. To accomplish this, you can use these strategies:

- Before invoking `mysql_stmt_fetch()` to retrieve individual rows, pass `STMT_ATTR_UPDATE_MAX_LENGTH` to `mysql_stmt_attr_set()`, then invoke `mysql_stmt_store_result()` to buffer the entire result on the client side. Setting the `STMT_ATTR_UPDATE_MAX_LENGTH` attribute causes the maximal length of column values to be indicated by the `max_length` member of the result set metadata returned by `mysql_stmt_result_metadata()`.
- Invoke `mysql_stmt_fetch()` with a zero-length buffer for the column in question and a pointer in which the real length can be stored. Then use the real length with `mysql_stmt_fetch_column()`.

```
real_length= 0;

bind[0].buffer= 0;
bind[0].buffer_length= 0;
bind[0].length= &real_length
mysql_stmt_bind_result(stmt, bind);

mysql_stmt_fetch(stmt);
if (real_length > 0)
{
    data= malloc(real_length);
    bind[0].buffer= data;
    bind[0].buffer_length= real_length;
    mysql_stmt_fetch_column(stmt, bind, 0, 0);
}
```

## Return Values

| Return Value                      | Description   |
|-----------------------------------|---|
| 0                                 | Successful, the data has been fetched to application data buffers.  |
| 1                                 | Error occurred. Error code and message can be obtained by calling <code>mysql_stmt_errno()</code> and <code>mysql_stmt_error()</code> . |
| <code>MYSQL_NO_DATA</code>        | No more rows/data exists  |
| <code>MYSQL_DATA_TRUNCATED</code> | Data truncation occurred  |

`MYSQL_DATA_TRUNCATED` is returned when truncation reporting is enabled. To determine which column values were truncated when this value is returned, check the `error` members of the `MYSQL_BIND` structures used for fetching values. Truncation reporting is enabled by default, but can be controlled by calling `mysql_options()` with the `MYSQL_REPORT_DATA_TRUNCATION` option.

## Errors

- `CR_COMMANDS_OUT_OF_SYNC`  
Commands were executed in an improper order.
- `CR_OUT_OF_MEMORY`

Out of memory.

- [CR\\_SERVER\\_GONE\\_ERROR](#)

The MySQL server has gone away.

- [CR\\_SERVER\\_LOST](#)

The connection to the server was lost during the query.

- [CR\\_UNKNOWN\\_ERROR](#)

An unknown error occurred.

- [CR\\_UNSUPPORTED\\_PARAM\\_TYPE](#)

The buffer type is [MYSQL\\_TYPE\\_DATE](#), [MYSQL\\_TYPE\\_TIME](#), [MYSQL\\_TYPE\\_DATETIME](#), or [MYSQL\\_TYPE\\_TIMESTAMP](#), but the data type is not [DATE](#), [TIME](#), [DATETIME](#), or [TIMESTAMP](#).

- All other unsupported conversion errors are returned from [mysql\\_stmt\\_bind\\_result\(\)](#).

## Example

The following example demonstrates how to fetch data from a table using [mysql\\_stmt\\_result\\_metadata\(\)](#), [mysql\\_stmt\\_bind\\_result\(\)](#), and [mysql\\_stmt\\_fetch\(\)](#). (This example expects to retrieve the two rows inserted by the example shown in [Section 26.8.11.10](#), “[mysql\\_stmt\\_execute\(\)](#)”.) The [mysql](#) variable is assumed to be a valid connection handle.

```
#define STRING_SIZE 50

#define SELECT_SAMPLE "SELECT col1, col2, col3, col4 \
                      FROM test_table"

MYSQL_STMT      *stmt;
MYSQL_BIND      bind[4];
MYSQL_RES       *prepare_meta_result;
MYSQL_TIME      ts;
unsigned long    length[4];
int             param_count, column_count, row_count;
short           small_data;
int             int_data;
char            str_data[STRING_SIZE];
my_bool         is_null[4];
my_bool         error[4];

/* Prepare a SELECT query to fetch data from test_table */
stmt = mysql_stmt_init(mysql);
if (!stmt)
{
    fprintf(stderr, " mysql_stmt_init(), out of memory\n");
    exit(0);
}
if (mysql_stmt_prepare(stmt, SELECT_SAMPLE, strlen(SELECT_SAMPLE)))
{
    fprintf(stderr, " mysql_stmt_prepare(), SELECT failed\n");
    fprintf(stderr, " %s\n", mysql_stmt_error(stmt));
    exit(0);
}
fprintf(stdout, " prepare, SELECT successful\n");

/* Get the parameter count from the statement */
param_count= mysql_stmt_param_count(stmt);
fprintf(stdout, " total parameters in SELECT: %d\n", param_count);

if (param_count != 0) /* validate parameter count */
{
    fprintf(stderr, " invalid parameter count returned by MySQL\n");
```

```
    exit(0);
}

/* Fetch result set meta information */
prepare_meta_result = mysql_stmt_result_metadata(stmt);
if (!prepare_meta_result)
{
    fprintf(stderr,
        " mysql_stmt_result_metadata(), \
        returned no meta information\n");
    fprintf(stderr, " %s\n", mysql_stmt_error(stmt));
    exit(0);
}

/* Get total columns in the query */
column_count= mysql_num_fields(prepare_meta_result);
fprintf(stdout,
    " total columns in SELECT statement: %d\n",
    column_count);

if (column_count != 4) /* validate column count */
{
    fprintf(stderr, " invalid column count returned by MySQL\n");
    exit(0);
}

/* Execute the SELECT query */
if (mysql_stmt_execute(stmt))
{
    fprintf(stderr, " mysql_stmt_execute(), failed\n");
    fprintf(stderr, " %s\n", mysql_stmt_error(stmt));
    exit(0);
}

/* Bind the result buffers for all 4 columns before fetching them */

memset(bind, 0, sizeof(bind));

/* INTEGER COLUMN */
bind[0].buffer_type= MYSQL_TYPE_LONG;
bind[0].buffer= (char *)&int_data;
bind[0].is_null= &is_null[0];
bind[0].length= &length[0];
bind[0].error= &error[0];

/* STRING COLUMN */
bind[1].buffer_type= MYSQL_TYPE_STRING;
bind[1].buffer= (char *)str_data;
bind[1].buffer_length= STRING_SIZE;
bind[1].is_null= &is_null[1];
bind[1].length= &length[1];
bind[1].error= &error[1];

/* SMALLINT COLUMN */
bind[2].buffer_type= MYSQL_TYPE_SHORT;
bind[2].buffer= (char *)&small_data;
bind[2].is_null= &is_null[2];
bind[2].length= &length[2];
bind[2].error= &error[2];

    exit(0);
}

/* Free the prepared result metadata */
mysql_free_result(prepare_meta_result);

/* Close the statement */
if (mysql_stmt_close(stmt))
{
    fprintf(stderr, " failed while closing the statement\n");
    fprintf(stderr, " %s\n", mysql_stmt_error(stmt));
    exit(0);
}
```

### 26.8.11.12 `mysql_stmt_fetch_column()`

```
int mysql_stmt_fetch_column(MYSQL_STMT *stmt, MYSQL_BIND *bind, unsigned int
column, unsigned long offset)
```

#### Description

Fetch one column from the current result set row. `bind` provides the buffer where data should be placed. It should be set up the same way as for `mysql_stmt_bind_result()`. `column` indicates which column to fetch. The first column is numbered 0. `offset` is the offset within the data value at which to begin retrieving data. This can be used for fetching the data value in pieces. The beginning of the value is offset 0.

#### Return Values

Zero for success. Nonzero if an error occurred.

#### Errors

- `CR_INVALID_PARAMETER_NO`  
Invalid column number.
- `CR_NO_DATA`  
The end of the result set has already been reached.

### 26.8.11.13 `mysql_stmt_field_count()`

```
unsigned int mysql_stmt_field_count(MYSQL_STMT *stmt)
```

#### Description

Returns the number of columns for the most recent statement for the statement handler. This value is zero for statements such as `INSERT` or `DELETE` that do not produce result sets.

`mysql_stmt_field_count()` can be called after you have prepared a statement by invoking `mysql_stmt_prepare()`.

#### Return Values

An unsigned integer representing the number of columns in a result set.

#### Errors

None.

### 26.8.11.14 `mysql_stmt_free_result()`

```
my_bool mysql_stmt_free_result(MYSQL_STMT *stmt)
```

#### Description

Releases memory associated with the result set produced by execution of the prepared statement. If there is a cursor open for the statement, `mysql_stmt_free_result()` closes it.

#### Return Values

Zero for success. Nonzero if an error occurred.

#### Errors

### 26.8.11.15 `mysql_stmt_init()`

```
MYSQL_STMT *mysql_stmt_init(MYSQL *mysql)
```

## Description

Create a `MYSQL_STMT` handle. The handle should be freed with `mysql_stmt_close(MYSQL_STMT *)`.

See also [Section 26.8.9, “C API Prepared Statement Data Structures”](#), for more information.

## Return Values

A pointer to a `MYSQL_STMT` structure in case of success. `NULL` if out of memory.

## Errors

- `CR_OUT_OF_MEMORY`

Out of memory.

### 26.8.11.16 `mysql_stmt_insert_id()`

```
my_ulonglong mysql_stmt_insert_id(MYSQL_STMT *stmt)
```

## Description

Returns the value generated for an `AUTO_INCREMENT` column by the prepared `INSERT` or `UPDATE` statement. Use this function after you have executed a prepared `INSERT` statement on a table which contains an `AUTO_INCREMENT` field.

See [Section 26.8.7.38, “`mysql\_insert\_id\(\)`”](#), for more information.

## Return Values

Value for `AUTO_INCREMENT` column which was automatically generated or explicitly set during execution of prepared statement, or value generated by `LAST_INSERT_ID(expr)` function. Return value is undefined if statement does not set `AUTO_INCREMENT` value.

## Errors

None.

### 26.8.11.17 `mysql_stmt_next_result()`

```
int mysql_stmt_next_result(MYSQL_STMT *mysql)
```

## Description

This function is used when you use prepared `CALL` statements to execute stored procedures, which can return multiple result sets. Use a loop that calls `mysql_stmt_next_result()` to determine whether there are more results. If a procedure has `OUT` or `INOUT` parameters, their values will be returned as a single-row result set following any other result sets. The values will appear in the order in which they are declared in the procedure parameter list.

`mysql_stmt_next_result()` returns a status to indicate whether more results exist. If `mysql_stmt_next_result()` returns an error, there are no more results.

Before each call to `mysql_stmt_next_result()`, you must call `mysql_stmt_free_result()` for the current result if it produced a result set (rather than just a result status).

After calling `mysql_stmt_next_result()` the state of the connection is as if you had called `mysql_stmt_execute()`. This means that you can call `mysql_stmt_bind_result()`, `mysql_stmt_affected_rows()`, and so forth.

It is also possible to test whether there are more results by calling `mysql_more_results()`. However, this function does not change the connection state, so if it returns true, you must still call `mysql_stmt_next_result()` to advance to the next result.

For an example that shows how to use `mysql_stmt_next_result()`, see [Section 26.8.20, “C API Support for Prepared CALL Statements”](#).

## Return Values

| Return Value | Description                              |
|--------------|--|
| 0            | Successful and there are more results    |
| -1           | Successful and there are no more results |
| >0           | An error occurred                        |

## Errors

- [CR\\_COMMANDS\\_OUT\\_OF\\_SYNC](#)  
Commands were executed in an improper order.
- [CR\\_SERVER\\_GONE\\_ERROR](#)  
The MySQL server has gone away.
- [CR\\_SERVER\\_LOST](#)  
The connection to the server was lost during the query.
- [CR\\_UNKNOWN\\_ERROR](#)  
An unknown error occurred.

### 26.8.11.18 `mysql_stmt_num_rows()`

```
my_ulonglong mysql_stmt_num_rows(MYSQL_STMT *stmt)
```

## Description

Returns the number of rows in the result set.

The use of `mysql_stmt_num_rows()` depends on whether you used `mysql_stmt_store_result()` to buffer the entire result set in the statement handle. If you use `mysql_stmt_store_result()`, `mysql_stmt_num_rows()` may be called immediately. Otherwise, the row count is unavailable unless you count the rows as you fetch them.

`mysql_stmt_num_rows()` is intended for use with statements that return a result set, such as `SELECT`. For statements such as `INSERT`, `UPDATE`, or `DELETE`, the number of affected rows can be obtained with `mysql_stmt_affected_rows()`.

## Return Values

The number of rows in the result set.

## Errors

None.

### 26.8.11.19 `mysql_stmt_param_count()`

```
unsigned long mysql_stmt_param_count(MYSQL_STMT *stmt)
```

**Description**

Returns the number of parameter markers present in the prepared statement.

**Return Values**

An unsigned long integer representing the number of parameters in a statement.

**Errors**

None.

**Example**

See the Example in [Section 26.8.11.10, “mysql\\_stmt\\_execute\(\)”](#).

**26.8.11.20 mysql\_stmt\_param\_metadata()**

```
MYSQL_RES *mysql_stmt_param_metadata(MYSQL_STMT *stmt)
```

This function currently does nothing.

**Description****Return Values****Errors****26.8.11.21 mysql\_stmt\_prepare()**

```
int mysql_stmt_prepare(MYSQL_STMT *stmt, const char *stmt_str, unsigned long length)
```

**Description**

Given the statement handle returned by `mysql_stmt_init()`, prepares the SQL statement pointed to by the string `stmt_str` and returns a status value. The string length should be given by the `length` argument. The string must consist of a single SQL statement. You should not add a terminating semicolon (;) or \g to the statement.

The application can include one or more parameter markers in the SQL statement by embedding question mark (?) characters into the SQL string at the appropriate positions.

The markers are legal only in certain places in SQL statements. For example, they are permitted in the `VALUES()` list of an `INSERT` statement (to specify column values for a row), or in a comparison with a column in a `WHERE` clause to specify a comparison value. However, they are not permitted for identifiers (such as table or column names), or to specify both operands of a binary operator such as the `=` equal sign. The latter restriction is necessary because it would be impossible to determine the parameter type. In general, parameters are legal only in Data Manipulation Language (DML) statements, and not in Data Definition Language (DDL) statements.

The parameter markers must be bound to application variables using `mysql_stmt_bind_param()` before executing the statement.

Metadata changes to tables or views referred to by prepared statements are detected and cause automatic reparation of the statement when it is next executed. For more information, see [Section 9.10.4, “Caching of Prepared Statements and Stored Programs”](#).

**Return Values**

Zero for success. Nonzero if an error occurred.

## Errors

- [CR\\_COMMANDS\\_OUT\\_OF\\_SYNC](#)

Commands were executed in an improper order.

- [CR\\_OUT\\_OF\\_MEMORY](#)

Out of memory.

- [CR\\_SERVER\\_GONE\\_ERROR](#)

The MySQL server has gone away.

- [CR\\_SERVER\\_LOST](#)

The connection to the server was lost during the query

- [CR\\_UNKNOWN\\_ERROR](#)

An unknown error occurred.

If the prepare operation was unsuccessful (that is, `mysql_stmt_prepare()` returns nonzero), the error message can be obtained by calling `mysql_stmt_error()`.

## Example

See the Example in [Section 26.8.11.10](#), “`mysql_stmt_execute()`”.

### 26.8.11.22 `mysql_stmt_reset()`

```
my_bool mysql_stmt_reset(MYSQL_STMT *stmt)
```

## Description

Resets a prepared statement on client and server to state after prepare. It resets the statement on the server, data sent using `mysql_stmt_send_long_data()`, unbuffered result sets and current errors. It does not clear bindings or stored result sets. Stored result sets will be cleared when executing the prepared statement (or closing it).

To re-prepare the statement with another query, use `mysql_stmt_prepare()`.

## Return Values

Zero for success. Nonzero if an error occurred.

## Errors

- [CR\\_COMMANDS\\_OUT\\_OF\\_SYNC](#)

Commands were executed in an improper order.

- [CR\\_SERVER\\_GONE\\_ERROR](#)

The MySQL server has gone away.

- [CR\\_SERVER\\_LOST](#)

The connection to the server was lost during the query

- [CR\\_UNKNOWN\\_ERROR](#)

An unknown error occurred.

### 26.8.11.23 `mysql_stmt_result_metadata()`

```
MYSQL_RES *mysql_stmt_result_metadata(MYSQL_STMT *stmt)
```

#### Description

If a statement passed to `mysql_stmt_prepare()` is one that produces a result set, `mysql_stmt_result_metadata()` returns the result set metadata in the form of a pointer to a `MYSQL_RES` structure that can be used to process the meta information such as number of fields and individual field information. This result set pointer can be passed as an argument to any of the field-based API functions that process result set metadata, such as:

- `mysql_num_fields()`
- `mysql_fetch_field()`
- `mysql_fetch_field_direct()`
- `mysql_fetch_fields()`
- `mysql_field_count()`
- `mysql_field_seek()`
- `mysql_field_tell()`
- `mysql_free_result()`

The result set structure should be freed when you are done with it, which you can do by passing it to `mysql_free_result()`. This is similar to the way you free a result set obtained from a call to `mysql_store_result()`.

The result set returned by `mysql_stmt_result_metadata()` contains only metadata. It does not contain any row results. The rows are obtained by using the statement handle with `mysql_stmt_fetch()`.

#### Return Values

A `MYSQL_RES` result structure. `NULL` if no meta information exists for the prepared query.

#### Errors

- `CR_OUT_OF_MEMORY`  
Out of memory.
- `CR_UNKNOWN_ERROR`  
An unknown error occurred.

#### Example

See the Example in [Section 26.8.11.11, “mysql\\_stmt\\_fetch\(\)”](#).

### 26.8.11.24 `mysql_stmt_row_seek()`

```
MYSQL_ROW_OFFSET mysql_stmt_row_seek(MYSQL_STMT *stmt, MYSQL_ROW_OFFSET offset)
```

#### Description

Sets the row cursor to an arbitrary row in a statement result set. The `offset` value is a row offset that should be a value returned from `mysql_stmt_row_tell()` or from `mysql_stmt_row_seek()`.

This value is not a row number; if you want to seek to a row within a result set by number, use `mysql_stmt_data_seek()` instead.

This function requires that the result set structure contains the entire result of the query, so `mysql_stmt_row_seek()` may be used only in conjunction with `mysql_stmt_store_result()`.

## Return Values

The previous value of the row cursor. This value may be passed to a subsequent call to `mysql_stmt_row_seek()`.

## Errors

None.

### 26.8.11.25 `mysql_stmt_row_tell()`

```
MYSQL_ROW_OFFSET mysql_stmt_row_tell(MYSQL_STMT *stmt)
```

## Description

Returns the current position of the row cursor for the last `mysql_stmt_fetch()`. This value can be used as an argument to `mysql_stmt_row_seek()`.

You should use `mysql_stmt_row_tell()` only after `mysql_stmt_store_result()`.

## Return Values

The current offset of the row cursor.

## Errors

None.

### 26.8.11.26 `mysql_stmt_send_long_data()`

```
my_bool mysql_stmt_send_long_data(MYSQL_STMT *stmt, unsigned int
parameter_number, const char *data, unsigned long length)
```

## Description

Enables an application to send parameter data to the server in pieces (or “chunks”). Call this function after `mysql_stmt_bind_param()` and before `mysql_stmt_execute()`. It can be called multiple times to send the parts of a character or binary data value for a column, which must be one of the `TEXT` or `BLOB` data types.

`parameter_number` indicates which parameter to associate the data with. Parameters are numbered beginning with 0. `data` is a pointer to a buffer containing data to be sent, and `length` indicates the number of bytes in the buffer.

#### Note

The next `mysql_stmt_execute()` call ignores the bind buffer for all parameters that have been used with `mysql_stmt_send_long_data()` since last `mysql_stmt_execute()` or `mysql_stmt_reset()`.

If you want to reset/forget the sent data, you can do it with `mysql_stmt_reset()`. See [Section 26.8.11.22, “mysql\\_stmt\\_reset\(\)”](#).

The `max_allowed_packet` system variable controls the maximum size of parameter values that can be sent with `mysql_stmt_send_long_data()`.

## Return Values

Zero for success. Nonzero if an error occurred.

## Errors

- [CR\\_INVALID\\_BUFFER\\_USE](#)

The parameter does not have a string or binary type.

- [CR\\_INVALID\\_PARAMETER\\_NO](#)

Invalid parameter number.

- [CR\\_COMMANDS\\_OUT\\_OF\\_SYNC](#)

Commands were executed in an improper order.

- [CR\\_SERVER\\_GONE\\_ERROR](#)

The MySQL server has gone away.

- [CR\\_OUT\\_OF\\_MEMORY](#)

Out of memory.

- [CR\\_UNKNOWN\\_ERROR](#)

An unknown error occurred.

## Example

The following example demonstrates how to send the data for a [TEXT](#) column in chunks. It inserts the data value 'MySQL - The most popular Open Source database' into the `text_column` column. The `mysql` variable is assumed to be a valid connection handle.

```
#define INSERT_QUERY "INSERT INTO \  
                        test_long_data(text_column) VALUES(?)"  
  
MYSQL_BIND bind[1];  
long          length;  
  
stmt = mysql_stmt_init(mysql);  
if (!stmt)  
{  
    fprintf(stderr, " mysql_stmt_init(), out of memory\n");  
    exit(0);  
}  
if (mysql_stmt_prepare(stmt, INSERT_QUERY, strlen(INSERT_QUERY))  
    {  
    fprintf(stderr, "\n mysql_stmt_prepare(), INSERT failed");  
    fprintf(stderr, "\n %s", mysql_stmt_error(stmt));  
    exit(0);  
}  
memset(bind, 0, sizeof(bind));  
bind[0].buffer_type= MYSQL_TYPE_STRING;  
bind[0].length= &length;  
bind[0].is_null= 0;  
  
/* Bind the buffers */  
if (mysql_stmt_bind_param(stmt, bind))  
{  
    fprintf(stderr, "\n param bind failed");  
    fprintf(stderr, "\n %s", mysql_stmt_error(stmt));  
    exit(0);  
}
```

```
/* Supply data in chunks to server */
if (mysql_stmt_send_long_data(stmt,0,"MySQL",5))
{
    fprintf(stderr, "\n send_long_data failed");
    fprintf(stderr, "\n %s", mysql_stmt_error(stmt));
    exit(0);
}

/* Supply the next piece of data */
if (mysql_stmt_send_long_data(stmt,0,
    " - The most popular Open Source database",40))
{
    fprintf(stderr, "\n send_long_data failed");
    fprintf(stderr, "\n %s", mysql_stmt_error(stmt));
    exit(0);
}

/* Now, execute the query */
if (mysql_stmt_execute(stmt))
{
    fprintf(stderr, "\n mysql_stmt_execute failed");
    fprintf(stderr, "\n %s", mysql_stmt_error(stmt));
    exit(0);
}
```

### 26.8.11.27 `mysql_stmt_sqlstate()`

```
const char *mysql_stmt_sqlstate(MYSQL_STMT *stmt)
```

#### Description

For the statement specified by `stmt`, `mysql_stmt_sqlstate()` returns a null-terminated string containing the SQLSTATE error code for the most recently invoked prepared statement API function that can succeed or fail. The error code consists of five characters. "00000" means "no error." The values are specified by ANSI SQL and ODBC. For a list of possible values, see [Appendix B, Errors, Error Codes, and Common Problems](#).

Not all MySQL errors are mapped to SQLSTATE codes. The value "HY000" (general error) is used for unmapped errors.

#### Return Values

A null-terminated character string containing the SQLSTATE error code.

### 26.8.11.28 `mysql_stmt_store_result()`

```
int mysql_stmt_store_result(MYSQL_STMT *stmt)
```

#### Description

Result sets are produced by calling `mysql_stmt_execute()` to executed prepared statements for SQL statements such as `SELECT`, `SHOW`, `DESCRIBE`, and `EXPLAIN`. By default, result sets for successfully executed prepared statements are not buffered on the client and `mysql_stmt_fetch()` fetches them one at a time from the server. To cause the complete result set to be buffered on the client, call `mysql_stmt_store_result()` after binding data buffers with `mysql_stmt_bind_result()` and before calling `mysql_stmt_fetch()` to fetch rows. (For an example, see [Section 26.8.11.11, "mysql\\_stmt\\_fetch\(\)"](#).)

`mysql_stmt_store_result()` is optional for result set processing, unless you will call `mysql_stmt_data_seek()`, `mysql_stmt_row_seek()`, or `mysql_stmt_row_tell()`. Those functions require a seekable result set.

It is unnecessary to call `mysql_stmt_store_result()` after executing an SQL statement that does not produce a result set, but if you do, it does not harm or cause any notable

performance problem. You can detect whether the statement produced a result set by checking if `mysql_stmt_result_metadata()` returns `NULL`. For more information, refer to [Section 26.8.11.23](#), “`mysql_stmt_result_metadata()`”.

**Note**

MySQL does not by default calculate `MYSQL_FIELD->max_length` for all columns in `mysql_stmt_store_result()` because calculating this would slow down `mysql_stmt_store_result()` considerably and most applications do not need `max_length`. If you want `max_length` to be updated, you can call `mysql_stmt_attr_set(MYSQL_STMT, STMT_ATTR_UPDATE_MAX_LENGTH, &flag)` to enable this. See [Section 26.8.11.3](#), “`mysql_stmt_attr_set()`”.

**Return Values**

Zero for success. Nonzero if an error occurred.

**Errors**

- `CR_COMMANDS_OUT_OF_SYNC`  
Commands were executed in an improper order.
- `CR_OUT_OF_MEMORY`  
Out of memory.
- `CR_SERVER_GONE_ERROR`  
The MySQL server has gone away.
- `CR_SERVER_LOST`  
The connection to the server was lost during the query.
- `CR_UNKNOWN_ERROR`  
An unknown error occurred.

## 26.8.12 C API Threaded Function Descriptions

To create a threaded client, use the functions described in the following sections. See also [Section 26.8.4.3](#), “[Writing C API Threaded Client Programs](#)”.

### 26.8.12.1 `my_init()`

```
void my_init(void)
```

**Description**

`my_init()` initializes some global variables that MySQL needs. It also calls `mysql_thread_init()` for this thread.

It is necessary for `my_init()` to be called early in the initialization phase of a program's use of the MySQL library. However, `my_init()` is automatically called by `mysql_init()`, `mysql_library_init()`, `mysql_server_init()`, and `mysql_connect()`. If you ensure that your program invokes one of those functions before any other MySQL calls, there is no need to invoke `my_init()` explicitly.

To access the prototype for `my_init()`, your program should include these header files:

```
#include <my_global.h>
#include <my_sys.h>
```

## Return Values

None.

### 26.8.12.2 `mysql_thread_end()`

```
void mysql_thread_end(void)
```

## Description

Call this function before calling `pthread_exit()` to free memory allocated by `mysql_thread_init()`.

`mysql_thread_end()` is not invoked automatically by the client library. Before MySQL 5.7.9, it must be called for each `mysql_thread_init()` call to avoid a memory leak. As of MySQL 5.7.9, C API internals were reimplemented to reduce the amount of information allocated by `mysql_thread_init()` that must be freed by `mysql_thread_end()`:

- For release/production builds without debugging support enabled, `mysql_thread_end()` need not be called.
- For debug builds, `mysql_thread_init()` allocates debugging information for the DBUG package (see [Section 27.5.3, “The DBUG Package”](#)). `mysql_thread_end()` must be called for each `mysql_thread_init()` call to avoid a memory leak.

## Return Values

None.

### 26.8.12.3 `mysql_thread_init()`

```
my_bool mysql_thread_init(void)
```

## Description

This function must be called early within each created thread to initialize thread-specific variables. However, you may not necessarily need to invoke it explicitly: `mysql_thread_init()` is automatically called by `my_init()`, which itself is automatically called by `mysql_init()`, `mysql_library_init()`, `mysql_server_init()`, and `mysql_connect()`. If you invoke any of those functions, `mysql_thread_init()` will be called for you.

## Return Values

Zero for success. Nonzero if an error occurred.

### 26.8.12.4 `mysql_thread_safe()`

```
unsigned int mysql_thread_safe(void)
```

## Description

This function indicates whether the client library is compiled as thread-safe.

## Return Values

1 if the client library is thread-safe, 0 otherwise.

## 26.8.13 C API Embedded Server Function Descriptions

MySQL applications can be written to use an embedded server. See [Section 26.7, “libmysqld, the Embedded MySQL Server Library”](#). To write such an application, you must link it against the `libmysqld` library by using the `-lmysqld` flag rather than linking it against the `libmysqlclient` client library by using the `-libmysqlclient` flag. However, the calls to initialize and finalize the library are the same whether you write a client application or one that uses the embedded server: Call `mysql_library_init()` to initialize the library and `mysql_library_end()` when you are done with it. See [Section 26.8.6, “C API Function Overview”](#).

### 26.8.13.1 `mysql_server_init()`

```
int mysql_server_init(int argc, char **argv, char **groups)
```

#### Description

This function initializes the MySQL library, which must be done before you call any other MySQL function. However, `mysql_server_init()` is deprecated and you should call `mysql_library_init()` instead. See [Section 26.8.7.41, “mysql\\_library\\_init\(\)”](#).

#### Return Values

Zero for success. Nonzero if an error occurred.

### 26.8.13.2 `mysql_server_end()`

```
void mysql_server_end(void)
```

#### Description

This function finalizes the MySQL library, which should be done when you are done using the library. However, `mysql_server_end()` is deprecated and `mysql_library_end()` should be used instead. See [Section 26.8.7.40, “mysql\\_library\\_end\(\)”](#).

#### Return Values

None.

## 26.8.14 C API Client Plugin Functions

This section describes functions used for the client-side plugin API. They enable management of client plugins. For a description of the `st_mysql_client_plugin` structure used by these functions, see [Client Plugin Descriptors](#).

It is unlikely that a client program needs to call the functions in this section. For example, a client that supports the use of authentication plugins normally causes a plugin to be loaded by calling `mysql_options()` to set the `MYSQL_DEFAULT_AUTH` and `MYSQL_PLUGIN_DIR` options:

```
char *plugin_dir = "path_to_plugin_dir";
char *default_auth = "plugin_name";

/* ... process command-line options ... */

mysql_options(&mysql, MYSQL_PLUGIN_DIR, plugin_dir);
mysql_options(&mysql, MYSQL_DEFAULT_AUTH, default_auth);
```

Typically, the program will also accept `--plugin-dir` and `--default-auth` options that enable users to override the default values.

### 26.8.14.1 `mysql_client_find_plugin()`

```
struct st_mysql_client_plugin *mysql_client_find_plugin(MYSQL *mysql, const
char *name, int type)
```

## Description

Returns a pointer to a loaded plugin, loading the plugin first if necessary. An error occurs if the type is invalid or the plugin cannot be found or loaded.

Specify the parameters as follows:

- `mysql`: A pointer to a `MYSQL` structure. The plugin API does not require a connection to a MySQL server, but this structure must be properly initialized. The structure is used to obtain connection-related information.
- `name`: The plugin name.
- `type`: The plugin type.

## Return Values

A pointer to the plugin for success. `NULL` if an error occurred.

## Errors

To check for errors, call the `mysql_error()` or `mysql_errno()` function. See [Section 26.8.7.15, “mysql\\_error\(\)”](#), and [Section 26.8.7.14, “mysql\\_errno\(\)”](#).

## Example

```
MYSQL mysql;
struct st_mysql_client_plugin *p;

if ((p = mysql_client_find_plugin(&mysql, "myplugin",
                                MYSQL_CLIENT_AUTHENTICATION_PLUGIN, 0)))
{
    printf("Plugin version: %d.%d.%d\n", p->version[0], p->version[1], p->version[2]);
}
```

### 26.8.14.2 mysql\_client\_register\_plugin()

```
struct st_mysql_client_plugin *mysql_client_register_plugin(MYSQL *mysql,
struct st_mysql_client_plugin *plugin)
```

## Description

Adds a plugin structure to the list of loaded plugins. An error occurs if the plugin is already loaded.

Specify the parameters as follows:

- `mysql`: A pointer to a `MYSQL` structure. The plugin API does not require a connection to a MySQL server, but this structure must be properly initialized. The structure is used to obtain connection-related information.
- `plugin`: A pointer to the plugin structure.

## Return Values

A pointer to the plugin for success. `NULL` if an error occurred.

## Errors

To check for errors, call the `mysql_error()` or `mysql_errno()` function. See [Section 26.8.7.15, “mysql\\_error\(\)”](#), and [Section 26.8.7.14, “mysql\\_errno\(\)”](#).

### 26.8.14.3 `mysql_load_plugin()`

```
struct st_mysql_client_plugin *mysql_load_plugin(MYSQL *mysql, const char
*name, int type, int argc, ...)
```

#### Description

Loads a MySQL client plugin, specified by name and type. An error occurs if the type is invalid or the plugin cannot be loaded.

It is not possible to load multiple plugins of the same type. An error occurs if you try to load a plugin of a type already loaded.

Specify the parameters as follows:

- `mysql`: A pointer to a `MYSQL` structure. The plugin API does not require a connection to a MySQL server, but this structure must be properly initialized. The structure is used to obtain connection-related information.
- `name`: The name of the plugin to load.
- `type`: The type of plugin to load, or `-1` to disable type checking. If type is not `-1`, only plugins matching the type are considered for loading.
- `argc`: The number of following arguments (0 if there are none). Interpretation of any following arguments depends on the plugin type.

Another way to cause plugins to be loaded is to set the `LIBMYSQL_PLUGINS` environment variable to a semicolon-separated list of plugin names. For example:

```
shell> export LIBMYSQL_PLUGINS="myplugin1;myplugin2"
```

Plugins named by `LIBMYSQL_PLUGINS` are loaded when the client program calls `mysql_library_init()`. No error is reported if problems occur loading these plugins.

As of MySQL 5.7.1, the `LIBMYSQL_PLUGIN_DIR` environment variable can be set to the path name of the directory in which to look for client plugins. This variable is used in two ways:

- During client plugin preloading, the value of the `--plugin-dir` option is not available, so client plugin loading fails unless the plugins are located in the hardwired default directory. If the plugins are located elsewhere, `LIBMYSQL_PLUGIN_DIR` environment variable can be set to the proper directory to enable plugin preloading to succeed.
- For explicit client plugin loading, the `mysql_load_plugin()` and `mysql_load_plugin_v()` C API functions use the `LIBMYSQL_PLUGIN_DIR` value if it exists and the `--plugin-dir` option was not given. If `--plugin-dir` is given, `mysql_load_plugin()` and `mysql_load_plugin_v()` ignore `LIBMYSQL_PLUGIN_DIR`.

#### Return Values

A pointer to the plugin if it was loaded successfully. `NULL` if an error occurred.

#### Errors

To check for errors, call the `mysql_error()` or `mysql_errno()` function. See [Section 26.8.7.15](#), “`mysql_error()`”, and [Section 26.8.7.14](#), “`mysql_errno()`”.

#### Example

```
MYSQL mysql;

if(!mysql_load_plugin(&mysql, "myplugin",
                     MYSQL_CLIENT_AUTHENTICATION_PLUGIN, 0))
{
    fprintf(stderr, "Error: %s\n", mysql_error(&mysql));
    exit(-1);
}
```

### See Also

See also [Section 26.8.14.3, “mysql\\_load\\_plugin\(\)”](#), [Section 26.8.7.15, “mysql\\_error\(\)”](#), [Section 26.8.7.14, “mysql\\_errno\(\)”](#).

### 26.8.14.4 mysql\_load\_plugin\_v()

```
struct st_mysql_client_plugin *mysql_load_plugin_v(MYSQL *mysql, const char
*name, int type, int argc, va_list args)
```

#### Description

This function is equivalent to `mysql_load_plugin()`, but it accepts a `va_list` instead of a variable list of parameters.

### See Also

See also [Section 26.8.14.3, “mysql\\_load\\_plugin\(\)”](#).

### 26.8.14.5 mysql\_plugin\_options()

```
int mysql_plugin_options(struct st_mysql_client_plugin *plugin, const char
*option, const void *value)
```

#### Description

Passes an option type and value to a plugin. This function can be called multiple times to set several options. If the plugin does not have an option handler, an error occurs.

Specify the parameters as follows:

- `plugin`: A pointer to the plugin structure.
- `option`: The option to be set.
- `value`: A pointer to the option value.

### Return Values

Zero for success, 1 if an error occurred. If the plugin has an option handler, that handler should also return zero for success and 1 if an error occurred.

## 26.8.15 Common Questions and Problems When Using the C API

### 26.8.15.1 Why mysql\_store\_result() Sometimes Returns NULL After mysql\_query() Returns Success

It is possible for `mysql_store_result()` to return `NULL` following a successful call to `mysql_query()`. When this happens, it means one of the following conditions occurred:

- There was a `malloc()` failure (for example, if the result set was too large).
- The data could not be read (an error occurred on the connection).

- The query returned no data (for example, it was an `INSERT`, `UPDATE`, or `DELETE`).

You can always check whether the statement should have produced a nonempty result by calling `mysql_field_count()`. If `mysql_field_count()` returns zero, the result is empty and the last query was a statement that does not return values (for example, an `INSERT` or a `DELETE`). If `mysql_field_count()` returns a nonzero value, the statement should have produced a nonempty result. See the description of the `mysql_field_count()` function for an example.

You can test for an error by calling `mysql_error()` or `mysql_errno()`.

### 26.8.15.2 What Results You Can Get from a Query

In addition to the result set returned by a query, you can also get the following information:

- `mysql_affected_rows()` returns the number of rows affected by the last query when doing an `INSERT`, `UPDATE`, or `DELETE`.

For a fast re-create, use `TRUNCATE TABLE`.

- `mysql_num_rows()` returns the number of rows in a result set. With `mysql_store_result()`, `mysql_num_rows()` may be called as soon as `mysql_store_result()` returns. With `mysql_use_result()`, `mysql_num_rows()` may be called only after you have fetched all the rows with `mysql_fetch_row()`.
- `mysql_insert_id()` returns the ID generated by the last query that inserted a row into a table with an `AUTO_INCREMENT` index. See [Section 26.8.7.38](#), “`mysql_insert_id()`”.
- Some queries (`LOAD DATA INFILE ...`, `INSERT INTO ... SELECT ...`, `UPDATE`) return additional information. The result is returned by `mysql_info()`. See the description for `mysql_info()` for the format of the string that it returns. `mysql_info()` returns a `NULL` pointer if there is no additional information.

### 26.8.15.3 How to Get the Unique ID for the Last Inserted Row

If you insert a record into a table that contains an `AUTO_INCREMENT` column, you can obtain the value stored into that column by calling the `mysql_insert_id()` function.

You can check from your C applications whether a value was stored in an `AUTO_INCREMENT` column by executing the following code (which assumes that you've checked that the statement succeeded). It determines whether the query was an `INSERT` with an `AUTO_INCREMENT` index:

```
if ((result = mysql_store_result(&mysql)) == 0 &&
    mysql_field_count(&mysql) == 0 &&
    mysql_insert_id(&mysql) != 0)
{
    used_id = mysql_insert_id(&mysql);
}
```

When a new `AUTO_INCREMENT` value has been generated, you can also obtain it by executing a `SELECT LAST_INSERT_ID()` statement with `mysql_query()` and retrieving the value from the result set returned by the statement.

When inserting multiple values, the last automatically incremented value is returned.

For `LAST_INSERT_ID()`, the most recently generated ID is maintained in the server on a per-connection basis. It is not changed by another client. It is not even changed if you update another `AUTO_INCREMENT` column with a nonmagic value (that is, a value that is not `NULL` and not 0). Using `LAST_INSERT_ID()` and `AUTO_INCREMENT` columns simultaneously from multiple clients is perfectly valid. Each client will receive the last inserted ID for the last statement *that* client executed.

If you want to use the ID that was generated for one table and insert it into a second table, you can use SQL statements like this:

```
INSERT INTO foo (auto,text)
VALUES(NULL,'text');           # generate ID by inserting NULL
INSERT INTO foo2 (id,text)
VALUES(LAST_INSERT_ID(),'text'); # use ID in second table
```

`mysql_insert_id()` returns the value stored into an `AUTO_INCREMENT` column, whether that value is automatically generated by storing `NULL` or `0` or was specified as an explicit value. `LAST_INSERT_ID()` returns only automatically generated `AUTO_INCREMENT` values. If you store an explicit value other than `NULL` or `0`, it does not affect the value returned by `LAST_INSERT_ID()`.

For more information on obtaining the last ID in an `AUTO_INCREMENT` column:

- For information on `LAST_INSERT_ID()`, which can be used within an SQL statement, see [Section 13.14, “Information Functions”](#).
- For information on `mysql_insert_id()`, the function you use from within the C API, see [Section 26.8.7.38, “mysql\\_insert\\_id\(\)”](#).
- For information on obtaining the auto-incremented value when using Connector/J, see [Retrieving AUTO\\_INCREMENT Column Values through JDBC](#).
- For information on obtaining the auto-incremented value when using Connector/ODBC, see [Obtaining Auto-Increment Values](#).

## 26.8.16 Controlling Automatic Reconnection Behavior

The MySQL client library can perform an automatic reconnection to the server if it finds that the connection is down when you attempt to send a statement to the server to be executed. If auto-reconnect is enabled, the library tries once to reconnect to the server and send the statement again.

Auto-reconnect is disabled by default.

If it is important for your application to know that the connection has been dropped (so that it can exit or take action to adjust for the loss of state information), be sure that auto-reconnect is disabled. To ensure this, call `mysql_options()` with the `MYSQL_OPT_RECONNECT` option:

```
my_bool reconnect = 0;
mysql_options(&mysql, MYSQL_OPT_RECONNECT, &reconnect);
```

If the connection has gone down, the effect of `mysql_ping()` depends on the auto-reconnect state. If auto-reconnect is enabled, `mysql_ping()` performs a reconnect. Otherwise, it returns an error.

Some client programs might provide the capability of controlling automatic reconnection. For example, `mysql` reconnects by default, but the `--skip-reconnect` option can be used to suppress this behavior.

If an automatic reconnection does occur (for example, as a result of calling `mysql_ping()`), there is no explicit indication of it. To check for reconnection, call `mysql_thread_id()` to get the original connection identifier before calling `mysql_ping()`, then call `mysql_thread_id()` again to see whether the identifier changed.

Automatic reconnection can be convenient because you need not implement your own reconnect code, but if a reconnection does occur, several aspects of the connection state are reset on the server side and your application will not be notified.

The connection-related state is affected as follows:

- Any active transactions are rolled back and autocommit mode is reset.
- All table locks are released.

- All `TEMPORARY` tables are closed (and dropped).
- Session system variables are reinitialized to the values of the corresponding global system variables, including system variables that are set implicitly by statements such as `SET NAMES`.
- User variable settings are lost.
- Prepared statements are released.
- `HANDLER` variables are closed.
- The value of `LAST_INSERT_ID()` is reset to 0.
- Locks acquired with `GET_LOCK()` are released.
- The association of the client with the Performance Schema `threads` table row that determines connection thread instrumentation is lost. If the client reconnects after a disconnect, the session is associated with a new row in the `threads` table and the thread monitoring state may be different. See [Section 24.10.16.3, “The threads Table”](#).

If the connection drops, it is possible that the session associated with the connection on the server side will still be running if the server has not yet detected that the client is no longer connected. In this case, any locks held by the original connection still belong to that session, so you may want to kill it by calling `mysql_kill()`.

## 26.8.17 C API Support for Multiple Statement Execution

By default, `mysql_query()` and `mysql_real_query()` interpret their statement string argument as a single statement to be executed, and you process the result according to whether the statement produces a result set (a set of rows, as for `SELECT`) or an affected-rows count (as for `INSERT`, `UPDATE`, and so forth).

MySQL also supports the execution of a string containing multiple statements separated by semicolon (;) characters. This capability is enabled by special options that are specified either when you connect to the server with `mysql_real_connect()` or after connecting by calling `mysql_set_server_option()`.

Executing a multiple-statement string can produce multiple result sets or row-count indicators. Processing these results involves a different approach than for the single-statement case: After handling the result from the first statement, it is necessary to check whether more results exist and process them in turn if so. To support multiple-result processing, the C API includes the `mysql_more_results()` and `mysql_next_result()` functions. These functions are used at the end of a loop that iterates as long as more results are available. *Failure to process the result this way may result in a dropped connection to the server.*

Multiple-result processing also is required if you execute `CALL` statements for stored procedures. Results from a stored procedure have these characteristics:

- Statements within the procedure may produce result sets (for example, if it executes `SELECT` statements). These result sets are returned in the order that they are produced as the procedure executes.

In general, the caller cannot know how many result sets a procedure will return. Procedure execution may depend on loops or conditional statements that cause the execution path to differ from one call to the next. Therefore, you must be prepared to retrieve multiple results.

- The final result from the procedure is a status result that includes no result set. The status indicates whether the procedure succeeded or an error occurred.

The multiple statement and result capabilities can be used only with `mysql_query()` or `mysql_real_query()`. They cannot be used with the prepared statement interface. Prepared

statement handles are defined to work only with strings that contain a single statement. See [Section 26.8.8, “C API Prepared Statements”](#).

To enable multiple-statement execution and result processing, the following options may be used:

- The `mysql_real_connect()` function has a `flags` argument for which two option values are relevant:
  - `CLIENT_MULTI_RESULTS` enables the client program to process multiple results. This option *must* be enabled if you execute `CALL` statements for stored procedures that produce result sets. Otherwise, such procedures result in an error `Error 1312 (0A000): PROCEDURE proc_name can't return a result set in the given context`. In MySQL 5.7, `CLIENT_MULTI_RESULTS` is enabled by default.
  - `CLIENT_MULTI_STATEMENTS` enables `mysql_query()` and `mysql_real_query()` to execute statement strings containing multiple statements separated by semicolons. This option also enables `CLIENT_MULTI_RESULTS` implicitly, so a `flags` argument of `CLIENT_MULTI_STATEMENTS` to `mysql_real_connect()` is equivalent to an argument of `CLIENT_MULTI_STATEMENTS | CLIENT_MULTI_RESULTS`. That is, `CLIENT_MULTI_STATEMENTS` is sufficient to enable multiple-statement execution and all multiple-result processing.
- After the connection to the server has been established, you can use the `mysql_set_server_option()` function to enable or disable multiple-statement execution by passing it an argument of `MYSQL_OPTION_MULTI_STATEMENTS_ON` or `MYSQL_OPTION_MULTI_STATEMENTS_OFF`. Enabling multiple-statement execution with this function also enables processing of “simple” results for a multiple-statement string where each statement produces a single result, but is *not* sufficient to permit processing of stored procedures that produce result sets.

The following procedure outlines a suggested strategy for handling multiple statements:

1. Pass `CLIENT_MULTI_STATEMENTS` to `mysql_real_connect()`, to fully enable multiple-statement execution and multiple-result processing.
2. After calling `mysql_query()` or `mysql_real_query()` and verifying that it succeeds, enter a loop within which you process statement results.
3. For each iteration of the loop, handle the current statement result, retrieving either a result set or an affected-rows count. If an error occurs, exit the loop.
4. At the end of the loop, call `mysql_next_result()` to check whether another result exists and initiate retrieval for it if so. If no more results are available, exit the loop.

One possible implementation of the preceding strategy is shown following. The final part of the loop can be reduced to a simple test of whether `mysql_next_result()` returns nonzero. The code as written distinguishes between no more results and an error, which enables a message to be printed for the latter occurrence.

```
/* connect to server with the CLIENT_MULTI_STATEMENTS option */
if (mysql_real_connect (mysql, host_name, user_name, password,
    db_name, port_num, socket_name, CLIENT_MULTI_STATEMENTS) == NULL)
{
    printf("mysql_real_connect() failed\n");
    mysql_close(mysql);
    exit(1);
}

/* execute multiple statements */
status = mysql_query(mysql,
    "DROP TABLE IF EXISTS test_table;\n
    CREATE TABLE test_table(id INT);\n
    INSERT INTO test_table VALUES(10);\n
```

```

        UPDATE test_table SET id=20 WHERE id=10;\
        SELECT * FROM test_table;\
        DROP TABLE test_table");
if (status)
{
    printf("Could not execute statement(s)");
    mysql_close(mysql);
    exit(0);
}

/* process each statement result */
do {
    /* did current statement return data? */
    result = mysql_store_result(mysql);
    if (result)
    {
        /* yes; process rows and free the result set */
        process_result_set(mysql, result);
        mysql_free_result(result);
    }
    else /* no result set or error */
    {
        if (mysql_field_count(mysql) == 0)
        {
            printf("%lld rows affected\n",
                mysql_affected_rows(mysql));
        }
        else /* some error occurred */
        {
            printf("Could not retrieve result set\n");
            break;
        }
    }
}
/* more results? -1 = no, >0 = error, 0 = yes (keep looping) */
if ((status = mysql_next_result(mysql)) > 0)
    printf("Could not execute statement\n");
} while (status == 0);

mysql_close(mysql);

```

## 26.8.18 C API Prepared Statement Problems

Here follows a list of the currently known problems with prepared statements:

- [TIME](#), [TIMESTAMP](#), and [DATETIME](#) do not support parts of seconds (for example, from [DATE\\_FORMAT\(\)](#)).
- When converting an integer to string, [ZEROFILL](#) is honored with prepared statements in some cases where the MySQL server does not print the leading zeros. (For example, with [MIN\(\*number-with-zerofill\*\)](#)).
- When converting a floating-point number to a string in the client, the rightmost digits of the converted value may differ slightly from those of the original value.
- Prepared statements use the query cache under the conditions described in [Section 9.10.3.1, “How the Query Cache Operates”](#).
- Prepared statements do not support multi-statements (that is, multiple statements within a single string separated by `;` characters).
- The capabilities of prepared [CALL](#) statements are described in [Section 26.8.20, “C API Support for Prepared CALL Statements”](#).

## 26.8.19 C API Prepared Statement Handling of Date and Time Values

The binary (prepared statement) protocol enables you to send and receive date and time values ([DATE](#), [TIME](#), [DATETIME](#), and [TIMESTAMP](#)), using the [MYSQL\\_TIME](#) structure. The members of this structure are described in [Section 26.8.9, “C API Prepared Statement Data Structures”](#).

To send temporal data values, create a prepared statement using `mysql_stmt_prepare()`. Then, before calling `mysql_stmt_execute()` to execute the statement, use the following procedure to set up each temporal parameter:

1. In the `MYSQL_BIND` structure associated with the data value, set the `buffer_type` member to the type that indicates what kind of temporal value you're sending. For `DATE`, `TIME`, `DATETIME`, or `TIMESTAMP` values, set `buffer_type` to `MYSQL_TYPE_DATE`, `MYSQL_TYPE_TIME`, `MYSQL_TYPE_DATETIME`, or `MYSQL_TYPE_TIMESTAMP`, respectively.
2. Set the `buffer` member of the `MYSQL_BIND` structure to the address of the `MYSQL_TIME` structure in which you pass the temporal value.
3. Fill in the members of the `MYSQL_TIME` structure that are appropriate for the type of temporal value to pass.

Use `mysql_stmt_bind_param()` to bind the parameter data to the statement. Then you can call `mysql_stmt_execute()`.

To retrieve temporal values, the procedure is similar, except that you set the `buffer_type` member to the type of value you expect to receive, and the `buffer` member to the address of a `MYSQL_TIME` structure into which the returned value should be placed. Use `mysql_stmt_bind_result()` to bind the buffers to the statement after calling `mysql_stmt_execute()` and before fetching the results.

Here is a simple example that inserts `DATE`, `TIME`, and `TIMESTAMP` data. The `mysql` variable is assumed to be a valid connection handle.

```
MYSQL_TIME  ts;
MYSQL_BIND  bind[3];
MYSQL_STMT  *stmt;

strmov(query, "INSERT INTO test_table(date_field, time_field, \
               timestamp_field) VALUES(?,?,?);");

stmt = mysql_stmt_init(mysql);
if (!stmt)
{
    fprintf(stderr, " mysql_stmt_init(), out of memory\n");
    exit(0);
}
if (mysql_stmt_prepare(mysql, query, strlen(query)))
{
    fprintf(stderr, "\n mysql_stmt_prepare(), INSERT failed");
    fprintf(stderr, "\n %s", mysql_stmt_error(stmt));
    exit(0);
}

/* set up input buffers for all 3 parameters */
bind[0].buffer_type= MYSQL_TYPE_DATE;
bind[0].buffer= (char *)&ts;
bind[0].is_null= 0;
bind[0].length= 0;
...
bind[1]= bind[2]= bind[0];
...

mysql_stmt_bind_param(stmt, bind);

/* supply the data to be sent in the ts structure */
ts.year= 2002;
ts.month= 02;
ts.day= 03;

ts.hour= 10;
ts.minute= 45;
ts.second= 20;
```

```
mysql_stmt_execute(stmt);
..
```

## 26.8.20 C API Support for Prepared CALL Statements

This section describes prepared-statement support in the C API for stored procedures executed using [CALL](#) statements:

Stored procedures executed using prepared [CALL](#) statements can be used in the following ways:

- A stored procedure can produce any number of result sets. The number of columns and the data types of the columns need not be the same for all result sets.
- The final values of [OUT](#) and [INOUT](#) parameters are available to the calling application after the procedure returns. These parameters are returned as an extra single-row result set following any result sets produced by the procedure itself. The row contains the values of the [OUT](#) and [INOUT](#) parameters in the order in which they are declared in the procedure parameter list.

The following discussion shows how to use these capabilities through the C API for prepared statements. To use prepared [CALL](#) statements through the [PREPARE](#) and [EXECUTE](#) statements, see [Section 14.2.1, “CALL Syntax”](#).

If an application might be compiled or executed in a context where a version of MySQL older than 5.5.3 is used, prepared [CALL](#) capabilities for multiple result sets and [OUT](#) or [INOUT](#) parameters might not be available:

- For the client side, the application will not compile unless the libraries are from MySQL 5.5.3 or higher (the API function and symbols introduced in that version will not be present).
- To verify at runtime that the server is recent enough, a client can use this test:

```
if (mysql_get_server_version(mysql) < 50503)
{
    fprintf(stderr,
        "Server does not support required CALL capabilities\n");
    mysql_close(mysql);
    exit (1);
}
```

An application that executes a prepared [CALL](#) statement should use a loop that fetches a result and then invokes `mysql_stmt_next_result()` to determine whether there are more results. The results consist of any result sets produced by the stored procedure followed by a final status value that indicates whether the procedure terminated successfully.

If the procedure has [OUT](#) or [INOUT](#) parameters, the result set preceding the final status value contains their values. To determine whether a result set contains parameter values, test whether the `SERVER_PS_OUT_PARAMS` bit is set in the `server_status` member of the `MYSQL` connection handler:

```
mysql->server_status & SERVER_PS_OUT_PARAMS
```

The following example uses a prepared [CALL](#) statement to execute a stored procedure that produces multiple result sets and that provides parameter values back to the caller by means of [OUT](#) and [INOUT](#) parameters. The procedure takes parameters of all three types ([IN](#), [OUT](#), [INOUT](#)), displays their initial values, assigns new values, displays the updated values, and returns. The expected return information from the procedure therefore consists of multiple result sets and a final status:

- One result set from a [SELECT](#) that displays the initial parameter values: `10, NULL, 30`. (The [OUT](#) parameter is assigned a value by the caller, but this assignment is expected to be ineffective: [OUT](#) parameters are seen as `NULL` within a procedure until assigned a value within the procedure.)
- One result set from a [SELECT](#) that displays the modified parameter values: `100, 200, 300`.

- One result set containing the final [OUT](#) and [INOUT](#) parameter values: 200, 300.
- A final status packet.

The code to execute the procedure:

```

MYSQL_STMT *stmt;
MYSQL_BIND ps_params[3]; /* input parameter buffers */
int         int_data[3];  /* input/output values */
my_bool     is_null[3];   /* output value nullability */
int         status;

/* set up stored procedure */
status = mysql_query(mysql, "DROP PROCEDURE IF EXISTS p1");
test_error(mysql, status);

status = mysql_query(mysql,
    "CREATE PROCEDURE p1("
    "  IN p_in INT, "
    "  OUT p_out INT, "
    "  INOUT p_inout INT) "
    "BEGIN "
    "  SELECT p_in, p_out, p_inout; "
    "  SET p_in = 100, p_out = 200, p_inout = 300; "
    "  SELECT p_in, p_out, p_inout; "
    "END");
test_error(mysql, status);

/* initialize and prepare CALL statement with parameter placeholders */
stmt = mysql_stmt_init(mysql);
if (!stmt)
{
    printf("Could not initialize statement\n");
    exit(1);
}
status = mysql_stmt_prepare(stmt, "CALL p1(?, ?, ?)", 16);
test_stmt_error(stmt, status);

/* initialize parameters: p_in, p_out, p_inout (all INT) */
memset(ps_params, 0, sizeof (ps_params));

ps_params[0].buffer_type = MYSQL_TYPE_LONG;
ps_params[0].buffer = (char *) &int_data[0];
ps_params[0].length = 0;
ps_params[0].is_null = 0;

ps_params[1].buffer_type = MYSQL_TYPE_LONG;
ps_params[1].buffer = (char *) &int_data[1];
ps_params[1].length = 0;
ps_params[1].is_null = 0;

ps_params[2].buffer_type = MYSQL_TYPE_LONG;
ps_params[2].buffer = (char *) &int_data[2];
ps_params[2].length = 0;
ps_params[2].is_null = 0;

/* bind parameters */
status = mysql_stmt_bind_param(stmt, ps_params);
test_stmt_error(stmt, status);

/* assign values to parameters and execute statement */
int_data[0] = 10; /* p_in */
int_data[1] = 20; /* p_out */
int_data[2] = 30; /* p_inout */

status = mysql_stmt_execute(stmt);
test_stmt_error(stmt, status);

/* process results until there are no more */
do {
    int i;

```

```

int num_fields;          /* number of columns in result */
MYSQL_FIELD *fields;     /* for result set metadata */
MYSQL_BIND *rs_bind;     /* for output buffers */

/* the column count is > 0 if there is a result set */
/* 0 if the result is only the final status packet */
num_fields = mysql_stmt_field_count(stmt);

if (num_fields > 0)
{
    /* there is a result set to fetch */
    printf("Number of columns in result: %d\n", (int) num_fields);

    /* what kind of result set is this? */
    printf("Data: ");
    if(mysql->server_status & SERVER_PS_OUT_PARAMS)
        printf("this result set contains OUT/INOUT parameters\n");
    else
        printf("this result set is produced by the procedure\n");

    MYSQL_RES *rs_metadata = mysql_stmt_result_metadata(stmt);
    test_stmt_error(stmt, rs_metadata == NULL);

    fields = mysql_fetch_fields(rs_metadata);

    rs_bind = (MYSQL_BIND *) malloc(sizeof (MYSQL_BIND) * num_fields);
    if (!rs_bind)
    {
        printf("Cannot allocate output buffers\n");
        exit(1);
    }
    memset(rs_bind, 0, sizeof (MYSQL_BIND) * num_fields);

    /* set up and bind result set output buffers */
    for (i = 0; i < num_fields; ++i)
    {
        rs_bind[i].buffer_type = fields[i].type;
        rs_bind[i].is_null = &is_null[i];

        switch (fields[i].type)
        {
            case MYSQL_TYPE_LONG:
                rs_bind[i].buffer = (char *) &(int_data[i]);
                rs_bind[i].buffer_length = sizeof (int_data);
                break;

            default:
                fprintf(stderr, "ERROR: unexpected type: %d.\n", fields[i].type);
                exit(1);
        }
    }
}

status = mysql_stmt_bind_result(stmt, rs_bind);
test_stmt_error(stmt, status);

/* fetch and display result set rows */
while (1)
{
    status = mysql_stmt_fetch(stmt);

    if (status == 1 || status == MYSQL_NO_DATA)
        break;

    for (i = 0; i < num_fields; ++i)
    {
        switch (rs_bind[i].buffer_type)
        {
            case MYSQL_TYPE_LONG:
                if (*rs_bind[i].is_null)
                    printf(" val[%d] = NULL;", i);
                else
                    printf(" val[%d] = %ld;",

```

```
        i, (long) *((int *) rs_bind[i].buffer));
        break;

        default:
            printf(" unexpected type (%d)\n",
                rs_bind[i].buffer_type);
    }
}
printf("\n");
}

mysql_free_result(rs_metadata); /* free metadata */
free(rs_bind);                /* free output buffers */
}
else
{
    /* no columns = final status packet */
    printf("End of procedure output\n");
}

/* more results? -1 = no, >0 = error, 0 = yes (keep looking) */
status = mysql_stmt_next_result(stmt);
if (status > 0)
    test_stmt_error(stmt, status);
} while (status == 0);

mysql_stmt_close(stmt);
```

Execution of the procedure should produce the following output:

```
Number of columns in result: 3
Data: this result set is produced by the procedure
val[0] = 10; val[1] = NULL; val[2] = 30;
Number of columns in result: 3
Data: this result set is produced by the procedure
val[0] = 100; val[1] = 200; val[2] = 300;
Number of columns in result: 2
Data: this result set contains OUT/INOUT parameters
val[0] = 200; val[1] = 300;
End of procedure output
```

The code uses two utility routines, `test_error()` and `test_stmt_error()`, to check for errors and terminate after printing diagnostic information if an error occurred:

```
static void test_error(MYSQL *mysql, int status)
{
    if (status)
    {
        fprintf(stderr, "Error: %s (errno: %d)\n",
            mysql_error(mysql), mysql_errno(mysql));
        exit(1);
    }
}

static void test_stmt_error(MYSQL_STMT *stmt, int status)
{
    if (status)
    {
        fprintf(stderr, "Error: %s (errno: %d)\n",
            mysql_stmt_error(stmt), mysql_stmt_errno(stmt));
        exit(1);
    }
}
```

## 26.9 MySQL PHP API

The MySQL PHP API manual is now published in standalone form, not as part of the MySQL Reference Manual. See [MySQL and PHP](#).

## 26.10 MySQL Perl API

The Perl `DBI` module provides a generic interface for database access. You can write a DBI script that works with many different database engines without change. To use DBI with MySQL, install the following:

1. The `DBI` module.
2. The `DBD::mysql` module. This is the DataBase Driver (DBD) module for Perl.
3. Optionally, the DBD module for any other type of database server you want to access.

Perl DBI is the recommended Perl interface. It replaces an older interface called `mysqlperl`, which should be considered obsolete.

These sections contain information about using Perl with MySQL and writing MySQL applications in Perl:

- For installation instructions for Perl DBI support, see [Section 2.12, “Perl Installation Notes”](#).
- For an example of reading options from option files, see [Section 6.6.4, “Using Client Programs in a Multiple-Server Environment”](#).
- For secure coding tips, see [Section 7.1.1, “Security Guidelines”](#).
- For debugging tips, see [Section 27.5.1.4, “Debugging mysqld under gdb”](#).
- For some Perl-specific environment variables, see [Section 5.9, “MySQL Program Environment Variables”](#).
- For considerations for running on OS X, see [Section 2.4, “Installing MySQL on OS X”](#).
- For ways to quote string literals, see [Section 10.1.1, “String Literals”](#).

DBI information is available at the command line, online, or in printed form:

- Once you have the `DBI` and `DBD::mysql` modules installed, you can get information about them at the command line with the `perldoc` command:

```
shell> perldoc DBI
shell> perldoc DBI:FAQ
shell> perldoc DBD:mysql
```

You can also use `pod2man`, `pod2html`, and so on to translate this information into other formats.

- For online information about Perl DBI, visit the DBI Web site, <http://dbi.perl.org/>. That site hosts a general DBI mailing list. Oracle Corporation hosts a list specifically about `DBD::mysql`; see [Section 1.6.1, “MySQL Mailing Lists”](#).
- For printed information, the official DBI book is *Programming the Perl DBI* (Alligator Descartes and Tim Bunce, O'Reilly & Associates, 2000). Information about the book is available at the DBI Web site, <http://dbi.perl.org/>.

For information that focuses specifically on using DBI with MySQL, see *MySQL and Perl for the Web* (Paul DuBois, New Riders, 2001). This book's Web site is <http://www.kitebird.com/mysql-perl/>.

## 26.11 MySQL Python API

`MySQLdb` is a third-party driver that provides MySQL support for Python, compliant with the Python DB API version 2.0. It can be found at <http://sourceforge.net/projects/mysql-python/>.

The new MySQL Connector/Python component provides an interface to the same Python API, and is built into the MySQL Server and supported by Oracle. See [MySQL Connector/Python Developer Guide](#) for details on the Connector, as well as coding guidelines for Python applications and sample Python code.

## 26.12 MySQL Ruby APIs

Two APIs are available for Ruby programmers developing MySQL applications:

- The MySQL/Ruby API is based on the `libmysqlclient` API library. For information on installing and using the MySQL/Ruby API, see [Section 26.12.1, “The MySQL/Ruby API”](#).
- The Ruby/MySQL API is written to use the native MySQL network protocol (a native driver). For information on installing and using the Ruby/MySQL API, see [Section 26.12.2, “The Ruby/MySQL API”](#).

For background and syntax information about the Ruby language, see [Ruby Programming Language](#).

### 26.12.1 The MySQL/Ruby API

The MySQL/Ruby module provides access to MySQL databases using Ruby through `libmysqlclient`.

For information on installing the module, and the functions exposed, see [MySQL/Ruby](#).

### 26.12.2 The Ruby/MySQL API

The Ruby/MySQL module provides access to MySQL databases using Ruby through a native driver interface using the MySQL network protocol.

For information on installing the module, and the functions exposed, see [Ruby/MySQL](#).

## 26.13 MySQL Tcl API

`MySQLtcl` is a simple API for accessing a MySQL database server from the [Tcl programming language](#). It can be found at <http://www.xdobry.de/mysqltcl/>.

## 26.14 MySQL Eiffel Wrapper

Eiffel MySQL is an interface to the MySQL database server using the [Eiffel programming language](#), written by Michael Ravits. It can be found at <http://efsa.sourceforge.net/archive/ravits/mysql.htm>.

## 27.1 MySQL Internals

This chapter describes a lot of things that you need to know when working on the MySQL code. To track or contribute to MySQL development, follow the instructions in [Section 2.9.3, “Installing MySQL Using a Development Source Tree”](#). If you are interested in MySQL internals, you should also subscribe to our [internals](#) mailing list. This list has relatively low traffic. For details on how to subscribe, please see [Section 1.6.1, “MySQL Mailing Lists”](#). Many MySQL developers at Oracle Corporation are on the [internals](#) list and we help other people who are working on the MySQL code. Feel free to use this list both to ask questions about the code and to send patches that you would like to contribute to the MySQL project!

### 27.1.1 MySQL Threads

The MySQL server creates the following threads:

- Connection manager threads handle client connection requests on the network interfaces that the server listens to. On all platforms, one manager thread handles TCP/IP connection requests. On Unix, this manager thread also handles Unix socket file connection requests. On Windows, a manager thread handles shared-memory connection requests, and another handles named-pipe connection requests. The server does not create threads to handle interfaces that it does not listen to. For example, a Windows server that does not have support for named-pipe connections enabled does not create a thread to handle them.
- Connection manager threads associate each client connection with a thread dedicated to it that handles authentication and request processing for that connection. Manager threads create a new thread when necessary but try to avoid doing so by consulting the thread cache first to see whether it contains a thread that can be used for the connection. When a connection ends, its thread is returned to the thread cache if the cache is not full.

For information about tuning the parameters that control thread resources, see [Section 9.12.5.1, “How MySQL Uses Threads for Client Connections”](#).

- On a master replication server, connections from slave servers are handled like client connections: There is one thread per connected slave.
- On a slave replication server, an I/O thread is started to connect to the master server and read updates from it. An SQL thread is started to apply updates read from the master. These two threads run independently and can be started and stopped independently.
- A signal thread handles all signals. This thread also normally handles alarms and calls `process_alarm()` to force timeouts on connections that have been idle too long.
- If `InnoDB` is used, there will be additional read and write threads by default. The number of these are controlled by the `innodb_read_io_threads` and `innodb_write_io_threads` parameters. See [Section 15.14, “InnoDB Startup Options and System Variables”](#).
- If the server is started with the `--flush_time=val` option, a dedicated thread is created to flush all tables every `val` seconds.
- If the event scheduler is active, there is one thread for the scheduler, and a thread for each event currently running. See [Section 22.4.1, “Event Scheduler Overview”](#).

`mysqladmin processlist` only shows the connection, replication, and event threads.

## 27.1.2 The MySQL Test Suite

The test system that is included in Unix source and binary distributions makes it possible for users and developers to perform regression tests on the MySQL code. These tests can be run on Unix.

You can also write your own test cases. For information about the MySQL Test Framework, including system requirements, see the manual available at <http://dev.mysql.com/doc/mysqltest/2.0/en/>.

The current set of test cases does not test everything in MySQL, but it should catch most obvious bugs in the SQL processing code, operating system or library issues, and is quite thorough in testing replication. Our goal is to have the tests cover 100% of the code. We welcome contributions to our test suite. You may especially want to contribute tests that examine the functionality critical to your system because this ensures that all future MySQL releases work well with your applications.

The test system consists of a test language interpreter (`mysqltest`), a Perl script to run all tests (`mysql-test-run.pl`), the actual test cases written in a special test language, and their expected results. To run the test suite on your system after a build, type `make test` from the source root directory, or change location to the `mysql-test` directory and type `./mysql-test-run.pl`. If you have installed a binary distribution, change location to the `mysql-test` directory under the installation root directory (for example, `/usr/local/mysql/mysql-test`), and run `./mysql-test-run.pl`. All tests should succeed. If any do not, feel free to try to find out why and report the problem if it indicates a bug in MySQL. See [Section 1.7, “How to Report Bugs or Problems”](#).

If one test fails, you should run `mysql-test-run.pl` with the `--force` option to check whether any other tests fail.

If you have a copy of `mysqld` running on the machine where you want to run the test suite, you do not have to stop it, as long as it is not using ports `9306` or `9307`. If either of those ports is taken, you should set the `MTR_BUILD_THREAD` environment variable to an appropriate value, and the test suite will use a different set of ports for master, slave, and NDB). For example:

```
shell> export MTR_BUILD_THREAD=31
shell> ./mysql-test-run.pl [options] [test_name]
```

In the `mysql-test` directory, you can run an individual test case with `./mysql-test-run.pl test_name`.

If you have a question about the test suite, or have a test case to contribute, send an email message to the MySQL `internals` mailing list. See [Section 1.6.1, “MySQL Mailing Lists”](#).

## 27.2 The MySQL Plugin API

MySQL supports a plugin API that enables creation of server components. Plugins can be loaded at server startup, or loaded and unloaded at runtime without restarting the server. The API is generic and does not specify what plugins can do. The components supported by this interface include, but are not limited to, storage engines, full-text parser plugins, and server extensions.

For example, full-text parser plugins can be used to replace or augment the built-in full-text parser. A plugin can parse text into words using rules that differ from those used by the built-in parser. This can be useful if you need to parse text with characteristics different from those expected by the built-in parser.

The plugin interface is more general than the older user-defined function (UDF) interface.

The plugin interface uses the `plugin` table in the `mysql` database to record information about plugins that have been installed permanently with the `INSTALL PLUGIN` statement. This table is created as part of the MySQL installation process. Plugins can also be installed for a single server invocation with the `--plugin-load` option. Plugins installed this way are not recorded in the `plugin` table. See [Section 6.5.2, “Installing and Uninstalling Plugins”](#).

MySQL supports an API for client plugins in addition to that for server plugins. This is used, for example, by authentication plugins where a server-side plugin and a client-side plugin cooperate to enable clients to connect to the server through a variety of authentication methods.

### Additional Resources

The book *MySQL 5.1 Plugin Development* by Sergei Golubchik and Andrew Hutchings provides a wealth of detail about the plugin API. Despite the fact that the book's title refers to MySQL Server 5.1, most of the information in it applies to later versions as well.

#### 27.2.1 Types of Plugins

The plugin API enables creation of plugins that implement several capabilities:

- [Storage engines](#)
- [Full-text parsers](#)
- [Daemons](#)
- [INFORMATION\\_SCHEMA tables](#)
- [Semisynchronous replication](#)
- [Auditing](#)
- [Authentication](#)
- [Password validation and strength checking](#)
- [Protocol tracing](#)
- [Query rewriting](#)
- [Secure keyring storage and retrieval](#)

The following sections provide an overview of these plugin types.

#### Storage Engine Plugins

The pluggable storage engine architecture used by MySQL Server enables storage engines to be written as plugins and loaded into and unloaded from a running server. For a description of this architecture, see [Section 16.11, “Overview of MySQL Storage Engine Architecture”](#).

For information on how to use the plugin API to write storage engines, see [MySQL Internals: Writing a Custom Storage Engine](#).

## Full-Text Parser Plugins

MySQL has a built-in parser that it uses by default for full-text operations (parsing text to be indexed, or parsing a query string to determine the terms to be used for a search). The built-in full-text parser is supported with [InnoDB](#) and [MyISAM](#) tables.

A character-based ngram full-text parser that supports Chinese, Japanese, and Korean (CJK), and a word-based MeCab parser plugin that supports Japanese were introduced in MySQL 5.7.6, for use with [InnoDB](#) and [MyISAM](#) tables.

For full-text processing, “parsing” means extracting words (or “tokens”, in the case of an n-gram character-based parser) from text or a query string based on rules that define which character sequences make up a word and where word boundaries lie.

When parsing for indexing purposes, the parser passes each word to the server, which adds it to a full-text index. When parsing a query string, the parser passes each word to the server, which accumulates the words for use in a search.

The parsing properties of the built-in full-text parser are described in [Section 13.9, “Full-Text Search Functions”](#). These properties include rules for determining how to extract words from text. The parser is influenced by certain system variables that cause words shorter or longer to be excluded, and by the stopword list that identifies common words to be ignored. For more information, see [Section 13.9.4, “Full-Text Stopwords”](#), and [Section 13.9.6, “Fine-Tuning MySQL Full-Text Search”](#).

The plugin API enables you to use a full-text parser other than the default built-in full-text parser. For example, if you are working with Japanese, you may choose to use the MeCab full-text parser. The plugin API also enables you to provide a full-text parser of your own so that you have control over the basic duties of a parser. A parser plugin can operate in either of two roles:

- The plugin can replace the built-in parser. In this role, the plugin reads the input to be parsed, splits it up into words, and passes the words to the server (either for indexing or for token accumulation). The ngram and MeCab parsers introduced in MySQL 5.7.6 operate as replacements for the built-in full-text parser.

You may choose to provide your own full-text parser if you need to use different rules from those of the built-in parser for determining how to split up input into words. For example, the built-in parser considers the text “case-sensitive” to consist of two words “case” and “sensitive,” whereas an application might need to treat the text as a single word.

- The plugin can act in conjunction with the built-in parser by serving as a front end for it. In this role, the plugin extracts text from the input and passes the text to the parser, which splits up the text into words using its normal parsing rules. This parsing is affected by the [innodb\\_ft\\_xxx](#) or [ft\\_xxx](#) system variables and the stopword list.

One reason to use a parser this way is that you need to index content such as PDF documents, XML documents, or [.doc](#) files. The built-in parser is not intended for those types of input but a plugin can pull out the text from these input sources and pass it to the built-in parser.

It is also possible for a parser plugin to operate in both roles. That is, it could extract text from noncleartext input (the front end role), and also parse the text into words (thus replacing the built-in parser).

A full-text plugin is associated with full-text indexes on a per-index basis. That is, when you install a parser plugin initially, that does not cause it to be used for any full-text operations. It simply becomes available. For example, a full-text parser plugin becomes available to be named in a [WITH PARSE](#) clause when creating individual [FULLTEXT](#) indexes. To create such an index at table-creation time, do this:

```
CREATE TABLE t
(
  doc CHAR(255),
  FULLTEXT INDEX (doc) WITH PARSER parser_name
) ENGINE=InnoDB;
```

Or you can add the index after the table has been created:

```
ALTER TABLE t ADD FULLTEXT INDEX (doc) WITH PARSER parser_name;
```

The only SQL change for associating the parser with the index is the `WITH PARSER` clause. Searches are specified as before, with no changes needed for queries.

When you associate a parser plugin with a `FULLTEXT` index, the plugin is required for using the index. If the parser plugin is dropped, any index associated with it becomes unusable. Any attempt to use a table for which a plugin is not available results in an error, although `DROP TABLE` is still possible.

For more information about full-text plugins, see [Section 27.2.4.4, “Writing Full-Text Parser Plugins”](#). MySQL 5.7 supports full-text plugins with `MyISAM` and `InnoDB`. `InnoDB` support for full-text plugins was added in MySQL 5.7.3.

## Daemon Plugins

A daemon plugin is a simple type of plugin used for code that should be run by the server but that does not communicate with it. MySQL distributions include an example daemon plugin that writes periodic heartbeat messages to a file.

For more information about daemon plugins, see [Section 27.2.4.5, “Writing Daemon Plugins”](#).

## INFORMATION\_SCHEMA Plugins

`INFORMATION_SCHEMA` plugins enable the creation of tables containing server metadata that are exposed to users through the `INFORMATION_SCHEMA` database. For example, `InnoDB` uses `INFORMATION_SCHEMA` plugins to provide tables that contain information about current transactions and locks.

For more information about `INFORMATION_SCHEMA` plugins, see [Section 27.2.4.6, “Writing INFORMATION\\_SCHEMA Plugins”](#).

## Semisynchronous Replication Plugins

MySQL replication is asynchronous by default. With semisynchronous replication, a commit performed on the master side blocks before returning to the session that performed the transaction until at least one slave acknowledges that it has received and logged the events for the transaction. Semisynchronous replication is implemented through complementary master and client plugins. See [Section 18.3.9, “Semisynchronous Replication”](#).

For more information about semisynchronous replication plugins, see [Section 27.2.4.7, “Writing Semisynchronous Replication Plugins”](#).

## Audit Plugins

The MySQL server provides a pluggable audit interface that enables information about server operations to be reported to interested parties. Audit notification occurs for these operations (although the interface is general and the server could be modified to report others):

- Write a message to the general query log (if the log is enabled)
- Write a message to the error log

- Send a query result to a client

Audit plugins may register with the audit interface to receive notification about server operations. When an auditable event occurs within the server, the server determines whether notification is needed. For each registered audit plugin, the server checks the event against those event classes in which the plugin is interested and passes the event to the plugin if there is a match.

This interface enables audit plugins to receive notifications only about operations in event classes they consider significant and to ignore others. The interface provides for categorization of operations into event classes and further division into event subclasses within each class.

When an audit plugin is notified of an auditable event, it receives a pointer to the current THD structure and a pointer to a structure that contains information about the event. The plugin can examine the event and perform whatever auditing actions are appropriate. For example, the plugin can see what statement produced a result set or was logged, the number of rows in a result, who the current user was for an operation, or the error code for failed operations.

For more information about audit plugins, see [Section 27.2.4.8, “Writing Audit Plugins”](#).

## Authentication Plugins

MySQL supports pluggable authentication. Authentication plugins exist on both the server and client sides. Plugins on the server side implement authentication methods for use by clients when they connect to the server. A plugin on the client side communicates with a server-side plugin to provide the authentication information that it requires. A client-side plugin may interact with the user, performing tasks such as soliciting a password or other authentication credentials to be sent to the server. See [Section 7.3.8, “Pluggable Authentication”](#).

Pluggable authentication also enables proxy user capability, in which one user takes the identity of another user. A server-side authentication plugin can return to the server the name of the user whose identity the connecting user should have. See [Section 7.3.9, “Proxy Users”](#).

For more information about authentication plugins, see [Section 27.2.4.9, “Writing Authentication Plugins”](#).

## Password-Validation Plugins

The MySQL server provides an interface for writing plugins that test passwords. Such a plugin implements two capabilities:

- Rejection of too-weak passwords in statements that assign passwords (such as `CREATE USER`, `GRANT`, and `SET PASSWORD` statements), and passwords given as arguments to the `PASSWORD( )` and `OLD_PASSWORD( )` functions.
- Assessing the strength of potential passwords for the `VALIDATE_PASSWORD_STRENGTH( )` SQL function.

For information about writing this type of plugin, see [Section 27.2.4.10, “Writing Password-Validation Plugins”](#).

## Protocol Trace Plugins

MySQL supports the use of protocol trace plugins: client-side plugins that implement tracing of communication between a client and the server that takes place using the client/server protocol. This capability can be used in MySQL 5.7.2 and up.

For more information about protocol trace plugins, see [Section 27.2.4.11, “Writing Protocol Trace Plugins”](#).

## Query Rewrite Plugins

As of MySQL 5.7.6, MySQL Server supports query rewrite plugins that can examine and possibly modify statements received by the server before the server executes them. A query rewrite plugin takes statements either before or after the server has parsed them.

A preparse query rewrite plugin has these characteristics:

- The plugin enables rewriting of SQL statements arriving at the server before the server processes them.
- The plugin receives a statement string and may return a different string.

A postparse query rewrite plugin has these characteristics:

- The plugin enables statement rewriting based on parse trees.
- The server parses each statement and passes its parse tree to the plugin, which may traverse the tree. The plugin can return the original tree to the server for further processing, or construct a different tree and return that instead.
- The plugin can use the `mysql_parser` plugin service for these purposes:
  - To activate statement digest calculation and obtain the normalized version of statements independent of whether the Performance Schema produces digests.
  - To traverse parse trees.
  - To parse statements. This is useful if the plugin constructs a new statement string from the parse tree. The plugin can have the server parse the string to produce a new tree, then return that tree as the representation of the rewritten statement.

For more information about plugin services, see [Section 27.3, “MySQL Services for Plugins”](#).

Preparse and postparse query rewrite plugins share these characteristics:

- If a query rewrite plugin is installed, the `--log-raw` option affects statement logging as follows:
  - Without `--log-raw`, the server logs the statement returned by the query rewrite plugin. This may differ from the statement as received.
  - With `--log-raw`, the server logs the original statement as received.
- If a plugin rewrites a statement, the server decides whether to write it to the binary log (and thus to any replication slaves) based on the rewritten statement, not the original statement. If a plugin rewrites only `SELECT` statements to `SELECT` statements, there is no impact on binary logging because the server does not write `SELECT` statements to the binary log.
- If a plugin rewrites a statement, the server produces a `Note` message that the client can view using `SHOW WARNINGS`. Messages have this format, where `stmt_in` is the original statement and `stmt_out` is the rewritten statement:

```
Query 'stmt_in' rewritten to 'stmt_out' by a query rewrite plugin
```

MySQL distributions include a postparse query rewrite plugin named `Rewriter`. This plugin is rule based. You can add rows to its rules table to cause `SELECT` statement rewriting. For more information, see [Section 6.5.5, “The Rewriter Query Rewrite Plugin”](#).

Query rewrite plugins use the same API as audit plugins. For more information about audit plugins, see [Section 27.2.4.8, “Writing Audit Plugins”](#).

## Keyring Plugins

As of MySQL 5.7.11, MySQL Server supports keyring plugins that enable internal server components and plugins to securely store sensitive information for later retrieval.

All MySQL distributions include a keyring plugin named `keyring_file`. MySQL Enterprise Edition distributions include a keyring plugin named `keyring_okv`. See [Section 7.5.4, “The MySQL Keyring”](#).

For more information about keyring plugins, see [Section 27.2.4.12, “Writing Keyring Plugins”](#).

## 27.2.2 Plugin API Characteristics

The server plugin API has these characteristics:

- All plugins have several things in common.

Each plugin has a name that it can be referred to in SQL statements, as well as other metadata such as an author and a description that provide other information. This information can be examined in the `INFORMATION_SCHEMA.PLUGINS` table or using the `SHOW PLUGINS` statement.

- The plugin framework is extendable to accommodate different kinds of plugins.

Although some aspects of the plugin API are common to all types of plugins, the API also permits type-specific interface elements so that different types of plugins can be created. A plugin with one purpose can have an interface most appropriate to its own requirements and not the requirements of some other plugin type.

Interfaces for several types of plugins exist, such as storage engines, full-text parser, and `INFORMATION_SCHEMA` tables. Others can be added.

- Plugins can expose information to users.

A plugin can implement system and status variables that are available through the `SHOW VARIABLES` and `SHOW STATUS` statements.

- The plugin API includes versioning information.

The version information included in the plugin API enables a plugin library and each plugin that it contains to be self-identifying with respect to the API version that was used to build the library. If the API changes over time, the version numbers will change, but a server can examine a given plugin library's version information to determine whether it supports the plugins in the library.

There are two types of version numbers. The first is the version for the general plugin framework itself. Each plugin library includes this kind of version number. The second type of version applies to individual plugins. Each specific type of plugin has a version for its interface, so each plugin in a library has a type-specific version number. For example, a library containing a full-text parser plugin has a general plugin API version number, and the plugin has a version number specific to the full-text plugin interface.

- The plugin API implements security restrictions.

A plugin library must be installed in a specific dedicated directory for which the location is controlled by the server and cannot be changed at runtime. Also, the library must contain specific symbols that identify it as a plugin library. The server will not load something as a plugin if it was not built as a plugin.

- Plugins have access to server services.

The services interface exposes server functionality that plugins can access using ordinary function calls. For details, see [Section 27.3, “MySQL Services for Plugins”](#).

In some respects, the server plugin API is similar to the older user-defined function (UDF) API that it supersedes, but the plugin API has several advantages over the older interface. For example, UDFs

had no versioning information. Also, the newer plugin interface eliminates the security issues of the older UDF interface. The older interface for writing nonplugin UDFs permitted libraries to be loaded from any directory searched by the system's dynamic linker, and the symbols that identified the UDF library were relatively nonspecific.

The client plugin API has similar architectural characteristics, but client plugins have no direct access to the server the way server plugins do.

### 27.2.3 Plugin API Components

The server plugin implementation comprises several components.

SQL statements:

- `INSTALL PLUGIN` registers a plugin in the `mysql.plugin` table and loads the plugin code.
- `UNINSTALL PLUGIN` unregisters a plugin from the `mysql.plugin` table and unloads the plugin code.
- The `WITH PARSER` clause for full-text index creation associates a full-text parser plugin with a given `FULLTEXT` index.
- `SHOW PLUGINS` displays information about server plugins.

Command-line options and system variables:

- The `--plugin-load` option enables plugins to be loaded at server startup time.
- The `plugin_dir` system variable indicates the location of the directory where all plugins must be installed. The value of this variable can be specified at server startup with a `--plugin_dir=dir_name` option. `mysql_config --plugindir` displays the default plugin directory path name.

For additional information about plugin loading, see [Section 6.5.2, “Installing and Uninstalling Plugins”](#).

Plugin-related tables:

- The `INFORMATION_SCHEMA.PLUGINS` table contains plugin information.
- The `mysql.plugin` table lists each plugin that was installed with `INSTALL PLUGIN` and is required for plugin use. For new MySQL installations, this table is created during the installation process.

The client plugin implementation is simpler:

- For the `mysql_options()` C API function, the `MYSQL_DEFAULT_AUTH` and `MYSQL_PLUGIN_DIR` options enable client programs to load authentication plugins.
- There are C API functions that enable management of client plugins.

To examine how MySQL implements plugins, consult the following source files in a MySQL source distribution:

- In the `include/mysql` directory, `plugin.h` exposes the public plugin API. This file should be examined by anyone who wants to write a plugin library. `plugin_xxx.h` files provide additional information that pertains to specific types of plugins. `client_plugin.h` contains information specific to client plugins.
- In the `sql` directory, `sql_plugin.h` and `sql_plugin.cc` comprise the internal plugin implementation. `sql_acl.cc` is where the server uses authentication plugins. These files need not be consulted by plugin developers. They may be of interest for those who want to know more about how the server handles plugins.

- In the `sql-common` directory, `client_plugin.h` implements the C API client plugin functions, and `client.c` implements client authentication support. These files need not be consulted by plugin developers. They may be of interest for those who want to know more about how the server handles plugins.

## 27.2.4 Writing Plugins

To create a plugin library, you must provide the required descriptor information that indicates what plugins the library file contains, and write the interface functions for each plugin.

Every server plugin must have a general descriptor that provides information to the plugin API, and a type-specific descriptor that provides information about the plugin interface for a given type of plugin. The structure of the general descriptor is the same for all plugin types. The structure of the type-specific descriptor varies among plugin types and is determined by the requirements of what the plugin needs to do. The server plugin interface also enables plugins to expose status and system variables. These variables become visible through the `SHOW STATUS` and `SHOW VARIABLES` statements and the corresponding `INFORMATION_SCHEMA` tables.

For client-side plugins, the architecture is a bit different. Each plugin must have a descriptor, but there is no division into separate general and type-specific descriptors. Instead, the descriptor begins with a fixed set of members common to all client plugin types, and the common members are followed by any additional members required to implement the specific plugin type.

You can write plugins in C or C++ (or another language that can use C calling conventions). Plugins are loaded and unloaded dynamically, so your operating system must support dynamic loading and you must have compiled the calling application dynamically (not statically). For server plugins, this means that `mysqld` must be compiled dynamically.

A server plugin contains code that becomes part of the running server, so when you write the plugin, you are bound by any and all constraints that otherwise apply to writing server code. For example, you may have problems if you attempt to use functions from the `libstdc++` library. These constraints may change in future versions of the server, so it is possible that server upgrades will require revisions to plugins originally written for older servers. For information about these constraints, see [Section 2.9.4, “MySQL Source-Configuration Options”](#), and [Section 2.9.5, “Dealing with Problems Compiling MySQL”](#).

Client plugin writers should avoid dependencies on what symbols the calling application has because you cannot be sure what applications will use the plugin.

### 27.2.4.1 Overview of Plugin Writing

The following procedure provides an overview of the steps needed to create a plugin library. The next sections provide additional details on setting plugin data structures and writing specific types of plugins.

1. In the plugin source file, include the header files that the plugin library needs. The `plugin.h` file is required, and the library might require other files as well. For example:

```
#include <stdlib.h>
#include <ctype.h>
#include <mysql/plugin.h>
```

2. Set up the descriptor information for the plugin library file. For server plugins, write the library descriptor, which must contain the general plugin descriptor for each server plugin in the file. For more information, see [Server Plugin Library and Plugin Descriptors](#). In addition, set up the type-specific descriptor for each server plugin in the library. Each plugin's general descriptor points to its type-specific descriptor.

For client plugins, write the client descriptor. For more information, see [Client Plugin Descriptors](#).

3. Write the plugin interface functions for each plugin. For example, each plugin's general plugin descriptor points to the initialization and deinitialization functions that the server should invoke when

it loads and unloads the plugin. The plugin's type-specific description may also point to interface functions.

4. For server plugins, set up the status and system variables, if there are any.
5. Compile the plugin library as a shared library and install it in the plugin directory. For more information, see [Section 27.2.4.3, “Compiling and Installing Plugin Libraries”](#).
6. For server plugins, register the plugin with the server. For more information, see [Section 6.5.2, “Installing and Uninstalling Plugins”](#).
7. Test the plugin to verify that it works properly.

### 27.2.4.2 Plugin Data Structures

A plugin library file includes descriptor information to indicate what plugins it contains.

If the plugin library contains any server plugins, it must include the following descriptor information:

- A library descriptor indicates the general server plugin API version number used by the library and contains a general plugin descriptor for each server plugin in the library. To provide the framework for this descriptor, invoke two macros from the `plugin.h` header file:

```
mysql_declare_plugin(name)
... one or more server plugin descriptors here ...
mysql_declare_plugin_end;
```

The macros expand to provide a declaration for the API version automatically. You must provide the plugin descriptors.

- Within the library descriptor, each general server plugin is described by a `st_mysql_plugin` structure. This plugin descriptor structure contains information that is common to every type of server plugin: A value that indicates the plugin type; the plugin name, author, description, and license type; pointers to the initialization and deinitialization functions that the server invokes when it loads and unloads the plugin, and pointers to any status or system variables the plugin implements.
- Each general server plugin descriptor within the library descriptor also contains a pointer to a type-specific plugin descriptor. The structure of the type-specific descriptors varies from one plugin type to another because each type of plugin can have its own API. A type-specific plugin descriptor contains a type-specific API version number and pointers to the functions that are needed to implement that plugin type. For example, a full-text parser plugin has initialization and deinitialization functions, and a main parsing function. The server invokes these functions when it uses the plugin to parse text.

The plugin library also contains the interface functions that are referenced by the general and type-specific descriptors for each plugin in the library.

If the plugin library contains a client plugin, it must include a descriptor for the plugin. The descriptor begins with a fixed set of members common to all client plugins, followed by any members specific to the plugin type. To provide the descriptor framework, invoke two macros from the `client_plugin.h` header file:

```
mysql_declare_client_plugin(plugin_type)
... members common to all client plugins ...
... type-specific extra members ...
mysql_end_client_plugin;
```

The plugin library also contains any interface functions referenced by the client descriptor.

The `mysql_declare_plugin()` and `mysql_declare_client_plugin()` macros differ somewhat in how they can be invoked, which has implications for the contents of plugin libraries. The following guidelines summarize the rules:

- `mysql_declare_plugin()` and `mysql_declare_client_plugin()` can both be used in the same source file, which means that a plugin library can contain both server and client plugins. However, each of `mysql_declare_plugin()` and `mysql_declare_client_plugin()` can be used at most once.
- `mysql_declare_plugin()` permits multiple server plugin declarations, so a plugin library can contain multiple server plugins.
- `mysql_declare_client_plugin()` permits only a single client plugin declaration. To create multiple client plugins, separate plugin libraries must be used.

When a client program looks for a client plugin that is in a plugin library and not built into `libmysqlclient`, it looks for a file with a base name that is the same as the plugin name. For example, if a program needs to use a client authentication plugin named `auth_xxx` on a system that uses `.so` as the library suffix, it looks in the file named `auth_xxx.so`. (On OS X, the program looks first for `auth_xxx.dylib`, then for `auth_xxx.so`.) For this reason, if a plugin library contains a client plugin, the library must have the same base name as that plugin.

The same is not true for a library that contains server plugins. The `--plugin-load` option and the `INSTALL PLUGIN` statement provide the library file name explicitly, so there need be no explicit relationship between the library name and the name of any server plugins it contains.

## Server Plugin Library and Plugin Descriptors

Every plugin library that contains server plugins must include a library descriptor that contains the general plugin descriptor for each server plugin in the file. This section discusses how to write the library and general descriptors for server plugins.

The library descriptor must define two symbols:

- `_mysql_plugin_interface_version_` specifies the version number of the general plugin framework. This is given by the `MYSQL_PLUGIN_INTERFACE_VERSION` symbol, which is defined in the `plugin.h` file.
- `_mysql_plugin_declarations_` defines an array of plugin declarations, terminated by a declaration with all members set to 0. Each declaration is an instance of the `st_mysql_plugin` structure (also defined in `plugin.h`). There must be one of these for each server plugin in the library.

If the server does not find those two symbols in a library, it does not accept it as a legal plugin library and rejects it with an error. This prevents use of a library for plugin purposes unless it was built specifically as a plugin library.

The conventional way to define the two required symbols is by using the `mysql_declare_plugin()` and `mysql_declare_plugin_end` macros from the `plugin.h` file:

```
mysql_declare_plugin(name)
... one or more server plugin descriptors here ...
mysql_declare_plugin_end;
```

Each server plugin must have a general descriptor that provides information to the server plugin API. The general descriptor has the same structure for all plugin types. The `st_mysql_plugin` structure in the `plugin.h` file defines this descriptor:

```
struct st_mysql_plugin
{
    int type;                /* the plugin type (a MYSQL_XXX_PLUGIN value) */
    void *info;              /* pointer to type-specific plugin descriptor */
    const char *name;        /* plugin name */
    const char *author;      /* plugin author (for I_S.PLUGINS) */
    const char *descr;       /* general descriptive text (for I_S.PLUGINS) */
    int license;             /* the plugin license (PLUGIN_LICENSE_XXX) */
}
```

```

int (*init)(void *); /* the function to invoke when plugin is loaded */
int (*deinit)(void *); /* the function to invoke when plugin is unloaded */
unsigned int version; /* plugin version (for I_S.PLUGINS) */
struct st_mysql_show_var *status_vars;
struct st_mysql_sys_var **system_vars;
void * __reserved1; /* reserved for dependency checking */
unsigned long flags; /* flags for plugin */
};

```

The `st_mysql_plugin` descriptor structure members are used as follows. `char *` members should be specified as null-terminated strings.

- **type**: The plugin type. This must be one of the plugin-type values from `plugin.h`:

```

/*
 * The allowable types of plugins
 */
#define MYSQL_UDF_PLUGIN 0 /* User-defined function */
#define MYSQL_STORAGE_ENGINE_PLUGIN 1 /* Storage Engine */
#define MYSQL_FTPARSER_PLUGIN 2 /* Full-text parser plugin */
#define MYSQL_DAEMON_PLUGIN 3 /* The daemon/raw plugin type */
#define MYSQL_INFORMATION_SCHEMA_PLUGIN 4 /* The I_S plugin type */
#define MYSQL_AUDIT_PLUGIN 5 /* The Audit plugin type */
#define MYSQL_REPLICATION_PLUGIN 6 /* The replication plugin type */
#define MYSQL_AUTHENTICATION_PLUGIN 7 /* The authentication plugin type */
...

```

For example, for a full-text parser plugin, the `type` value is `MYSQL_FTPARSER_PLUGIN`.

- **info**: A pointer to the type-specific descriptor for the plugin. This descriptor's structure depends on the particular type of plugin, unlike that of the general plugin descriptor structure. For version-control purposes, the first member of the type-specific descriptor for every plugin type is expected to be the interface version for the type. This enables the server to check the type-specific version for every plugin no matter its type. Following the version number, the descriptor includes any other members needed, such as callback functions and other information needed by the server to invoke the plugin properly. Later sections on writing particular types of server plugins describe the structure of their type-specific descriptors.
- **name**: A string that gives the plugin name. This is the name that will be listed in the `mysql.plugin` table and by which you refer to the plugin in SQL statements such as `INSTALL PLUGIN` and `UNINSTALL PLUGIN`, or with the `--plugin-load` option. The name is also visible in the `INFORMATION_SCHEMA.PLUGINS` table or the output from `SHOW PLUGINS`.

The plugin name should not begin with the name of any server option. If it does, the server will fail to initialize it. For example, the server has a `--socket` option, so you should not use a plugin name such as `socket`, `socket_plugin`, and so forth.

- **author**: A string naming the plugin author. This can be whatever you like.
- **desc**: A string that provides a general description of the plugin. This can be whatever you like.
- **license**: The plugin license type. The value can be one of `PLUGIN_LICENSE_PROPRIETARY`, `PLUGIN_LICENSE_GPL`, or `PLUGIN_LICENSE_BSD`.
- **init**: A once-only initialization function, or `NULL` if there is no such function. The server executes this function when it loads the plugin, which happens for `INSTALL PLUGIN` or, for plugins listed in the `mysql.plugin` table, at server startup. The function takes one argument that points to the internal structure used to identify the plugin. It returns zero for success and nonzero for failure.
- **deinit**: A once-only deinitialization function, or `NULL` if there is no such function. The server executes this function when it unloads the plugin, which happens for `UNINSTALL PLUGIN` or, for plugins listed in the `mysql.plugin` table, at server shutdown. The function takes one argument that points to the internal structure used to identify the plugin. It returns zero for success and nonzero for failure.

- **version**: The plugin version number. When the plugin is installed, this value can be retrieved from the `INFORMATION_SCHEMA.PLUGINS` table. The value includes major and minor numbers. If you write the value as a hex constant, the format is `0xMMNN`, where `MM` and `NN` are the major and minor numbers, respectively. For example, `0x0302` represents version 3.2.
- **status\_vars**: A pointer to a structure for status variables associated with the plugin, or `NULL` if there are no such variables. When the plugin is installed, these variables are displayed in the output of the `SHOW STATUS` statement.

The `status_vars` member, if not `NULL`, points to an array of `st_mysql_show_var` structures that describe status variables. See [Server Plugin Status and System Variables](#).

- **system\_vars**: A pointer to a structure for system variables associated with the plugin, or `NULL` if there are no such variables. These options and system variables can be used to help initialize variables within the plugin.

The `system_vars` member, if not `NULL`, points to an array of `st_mysql_sys_var` structures that describe system variables. See [Server Plugin Status and System Variables](#).

- **\_\_reserved1**: A placeholder for the future. It should be set to `NULL`.
- **flags**: Plugin flags. Individual bits correspond to different flags. The value should be set to the OR of the applicable flags. These flags are available:

```
#define PLUGIN_OPT_NO_INSTALL    1UL    /* Not dynamically loadable */
#define PLUGIN_OPT_NO_UNINSTALL 2UL    /* Not dynamically unloadable */
```

`PLUGIN_OPT_NO_INSTALL` indicates that the plugin cannot be loaded at runtime with the `INSTALL PLUGIN` statement. This is appropriate for plugins that must be loaded at server startup with the `--plugin-load` option. `PLUGIN_OPT_NO_UNINSTALL` indicates that the plugin cannot be unloaded at runtime with the `UNINSTALL PLUGIN` statement.

The server invokes the `init` and `deinit` functions in the general plugin descriptor only when loading and unloading the plugin. They have nothing to do with use of the plugin such as happens when an SQL statement causes the plugin to be invoked.

For example, the descriptor information for a library that contains a single full-text parser plugin named `simple_parser` looks like this:

```
mysql_declare_plugin(ftexample)
{
    MYSQL_FTPARSER_PLUGIN,          /* type */
    &simple_parser_descriptor,        /* descriptor */
    "simple_parser",                  /* name */
    "Oracle Corporation",           /* author */
    "Simple Full-Text Parser",       /* description */
    PLUGIN_LICENSE_GPL,             /* plugin license */
    simple_parser_plugin_init,       /* init function (when loaded) */
    simple_parser_plugin_deinit,     /* deinit function (when unloaded) */
    0x0001,                         /* version */
    simple_status,                   /* status variables */
    simple_system_variables,         /* system variables */
    NULL,
    0
}
mysql_declare_plugin_end;
```

For a full-text parser plugin, the type must be `MYSQL_FTPARSER_PLUGIN`. This is the value that identifies the plugin as being legal for use in a `WITH PARSER` clause when creating a `FULLTEXT` index. (No other plugin type is legal for this clause.)

`plugin.h` defines the `mysql_declare_plugin()` and `mysql_declare_plugin_end` macros like this:

```

#ifndef MYSQL_DYNAMIC_PLUGIN
#define __MYSQL_DECLARE_PLUGIN(NAME, VERSION, PSIZE, DECLS) \
MYSQL_PLUGIN_EXPORT int VERSION= MYSQL_PLUGIN_INTERFACE_VERSION; \
MYSQL_PLUGIN_EXPORT int PSIZE= sizeof(struct st_mysql_plugin); \
MYSQL_PLUGIN_EXPORT struct st_mysql_plugin DECLS[]= {
#else
#define __MYSQL_DECLARE_PLUGIN(NAME, VERSION, PSIZE, DECLS) \
MYSQL_PLUGIN_EXPORT int _mysql_plugin_interface_version= MYSQL_PLUGIN_INTERFACE_VERSION; \
MYSQL_PLUGIN_EXPORT int _mysql_sizeof_struct_st_plugin= sizeof(struct st_mysql_plugin); \
MYSQL_PLUGIN_EXPORT struct st_mysql_plugin _mysql_plugin_declarations[]= {
#endif

#define mysql_declare_plugin(NAME) \
__MYSQL_DECLARE_PLUGIN(NAME, \
    builtin_ ## NAME ## _plugin_interface_version, \
    builtin_ ## NAME ## _sizeof_struct_st_plugin, \
    builtin_ ## NAME ## _plugin)

#define mysql_declare_plugin_end ,{0,0,0,0,0,0,0,0,0,0,0,0}

```

### Note

Those declarations define the `_mysql_plugin_interface_version` symbol only if the `MYSQL_DYNAMIC_PLUGIN` symbol is defined. This means that `-DMYSQL_DYNAMIC_PLUGIN` must be provided as part of the compilation command to build the plugin as a shared library.

When the macros are used as just shown, they expand to the following code, which defines both of the required symbols (`_mysql_plugin_interface_version` and `_mysql_plugin_declarations`):

```

int _mysql_plugin_interface_version= MYSQL_PLUGIN_INTERFACE_VERSION;
int _mysql_sizeof_struct_st_plugin= sizeof(struct st_mysql_plugin);
struct st_mysql_plugin _mysql_plugin_declarations[]= {
{
    MYSQL_FTPARSER_PLUGIN,          /* type */
    &simple_parser_descriptor,        /* descriptor */
    "simple_parser",                  /* name */
    "Oracle Corporation",            /* author */
    "Simple Full-Text Parser",        /* description */
    PLUGIN_LICENSE_GPL,              /* plugin license */
    simple_parser_plugin_init,        /* init function (when loaded) */
    simple_parser_plugin_deinit,      /* deinit function (when unloaded) */
    0x0001,                          /* version */
    simple_status,                   /* status variables */
    simple_system_variables,          /* system variables */
    NULL,
    0
}
, {0,0,0,0,0,0,0,0,0,0,0,0}
};

```

The preceding example declares a single plugin in the general descriptor, but it is possible to declare multiple plugins. List the declarations one after the other between `mysql_declare_plugin()` and `mysql_declare_plugin_end`, separated by commas.

MySQL server plugins can be written in C or C++ (or another language that can use C calling conventions). If you write a C++ plugin, one C++ feature that you should not use is nonconstant variables to initialize global structures. Members of structures such as the `st_mysql_plugin` structure should be initialized only with constant variables. The `simple_parser` descriptor shown earlier is permissible in a C++ plugin because it satisfies that requirement:

```

mysql_declare_plugin(ftexample)
{
    MYSQL_FTPARSER_PLUGIN,          /* type */
    &simple_parser_descriptor,        /* descriptor */

```

```

"simple_parser",          /* name */
"Oracle Corporation",    /* author */
"Simple Full-Text Parser", /* description */
PLUGIN_LICENSE_GPL,      /* plugin license */
simple_parser_plugin_init, /* init function (when loaded) */
simple_parser_plugin_deinit, /* deinit function (when unloaded) */
0x0001,                  /* version */
simple_status,            /* status variables */
simple_system_variables,  /* system variables */
NULL,
0
}
mysql_declare_plugin_end;

```

Here is another valid way to write the general descriptor. It uses constant variables to indicate the plugin name, author, and description:

```

const char *simple_parser_name = "simple_parser";
const char *simple_parser_author = "Oracle Corporation";
const char *simple_parser_description = "Simple Full-Text Parser";

mysql_declare_plugin(ftexample)
{
    MYSQL_FTPARSER_PLUGIN, /* type */
    &simple_parser_descriptor, /* descriptor */
    simple_parser_name, /* name */
    simple_parser_author, /* author */
    simple_parser_description, /* description */
    PLUGIN_LICENSE_GPL, /* plugin license */
    simple_parser_plugin_init, /* init function (when loaded) */
    simple_parser_plugin_deinit, /* deinit function (when unloaded) */
    0x0001, /* version */
    simple_status, /* status variables */
    simple_system_variables, /* system variables */
    NULL,
    0
}
mysql_declare_plugin_end;

```

However, the following general descriptor is invalid. It uses structure members to indicate the plugin name, author, and description, but structures are not considered constant initializers in C++:

```

typedef struct
{
    const char *name;
    const char *author;
    const char *description;
} plugin_info;

plugin_info parser_info = {
    "simple_parser",
    "Oracle Corporation",
    "Simple Full-Text Parser"
};

mysql_declare_plugin(ftexample)
{
    MYSQL_FTPARSER_PLUGIN, /* type */
    &simple_parser_descriptor, /* descriptor */
    parser_info.name, /* name */
    parser_info.author, /* author */
    parser_info.description, /* description */
    PLUGIN_LICENSE_GPL, /* plugin license */
    simple_parser_plugin_init, /* init function (when loaded) */
    simple_parser_plugin_deinit, /* deinit function (when unloaded) */
    0x0001, /* version */
    simple_status, /* status variables */
    simple_system_variables, /* system variables */
    NULL,
    0
}

```

```

}
mysql_declare_plugin_end;

```

## Server Plugin Status and System Variables

The server plugin interface enables plugins to expose status and system variables using the `status_vars` and `system_vars` members of the general plugin descriptor.

The `status_vars` member of the general plugin descriptor, if not 0, points to an array of `st_mysql_show_var` structures, each of which describes one status variable, followed by a structure with all members set to 0. The `st_mysql_show_var` structure has this definition:

```

struct st_mysql_show_var {
    const char *name;
    char *value;
    enum enum_mysql_show_type type;
};

```

When the plugin is installed, the plugin name and the `name` value are joined with an underscore to form the name displayed by `SHOW STATUS`.

The following table shows the permissible status variable `type` values and what the corresponding variable should be.

**Table 27.1 Server Plugin Status Variable Types**

| Variable Type              | Meaning   |
|----------------------------|---|
| <code>SHOW_BOOL</code>     | Pointer to a boolean variable                           |
| <code>SHOW_INT</code>      | Pointer to an integer variable                          |
| <code>SHOW_LONG</code>     | Pointer to a long integer variable                      |
| <code>SHOW_LONGLONG</code> | Pointer to a longlong integer variable                  |
| <code>SHOW_CHAR</code>     | A string  |
| <code>SHOW_CHAR_PTR</code> | Pointer to a string                                     |
| <code>SHOW_ARRAY</code>    | Pointer to another <code>st_mysql_show_var</code> array |
| <code>SHOW_FUNC</code>     | Pointer to a function                                   |
| <code>SHOW_DOUBLE</code>   | Pointer to a double                                     |

For the `SHOW_FUNC` type, the function is called and fills in its `out` parameter, which then provides information about the variable to be displayed. The function has this signature:

```

#define SHOW_VAR_FUNC_BUFF_SIZE 1024

typedef int (*mysql_show_var_func) (void *thd,
                                   struct st_mysql_show_var *out,
                                   char *buf);

```

The `system_vars` member, if not 0, points to an array of `st_mysql_sys_var` structures, each of which describes one system variable (which can also be set from the command-line or configuration file), followed by a structure with all members set to 0. The `st_mysql_sys_var` structure is defined as follows:

```

struct st_mysql_sys_var {
    int flags;
    const char *name, *comment;
    int (*check)(THD*, struct st_mysql_sys_var *, void*, st_mysql_value*);
    void (*update)(THD*, struct st_mysql_sys_var *, void*, const void*);
};

```

Additional fields are append as required depending upon the flags.

For convenience, a number of macros are defined that make creating new system variables within a plugin much simpler.

Throughout the macros, the following fields are available:

- `name`: An unquoted identifier for the system variable.
- `varname`: The identifier for the static variable. Where not available, it is the same as the `name` field.
- `opt`: Additional use flags for the system variable. The following table shows the permissible flags.

**Table 27.2 Server Plugin System Variable Flags**

| Flag Value                       | Description   |
|----------------------------------|---|
| <code>PLUGIN_VAR_READONLY</code> | The system variable is read only  |
| <code>PLUGIN_VAR_NOSYSVAR</code> | The system variable is not user visible at runtime  |
| <code>PLUGIN_VAR_NOCMDOPT</code> | The system variable is not configurable from the command line                                 |
| <code>PLUGIN_VAR_NOCMDARG</code> | No argument is required at the command line (typically used for boolean variables)            |
| <code>PLUGIN_VAR_RQCMDARG</code> | An argument is required at the command line (this is the default)                             |
| <code>PLUGIN_VAR_OPCMDARG</code> | An argument is optional at the command line   |
| <code>PLUGIN_VAR_MEMALLOC</code> | Used for string variables; indicates that memory is to be allocated for storage of the string |

- `comment`: A descriptive comment to be displayed in the server help message. `NULL` if this variable is to be hidden.
- `check`: The check function, `NULL` for default.
- `update`: The update function, `NULL` for default.
- `default`: The variable default value.
- `minimum`: The variable minimum value.
- `maximum`: The variable maximum value.
- `blocksize`: The variable block size. When the value is set, it is rounded to the nearest multiple of `blocksize`.

A system variable may be accessed either by using the static variable directly or by using the `SYSVAR()` accessor macro. The `SYSVAR()` macro is provided for completeness. Usually it should be used only when the code cannot directly access the underlying variable.

For example:

```
static int my_foo;
static MYSQL_SYSVAR_INT(foo_var, my_foo,
                        PLUGIN_VAR_RQCMDARG, "foo comment",
                        NULL, NULL, 0, 0, INT_MAX, 0);
...
SYSVAR(foo_var)= value;
value= SYSVAR(foo_var);
my_foo= value;
value= my_foo;
```

Session variables may be accessed only through the `THDVAR()` accessor macro. For example:

```
static MYSQL_THDVAR_BOOL(some_flag,
                        PLUGIN_VAR_NOCMDARG, "flag comment",
                        NULL, NULL, FALSE);
```

```
...
    if (THDVAR(thd, some_flag))
    {
        do_something();
        THDVAR(thd, some_flag)= FALSE;
    }
}
```

All global and session system variables must be published to `mysqld` before use. This is done by constructing a `NULL`-terminated array of the variables and linking to it in the plugin public interface. For example:

```
static struct st_mysql_sys_var *my_plugin_vars[] = {
    MYSQL_SYSVAR(foo_var),
    MYSQL_SYSVAR(some_flag),
    NULL
};
mysql_declare_plugin(fooplug)
{
    MYSQL_..._PLUGIN,
    &plugin_data,
    "fooplug",
    "foo author",
    "This does foo!",
    PLUGIN_LICENSE_GPL,
    foo_init,
    foo_fini,
    0x0001,
    NULL,
    my_plugin_vars,
    NULL,
    0
}
mysql_declare_plugin_end;
```

The following convenience macros enable you to declare different types of system variables:

- Boolean system variables of type `my_bool`, which is a 1-byte boolean. (0 = FALSE, 1 = TRUE)

```
MYSQL_THDVAR_BOOL(name, opt, comment, check, update, default)
MYSQL_SYSVAR_BOOL(name, varname, opt, comment, check, update, default)
```

- String system variables of type `char*`, which is a pointer to a null-terminated string.

```
MYSQL_THDVAR_STR(name, opt, comment, check, update, default)
MYSQL_SYSVAR_STR(name, varname, opt, comment, check, update, default)
```

- Integer system variables, of which there are several varieties.

- An `int` system variable, which is typically a 4-byte signed word.

```
MYSQL_THDVAR_INT(name, opt, comment, check, update, default, min, max, blk)
MYSQL_SYSVAR_INT(name, varname, opt, comment, check, update, default,
    minimum, maximum, blocksize)
```

- An `unsigned int` system variable, which is typically a 4-byte unsigned word.

```
MYSQL_THDVAR_UINT(name, opt, comment, check, update, default, min, max, blk)
MYSQL_SYSVAR_UINT(name, varname, opt, comment, check, update, default,
    minimum, maximum, blocksize)
```

- A `long` system variable, which is typically either a 4- or 8-byte signed word.

```
MYSQL_THDVAR_LONG(name, opt, comment, check, update, default, min, max, blk)
MYSQL_SYSVAR_LONG(name, varname, opt, comment, check, update, default,
```

```
minimum, maximum, blocksize)
```

- An `unsigned long` system variable, which is typically either a 4- or 8-byte unsigned word.

```
MYSQL_THDVAR_ULONG(name, opt, comment, check, update, default, min, max, blk)
MYSQL_SYSVAR_ULONG(name, varname, opt, comment, check, update, default,
                    minimum, maximum, blocksize)
```

- A `long long` system variable, which is typically an 8-byte signed word.

```
MYSQL_THDVAR_LONGLONG(name, opt, comment, check, update,
                       default, minimum, maximum, blocksize)
MYSQL_SYSVAR_LONGLONG(name, varname, opt, comment, check, update,
                       default, minimum, maximum, blocksize)
```

- An `unsigned long long` system variable, which is typically an 8-byte unsigned word.

```
MYSQL_THDVAR_ULONGLONG(name, opt, comment, check, update,
                        default, minimum, maximum, blocksize)
MYSQL_SYSVAR_ULONGLONG(name, varname, opt, comment, check, update,
                        default, minimum, maximum, blocksize)
```

- A `double` system variable, which is typically an 8-byte signed word. These accessor macros were added in MySQL 5.7.2.

```
MYSQL_THDVAR_DOUBLE(name, opt, comment, check, update,
                     default, minimum, maximum, blocksize)
MYSQL_SYSVAR_DOUBLE(name, varname, opt, comment, check, update,
                     default, minimum, maximum, blocksize)
```

- An `unsigned long` system variable, which is typically either a 4- or 8-byte unsigned word. The range of possible values is an ordinal of the number of elements in the `typelib`, starting from 0.

```
MYSQL_THDVAR_ENUM(name, opt, comment, check, update, default, typelib)
MYSQL_SYSVAR_ENUM(name, varname, opt, comment, check, update,
                  default, typelib)
```

- An `unsigned long long` system variable, which is typically an 8-byte unsigned word. Each bit represents an element in the `typelib`.

```
MYSQL_THDVAR_SET(name, opt, comment, check, update, default, typelib)
MYSQL_SYSVAR_SET(name, varname, opt, comment, check, update,
                 default, typelib)
```

Internally, all mutable and plugin system variables are stored in a `HASH` structure.

Display of the server command-line help text is handled by compiling a `DYNAMIC_ARRAY` of all variables relevant to command-line options, sorting them, and then iterating through them to display each option.

When a command-line option has been handled, it is then removed from the `argv` by the `handle_option()` function (`my_getopt.c`); in effect, it is consumed.

The server processes command-line options during the plugin installation process, immediately after the plugin has been successfully loaded but before the plugin initialization function has been called

Plugins loaded at runtime do not benefit from any configuration options and must have usable defaults. Once they are installed, they are loaded at `mysqld` initialization time and configuration options can be set at the command line or within `my.cnf`.

Plugins should consider the `thd` parameter to be read only.

## Client Plugin Descriptors

Each client plugin must have a descriptor that provides information to the client plugin API. The descriptor structure begins with a fixed set of members common to all client plugins, followed by any members specific to the plugin type.

The `st_mysql_client_plugin` structure in the `client_plugin.h` file defines a “generic” descriptor that contains the common members:

```
struct st_mysql_client_plugin
{
    int type;
    unsigned int interface_version;
    const char *name;
    const char *author;
    const char *desc;
    unsigned int version[3];
    const char *license;
    void *mysql_api;
    int (*init)(char *, size_t, int, va_list);
    int (*deinit)();
    int (*options)(const char *option, const void *);
};
```

The common `st_mysql_client_plugin` descriptor structure members are used as follows. `char *` members should be specified as null-terminated strings.

- `type`: The plugin type. This must be one of the plugin-type values from `client_plugin.h`, such as `MYSQL_CLIENT_AUTHENTICATION_PLUGIN`.
- `interface_version`: The plugin interface version. For example, this is `MYSQL_CLIENT_AUTHENTICATION_PLUGIN_INTERFACE_VERSION` for an authentication plugin.
- `name`: A string that gives the plugin name. This is the name by which you refer to the plugin when you call `mysql_options()` with the `MYSQL_DEFAULT_AUTH` option or specify the `--default-auth` option to a MySQL client program.
- `author`: A string naming the plugin author. This can be whatever you like.
- `desc`: A string that provides a general description of the plugin. This can be whatever you like.
- `version`: The plugin version as an array of three integers indicating the major, minor, and teeny versions. For example, `{1,2,3}` indicates version 1.2.3.
- `license`: A string that specifies the license type.
- `mysql_api`: For internal use. Specify it as `NULL` in the plugin descriptor.
- `init`: A once-only initialization function, or `NULL` if there is no such function. The client library executes this function when it loads the plugin. The function returns zero for success and nonzero for failure.

The `init` function uses its first two arguments to return an error message if an error occurs. The first argument is a pointer to a `char` buffer, and the second argument indicates the buffer length. Any message returned by the `init` function must be null-terminated, so the maximum message length is the buffer length minus one. The next arguments are passed to `mysql_load_plugin()`. The first indicates how many more arguments there are (0 if none), followed by any remaining arguments.

- `deinit`: A once-only deinitialization function, or `NULL` if there is no such function. The client library executes this function when it unloads the plugin. The function takes no arguments. It returns zero for success and nonzero for failure.
- `options`: A function for handling options passed to the plugin, or `NULL` if there is no such function. The function takes two arguments representing the option name and a pointer to its value. The function returns zero for success and nonzero for failure.

For a given client plugin type, the common descriptor members may be followed by additional members necessary to implement plugins of that type. For example, the `st_mysql_client_plugin_AUTHENTICATION` structure for authentication plugins has a function at the end that the client library calls to perform authentication.

To declare a plugin, use the `mysql_declare_client_plugin()` and `mysql_end_client_plugin` macros:

```
mysql_declare_client_plugin(plugin_type)
... members common to all client plugins ...
... type-specific extra members ...
mysql_end_client_plugin;
```

Do not specify the `type` or `interface_version` member explicitly. The `mysql_declare_client_plugin()` macro uses the `plugin_type` argument to generate their values automatically. For example, declare an authentication client plugin like this:

```
mysql_declare_client_plugin(AUTHENTICATION)
"my_auth_plugin",
"Author Name",
"My Client Authentication Plugin",
{1,0,0},
"GPL",
NULL,
my_auth_init,
my_auth_deinit,
my_auth_options,
my_auth_main
mysql_end_client_plugin;
```

This declaration uses the `AUTHENTICATION` argument to set the `type` and `interface_version` members to `MYSQL_CLIENT_AUTHENTICATION_PLUGIN` and `MYSQL_CLIENT_AUTHENTICATION_PLUGIN_INTERFACE_VERSION`.

Depending on the plugin type, the descriptor may have other members following the common members. For example, for an authentication plugin, there is a function (`my_auth_main()` in the descriptor just shown) that handles communication with the server. See [Section 27.2.4.9, “Writing Authentication Plugins”](#).

Normally, a client program that supports the use of authentication plugins causes a plugin to be loaded by calling `mysql_options()` to set the `MYSQL_DEFAULT_AUTH` and `MYSQL_PLUGIN_DIR` options:

```
char *plugin_dir = "path_to_plugin_dir";
char *default_auth = "plugin_name";

/* ... process command-line options ... */

mysql_options(&mysql, MYSQL_PLUGIN_DIR, plugin_dir);
mysql_options(&mysql, MYSQL_DEFAULT_AUTH, default_auth);
```

Typically, the program will also accept `--plugin-dir` and `--default-auth` options that enable users to override the default values.

Should a client program require lower-level plugin management, the client library contains functions that take an `st_mysql_client_plugin` argument. See [Section 26.8.14, “C API Client Plugin Functions”](#).

### 27.2.4.3 Compiling and Installing Plugin Libraries

After your plugin is written, you must compile it and install it. The procedure for compiling shared objects varies from system to system. If you build your library using `CMake`, it should be able to generate the correct compilation commands for your system. If the library is named `somepluglib`, you should end up with a shared library file that has a name something like `somepluglib.so`. (The `.so` file name suffix might differ on your system.)

To use `CMake`, you'll need to set up the configuration files to enable the plugin to be compiled and installed. Use the plugin examples under the `plugin` directory of a MySQL source distribution as a guide.

Create `CMakeLists.txt`, which should look something like this:

```
MYSQL_ADD_PLUGIN(somepluglib somepluglib.c
  MODULE_ONLY MODULE_OUTPUT_NAME "somepluglib")
```

When `CMake` generates the `Makefile`, it should take care of passing to the compilation command the `-DMYSQL_DYNAMIC_PLUGIN` flag, and passing to the linker the `-lmysqservices` flag, which is needed to link in any functions from services provided through the plugin services interface. See [Section 27.3, "MySQL Services for Plugins"](#).

Run `CMake`, then run `make`:

```
shell> cmake .
shell> make
```

If you need to specify configuration options to `CMake`, see [Section 2.9.4, "MySQL Source-Configuration Options"](#), for a list. For example, you might want to specify `CMAKE_INSTALL_PREFIX` to indicate the MySQL base directory under which the plugin should be installed. You can see what value to use for this option with `SHOW VARIABLES`:

```
mysql> SHOW VARIABLES LIKE 'basedir';
+-----+-----+
| Variable_name | Value                |
+-----+-----+
| base          | /usr/local/mysql    |
+-----+-----+
```

The location of the plugin directory where you should install the library is given by the `plugin_dir` system variable. For example:

```
mysql> SHOW VARIABLES LIKE 'plugin_dir';
+-----+-----+
| Variable_name | Value                                     |
+-----+-----+
| plugin_dir    | /usr/local/mysql/lib/mysql/plugin      |
+-----+-----+
```

To install the plugin library, use `make`:

```
shell> make install
```

Verify that `make install` installed the plugin library in the proper directory. After installing it, make sure that the library permissions permit it to be executed by the server.

#### 27.2.4.4 Writing Full-Text Parser Plugins

MySQL supports server-side full-text parser plugins with `MyISAM` and `InnoDB`. Full-text parser plugins are supported with `InnoDB` as of MySQL 5.7.3. For introductory information about full-text parser plugins, see [Full-Text Parser Plugins](#).

A full-text parser plugin can be used to replace or modify the built-in full-text parser. This section describes how to write a full-text parser plugin named `simple_parser`. This plugin performs parsing based on simpler rules than those used by the MySQL built-in full-text parser: Words are nonempty runs of whitespace characters.

The instructions use the source code in the `plugin/fulltext` directory of MySQL source distributions, so change location into that directory. The following procedure describes how the plugin library is created:

1. To write a full-text parser plugin, include the following header file in the plugin source file. Other MySQL or general header files might also be needed, depending on the plugin capabilities and requirements.

```
#include <mysql/plugin.h>
```

`plugin.h` defines the `MYSQL_FTPARSER_PLUGIN` server plugin type and the data structures needed to declare the plugin.

2. Set up the library descriptor for the plugin library file.

This descriptor contains the general plugin descriptor for the server plugin. For a full-text parser plugin, the type must be `MYSQL_FTPARSER_PLUGIN`. This is the value that identifies the plugin as being legal for use in a `WITH PARSER` clause when creating a `FULLTEXT` index. (No other plugin type is legal for this clause.)

For example, the library descriptor for a library that contains a single full-text parser plugin named `simple_parser` looks like this:

```
mysql_declare_plugin(ftexample)
{
    MYSQL_FTPARSER_PLUGIN,      /* type */
    &simple_parser_descriptor,    /* descriptor */
    "simple_parser",             /* name */
    "Oracle Corporation",       /* author */
    "Simple Full-Text Parser",   /* description */
    PLUGIN_LICENSE_GPL,         /* plugin license */
    simple_parser_plugin_init,   /* init function (when loaded) */
    simple_parser_plugin_deinit, /* deinit function (when unloaded) */
    0x0001,                     /* version */
    simple_status,               /* status variables */
    simple_system_variables,     /* system variables */
    NULL,
    0
}
mysql_declare_plugin_end;
```

The `name` member (`simple_parser`) indicates the name to use for references to the plugin in statements such as `INSTALL PLUGIN` or `UNINSTALL PLUGIN`. This is also the name displayed by `SHOW PLUGINS` or `INFORMATION_SCHEMA.PLUGINS`.

For more information, see [Server Plugin Library and Plugin Descriptors](#).

3. Set up the type-specific plugin descriptor.

Each general plugin descriptor in the library descriptor points to a type-specific descriptor. For a full-text parser plugin, the type-specific descriptor is an instance of the `st_mysql_ftparser` structure in the `plugin.h` file:

```
struct st_mysql_ftparser
{
    int interface_version;
    int (*parse)(MYSQL_FTPARSER_PARAM *param);
    int (*init)(MYSQL_FTPARSER_PARAM *param);
    int (*deinit)(MYSQL_FTPARSER_PARAM *param);
};
```

As shown by the structure definition, the descriptor has an interface version number and contains pointers to three functions.

The interface version number is specified using a symbol, which is in the form: `MYSQL_XXX_INTERFACE_VERSION`. For full-text parser plugins, the symbol is `MYSQL_FTPARSER_INTERFACE_VERSION`. In the source code, you will find the actual interface

version number for the full-text parser plugin defined in `include/mysql/plugin_ftparser.h`. With the introduction of full-text parser plugin support for `InnoDB`, the interface version number has been incremented in MySQL 5.7.3 from `0x0100` to `0x0101`.

The `init` and `deinit` members should point to a function or be set to 0 if the function is not needed. The `parse` member must point to the function that performs the parsing.

In the `simple_parser` declaration, that descriptor is indicated by `&simple_parser_descriptor`. The descriptor specifies the version number for the full-text plugin interface (as given by `MYSQL_FTPARSER_INTERFACE_VERSION`), and the plugin's parsing, initialization, and deinitialization functions:

```
static struct st_mysql_ftparser simple_parser_descriptor=
{
    MYSQL_FTPARSER_INTERFACE_VERSION, /* interface version      */
    simple_parser_parse,               /* parsing function        */
    simple_parser_init,                /* parser init function    */
    simple_parser_deinit               /* parser deinit function */
};
```

A full-text parser plugin is used in two different contexts, indexing and searching. In both contexts, the server calls the initialization and deinitialization functions at the beginning and end of processing each SQL statement that causes the plugin to be invoked. However, during statement processing, the server calls the main parsing function in context-specific fashion:

- For indexing, the server calls the parser for each column value to be indexed.
- For searching, the server calls the parser to parse the search string. The parser might also be called for rows processed by the statement. In natural language mode, there is no need for the server to call the parser. For boolean mode phrase searches or natural language searches with query expansion, the parser is used to parse column values for information that is not in the index. Also, if a boolean mode search is done for a column that has no `FULLTEXT` index, the built-in parser will be called. (Plugins are associated with specific indexes. If there is no index, no plugin is used.)

The plugin declaration in the general plugin descriptor has `init` and `deinit` members that point initialization and deinitialization functions, and so does the type-specific plugin descriptor to which it points. However, these pairs of functions have different purposes and are invoked for different reasons:

- For the plugin declaration in the general plugin descriptor, the initialization and deinitialization functions are invoked when the plugin is loaded and unloaded.
- For the type-specific plugin descriptor, the initialization and deinitialization functions are invoked per SQL statement for which the plugin is used.

Each interface function named in the plugin descriptor should return zero for success or nonzero for failure, and each of them receives an argument that points to a `MYSQL_FTPARSER_PARAM` structure containing the parsing context. The structure has this definition:

```
typedef struct st_mysql_ftparser_param
{
    int (*mysql_parse)(struct st_mysql_ftparser_param *,
                      char *doc, int doc_len);
    int (*mysql_add_word)(struct st_mysql_ftparser_param *,
                        char *word, int word_len,
                        MYSQL_FTPARSER_BOOLEAN_INFO *boolean_info);
    void *ftparser_state;
    void *mysql_ftparam;
    struct charset_info_st *cs;
    char *doc;
    int length;
};
```

```
int flags;
enum enum_ftparser_mode mode;
} MYSQL_FTPARSER_PARAM;
```

The structure members are used as follows:

- `mysql_parse`: A pointer to a callback function that invokes the server's built-in parser. Use this callback when the plugin acts as a front end to the built-in parser. That is, when the plugin parsing function is called, it should process the input to extract the text and pass the text to the `mysql_parse` callback.

The first parameter for this callback function should be the `param` value itself:

```
param->mysql_parse(param, ...);
```

A front end plugin can extract text and pass it all at once to the built-in parser, or it can extract and pass text to the built-in parser a piece at a time. However, in this case, the built-in parser treats the pieces of text as though there are implicit word breaks between them.

- `mysql_add_word`: A pointer to a callback function that adds a word to a full-text index or to the list of search terms. Use this callback when the parser plugin replaces the built-in parser. That is, when the plugin parsing function is called, it should parse the input into words and invoke the `mysql_add_word` callback for each word.

The first parameter for this callback function should be the `param` value itself:

```
param->mysql_add_word(param, ...);
```

- `ftparser_state`: This is a generic pointer. The plugin can set it to point to information to be used internally for its own purposes.
- `mysql_ftparam`: This is set by the server. It is passed as the first argument to the `mysql_parse` or `mysql_add_word` callback.
- `cs`: A pointer to information about the character set of the text, or 0 if no information is available.
- `doc`: A pointer to the text to be parsed.
- `length`: The length of the text to be parsed, in bytes.
- `flags`: Parser flags. This is zero if there are no special flags. The only nonzero flag is `MYSQL_FTFLAGS_NEED_COPY`, which means that `mysql_add_word()` must save a copy of the word (that is, it cannot use a pointer to the word because the word is in a buffer that will be overwritten.)

This flag might be set or reset by MySQL before calling the parser plugin, by the parser plugin itself, or by the `mysql_parse()` function.

- `mode`: The parsing mode. This value will be one of the following constants:
  - `MYSQL_FTPARSER_SIMPLE_MODE`: Parse in fast and simple mode, which is used for indexing and for natural language queries. The parser should pass to the server only those words that should be indexed. If the parser uses length limits or a stopword list to determine which words to ignore, it should not pass such words to the server.
  - `MYSQL_FTPARSER_WITH_STOPWORDS`: Parse in stopword mode. This is used in boolean searches for phrase matching. The parser should pass all words to the server, even stopwords or words that are outside any normal length limits.

- `MYSQL_FTPARSER_FULL_BOOLEAN_INFO`: Parse in boolean mode. This is used for parsing boolean query strings. The parser should recognize not only words but also boolean-mode operators and pass them to the server as tokens using the `mysql_add_word` callback. To tell the server what kind of token is being passed, the plugin needs to fill in a `MYSQL_FTPARSER_BOOLEAN_INFO` structure and pass a pointer to it.

#### Note

For `MyISAM`, the stopword list and `ft_min_word_len` and `ft_max_word_len` are checked inside the tokenizer. For `InnoDB`, the stopword list and equivalent word length variable settings (`innodb_ft_min_token_size` and `innodb_ft_max_token_size`) are checked outside of the tokenizer. As a result, `InnoDB` plugin parsers do not need to check the stopword list, `innodb_ft_min_token_size`, or `innodb_ft_max_token_size`. Instead, it is recommended that all words be returned to `InnoDB`. However, if you want to check stopwords within your plugin parser, use `MYSQL_FTPARSER_SIMPLE_MODE`, which is for full-text search index and natural language search. For `MYSQL_FTPARSER_WITH_STOPWORDS` and `MYSQL_FTPARSER_FULL_BOOLEAN_INFO` modes, it is recommended that all words be returned to `InnoDB` including stopwords, in case of phrase searches.

If the parser is called in boolean mode, the `param->mode` value will be `MYSQL_FTPARSER_FULL_BOOLEAN_INFO`. The `MYSQL_FTPARSER_BOOLEAN_INFO` structure that the parser uses for passing token information to the server looks like this:

```
typedef struct st_mysql_ftparser_boolean_info
{
    enum enum_ft_token_type type;
    int yesno;
    int weight_adjust;
    char wasign;
    char trunc;
    int position;
    /* These are parser state and must be removed. */
    char prev;
    char *quot;
} MYSQL_FTPARSER_BOOLEAN_INFO;
```

The parser should fill in the structure members as follows:

- `type`: The token type. The following table shows the permissible types.

**Table 27.3 Full-Text Parser Token Types**

| Token Value                       | Meaning                                   |
|-----------------------------------|---|
| <code>FT_TOKEN_EOF</code>         | End of data                               |
| <code>FT_TOKEN_WORD</code>        | A regular word                            |
| <code>FT_TOKEN_LEFT_PAREN</code>  | The beginning of a group or subexpression |
| <code>FT_TOKEN_RIGHT_PAREN</code> | The end of a group or subexpression       |
| <code>FT_TOKEN_STOPWORD</code>    | A stopwords                               |

- `yesno`: Whether the word must be present for a match to occur. 0 means that the word is optional but increases the match relevance if it is present. Values larger than 0 mean that the word must be present. Values smaller than 0 mean that the word must not be present.

- `weight_adjust`: A weighting factor that determines how much a match for the word counts. It can be used to increase or decrease the word's importance in relevance calculations. A value of zero indicates no weight adjustment. Values greater than or less than zero mean higher or lower weight, respectively. The examples at [Section 13.9.2, “Boolean Full-Text Searches”](#), that use the `<` and `>` operators illustrate how weighting works.
- `wasign`: The sign of the weighting factor. A negative value acts like the `~` boolean-search operator, which causes the word's contribution to the relevance to be negative.
- `trunc`: Whether matching should be done as if the boolean-mode `*` truncation operator had been given.
- `position`: Start position of the word in the document, in bytes. Used by [InnoDB](#) full-text search (FTS). The `position` member is new as of MySQL 5.7.3. For existing plugins that are called in boolean mode, support must be added for the position member.

Plugins should not use the `prev` and `quot` members of the `MYSQL_FTPARSER_BOOLEAN_INFO` structure.

#### Note

The plugin parser framework does not support:

- The `@distance` boolean operator.
- A leading plus sign (+) or minus sign (-) boolean operator followed by a space and then a word ('+ apple' or '- apple'). The leading plus or minus sign must be directly adjacent to the word, for example: '+apple' or '-apple'.

For information about boolean full-text search operators, see [Section 13.9.2, “Boolean Full-Text Searches”](#).

#### 4. Set up the plugin interface functions.

The general plugin descriptor in the library descriptor names the initialization and deinitialization functions that the server should invoke when it loads and unloads the plugin. For `simple_parser`, these functions do nothing but return zero to indicate that they succeeded:

```
static int simple_parser_plugin_init(void *arg __attribute__((unused)))
{
    return(0);
}

static int simple_parser_plugin_deinit(void *arg __attribute__((unused)))
{
    return(0);
}
```

Because those functions do not actually do anything, you could omit them and specify 0 for each of them in the plugin declaration.

The type-specific plugin descriptor for `simple_parser` names the initialization, deinitialization, and parsing functions that the server invokes when the plugin is used. For `simple_parser`, the initialization and deinitialization functions do nothing:

```
static int simple_parser_init(MYSQL_FTPARSER_PARAM *param
                             __attribute__((unused)))
{
    return(0);
}
```

```
static int simple_parser_deinit(MYSQL_FTPARSER_PARAM *param
                               __attribute__((unused)))
{
    return(0);
}
```

Here too, because those functions do nothing, you could omit them and specify 0 for each of them in the plugin descriptor.

The main parsing function, `simple_parser_parse()`, acts as a replacement for the built-in full-text parser, so it needs to split text into words and pass each word to the server. The parsing function's first argument is a pointer to a structure that contains the parsing context. This structure has a `doc` member that points to the text to be parsed, and a `length` member that indicates how long the text is. The simple parsing done by the plugin considers nonempty runs of whitespace characters to be words, so it identifies words like this:

```
static int simple_parser_parse(MYSQL_FTPARSER_PARAM *param)
{
    char *end, *start, *docend= param->doc + param->length;

    for (end= start= param->doc;; end++)
    {
        if (end == docend)
        {
            if (end > start)
                add_word(param, start, end - start);
            break;
        }
        else if (isspace(*end))
        {
            if (end > start)
                add_word(param, start, end - start);
            start= end + 1;
        }
    }
    return(0);
}
```

As the parser finds each word, it invokes a function `add_word()` to pass the word to the server. `add_word()` is a helper function only; it is not part of the plugin interface. The parser passes the parsing context pointer to `add_word()`, as well as a pointer to the word and a length value:

```
static void add_word(MYSQL_FTPARSER_PARAM *param, char *word, size_t len)
{
    MYSQL_FTPARSER_BOOLEAN_INFO bool_info=
        { FT_TOKEN_WORD, 0, 0, 0, 0, 0, ' ', 0 };

    param->mysql_add_word(param, word, len, &bool_info);
}
```

#### Note

Prior to MySQL 5.7.3, the sixth `MYSQL_FTPARSER_BOOLEAN_INFO` member (just before the `' '` member) is not present.

For boolean-mode parsing, `add_word()` fills in the members of the `bool_info` structure as described earlier in the discussion of the `st_mysql_ftparser_boolean_info` structure.

5. Set up the status variables. For the `simple_parser` plugin, the following status variable array sets up one status variable with a value that is static text, and another with a value that is stored in a long integer variable:

```
long number_of_calls= 0;
```

```
struct st_mysql_show_var simple_status[]=
{
  {"static", (char *)"just a static text", SHOW_CHAR},
  {"called", (char *)&number_of_calls, SHOW_LONG},
  {0,0,0}
};
```

When the plugin is installed, the plugin name and the `name` value are joined with an underscore to form the name displayed by `SHOW STATUS`. For the array just shown, the resulting status variable names are `simple_parser_static` and `simple_parser_called`. This convention means that you can easily display the variables for a plugin using its name:

```
mysql> SHOW STATUS LIKE 'simple_parser%';
+-----+-----+
| Variable_name | Value |
+-----+-----+
| simple_parser_static | just a static text |
| simple_parser_called | 0 |
+-----+-----+
```

6. To compile and install a plugin library file, use the instructions in [Section 27.2.4.3, “Compiling and Installing Plugin Libraries”](#). To make the library file available for use, install it in the plugin directory (the directory named by the `plugin_dir` system variable). For the `simple_parser` plugin, it is compiled and installed when you build MySQL from source. It is also included in binary distributions. The build process produces a shared object library with a name of `mypluglib.so` (the `.so` suffix might differ depending on your platform).
7. To use the plugin, register it with the server. For example, to register the plugin at runtime, use this statement (adjust the `.so` suffix for your platform as necessary):

```
INSTALL PLUGIN simple_parser SONAME 'mypluglib.so';
```

For additional information about plugin loading, see [Section 6.5.2, “Installing and Uninstalling Plugins”](#).

8. To verify plugin installation, examine the `INFORMATION_SCHEMA.PLUGINS` table or use the `SHOW PLUGINS` statement. See [Section 6.5.3, “Obtaining Server Plugin Information”](#).
9. Test the plugin to verify that it works properly.

Create a table that contains a string column and associate the parser plugin with a `FULLTEXT` index on the column:

```
mysql> CREATE TABLE t (c VARCHAR(255),
-> FULLTEXT (c) WITH PARSER simple_parser
-> ) ENGINE=MyISAM;
Query OK, 0 rows affected (0.01 sec)
```

Insert some text into the table and try some searches. These should verify that the parser plugin treats all nonwhitespace characters as word characters:

```
mysql> INSERT INTO t VALUES
-> ('latin1_general_cs is a case-sensitive collation'),
-> ('I\'d like a case of oranges'),
-> ('this is sensitive information'),
-> ('another row'),
-> ('yet another row');
Query OK, 5 rows affected (0.02 sec)
Records: 5 Duplicates: 0 Warnings: 0

mysql> SELECT c FROM t;
+-----+
| c |
+-----+
```

```

| c |
+-----+
| latin1_general_cs is a case-sensitive collation |
| I'd like a case of oranges |
| this is sensitive information |
| another row |
| yet another row |
+-----+
5 rows in set (0.00 sec)

mysql> SELECT MATCH(c) AGAINST('case') FROM t;
+-----+
| MATCH(c) AGAINST('case') |
+-----+
| 0 |
| 1.2968142032623 |
| 0 |
| 0 |
| 0 |
+-----+
5 rows in set (0.00 sec)

mysql> SELECT MATCH(c) AGAINST('sensitive') FROM t;
+-----+
| MATCH(c) AGAINST('sensitive') |
+-----+
| 0 |
| 0 |
| 1.3253291845322 |
| 0 |
| 0 |
+-----+
5 rows in set (0.01 sec)

mysql> SELECT MATCH(c) AGAINST('case-sensitive') FROM t;
+-----+
| MATCH(c) AGAINST('case-sensitive') |
+-----+
| 1.3109166622162 |
| 0 |
| 0 |
| 0 |
| 0 |
+-----+
5 rows in set (0.01 sec)

mysql> SELECT MATCH(c) AGAINST('I\'d') FROM t;
+-----+
| MATCH(c) AGAINST('I\'d') |
+-----+
| 0 |
| 1.2968142032623 |
| 0 |
| 0 |
| 0 |
+-----+
5 rows in set (0.01 sec)

```

Neither “case” nor “insensitive” match “case-insensitive” the way that they would for the built-in parser.

### 27.2.4.5 Writing Daemon Plugins

A daemon plugin is a simple type of plugin used for code that should be run by the server but that does not communicate with it. This section describes how to write a daemon server plugin, using the example plugin found in the [plugin/daemon\\_example](#) directory of MySQL source distributions. That directory contains the [daemon\\_example.cc](#) source file for a daemon plugin named [daemon\\_example](#) that writes a heartbeat string at regular intervals to a file named [mysql-heartbeat.log](#) in the data directory.

To write a daemon plugin, include the following header file in the plugin source file. Other MySQL or general header files might also be needed, depending on the plugin capabilities and requirements.

```
#include <mysql/plugin.h>
```

`plugin.h` defines the `MYSQL_DAEMON_PLUGIN` server plugin type and the data structures needed to declare the plugin.

The `daemon_example.cc` file sets up the library descriptor as follows. The library descriptor includes a single general server plugin descriptor.

```
mysql_declare_plugin(daemon_example)
{
    MYSQL_DAEMON_PLUGIN,
    &daemon_example_plugin,
    "daemon_example",
    "Brian Aker",
    "Daemon example, creates a heartbeat beat file in mysql-heartbeat.log",
    PLUGIN_LICENSE_GPL,
    daemon_example_plugin_init, /* Plugin Init */
    daemon_example_plugin_deinit, /* Plugin Deinit */
    0x0100 /* 1.0 */,
    NULL, /* status variables */
    NULL, /* system variables */
    NULL, /* config options */
    0, /* flags */
}
mysql_declare_plugin_end;
```

The `name` member (`daemon_example`) indicates the name to use for references to the plugin in statements such as `INSTALL PLUGIN` or `UNINSTALL PLUGIN`. This is also the name displayed by `SHOW PLUGINS` or `INFORMATION_SCHEMA.PLUGINS`.

The second member of the plugin descriptor, `daemon_example_plugin`, points to the type-specific daemon plugin descriptor. This structure consists only of the type-specific API version number:

```
struct st_mysql_daemon daemon_example_plugin=
{ MYSQL_DAEMON_INTERFACE_VERSION };
```

The type-specific structure has no interface functions. There is no communication between the server and the plugin, except that the server calls the initialization and deinitialization functions from the general plugin descriptor to start and stop the plugin:

- `daemon_example_plugin_init()` opens the heartbeat file and spawns a thread that wakes up periodically and writes the next message to the file.
- `daemon_example_plugin_deinit()` closes the file and performs other cleanup.

To compile and install a plugin library file, use the instructions in [Section 27.2.4.3, “Compiling and Installing Plugin Libraries”](#). To make the library file available for use, install it in the plugin directory (the directory named by the `plugin_dir` system variable). For the `daemon_example` plugin, it is compiled and installed when you build MySQL from source. It is also included in binary distributions. The build process produces a shared object library with a name of `libdaemon_example.so` (the `.so` suffix might differ depending on your platform).

To use the plugin, register it with the server. For example, to register the plugin at runtime, use this statement (adjust the `.so` suffix for your platform as necessary):

```
INSTALL PLUGIN daemon_example SONAME 'libdaemon_example.so';
```

For additional information about plugin loading, see [Section 6.5.2, “Installing and Uninstalling Plugins”](#).

To verify plugin installation, examine the `INFORMATION_SCHEMA.PLUGINS` table or use the `SHOW PLUGINS` statement. See [Section 6.5.3, “Obtaining Server Plugin Information”](#).

While the plugin is loaded, it writes a heartbeat string at regular intervals to a file named `mysql-heartbeat.log` in the data directory. This file grows without limit, so after you have satisfied yourself that the plugin operates correctly, unload it:

```
UNINSTALL PLUGIN daemon_example;
```

#### 27.2.4.6 Writing INFORMATION\_SCHEMA Plugins

This section describes how to write a server-side `INFORMATION_SCHEMA` table plugin. For example code that implements such plugins, see the `sql/sql_show.cc` file of a MySQL source distribution. You can also look at the example plugins found in the `InnoDB` source. See the `handler/i_s.cc` and `handler/ha_innodb.cc` files within the `InnoDB` source tree (in the `storage/innobase` directory).

To write an `INFORMATION_SCHEMA` table plugin, include the following header files in the plugin source file. Other MySQL or general header files might also be needed, depending on the plugin capabilities and requirements.

```
#include <sql_class.h>
#include <table.h>
```

These header files are located in the `sql` directory of MySQL source distributions. They contain C++ structures, so the source file for an `INFORMATION_SCHEMA` plugin must be compiled as C++ (not C) code.

The source file for the example plugin developed here is named `simple_i_s_table.cc`. It creates a simple `INFORMATION_SCHEMA` table named `SIMPLE_I_S_TABLE` that has two columns named `NAME` and `VALUE`. The general descriptor for a plugin library that implements the table looks like this:

```
mysql_declare_plugin(simple_i_s_library)
{
    MYSQL_INFORMATION_SCHEMA_PLUGIN,
    &simple_table_info,           /* type-specific descriptor */
    "SIMPLE_I_S_TABLE",         /* table name */
    "Author Name",              /* author */
    "Simple INFORMATION_SCHEMA table", /* description */
    PLUGIN_LICENSE_GPL,         /* license type */
    simple_table_init,          /* init function */
    NULL,
    0x0100,                     /* version = 1.0 */
    NULL,                       /* no status variables */
    NULL,                       /* no system variables */
    NULL,                       /* no reserved information */
    0                           /* no flags */
}
mysql_declare_plugin_end;
```

The `name` member (`SIMPLE_I_S_TABLE`) indicates the name to use for references to the plugin in statements such as `INSTALL PLUGIN` or `UNINSTALL PLUGIN`. This is also the name displayed by `SHOW PLUGINS` or `INFORMATION_SCHEMA.PLUGINS`.

The `simple_table_info` member of the general descriptor points to the type-specific descriptor, which consists only of the type-specific API version number:

```
static struct st_mysql_information_schema simple_table_info =
{ MYSQL_INFORMATION_SCHEMA_INTERFACE_VERSION };
```

The general descriptor points to the initialization and deinitialization functions:

- The initialization function provides information about the table structure and a function that populates the table.

- The deinitialization function performs any required cleanup. If no cleanup is needed, this descriptor member can be `NULL` (as in the example shown).

The initialization function should return 0 for success, 1 if an error occurs. The function receives a generic pointer, which it should interpret as a pointer to the table structure:

```
static int table_init(void *ptr)
{
    ST_SCHEMA_TABLE *schema_table= (ST_SCHEMA_TABLE*)ptr;

    schema_table->fields_info= simple_table_fields;
    schema_table->fill_table= simple_fill_table;
    return 0;
}
```

The function should set these two members of the table structure:

- `fields_info`: An array of `ST_FIELD_INFO` structures that contain information about each column.
- `fill_table`: A function that populates the table.

The array pointed to by `fields_info` should contain one element per column of the `INFORMATION_SCHEMA` plus a terminating element. The following `simple_table_fields` array for the example plugin indicates that `SIMPLE_I_S_TABLE` has two columns. `NAME` is string-valued with a length of 10 and `VALUE` is integer-valued with a display width of 20. The last structure marks the end of the array.

```
static ST_FIELD_INFO simple_table_fields[]=
{
    {"NAME", 10, MYSQL_TYPE_STRING, 0, 0 0, 0},
    {"VALUE", 6, MYSQL_TYPE_LONG, 0, MY_I_S_UNSIGNED, 0, 0},
    {0, 0, MYSQL_TYPE_NULL, 0, 0, 0, 0}
};
```

For more information about the column information structure, see the definition of `ST_FIELD_INFO` in the `table.h` header file. The permissible `MYSQL_TYPE_XXX` type values are those used in the C API; see [Section 26.8.5, “C API Data Structures”](#).

The `fill_table` member should be set to a function that populates the table and returns 0 for success, 1 if an error occurs. For the example plugin, the `simple_fill_table()` function looks like this:

```
static int simple_fill_table(THD *thd, TABLE_LIST *tables, Item *cond)
{
    TABLE *table= tables->table;

    table->field[0]->store("Name 1", 6, system_charset_info);
    table->field[1]->store(1);
    if (schema_table_store_record(thd, table))
        return 1;
    table->field[0]->store("Name 2", 6, system_charset_info);
    table->field[1]->store(2);
    if (schema_table_store_record(thd, table))
        return 1;
    return 0;
}
```

For each row of the `INFORMATION_SCHEMA` table, this function initializes each column, then calls `schema_table_store_record()` to install the row. The `store()` method arguments depend on the type of value to be stored. For column 0 (`NAME`, a string), `store()` takes a pointer to a string, its length, and information about the character set of the string:

```
store(const char *to, uint length, CHARSET_INFO *cs);
```

For column 1 (`VALUE`, an integer), `store()` takes the value and a flag indicating whether it is unsigned:

```
store(longlong nr, bool unsigned_value);
```

For other examples of how to populate `INFORMATION_SCHEMA` tables, search for instances of `schema_table_store_record()` in `sql_show.cc`.

To compile and install a plugin library file, use the instructions in [Section 27.2.4.3, “Compiling and Installing Plugin Libraries”](#). To make the library file available for use, install it in the plugin directory (the directory named by the `plugin_dir` system variable).

To test the plugin, install it:

```
mysql> INSTALL PLUGIN SIMPLE_I_S_TABLE SONAME 'simple_i_s_table.so';
```

Verify that the table is present:

```
mysql> SELECT TABLE_NAME FROM INFORMATION_SCHEMA.TABLES
-> WHERE TABLE_NAME = 'SIMPLE_I_S_TABLE';
+-----+
| TABLE_NAME |
+-----+
| SIMPLE_I_S_TABLE |
+-----+
```

Try to select from it:

```
mysql> SELECT * FROM INFORMATION_SCHEMA.SIMPLE_I_S_TABLE;
+-----+-----+
| NAME | VALUE |
+-----+-----+
| Name 1 | 1 |
| Name 2 | 2 |
+-----+-----+
```

Uninstall it:

```
mysql> UNINSTALL PLUGIN SIMPLE_I_S_TABLE;
```

### 27.2.4.7 Writing Semisynchronous Replication Plugins

This section describes how to write server-side semisynchronous replication plugins, using the example plugins found in the `plugin/semisync` directory of MySQL source distributions. That directory contains the source files for master and slave plugins named `rpl_semi_sync_master` and `rpl_semi_sync_slave`. The information here covers only how to set up the plugin framework. For details about how the plugins implement replication functions, see the source.

To write a semisynchronous replication plugin, include the following header file in the plugin source file. Other MySQL or general header files might also be needed, depending on the plugin capabilities and requirements.

```
#include <mysql/plugin.h>
```

`plugin.h` defines the `MYSQL_REPLICATION_PLUGIN` server plugin type and the data structures needed to declare the plugin.

For the master side, `semisync_master_plugin.cc` contains this general descriptor for a plugin named `rpl_semi_sync_master`:

```
mysql_declare_plugin(semi_sync_master)
```

```
{
    MYSQL_REPLICATION_PLUGIN,
    &semi_sync_master_plugin,
    "rpl_semi_sync_master",
    "He Zhenxing",
    "Semi-synchronous replication master",
    PLUGIN_LICENSE_GPL,
    semi_sync_master_plugin_init, /* Plugin Init */
    semi_sync_master_plugin_deinit, /* Plugin Deinit */
    0x0100 /* 1.0 */,
    semi_sync_master_status_vars, /* status variables */
    semi_sync_master_system_vars, /* system variables */
    NULL, /* config options */
    0, /* flags */
}
mysql_declare_plugin_end;
```

For the slave side, `semisync_slave_plugin.cc` contains this general descriptor for a plugin named `rpl_semi_sync_slave`:

```
mysql_declare_plugin(semi_sync_slave)
{
    MYSQL_REPLICATION_PLUGIN,
    &semi_sync_slave_plugin,
    "rpl_semi_sync_slave",
    "He Zhenxing",
    "Semi-synchronous replication slave",
    PLUGIN_LICENSE_GPL,
    semi_sync_slave_plugin_init, /* Plugin Init */
    semi_sync_slave_plugin_deinit, /* Plugin Deinit */
    0x0100 /* 1.0 */,
    semi_sync_slave_status_vars, /* status variables */
    semi_sync_slave_system_vars, /* system variables */
    NULL, /* config options */
    0, /* flags */
}
mysql_declare_plugin_end;
```

For both the master and slave plugins, the general descriptor has pointers to the type-specific descriptor, the initialization and deinitialization functions, and to the status and system variables implemented by the plugin. For information about variable setup, see [Server Plugin Status and System Variables](#). The following remarks discuss the type-specific descriptor and the initialization and deinitialization functions for the master plugin but apply similarly to the slave plugin.

The `semi_sync_master_plugin` member of the master general descriptor points to the type-specific descriptor, which consists only of the type-specific API version number:

```
struct Mysql_replication semi_sync_master_plugin= {
    MYSQL_REPLICATION_INTERFACE_VERSION
};
```

The initialization and deinitialization function declarations look like this:

```
static int semi_sync_master_plugin_init(void *p);
static int semi_sync_master_plugin_deinit(void *p);
```

The initialization function uses the pointer to register transaction and binary logging “observers” with the server. After successful initialization, the server takes care of invoking the observers at the appropriate times. (For details on the observers, see the source files.) The deinitialization function cleans up by deregistering the observers. Each function returns 0 for success or 1 if an error occurs.

To compile and install a plugin library file, use the instructions in [Section 27.2.4.3, “Compiling and Installing Plugin Libraries”](#). To make the library file available for use, install it in the plugin directory (the directory named by the `plugin_dir` system variable). For the `rpl_semi_sync_master` and `rpl_semi_sync_slave` plugins, they are compiled and installed when you build MySQL from source.

They are also included in binary distributions. The build process produces shared object libraries with names of `semisync_master.so` and `semisync_slave.so` (the `.so` suffix might differ depending on your platform).

### 27.2.4.8 Writing Audit Plugins

This section describes how to write a server-side audit plugin, using the example plugin found in the `plugin/audit_null` directory of MySQL source distributions. The `audit_null.c` and `audit_null_variables.h` source files in that directory implement an audit plugin named `NULL_AUDIT`.

#### Note

Changes were made in MySQL 5.7.8 to reimplement query rewrite plugins as audit plugins, and then the audit plugin API itself was extensively revised in 5.7.9 (including the parts for query rewrite plugins). For these reasons, the discussion here describes the audit plugin API as of MySQL 5.7.9. The API prior to 5.7.8 is much like that for MySQL 5.6. To write audit plugins against the older API, see [Writing Audit Plugins](#) in [MySQL 5.6 Reference Manual](#).

#### Note

Other examples of plugins that use the audit plugin API are the query rewrite plugin (see [Section 6.5.5, “The Rewriter Query Rewrite Plugin”](#)) and the Version Tokens plugin (see [Section 6.5.6, “Version Tokens”](#)).

Within the server, the pluggable audit interface is implemented in the `sql_audit.h` and `sql_audit.cc` files in the `sql` directory of MySQL source distributions. Additionally, several places in the server call the audit interface when an auditable event occurs, so that registered audit plugins can be notified about the event if necessary. To see where such calls occur, search the server source files for invocations of functions with names of the form `mysql_audit_xxx()`. Audit notification occurs for server operations such as these:

- Client connect and disconnect events
- Writing a message to the general query log (if the log is enabled)
- Writing a message to the error log
- Sending a query result to a client

To write an audit plugin, include the following header file in the plugin source file. Other MySQL or general header files might also be needed, depending on the plugin capabilities and requirements.

```
#include <mysql/plugin_audit.h>
```

`plugin_audit.h` includes `plugin.h`, so you need not include the latter file explicitly. `plugin.h` defines the `MYSQL_AUDIT_PLUGIN` server plugin type and the data structures needed to declare the plugin. `plugin_audit.h` defines data structures specific to audit plugins.

### Audit Plugin General Descriptor

An audit plugin, like any MySQL server plugin, has a general plugin descriptor (see [Server Plugin Library and Plugin Descriptors](#)) and a type-specific plugin descriptor. In `audit_null.c`, the general descriptor for `audit_null` looks like this:

```
mysql_declare_plugin(audit_null)
{
    MYSQL_AUDIT_PLUGIN,          /* type                */
    &audit_null_descriptor,       /* descriptor          */
    "NULL_AUDIT",                /* name                */
    "Oracle Corp",               /* author              */
}
```

```

"Simple NULL Audit",          /* description */
PLUGIN_LICENSE_GPL,          /* init function (when loaded) */
audit_null_plugin_init,      /* deinit function (when unloaded) */
audit_null_plugin_deinit,    /* version */
0x0003,                      /* status variables */
simple_status,                /* system variables */
system_variables,            /* system variables */
NULL,
0,
}
mysql_declare_plugin_end;

```

The first member, `MYSQL_AUDIT_PLUGIN`, identifies this plugin as an audit plugin.

`audit_null_descriptor` points to the type-specific plugin descriptor, described later.

The `name` member (`NULL_AUDIT`) indicates the name to use for references to the plugin in statements such as `INSTALL PLUGIN` or `UNINSTALL PLUGIN`. This is also the name displayed by `INFORMATION_SCHEMA.PLUGINS` or `SHOW PLUGINS`.

The `audit_null_plugin_init` initialization function performs plugin initialization when the plugin is loaded. The `audit_null_plugin_deinit` function performs cleanup with the plugin is unloaded.

The general plugin descriptor also refers to `simple_status` and `system_variables`, structures that expose several status and system variables. When the plugin is enabled, these variables can be inspected using `SHOW` statements (`SHOW STATUS`, `SHOW VARIABLES`) or the appropriate Performance Schema tables.

The `simple_status` structure declares several status variables with names of the form `Audit_null_xxx`. `NULL_AUDIT` increments the `Audit_null_called` status variable for every notification that it receives. The other status variables are more specific and `NULL_AUDIT` increments them only for notifications of specific events.

`system_variables` is an array of system variable elements, each of which is defined using a `MYSQL_THDVAR_xxx` macro. These system variables have names of the form `null_audit_xxx`. These variables can be used to communicate with the plugin at runtime.

## Audit Plugin Type-Specific Descriptor

The `audit_null_descriptor` value in the general plugin descriptor points to the type-specific plugin descriptor. For audit plugins, this descriptor has the following structure (defined in `plugin_audit.h`):

```

struct st_mysql_audit
{
    int interface_version;
    void (*release_thd)(MYSQL_THD);
    int (*event_notify)(MYSQL_THD, mysql_event_class_t, const void *);
    unsigned long class_mask[MYSQL_AUDIT_CLASS_MASK_SIZE];
};

```

The type-specific descriptor for audit plugins has these members:

- `interface_version`: By convention, type-specific plugin descriptors begin with the interface version for the given plugin type. The server checks `interface_version` when it loads the plugin to see whether the plugin is compatible with it. For audit plugins, the value of the `interface_version` member is `MYSQL_AUDIT_INTERFACE_VERSION` (defined in `plugin_audit.h`).
- `release_thd`: A function that the server calls to inform the plugin that it is being dissociated from its thread context. This should be `NULL` if there is no such function.
- `event_notify`: A function that the server calls to notify the plugin that an auditable event has occurred. This function should not be `NULL`; that would not make sense because no auditing would occur.

- `class_mask`: An array of `MYSQL_AUDIT_CLASS_MASK_SIZE` elements. Each element specifies a bit mask for a given event class to indicate the subclasses for which the plugin wants notification. (This is how the plugin “subscribes” to events of interest.) An element should be 0 to ignore events for the corresponding event class.

The server uses the `event_notify` and `release_thd` functions together. They are called within the context of a specific thread, and a thread might perform an activity that produces several event notifications. The first time the server calls `event_notify` for a thread, it creates a binding of the plugin to the thread. The plugin cannot be uninstalled while this binding exists. When no more events for the thread will occur, the server informs the plugin of this by calling the `release_thd` function, and then destroys the binding. For example, when a client issues a statement, the thread processing the statement might notify audit plugins about the result set produced by the statement and about the statement being logged. After these notifications occur, the server releases the plugin before putting the thread to sleep until the client issues another statement.

This design enables the plugin to allocate resources needed for a given thread in the first call to the `event_notify` function and release them in the `release_thd` function:

```
event_notify function:
    if memory is needed to service the thread
        allocate memory
    ... rest of notification processing ...

release_thd function:
    if memory was allocated
        release memory
    ... rest of release processing ...
```

That is more efficient than allocating and releasing memory repeatedly in the notification function.

For the `NULL_AUDIT` audit plugin, the type-specific plugin descriptor looks like this:

```
static struct st_mysql_audit audit_null_descriptor=
{
    MYSQL_AUDIT_INTERFACE_VERSION,          /* interface version */
    NULL,                                    /* release_thd function */
    audit_null_notify,                       /* notify function */
    { (unsigned long) MYSQL_AUDIT_GENERAL_ALL,
      (unsigned long) MYSQL_AUDIT_CONNECTION_ALL,
      (unsigned long) MYSQL_AUDIT_PARSE_ALL,
      (unsigned long) MYSQL_AUDIT_AUTHORIZATION_ALL,
      (unsigned long) MYSQL_AUDIT_TABLE_ACCESS_ALL,
      (unsigned long) MYSQL_AUDIT_GLOBAL_VARIABLE_ALL,
      (unsigned long) MYSQL_AUDIT_SERVER_STARTUP_ALL,
      (unsigned long) MYSQL_AUDIT_SERVER_SHUTDOWN_ALL,
      (unsigned long) MYSQL_AUDIT_COMMAND_ALL,
      (unsigned long) MYSQL_AUDIT_QUERY_ALL,
      (unsigned long) MYSQL_AUDIT_STORED_PROGRAM_ALL }
};
```

The server calls `audit_null_notify()` to pass audit event information to the plugin. There is no `release_thd` function.

The `class_mask` member is an array that indicates which event classes the plugin subscribes to. As shown, the array contents subscribe to all subclasses of all event classes that are available. To ignore all notifications for a given event class, specify the corresponding `class_mask` element as 0.

The number of `class_mask` elements corresponds to the number of event classes, each of which is listed in the `mysql_event_class_t` enumeration defined in `plugin_audit.h`:

```
typedef enum
{
    MYSQL_AUDIT_GENERAL_CLASS          = 0,
    MYSQL_AUDIT_CONNECTION_CLASS       = 1,
```

```

MYSQL_AUDIT_PARSE_CLASS          = 2,
MYSQL_AUDIT_AUTHORIZATION_CLASS  = 3,
MYSQL_AUDIT_TABLE_ACCESS_CLASS  = 4,
MYSQL_AUDIT_GLOBAL_VARIABLE_CLASS = 5,
MYSQL_AUDIT_SERVER_STARTUP_CLASS = 6,
MYSQL_AUDIT_SERVER_SHUTDOWN_CLASS = 7,
MYSQL_AUDIT_COMMAND_CLASS       = 8,
MYSQL_AUDIT_QUERY_CLASS         = 9,
MYSQL_AUDIT_STORED_PROGRAM_CLASS = 10,
/* This item must be last in the list. */
MYSQL_AUDIT_CLASS_MASK_SIZE
} mysql_event_class_t;

```

For any given event class, `plugin_audit.h` defines bit mask symbols for individual event subclasses, as well as an `xxx_ALL` symbol that is the union of the all subclass bit masks. For example, for `MYSQL_AUDIT_CONNECTION_CLASS` (the class that covers connect and disconnect events), `plugin_audit.h` defines these symbols:

```

typedef enum
{
    /** occurs after authentication phase is completed. */
    MYSQL_AUDIT_CONNECTION_CONNECT      = 1 << 0,
    /** occurs after connection is terminated. */
    MYSQL_AUDIT_CONNECTION_DISCONNECT   = 1 << 1,
    /** occurs after COM_CHANGE_USER RPC is completed. */
    MYSQL_AUDIT_CONNECTION_CHANGE_USER  = 1 << 2,
    /** occurs before authentication. */
    MYSQL_AUDIT_CONNECTION_PRE_AUTHENTICATE = 1 << 3
} mysql_event_connection_subclass_t;

#define MYSQL_AUDIT_CONNECTION_ALL (MYSQL_AUDIT_CONNECTION_CONNECT | \
                                     MYSQL_AUDIT_CONNECTION_DISCONNECT | \
                                     MYSQL_AUDIT_CONNECTION_CHANGE_USER | \
                                     MYSQL_AUDIT_CONNECTION_PRE_AUTHENTICATE)

```

To subscribe to all subclasses of the connection event class (as the `NULL_AUDIT` plugin does), a plugin specifies `MYSQL_AUDIT_CONNECTION_ALL` in the corresponding `class_mask` element (`class_mask[1]` in this case). To subscribe to only some subclasses, the plugin sets the `class_mask` element to the union of the subclasses of interest. For example, to subscribe only to the connect and change-user subclasses, the plugin sets `class_mask[1]` to this value:

```

MYSQL_AUDIT_CONNECTION_CONNECT | MYSQL_AUDIT_CONNECTION_CHANGE_USER

```

## Audit Plugin Notification Function

Most of the work for an audit plugin occurs in the notification function (the `event_notify` member of the type-specific plugin descriptor). The server calls this function for each auditable event. Audit plugin notification functions have this prototype:

```

int (*event_notify)(MYSQL_THD, mysql_event_class_t, const void *);

```

The second and third parameters of the `event_notify` function prototype represent the event class and a generic pointer to an event structure. (Events in different classes have different structures. The notification function can use the event class value to determine which event structure applies.) The function processes the event and returns a status indicating whether the server should continue processing the event or terminate it.

For `NULL_AUDIT`, the notification function is `audit_null_notify()`. This function increments a global event counter (which the plugin exposes as the value of the `Audit_null_called` status value), and then examines the event class to determine how to process the event structure:

```

static int audit_null_notify(MYSQL_THD thd __attribute__((unused)),
                             mysql_event_class_t event_class,
                             const void *event)

```

```

{
    ...

    number_of_calls++;

    if (event_class == MYSQL_AUDIT_GENERAL_CLASS)
    {
        const struct mysql_event_general *event_general=
            (const struct mysql_event_general *)event;
        ...
    }
    else if (event_class == MYSQL_AUDIT_CONNECTION_CLASS)
    {
        const struct mysql_event_connection *event_connection=
            (const struct mysql_event_connection *) event;
        ...
    }
    else if (event_class == MYSQL_AUDIT_PARSE_CLASS)
    {
        const struct mysql_event_parse *event_parse =
            (const struct mysql_event_parse *)event;
        ...
    }
    ...
}

```

The notification function interprets the `event` argument according to the value of `event_class`. The `event` argument is a generic pointer to the event record, the structure of which differs per event class. (The `plugin_audit.h` file contains the structures that define the contents of each event class.) For each class, `audit_null_notify()` casts the event to the appropriate class-specific structure and then checks its subclass to determine which subclass counter to increment. For example, the code to handle events in the connection-event class looks like this:

```

else if (event_class == MYSQL_AUDIT_CONNECTION_CLASS)
{
    const struct mysql_event_connection *event_connection=
        (const struct mysql_event_connection *) event;

    switch (event_connection->event_subclass)
    {
    case MYSQL_AUDIT_CONNECTION_CONNECT:
        number_of_calls_connection_connect++;
        break;
    case MYSQL_AUDIT_CONNECTION_DISCONNECT:
        number_of_calls_connection_disconnect++;
        break;
    case MYSQL_AUDIT_CONNECTION_CHANGE_USER:
        number_of_calls_connection_change_user++;
        break;
    case MYSQL_AUDIT_CONNECTION_PRE_AUTHENTICATE:
        number_of_calls_connection_pre_authenticate++;
        break;
    default:
        break;
    }
}

```

#### Note

The general event class (`MYSQL_AUDIT_GENERAL_CLASS`) is deprecated as of MySQL 5.7.9 and will be removed in a future MySQL release. To reduce plugin overhead, it is preferable to subscribe only to the more specific event classes of interest.

For some event classes, the `NULL_AUDIT` plugin performs other processing in addition to incrementing a counter. In any case, when the notification function finishes processing the event, it should return a status indicating whether the server should continue processing the event or terminate it.

## Audit Plugin Error Handling

Audit plugin notification functions can report a status value for the current event two ways:

- Use the notification function return value. In this case, the function returns zero if the server should continue processing the event, or nonzero if the server should terminate the event.
- Call the `my_message()` function to set the error state before returning from the notification function. In this case, the notification function return value is ignored and the server terminates event processing with an error. The `my_message()` arguments indicate which error to report, and its message. For example:

```
my_message(ER_AUDIT_API_ABORT, "This is my error message.", MYF(0));
```

Some events cannot be aborted. A nonzero return value is not taken into consideration and the `my_message()` error call must follow an `is_error()` check. For example:

```
if (!thd->get_stmt_da()->is_error())
{
    my_message(ER_AUDIT_API_ABORT, "This is my error message.", MYF(0));
}
```

Some events cannot be terminated:

- `MYSQL_AUDIT_CONNECTION_DISCONNECT`: The server cannot prevent a client from disconnecting.
- `MYSQL_AUDIT_COMMAND_END`: This event provides the status of a command that has finished executing, so there is no purpose to terminating it.

If an audit plugin returns nonzero status for a nonterminable event, the server ignores the status and continues processing the event. As of MySQL 5.7.9, that is also true if an audit plugin uses the `my_message()` function to terminate a nonterminable event.

## Audit Plugin Usage

To compile and install a plugin library file, use the instructions in [Section 27.2.4.3, “Compiling and Installing Plugin Libraries”](#). To make the library file available for use, install it in the plugin directory (the directory named by the `plugin_dir` system variable). For the `NULL_AUDIT` plugin, it is compiled and installed when you build MySQL from source. It is also included in binary distributions. The build process produces a shared object library with a name of `adt_null.so` (the `.so` suffix might differ depending on your platform).

To register the plugin at runtime, use this statement (adjust the `.so` suffix for your platform as necessary):

```
INSTALL PLUGIN NULL_AUDIT SONAME 'adt_null.so';
```

For additional information about plugin loading, see [Section 6.5.2, “Installing and Uninstalling Plugins”](#).

To verify plugin installation, examine the `INFORMATION_SCHEMA.PLUGINS` table or use the `SHOW PLUGINS` statement. See [Section 6.5.3, “Obtaining Server Plugin Information”](#).

While the audit plugin is installed, it exposes status variables that indicate the events for which the plugin has been called:

```
mysql> SHOW STATUS LIKE 'Audit_null%';
+-----+
| Variable_name | Value |
+-----+
| Audit_null_authorization_column | 0 |
| Audit_null_authorization_db | 0 |
```

|  |        |
|--|--------|
| Audit_null_authorization_procedure     | 0      |
| Audit_null_authorization_proxy         | 0      |
| Audit_null_authorization_table         | 0      |
| Audit_null_authorization_user          | 0      |
| Audit_null_called                      | 185547 |
| Audit_null_command_end                 | 20999  |
| Audit_null_command_start               | 21001  |
| Audit_null_connection_change_user      | 0      |
| Audit_null_connection_connect          | 5823   |
| Audit_null_connection_disconnect       | 5818   |
| Audit_null_connection_pre_authenticate | 5823   |
| Audit_null_general_error               | 1      |
| Audit_null_general_log                 | 26559  |
| Audit_null_general_result              | 19922  |
| Audit_null_general_status              | 21000  |
| Audit_null_global_variable_get         | 0      |
| Audit_null_global_variable_set         | 0      |
| Audit_null_parse_postparse             | 14648  |
| Audit_null_parse_preparse              | 14648  |
| Audit_null_query_nested_start          | 6      |
| Audit_null_query_nested_status_end     | 6      |
| Audit_null_query_start                 | 14648  |
| Audit_null_query_status_end            | 14647  |
| Audit_null_server_shutdown             | 0      |
| Audit_null_server_startup              | 1      |
| Audit_null_table_access_delete         | 104    |
| Audit_null_table_access_insert         | 2839   |
| Audit_null_table_access_read           | 97842  |
| Audit_null_table_access_update         | 278    |

`Audit_null_called` counts all events, and the other variables count instances of specific event subclasses. For example, the preceding `SHOW STATUS` statement causes the server to send a result to the client and to write a message to the general query log if that log is enabled. Thus, a client that issues the statement repeatedly causes `Audit_null_called`, `Audit_null_general_result`, and `Audit_null_general_log` to be incremented each time. (Before MySQL 5.7.5, notification of events for the general query log occur only if the general query log is enabled. As of 5.7.5, notifications occur whether or not that log is enabled.)

The status variables values are aggregated across all sessions. There are no counters for individual sessions.

`NULL_AUDIT` exposes several system variables that enable communication with the plugin at runtime:

```
mysql> SHOW VARIABLES LIKE 'null_audit%';
+-----+-----+
| Variable_name | Value |
+-----+-----+
| null_audit_abort_message | 1 |
| null_audit_abort_value | 1 |
| null_audit_event_order_check | 0 |
| null_audit_event_order_check_exact | 1 |
| null_audit_event_order_started | 0 |
| null_audit_event_record |  |
| null_audit_event_record_def |  |
+-----+-----+
```

To check the order of audit API calls, set the `null_audit_event_order_check` variable to the expected event order. For example:

```
SET null_audit_event_order_check =
  'MYSQL_AUDIT_CONNECTION_PRE_AUTHENTICATE;;; '
  'MYSQL_AUDIT_GENERAL_LOG;;; '
  'MYSQL_AUDIT_CONNECTION_CONNECT;;; ';
```

The statement takes advantage of the SQL syntax that concatenates adjacent strings into a single string.

The format of the value is:

```
'event_name;event_data;command' [';event_name;event_data;command'] ...
```

After the event order is matched, the `null_audit_event_order_check` value is replaced with a value of `EVENT-ORDER-OK`.

Specifying a command value of `ABORT_RET` makes it possible to abort the audit API call on the specified event. The following example aborts `INSERT` statement execution when its `MYSQL_AUDIT_QUERY_STATUS_END` event occurs:

```
SET null_audit_event_order_check =
'MYSQL_AUDIT_COMMAND_START;command_id="3";;'
'MYSQL_AUDIT_GENERAL_LOG;;; '
'MYSQL_AUDIT_QUERY_START;;; '
'MYSQL_AUDIT_QUERY_STATUS_END;;ABORT_RET';
```

After the audit plugin matches the preceding sequence, it aborts event processing and sends an error message to the client:

```
ERROR 3164 (HY000): Aborted by Audit API ('MYSQL_AUDIT_QUERY_STATUS_END';1).
```

Returning a nonzero value from the audit API notification routine is the standard way to abort event execution. It is also possible to specify a custom error code by setting the `null_audit_abort_value` variable to the value that the notification routine should return:

```
SET null_audit_abort_value = 123;
```

Aborting a sequence results in a standard message with the custom error code. Suppose that you set audit log system variables like this:

```
SET null_audit_abort_value = 123;
SET null_audit_event_order_check =
'MYSQL_AUDIT_COMMAND_START;command_id="3";;'
'MYSQL_AUDIT_GENERAL_LOG;;; '
'MYSQL_AUDIT_QUERY_START;;ABORT_RET';
```

Then execution of `SELECT 1` results in this error:

```
ERROR 3164 (HY000): Aborted by Audit API ('MYSQL_AUDIT_QUERY_START';123).
```

An event can be also aborted with a custom message, specified by setting the `null_audit_abort_message` variable: Suppose that you set audit log system variables like this:

```
SET null_audit_abort_message = 'Custom error text.';
SET null_audit_event_order_check =
'MYSQL_AUDIT_COMMAND_START;command_id="3";;'
'MYSQL_AUDIT_GENERAL_LOG;;; '
'MYSQL_AUDIT_QUERY_START;;ABORT_RET';
```

Then aborting a sequence results in the following error:

```
ERROR 3164 (HY000): Custom error text.
```

For test-creation purposes, it is possible to record events that pass through the plugin. Recording starts by specifying start and end events in the `null_audit_event_record_def` variable:

```
SET null_audit_event_record_def =  
'MYSQL_AUDIT_COMMAND_START;MYSQL_AUDIT_COMMAND_END';
```

Statement execution results in storing the events that occur in the `null_audit_event_record` variable.

To disable the plugin after testing it, use this statement to unload it:

```
UNINSTALL PLUGIN NULL_AUDIT;
```

### 27.2.4.9 Writing Authentication Plugins

MySQL supports pluggable authentication, in which plugins are invoked to authenticate client connections. Authentication plugins enable the use of authentication methods other than the built-in method of passwords stored in the `mysql.user` table. For example, plugins can be written to access external authentication methods. Also, authentication plugins can support the proxy user capability, such that the connecting user is a proxy for another user and is treated, for purposes of access control, as having the privileges of a different user. For more information, see [Section 7.3.8, “Pluggable Authentication”](#), and [Section 7.3.9, “Proxy Users”](#).

An authentication plugin can be written for the server side or the client side. Server-side plugins use the same plugin API that is used for the other server plugin types such as full-text parser or audit plugins (although with a different type-specific descriptor). Client-side plugins use the client plugin API.

Several header files contain information relevant to authentication plugins:

- `plugin.h`: Defines the `MYSQL_AUTHENTICATION_PLUGIN` server plugin type.
- `client_plugin.h`: Defines the API for client plugins. This includes the client plugin descriptor and function prototypes for client plugin C API calls (see [Section 26.8.14, “C API Client Plugin Functions”](#)).
- `plugin_auth.h`: Defines the part of the server plugin API specific to authentication plugins. This includes the type-specific descriptor for server-side authentication plugins and the `MYSQL_SERVER_AUTH_INFO` structure.
- `plugin_auth_common.h`: Contains common elements of client and server authentication plugins. This includes return value definitions and the `MYSQL_PLUGIN_VIO` structure.

To write an authentication plugin, include the following header files in the plugin source file. Other MySQL or general header files might also be needed, depending on the plugin capabilities and requirements.

- For a source file that implements a server authentication plugin, include this file:

```
#include <mysql/plugin_auth.h>
```

- For a source file that implements a client authentication plugin, or both client and server plugins, include these files:

```
#include <mysql/plugin_auth.h>  
#include <mysql/client_plugin.h>  
#include <mysql.h>
```

`plugin_auth.h` includes `plugin.h` and `plugin_auth_common.h`, so you need not include the latter files explicitly.

This section describes how to write a pair of simple server and client authentication plugins that work together.

### Warning

These plugins accept any non-empty password and the password is sent in clear text. This is insecure, so the plugins *should not be used in production environments*.

The server-side and client-side plugins developed here both are named `auth_simple`. As described in [Section 27.2.4.2, “Plugin Data Structures”](#), the plugin library file must have the same base name as the client plugin, so the source file name is `auth_simple.c` and produces a library named `auth_simple.so` (assuming that your system uses `.so` as the suffix for library files).

In MySQL source distributions, authentication plugin source is located in the `plugin/auth` directory and can be examined as a guide to writing other authentication plugins. Also, to see how the built-in authentication plugins are implemented, see `sql/sql_acl.cc` for plugins that are built in to the MySQL server and `sql-common/client.c` for plugins that are built in to the `libmysqlclient` client library. (For the built-in client plugins, note that the `auth_plugin_t` structures used there differ from the structures used with the usual client plugin declaration macros. In particular, the first two members are provided explicitly, not by declaration macros.)

## Writing the Server-Side Authentication Plugin

Declare the server-side plugin with the usual general descriptor format that is used for all server plugin types (see [Server Plugin Library and Plugin Descriptors](#)). For the `auth_simple` plugin, the descriptor looks like this:

```
mysql_declare_plugin(auth_simple)
{
    MYSQL_AUTHENTICATION_PLUGIN,
    &auth_simple_handler,           /* type-specific descriptor */
    "auth_simple",                 /* plugin name */
    "Author Name",                 /* author */
    "Any-password authentication plugin", /* description */
    PLUGIN_LICENSE_GPL,           /* license type */
    NULL,                         /* no init function */
    NULL,                         /* no deinit function */
    0x0100,                       /* version = 1.0 */
    NULL,                         /* no status variables */
    NULL,                         /* no system variables */
    NULL,                         /* no reserved information */
    0                             /* no flags */
}
mysql_declare_plugin_end;
```

The `name` member (`auth_simple`) indicates the name to use for references to the plugin in statements such as `INSTALL PLUGIN` or `UNINSTALL PLUGIN`. This is also the name displayed by `SHOW PLUGINS` or `INFORMATION_SCHEMA.PLUGINS`.

The `auth_simple_handler` member of the general descriptor points to the type-specific descriptor. For an authentication plugin, the type-specific descriptor is an instance of the `st_mysql_auth` structure (defined in `plugin_auth.h`):

```
struct st_mysql_auth
{
    int interface_version;
    const char *client_auth_plugin;
    int (*authenticate_user)(MYSQL_PLUGIN_VIO *vio, MYSQL_SERVER_AUTH_INFO *info);
    int (*generate_authentication_string)(char *outbuf,
        unsigned int *outbuflen, const char *inbuf, unsigned int inbuflen);
    int (*validate_authentication_string)(char* const inbuf, unsigned int buflen);
    int (*set_salt)(const char *password, unsigned int password_len,
        unsigned char* salt, unsigned char *salt_len);
    const unsigned long authentication_flags;
};
```

The `st_mysql_auth` structure has these members:

- `interface_version`: The type-specific API version number, always `MYSQL_AUTHENTICATION_INTERFACE_VERSION`
- `client_auth_plugin`: The client plugin name
- `authenticate_user`: A pointer to the main plugin function that communicates with the client
- `generate_authentication_string`: A pointer to a plugin function that generates a password digest from an authentication string (added in MySQL 5.7.6)
- `validate_authentication_string`: A pointer to a plugin function that validates a password digest (added in MySQL 5.7.6)
- `set_salt`: A pointer to a plugin function that converts a scrambled password to binary form (added in MySQL 5.7.6)
- `authentication_flags`: A flags word (added in MySQL 5.7.8)

The `client_auth_plugin` member should indicate the name of the client plugin if a specific plugin is required. A value of `NULL` means “any plugin.” In the latter case, whatever plugin the client uses will do. This is useful if the server plugin does not care about the client plugin or what user name or password it sends. For example, this might be true if the server plugin authenticates only local clients and uses some property of the operating system rather than the information sent by the client plugin.

For `auth_simple`, the type-specific descriptor looks like this:

```
static struct st_mysql_auth auth_simple_handler =
{
    MYSQL_AUTHENTICATION_INTERFACE_VERSION,
    "auth_simple",           /* required client-side plugin name */
    auth_simple_server       /* server-side plugin main function */
    generate_auth_string_hash, /* generate digest from password string */
    validate_auth_string_hash, /* validate password digest */
    set_salt,               /* generate password salt value */
    AUTH_FLAG_PRIVILEGED_USER_FOR_PASSWORD_CHANGE
};
```

The main function, `auth_simple_server()`, takes two arguments representing an I/O structure and a `MYSQL_SERVER_AUTH_INFO` structure. The structure definition, found in `plugin_auth.h`, looks like this:

```
typedef struct st_mysql_server_auth_info
{
    char *user_name;
    unsigned int user_name_length;
    const char *auth_string;
    unsigned long auth_string_length;
    char authenticated_as[MYSQL_USERNAME_LENGTH+1];
    char external_user[512];
    int password_used;
    const char *host_or_ip;
    unsigned int host_or_ip_length;
} MYSQL_SERVER_AUTH_INFO;
```

The character set for string members is UTF-8. If there is a `_length` member associated with a string, it indicates the string length in bytes. Strings are also null-terminated.

When an authentication plugin is invoked by the server, it should interpret the `MYSQL_SERVER_AUTH_INFO` structure members as follows. Some of these are used to set the value of SQL functions or system variables within the client session, as indicated.

- `user_name`: The user name sent by the client. The value becomes the `USER()` function value.

- `user_name_length`: The length of `user_name` in bytes.
- `auth_string`: The value of the `authentication_string` column of the `mysql.user` table row for the matching account name (that is, the row that matches the client user name and host name and that the server uses to determine how to authenticate the client).

Suppose that you create an account using the following statement:

```
CREATE USER 'my_user'@'localhost'
  IDENTIFIED WITH my_plugin AS 'my_auth_string';
```

When `my_user` connects from the local host, the server invokes `my_plugin` and passes `'my_auth_string'` to it as the `auth_string` value.

- `auth_string_length`: The length of `auth_string` in bytes.
- `authenticated_as`: The server sets this to the user name (the value of `user_name`). The plugin can alter it to indicate that the client should have the privileges of a different user. For example, if the plugin supports proxy users, the initial value is the name of the connecting (proxy) user, and the plugin can change this member to the proxied user name. The server then treats the proxy user as having the privileges of the proxied user (assuming that the other conditions for proxy user support are satisfied; see [Implementing Proxy User Support in Authentication Plugins](#)). The value is represented as a string at most `MYSQL_USER_NAME_LENGTH` bytes long, plus a terminating null. The value becomes the `CURRENT_USER()` function value.
- `external_user`: The server sets this to the empty string (null terminated). Its value becomes the `external_user` system variable value. If the plugin wants that system variable to have a different value, it should set this member accordingly; for example, to the connecting user name. The value is represented as a string at most 511 bytes long, plus a terminating null.
- `password_used`: This member applies when authentication fails. The plugin can set it or ignore it. The value is used to construct the failure error message of `Authentication fails. Password used: %s`. The value of `password_used` determines how `%s` is handled, as shown in the following table.

| <code>password_used</code> | <code>%s</code> Handling         |
|----------------------------|----------------------------------|
| 0                          | NO                               |
| 1                          | YES                              |
| 2                          | There will be no <code>%s</code> |

- `host_or_ip`: The name of the client host if it can be resolved, or the IP address otherwise.
- `host_or_ip_length`: The length of `host_or_ip` in bytes.

The `auth_simple` main function, `auth_simple_server()`, reads the password (a null-terminated string) from the client and succeeds if the password is nonempty (first byte not null):

```
static int auth_simple_server (MYSQL_PLUGIN_VIO *vio,
                              MYSQL_SERVER_AUTH_INFO *info)
{
    unsigned char *pkt;
    int pkt_len;

    /* read the password as null-terminated string, fail on error */
    if ((pkt_len= vio->read_packet(vio, &pkt)) < 0)
        return CR_ERROR;

    /* fail on empty password */
    if (!pkt_len || *pkt == '\0')
    {
        info->password_used= PASSWORD_USED_NO;
    }
}
```

```

    return CR_ERROR;
}

/* accept any nonempty password */
info->password_used= PASSWORD_USED_YES;

return CR_OK;
}

```

The main function should return one of the error codes shown in the following table.

| Error Code                               | Meaning                                    |
|--|--|
| <a href="#">CR_OK</a>                    | Success                                    |
| <a href="#">CR_OK_HANDSHAKE_COMPLETE</a> | Do not send a status packet back to client |
| <a href="#">CR_ERROR</a>                 | Error                                      |
| <a href="#">CR_AUTH_USER_CREDENTIALS</a> | Authentication failure                     |
| <a href="#">CR_AUTH_HANDSHAKE</a>        | Authentication handshake failure           |
| <a href="#">CR_AUTH_PLUGIN_ERROR</a>     | Internal plugin error                      |

For an example of how the handshake works, see the [plugin/auth/dialog.c](#) source file.

The server counts plugin errors in the Performance Schema [host\\_cache](#) table.

[auth\\_simple\\_server\(\)](#) is so basic that it does not use the authentication information structure except to set the member that indicates whether a password was received.

A plugin that supports proxy users must return to the server the name of the proxied user (the MySQL user whose privileges the client user should get). To do this, the plugin must set the [info->authenticated\\_as](#) member to the proxied user name. For information about proxying, see [Section 7.3.9, “Proxy Users”](#), and [Implementing Proxy User Support in Authentication Plugins](#).

The [generate\\_authentication\\_string](#) member of the plugin descriptor takes the password and generates a password hash (digest) from it:

- The first two arguments are pointers to the output buffer and its maximum length in bytes. The function should write the password hash to the output buffer and reset the length to the actual hash length.
- The second two arguments indicate the password input buffer and its length in bytes.
- The function returns 0 for success, 1 if an error occurred.

For the [auth\\_simple](#) plugin, the [generate\\_auth\\_string\\_hash\(\)](#) function implements the [generate\\_authentication\\_string](#) member. It just makes a copy of the password, unless it is too long to fit in the output buffer.

```

int generate_auth_string_hash(char *outbuf, unsigned int *buflen,
                             const char *inbuf, unsigned int inbuflen)
{
    /*
     * fail if buffer specified by server cannot be copied to output buffer
     */
    if (*buflen < inbuflen)
        return 1; /* error */
    strncpy(outbuf, inbuf, inbuflen);
    *buflen= strlen(inbuf);
    return 0; /* success */
}

```

The [validate\\_authentication\\_string](#) member of the plugin descriptor validates a password hash:

- The arguments are a pointer to the password hash and its length in bytes.
- The function returns 0 for success, 1 if the password hash cannot be validated.

For the `auth_simple` plugin, the `validate_auth_string_hash()` function implements the `validate_authentication_string` member. It returns success unconditionally:

```
int validate_auth_string_hash(char* const inbuf __attribute__((unused)),
                             unsigned int buflen __attribute__((unused)))
{
    return 0;    /* success */
}
```

The `set_salt` member of the plugin descriptor is used only by the `mysql_native_password` plugin (see [Section 7.5.1.1, “The Native Authentication Plugin”](#)). For other authentication plugins, you can use this trivial implementation:

```
int set_salt(const char* password __attribute__((unused)),
             unsigned int password_len __attribute__((unused)),
             unsigned char* salt __attribute__((unused)),
             unsigned char* salt_len)
{
    *salt_len= 0;
    return 0;    /* success */
}
```

The `authentication_flags` member of the plugin descriptor contains flags that affect plugin operation. The permitted flags are:

- `AUTH_FLAG_PRIVILEGED_USER_FOR_PASSWORD_CHANGE`: Credential changes are a privileged operation. If this flag is set, the server requires that the user has the global `CREATE USER` privilege or the `UPDATE` privilege for the `mysql` database.
- `AUTH_FLAG_USES_INTERNAL_STORAGE`: Whether the plugin uses internal storage (in the `authentication_string` column of `mysql.user` rows). If this flag is not set, attempts to set the password using `SET PASSWORD` fail and the server produces a warning.

## Writing the Client-Side Authentication Plugin

Declare the client-side plugin descriptor with the `mysql_declare_client_plugin()` and `mysql_end_client_plugin` macros (see [Client Plugin Descriptors](#)). For the `auth_simple` plugin, the descriptor looks like this:

```
mysql_declare_client_plugin(AUTHENTICATION)
    "auth_simple",           /* plugin name */
    "Author Name",          /* author */
    "Any-password authentication plugin", /* description */
    {1,0,0},                /* version = 1.0.0 */
    "GPL",                  /* license type */
    NULL,                   /* for internal use */
    NULL,                   /* no init function */
    NULL,                   /* no deinit function */
    NULL,                   /* no option-handling function */
    auth_simple_client      /* main function */
mysql_end_client_plugin;
```

The descriptor members from the plugin name through the option-handling function are common to all client plugin types. (For descriptions, see [Client Plugin Descriptors](#).) Following the common members, the descriptor has an additional member specific to authentication plugins. This is the “main” function, which handles communication with the server. The function takes two arguments representing an I/O structure and a connection handler. For our simple any-password plugin, the main function does nothing but write to the server the password provided by the user:

```
static int auth_simple_client (MYSQL_PLUGIN_VIO *vio, MYSQL *mysql)
{
    int res;

    /* send password as null-terminated string in clear text */
    res= vio->write_packet(vio, (const unsigned char *) mysql->passwd,
                           strlen(mysql->passwd) + 1);

    return res ? CR_ERROR : CR_OK;
}
```

The main function should return one of the error codes shown in the following table.

| Error Code                               | Meaning              |
|--|----------------------|
| <a href="#">CR_OK</a>                    | Success              |
| <a href="#">CR_OK_HANDSHAKE_COMPLETE</a> | Success, client done |
| <a href="#">CR_ERROR</a>                 | Error                |

[CR\\_OK\\_HANDSHAKE\\_COMPLETE](#) indicates that the client has done its part successfully and has read the last packet. A client plugin may return [CR\\_OK\\_HANDSHAKE\\_COMPLETE](#) if the number of round trips in the authentication protocol is not known in advance and the plugin must read another packet to determine whether authentication is finished.

## Using the Authentication Plugins

To compile and install a plugin library file, use the instructions in [Section 27.2.4.3, “Compiling and Installing Plugin Libraries”](#). To make the library file available for use, install it in the plugin directory (the directory named by the [plugin\\_dir](#) system variable).

Register the server-side plugin with the server. For example, to load the plugin at server startup, use a [--plugin-load=auth\\_simple.so](#) option (adjust the [.so](#) suffix for your platform as necessary).

Create a user for whom the server will use the [auth\\_simple](#) plugin for authentication:

```
mysql> CREATE USER 'x'@'localhost'
      -> IDENTIFIED WITH auth_simple;
```

Use a client program to connect to the server as user [x](#). The server-side [auth\\_simple](#) plugin communicates with the client program that it should use the client-side [auth\\_simple](#) plugin, and the latter sends the password to the server. The server plugin should reject connections that send an empty password and accept connections that send a nonempty password. Invoke the client program each way to verify this:

```
shell> mysql --user=x --skip-password
ERROR 1045 (28000): Access denied for user 'x'@'localhost' (using password: NO)

shell> mysql --user=x --password=abc
mysql>
```

Because the server plugin accepts any nonempty password, it should be considered insecure. After testing the plugin to verify that it works, restart the server without the [--plugin-load](#) option so as not to inadvertently leave the server running with an insecure authentication plugin loaded. Also, drop the user with [DROP USER 'x'@'localhost'](#).

For additional information about loading and using authentication plugins, see [Section 6.5.2, “Installing and Uninstalling Plugins”](#), and [Section 7.3.8, “Pluggable Authentication”](#).

If you are writing a client program that supports the use of authentication plugins, normally such a program causes a plugin to be loaded by calling [mysql\\_options\(\)](#) to set the [MYSQL\\_DEFAULT\\_AUTH](#) and [MYSQL\\_PLUGIN\\_DIR](#) options:

```
char *plugin_dir = "path_to_plugin_dir";
char *default_auth = "plugin_name";

/* ... process command-line options ... */

mysql_options(&mysql, MYSQL_PLUGIN_DIR, plugin_dir);
mysql_options(&mysql, MYSQL_DEFAULT_AUTH, default_auth);
```

Typically, the program will also accept `--plugin-dir` and `--default-auth` options that enable users to override the default values.

Should a client program require lower-level plugin management, the client library contains functions that take an `st_mysql_client_plugin` argument. See [Section 26.8.14, “C API Client Plugin Functions”](#).

## Implementing Proxy User Support in Authentication Plugins

One of the capabilities that pluggable authentication makes possible is proxy users (see [Section 7.3.9, “Proxy Users”](#)). For a server-side authentication plugin to participate in proxy user support, these conditions must be satisfied:

- When a connecting client should be treated as a proxy user, the plugin must return a different name in the `authenticated_as` member of the `MYSQL_SERVER_AUTH_INFO` structure, to indicate the proxied user name. It may also optionally set the `external_user` member, to set the value of the `external_user` system variable.
- Proxy user accounts must be set up to be authenticated by the plugin. Use the `CREATE USER` or `GRANT` statement to associate accounts with plugins.
- Proxy user accounts must have the `PROXY` privilege for the proxied accounts. Use the `GRANT` statement to grant this privilege.

In other words, the only aspect of proxy user support required of the plugin is that it set `authenticated_as` to the proxied user name. The rest is optional (setting `external_user`) or done by the DBA using SQL statements.

How does an authentication plugin determine which proxied user to return when the proxy user connects? That depends on the plugin. Typically, the plugin maps clients to proxied users based on the authentication string passed to it by the server. This string comes from the `AS` part of the `IDENTIFIED WITH` clause of the `CREATE USER` statement that specifies use of the plugin for authentication.

The plugin developer determines the syntax rules for the authentication string and implements the plugin according to those rules. Suppose that a plugin takes a comma-separated list of pairs that map external users to MySQL users. For example:

```
CREATE USER ''@%.example.com'
  IDENTIFIED WITH my_plugin AS 'extuser1=mysqlusera, extuser2=mysqluserb'
CREATE USER ''@%.example.org'
  IDENTIFIED WITH my_plugin AS 'extuser1=mysqluserc, extuser2=mysqluserd'
```

When the server invokes a plugin to authenticate a client, it passes the appropriate authentication string to the plugin. The plugin is responsible to:

1. Parse the string into its components to determine the mapping to use
2. Compare the client user name to the mapping
3. Return the proper MySQL user name

For example, if `extuser2` connects from an `example.com` host, the server passes `'extuser1=mysqlusera, extuser2=mysqluserb'` to the plugin, and the plugin should copy

`mysqluserb` into `authenticated_as`, with a terminating null byte. If `extuser2` connects from an `example.org` host, the server passes '`extuser1=mysqluserc, extuser2=mysqluserd`', and the plugin should copy `mysqluserd` instead.

If there is no match in the mapping, the action depends on the plugin. If a match is required, the plugin likely will return an error. Or the plugin might simply return the client name; in this case, it should not change `authenticated_as`, and the server will not treat the client as a proxy.

The following example demonstrates how to handle proxy users using a plugin named `auth_simple_proxy`. Like the `auth_simple` plugin described earlier, `auth_simple_proxy` accepts any nonempty password as valid (and thus should not be used in production environments). In addition, it examines the `auth_string` authentication string member and uses these very simple rules for interpreting it:

- If the string is empty, the plugin returns the user name as given and no proxying occurs. That is, the plugin leaves the value of `authenticated_as` unchanged.
- If the string is nonempty, the plugin treats it as the name of the proxied user and copies it to `authenticated_as` so that proxying occurs.

For testing, set up one account that is not proxied according to the preceding rules, and one that is. This means that one account has no `AS` clause, and one includes an `AS` clause that names the proxied user:

```
CREATE USER 'plugin_user1'@'localhost'
  IDENTIFIED WITH auth_simple_proxy;
CREATE USER 'plugin_user2'@'localhost'
  IDENTIFIED WITH auth_simple_proxy AS 'proxied_user';
```

In addition, create an account for the proxied user and grant `plugin_user2` the `PROXY` privilege for it:

```
CREATE USER 'proxied_user'@'localhost'
  IDENTIFIED BY 'proxied_user_pass';
GRANT PROXY
  ON 'proxied_user'@'localhost'
  TO 'plugin_user2'@'localhost';
```

Before the server invokes an authentication plugin, it sets `authenticated_as` to the client user name. To indicate that the user is a proxy, the plugin should set `authenticated_as` to the proxied user name. For `auth_simple_proxy`, this means that it must examine the `auth_string` value, and, if the value is nonempty, copy it to the `authenticated_as` member to return it as the name of the proxied user. In addition, when proxying occurs, the plugin sets the `external_user` member to the client user name; this becomes the value of the `external_user` system variable.

```
static int auth_simple_proxy_server (MYSQL_PLUGIN_VIO *vio,
                                     MYSQL_SERVER_AUTH_INFO *info)
{
    unsigned char *pkt;
    int pkt_len;

    /* read the password as null-terminated string, fail on error */
    if ((pkt_len= vio->read_packet(vio, &pkt)) < 0)
        return CR_ERROR;

    /* fail on empty password */
    if (!pkt_len || *pkt == '\0')
    {
        info->password_used= PASSWORD_USED_NO;
        return CR_ERROR;
    }

    /* accept any nonempty password */
    info->password_used= PASSWORD_USED_YES;
```

```

/* if authentication string is nonempty, use as proxied user name */
/* and use client name as external_user value */
if (info->auth_string_length > 0)
{
    strcpy (info->authenticated_as, info->auth_string);
    strcpy (info->external_user, info->user_name);
}

return CR_OK;
}

```

After a successful connection, the `USER()` function should indicate the connecting client user and host name, and `CURRENT_USER()` should indicate the account whose privileges apply during the session. The latter value should be the connecting user account if no proxying occurs or the proxied account if proxying does occur.

Compile and install the plugin, then test it. First, connect as `plugin_user1`:

```
shell> mysql --user=plugin_user1 --password=x
```

In this case, there should be no proxying:

```

mysql> SELECT USER(), CURRENT_USER(), @@proxy_user, @@external_user\G
***** 1. row *****
      USER(): plugin_user1@localhost
    CURRENT_USER(): plugin_user1@localhost
      @@proxy_user: NULL
    @@external_user: NULL

```

Then connect as `plugin_user2`:

```
shell> mysql --user=plugin_user2 --password=x
```

In this case, `plugin_user2` should be proxied to `proxied_user`:

```

mysql> SELECT USER(), CURRENT_USER(), @@proxy_user, @@external_user\G
***** 1. row *****
      USER(): plugin_user2@localhost
    CURRENT_USER(): proxied_user@localhost
      @@proxy_user: 'plugin_user2'@'localhost'
    @@external_user: 'plugin_user2'@'localhost'

```

#### 27.2.4.10 Writing Password-Validation Plugins

This section describes how to write a server-side password-validation plugin. The instructions are based on the source code in the `plugin/password_validation` directory of MySQL source distributions. The `validate_password.cc` source file in that directory implements the plugin named `validate_password`.

To write a password-validation plugin, include the following header file in the plugin source file. Other MySQL or general header files might also be needed, depending on the plugin capabilities and requirements.

```
#include <mysql/plugin_validate_password.h>
```

`plugin_validate_password.h` includes `plugin.h`, so you need not include the latter file explicitly. `plugin.h` defines the `MYSQL_VALIDATE_PASSWORD_PLUGIN` server plugin type and the data structures needed to declare the plugin. `plugin_validate_password.h` defines data structures specific to password-validation plugins.

A password-validation plugin, like any MySQL server plugin, has a general plugin descriptor (see [Server Plugin Library and Plugin Descriptors](#)). In `validate_password.cc`, the general descriptor for `validate_password` looks like this:

```
mysql_declare_plugin(validate_password)
{
    MYSQL_VALIDATE_PASSWORD_PLUGIN,      /* type */
    &validate_password_descriptor,        /* descriptor */
    "validate_password",                  /* name */
    "Oracle Corporation",                 /* author */
    "check password strength",             /* description */
    PLUGIN_LICENSE_GPL,
    validate_password_init,               /* init function (when loaded) */
    validate_password_deinit,             /* deinit function (when unloaded) */
    0x0100,                               /* version */
    NULL,
    validate_password_system_variables,    /* system variables */
    NULL,
    0,
}
mysql_declare_plugin_end;
```

The `name` member (`validate_password`) indicates the name to use for references to the plugin in statements such as `INSTALL PLUGIN` or `UNINSTALL PLUGIN`. This is also the name displayed by `INFORMATION_SCHEMA.PLUGINS` or `SHOW PLUGINS`.

The general descriptor also refers to `validate_password_system_variables`, a structure that exposes several system variables to the `SHOW VARIABLES` statement:

```
static struct st_mysql_sys_var* validate_password_system_variables[] = {
    MYSQL_SYSVAR(length),
    MYSQL_SYSVAR(number_count),
    MYSQL_SYSVAR(mixed_case_count),
    MYSQL_SYSVAR(special_char_count),
    MYSQL_SYSVAR(policy),
    MYSQL_SYSVAR(dictionary_file),
    NULL
};
```

The `validate_password_init` initialization function reads the dictionary file if one was specified, and the `validate_password_deinit` function frees data structures associated with the file.

The `validate_password_descriptor` value in the general descriptor points to the type-specific descriptor. For password-validation plugins, this descriptor has the following structure:

```
struct st_mysql_validate_password
{
    int interface_version;
    /*
     * This function returns TRUE for passwords which satisfy the password
     * policy (as chosen by plugin variable) and FALSE for all other
     * password
     */
    int (*validate_password)(mysql_string_handle password);
    /*
     * This function returns the password strength (0-100) depending
     * upon the policies
     */
    int (*get_password_strength)(mysql_string_handle password);
};
```

The type-specific descriptor has these members:

- `interface_version`: By convention, type-specific plugin descriptors begin with the interface version for the given plugin type. The server checks `interface_version` when it loads the plugin

to see whether the plugin is compatible with it. For password-validation plugins, the value of the `interface_version` member is `MYSQL_VALIDATE_PASSWORD_INTERFACE_VERSION` (defined in `plugin_validate_password.h`).

- `validate_password`: A function that the server calls to test whether a password satisfies the current password policy. It returns 1 if the password is okay and 0 otherwise. The argument is the password, passed as a `mysql_string_handle` value. This data type is implemented by the `mysql_string` server service. For details, see the `string_service.h` and `string_service.cc` source files in the `sql` directory.
- `get_password_strength`: A function that the server calls to assess the strength of a password. It returns a value from 0 (weak) to 100 (strong). The argument is the password, passed as a `mysql_string_handle` value.

For the `validate_password` plugin, the type-specific descriptor looks like this:

```
static struct st_mysql_validate_password validate_password_descriptor=
{
    MYSQL_VALIDATE_PASSWORD_INTERFACE_VERSION,
    validate_password,                /* validate function          */
    get_password_strength             /* validate strength function */
};
```

To compile and install a plugin library file, use the instructions in [Section 27.2.4.3, “Compiling and Installing Plugin Libraries”](#). To make the library file available for use, install it in the plugin directory (the directory named by the `plugin_dir` system variable). For the `validate_password` plugin, it is compiled and installed when you build MySQL from source. It is also included in binary distributions. The build process produces a shared object library with a name of `validate_password.so` (the `.so` suffix might differ depending on your platform).

To register the plugin at runtime, use this statement (adjust the `.so` suffix for your platform as necessary):

```
INSTALL PLUGIN validate_password SONAME 'validate_password.so';
```

For additional information about plugin loading, see [Section 6.5.2, “Installing and Uninstalling Plugins”](#).

To verify plugin installation, examine the `INFORMATION_SCHEMA.PLUGINS` table or use the `SHOW PLUGINS` statement. See [Section 6.5.3, “Obtaining Server Plugin Information”](#).

While the `validate_password` plugin is installed, it exposes system variables that indicate the password-checking parameters:

```
mysql> SHOW VARIABLES LIKE 'validate_password%';
+-----+-----+
| Variable_name | Value |
+-----+-----+
| validate_password_dictionary_file |      |
| validate_password_length | 8 |
| validate_password_mixed_case_count | 1 |
| validate_password_number_count | 1 |
| validate_password_policy | MEDIUM |
| validate_password_special_char_count | 1 |
+-----+-----+
```

For descriptions of these variables, see [Section 7.5.3.2, “Password Validation Plugin Options and Variables”](#).

To disable the plugin after testing it, use this statement to unload it:

```
UNINSTALL PLUGIN validate_password;
```

### 27.2.4.11 Writing Protocol Trace Plugins

MySQL supports the use of protocol trace plugins: client-side plugins that implement tracing of communication between a client and the server that takes place using the client/server protocol. This capability can be used in MySQL 5.7.2 and up.

#### Using the Test Protocol Trace Plugin

MySQL includes a test protocol trace plugin that serves to illustrate the information available from such plugins, and as a guide to writing other protocol trace plugins. To see how the test plugin works, use a MySQL source distribution; binary distributions are built with the test plugin disabled.

Enable the test protocol trace plugin by configuring MySQL with the `WITH_TEST_TRACE_PLUGIN` `CMake` option enabled. This causes the test trace plugin to be built and MySQL client programs to load it, but the plugin has no effect by default. Control the plugin using these environment variables:

- `MYSQL_TEST_TRACE_DEBUG`: Set this variable to a value other than 0 to cause the test plugin to produce diagnostic output on `stderr`.
- `MYSQL_TEST_TRACE_CRASH`: Set this variable to a value other than 0 to cause the test plugin to abort the client program if it detects an invalid trace event.

#### Caution

Diagnostic output from the test protocol trace plugin can disclose passwords and other sensitive information.

Given a MySQL installation built from source with the test plugin enabled, you can see a trace of the communication between the `mysql` client and the MySQL server as follows:

```
shell> export MYSQL_TEST_TRACE_DEBUG=1
shqll> mysql
test_trace: Test trace plugin initialized
test_trace: Starting tracing in stage CONNECTING
test_trace: stage: CONNECTING, event: CONNECTING
test_trace: stage: CONNECTING, event: CONNECTED
test_trace: stage: WAIT_FOR_INIT_PACKET, event: READ_PACKET
test_trace: stage: WAIT_FOR_INIT_PACKET, event: PACKET_RECEIVED
test_trace: packet received: 87 bytes
  0A 35 2E 37 2E 33 2D 6D 31 33 2D 64 65 62 75 67  .5.7.3-m13-debug
  2D 6C 6F 67 00 04 00 00 00 2B 7C 4F 55 3F 79 67  -log.....+|OU?yg
test_trace: 004: stage: WAIT_FOR_INIT_PACKET, event: INIT_PACKET_RECEIVED
test_trace: 004: stage: AUTHENTICATE, event: AUTH_PLUGIN
test_trace: 004: Using authentication plugin: mysql_native_password
test_trace: 004: stage: AUTHENTICATE, event: SEND_AUTH_RESPONSE
test_trace: 004: sending packet: 188 bytes
  85 A6 7F 00 00 00 00 01 21 00 00 00 00 00 00 00  .?.!.....
  00 00 00 00 00 00 00 00 00 00 00 00 00 00 00 00  .....
...
mysql> quit
test_trace: 008: stage: READY_FOR_COMMAND, event: SEND_COMMAND
test_trace: 008: QUIT
test_trace: 008: stage: READY_FOR_COMMAND, event: PACKET_SENT
test_trace: 008: packet sent: 0 bytes
test_trace: 008: stage: READY_FOR_COMMAND, event: DISCONNECTED
test_trace: 008: Connection closed
test_trace: 008: Tracing connection has ended
Bye
test_trace: Test trace plugin de-initialized
```

To disable trace output, do this:

```
shell> MYSQL_TEST_TRACE_DEBUG=
```

## Using Your Own Protocol Trace Plugins

### Note

To use your own protocol trace plugins, you must configure MySQL with the `WITH_TEST_TRACE_PLUGIN` CMake option *disabled* because only one protocol trace plugin can be loaded at a time and an error occurs for attempts to load a second one. If you have already built MySQL with the test protocol trace plugin enabled to see how it works, you must rebuild MySQL without it before you can use your own plugins.

This section discusses how to write a basic protocol trace plugin named `simple_trace`. This plugin provides a framework showing how to set up the client plugin descriptor and create the trace-related callback functions. In `simple_trace`, these functions are rudimentary and do little other than illustrate the arguments required. To see in detail how a trace plugin can make use of trace event information, check the source file for the test protocol trace plugin (`test_trace_plugin.cc` in the `libmysql` directory of a MySQL source distribution). However, note that the `st_mysql_client_plugin_TRACE` structure used there differs from the structures used with the usual client plugin declaration macros. In particular, the first two members are defined explicitly, not implicitly by declaration macros.

Several header files contain information relevant to protocol trace plugins:

- `client_plugin.h`: Defines the API for client plugins. This includes the client plugin descriptor and function prototypes for client plugin C API calls (see [Section 26.8.14, “C API Client Plugin Functions”](#)).
- `plugin_trace.h`: Contains declarations for client-side plugins of type `MYSQL_CLIENT_TRACE_PLUGIN`. It also contains descriptions of the permitted protocol stages, transitions between stages, and the types of events permitted at each stage.

To write a protocol trace plugin, include the following header files in the plugin source file. Other MySQL or general header files might also be needed, depending on the plugin capabilities and requirements.

```
#include <mysql/plugin_trace.h>
#include <mysql.h>
```

`plugin_trace.h` includes `client_plugin.h`, so you need not include the latter file explicitly.

Declare the client-side plugin descriptor with the `mysql_declare_client_plugin()` and `mysql_end_client_plugin` macros (see [Client Plugin Descriptors](#)). For the `simple_trace` plugin, the descriptor looks like this:

```
mysql_declare_client_plugin(TRACE)
    "simple_trace",           /* plugin name */
    "Author Name",          /* author */
    "Simple protocol trace plugin", /* description */
    {1,0,0},                /* version = 1.0.0 */
    "GPL",                  /* license type */
    NULL,                   /* for internal use */
    plugin_init,             /* initialization function */
    plugin_deinit,          /* deinitialization function */
    plugin_options,         /* option-handling function */
    trace_start,            /* start-trace function */
    trace_stop,             /* stop-trace function */
    trace_event             /* event-handling function */
mysql_end_client_plugin;
```

The descriptor members from the plugin name through the option-handling function are common to all client plugin types. The members following the common members implement trace event handling.

Function members for which the plugin needs no processing can be declared as `NULL` in the descriptor, in which case you need not write any corresponding function. For illustration purposes and to show the argument syntax, the following discussion implements all functions listed in the descriptor, even though some of them do nothing,

The initialization, deinitialization, and options functions common to all client plugins are declared as follows. For a description of the arguments and return values, see [Client Plugin Descriptors](#).

```
static int
plugin_init(char *errbuf, size_t errbuf_len, int argc, va_list args)
{
    return 0;
}

static int
plugin_deinit()
{
    return 0;
}

static int
plugin_options(const char *option, const void *value)
{
    return 0;
}
```

The trace-specific members of the client plugin descriptor are callback functions. The following descriptions provide more detail on how they are used. Each has a first argument that is a pointer to the plugin instance in case your implementation needs to access it.

`trace_start()`: This function is called at the start of each traced connection (each connection that starts after the plugin is loaded). It is passed the connection handler and the protocol stage at which tracing starts. `trace_start()` allocates memory needed by the `trace_event()` function, if any, and returns a pointer to it. If no memory is needed, this function returns `NULL`.

```
static void*
trace_start(struct st_mysql_client_plugin_TRACE *self,
            MYSQL *conn,
            enum protocol_stage stage)
{
    struct st_trace_data *plugin_data= malloc(sizeof(struct st_trace_data));

    fprintf(stderr, "Initializing trace: stage %d\n", stage);
    if (plugin_data)
    {
        memset(plugin_data, 0, sizeof(struct st_trace_data));
        fprintf(stderr, "Trace initialized\n");
        return plugin_data;
    }
    fprintf(stderr, "Could not initialize trace\n");
    exit(1);
}
```

`trace_stop()`: This function is called when tracing of the connection ends. That usually happens when the connection is closed, but can happen earlier. For example, `trace_event()` can return a nonzero value at any time and that causes tracing of the connection to terminate. `trace_stop()` is then called even though the connection has not ended.

`trace_stop()` is passed the connection handler and a pointer to the memory allocated by `trace_start()` (`NULL` if none). If the pointer is non-`NULL`, `trace_stop()` should deallocate the memory. This function returns no value.

```
static void
trace_stop(struct st_mysql_client_plugin_TRACE *self,
            MYSQL *conn,
```

```

        void *plugin_data)
{
    fprintf(stderr, "Terminating trace\n");
    if (plugin_data)
        free(plugin_data);
}

```

`trace_event()`: This function is called for each event occurrence. It is passed a pointer to the memory allocated by `trace_start()` (`NULL` if none), the connection handler, the current protocol stage and event codes, and event data. This function returns 0 to continue tracing, nonzero if tracing should stop.

```

static int
trace_event(struct st_mysql_client_plugin_TRACE *self,
            void *plugin_data,
            MYSQL *conn,
            enum protocol_stage stage,
            enum trace_event event,
            struct st_trace_event_args args)
{
    fprintf(stderr, "Trace event received: stage %d, event %d\n", stage, event);
    if (event == TRACE_EVENT_DISCONNECTED)
        fprintf(stderr, "Connection closed\n");
    return 0;
}

```

The tracing framework shuts down tracing of the connection when the connection ends, so `trace_event()` should return nonzero only if you want to terminate tracing of the connection early. Suppose that you want to trace only connections for a certain MySQL account. After authentication, you can check the user name for the connection and stop tracing if it is not the user in whom you are interested.

For each call to `trace_event()`, the `st_trace_event_args` structure contains the event data. It has this definition:

```

struct st_trace_event_args
{
    const char      *plugin_name;
    int             cmd;
    const unsigned char *hdr;
    size_t          hdr_len;
    const unsigned char *pkt;
    size_t          pkt_len;
};

```

For different event types, the `st_trace_event_args` structure contains the information described following. All lengths are in bytes. Unused members are set to `0/NULL`.

#### `AUTH_PLUGIN` event:

```

plugin_name  The name of the plugin

```

#### `SEND_COMMAND` event:

```

cmd          The command code
hdr          Pointer to the command packet header
hdr_len      Length of the header
pkt          Pointer to the command arguments
pkt_len      Length of the arguments

```

#### Other `SEND_XXX` and `XXX_RECEIVED` events:

```

pkt          Pointer to the data sent or received
pkt_len      Length of the data

```

`PACKET_SENT` event:

| pkt_len | Number of bytes sent |
|---------|----------------------|
|         |                      |

To compile and install a plugin library file, use the instructions in [Section 27.2.4.3, “Compiling and Installing Plugin Libraries”](#). To make the library file available for use, install it in the plugin directory (the directory named by the `plugin_dir` system variable).

After the plugin library file is compiled and installed in the plugin directory, you can test it easily by setting the `LIBMYSQL_PLUGINS` environment variable to the plugin name, which affects any client program that uses that variable. `mysql` is one such program:

```
shell> export LIBMYSQL_PLUGINS=simple_trace
shll> mysql
Initializing trace: stage 0
Trace initialized
Trace event received: stage 0, event 1
Trace event received: stage 0, event 2
...
Welcome to the MySQL monitor.  Commands end with ; or \g.
Trace event received
Trace event received
...
mysql> SELECT 1;
Trace event received: stage 4, event 12
Trace event received: stage 4, event 16
...
Trace event received: stage 8, event 14
Trace event received: stage 8, event 15
+----+
| 1 |
+----+
| 1 |
+----+
1 row in set (0.00 sec)

mysql> quit
Trace event received: stage 4, event 12
Trace event received: stage 4, event 16
Trace event received: stage 4, event 3
Connection closed
Terminating trace
Bye
```

To stop the trace plugin from being loaded, do this:

```
shell> LIBMYSQL_PLUGINS=
```

It is also possible to write client programs that directly load the plugin. You can tell the client where the plugin directory is located by calling `mysql_options()` to set the `MYSQL_PLUGIN_DIR` option:

```
char *plugin_dir = "path_to_plugin_dir";

/* ... process command-line options ... */

mysql_options(&mysql, MYSQL_PLUGIN_DIR, plugin_dir);
```

Typically, the program will also accept a `--plugin-dir` option that enables users to override the default value.

Should a client program require lower-level plugin management, the client library contains functions that take an `st_mysql_client_plugin` argument. See [Section 26.8.14, “C API Client Plugin Functions”](#).

## 27.2.4.12 Writing Keyring Plugins

MySQL Server supports a keyring service that enables internal server components and plugins to securely store sensitive information for later retrieval. This section describes how to write a server-side keyring plugin that can be used by service functions to perform key-management operations. For general keyring information, see [Section 7.5.4, “The MySQL Keyring”](#).

The instructions here are based on the source code in the `plugin/keyring` directory of MySQL source distributions. The source files in that directory implement a plugin named `keyring_file` that uses a file local to the server host for data storage.

To write a keyring plugin, include the following header file in the plugin source file. Other MySQL or general header files might also be needed, depending on the plugin capabilities and requirements.

```
#include <mysql/plugin_keyring.h>
```

`plugin_keyring.h` includes `plugin.h`, so you need not include the latter file explicitly. `plugin.h` defines the `MYSQL_KEYRING_PLUGIN` server plugin type and the data structures needed to declare the plugin. `plugin_keyring.h` defines data structures specific to keyring plugins.

A keyring plugin, like any MySQL server plugin, has a general plugin descriptor (see [Server Plugin Library and Plugin Descriptors](#)). In `keyring.cc`, the general descriptor for `keyring_file` looks like this:

```
mysql_declare_plugin(keyring_file)
{
    MYSQL_KEYRING_PLUGIN,      /* type */
    &keyring_descriptor,       /* descriptor */
    "keyring_file",            /* name */
    "Oracle Corporation",      /* author */
    "store/fetch authentication data to/from a flat file", /* description */
    PLUGIN_LICENSE_GPL,
    keyring_init,              /* init function (when loaded) */
    keyring_deinit,            /* deinit function (when unloaded) */
    0x0100,                    /* version */
    NULL,                      /* status variables */
    keyring_system_variables,   /* system variables */
    NULL,
    0,
}
mysql_declare_plugin_end;
```

The `name` member (`keyring_file`) indicates the plugin name. This is the name displayed by `INFORMATION_SCHEMA.PLUGINS` or `SHOW PLUGINS`.

The general descriptor also refers to `keyring_system_variables`, a structure that exposes a system variable to the `SHOW VARIABLES` statement:

```
static struct st_mysql_sys_var *keyring_system_variables[] = {
    MYSQL_SYSVAR(data),
    NULL
};
```

The `keyring_init` initialization function creates the data file if it does not exist, then reads it and initializes the keystore. The `keyring_deinit` function frees data structures associated with the file.

The `keyring_descriptor` value in the general descriptor points to the type-specific descriptor. For keyring plugins, this descriptor has the following structure:

```
struct st_mysql_keyring
{
    int interface_version;
    my_bool (*mysql_key_store)(const char *key_id, const char *key_type,
                              const char* user_id, const void *key, size_t key_len);
    my_bool (*mysql_key_fetch)(const char *key_id, char **key_type,
```

```

        const char *user_id, void **key, size_t *key_len);
my_bool (*mysql_key_remove)(const char *key_id, const char *user_id);
my_bool (*mysql_key_generate)(const char *key_id, const char *key_type,
                             const char *user_id, size_t key_len);
};

```

The type-specific descriptor has these members:

- `interface_version`: By convention, type-specific plugin descriptors begin with the interface version for the given plugin type. The server checks `interface_version` when it loads the plugin to see whether the plugin is compatible with it. For keyring plugins, the value of the `interface_version` member is `MYSQL_KEYRING_INTERFACE_VERSION` (defined in `plugin_keyring.h`).
- `mysql_key_store`: A function that obfuscates and stores a key in the keyring.
- `mysql_key_fetch`: A function that deobfuscates and retrieves a key from the keyring.
- `mysql_key_remove`: A function that removes a key from the keyring.
- `mysql_key_generate`: A function that generates a new random key and stores it in the keyring.

For the `keyring_file` plugin, the type-specific descriptor looks like this:

```

static struct st_mysql_keyring keyring_descriptor=
{
    MYSQL_KEYRING_INTERFACE_VERSION,
    mysql_key_store,
    mysql_key_fetch,
    mysql_key_remove,
    mysql_key_generate
};

```

The `mysql_key_XXX` functions implemented by a keyring plugin are analogous to the `my_key_XXX` functions exposed by the keyring service API. For example, the `mysql_key_store` plugin function is analogous to the `my_key_store` keyring service function. For information about the arguments to keyring service functions and how they are used, see [Section 27.3.2, “The Keyring Service”](#).

To compile and install a plugin library file, use the instructions in [Section 27.2.4.3, “Compiling and Installing Plugin Libraries”](#). To make the library file available for use, install it in the plugin directory (the directory named by the `plugin_dir` system variable). For the `keyring_file` plugin, it is compiled and installed when you build MySQL from source. It is also included in binary distributions. The build process produces a shared object library with a name of `keyring_file.so` (the `.so` suffix might differ depending on your platform).

Keyring plugins typically are loaded early during the server startup process so that they are available to built-in plugins and storage engines that might depend on them. For `keyring_file`, use these lines in the server `my.cnf` file (adjust the `.so` suffix for your platform as necessary):

```

[mysqld]
early-plugin-load=keyring_file.so

```

For additional information about plugin loading, see [Section 6.5.2, “Installing and Uninstalling Plugins”](#).

To verify plugin installation, examine the `INFORMATION_SCHEMA.PLUGINS` table or use the `SHOW PLUGINS` statement (see [Section 6.5.3, “Obtaining Server Plugin Information”](#)). For example:

```

mysql> SELECT PLUGIN_NAME, PLUGIN_STATUS FROM INFORMATION_SCHEMA.PLUGINS
       -> WHERE PLUGIN_NAME LIKE 'keyring%';
+-----+-----+
| PLUGIN_NAME | PLUGIN_STATUS |
+-----+-----+
| keyring_file | ACTIVE        |

```

While the `keyring_file` plugin is installed, it exposes a system variable that indicates the location of the data file it uses for secure information storage:

```
mysql> SHOW VARIABLES LIKE 'keyring_file%';
```

| Variable_name     | Value                            |
|-------------------|----------------------------------|
| keyring_file_data | /usr/local/mysql/keyring/keyring |

For a description of the `keyring_file_data` variable, see [Section 6.1.5, “Server System Variables”](#).

To disable the plugin after testing it, restart the server without an `--early-plugin-load` option that names the plugin.

## 27.3 MySQL Services for Plugins

MySQL server plugins have access to server “services.” The services interface exposes server functionality that plugins can call. It complements the plugin API and has these characteristics:

- Services enable plugins to access code inside the server using ordinary function calls. Services are also available to user-defined functions (UDFs).
- Services are portable and work on multiple platforms.
- The interface includes a versioning mechanism so that service versions supported by the server can be checked at load time against plugin versions. Versioning protects against incompatibilities between the version of a service that the server provides and the version of the service expected or required by a plugin.
- For information about plugins for testing plugin services, see [Plugins for Testing Plugin Services](#), in [The MySQL Test Framework, Version 2.0](#).

The plugin services interface differs from the plugin API as follows:

- The plugin API enables plugins to be used by the server. The calling initiative lies with the server to invoke plugins. This enables plugins to extend server functionality or register to receive notifications about server processing.
- The plugin services interface enables plugins to call code inside the server. The calling initiative lies with plugins to invoke service functions. This enables functionality already implemented in the server to be used by many plugins; they need not individually implement it themselves.

To determine what services exist and what functions they provide, look in the `include/mysql` directory of a MySQL source distribution. The relevant files are:

- `plugin.h` includes `services.h`, which is the “umbrella” header that includes all available service-specific header files.
- Service-specific headers have names of the form `service_xxx.h`.

Each service-specific header should contain comments that provide full usage documentation for a given service, including what service functions are available, their calling sequences, and return values.

Current services include the following, and others can be implemented:

- `locking_service`: A service that implements locks with three attributes: Lock namespace, lock name, and lock mode. This locking interface is available at two levels: 1) As a C language interface, callable as a plugin service from server plugins or user-defined functions; 2) At the SQL level, as a set of user-defined functions that map onto calls to the service routines. For more information, see [Section 27.3.1, “The Locking Service”](#).

- `my_plugin_log_service`: A service that enables plugins to report errors and specify error messages. The server writes the messages to its error log.
- `my_snprintf`: A string-formatting service that produces consistent results across platforms.
- `my_thd_scheduler`: A service for plugins to select a thread scheduler.
- `mysql_keyring`: A service for keyring storage. For more information, see [Section 27.3.2, “The Keyring Service”](#).
- `mysql_password_policy`: A service for password validation and strength checking.
- `mysql_string`: A service for string manipulation.
- `security_context`: A service that enables plugins to examine or manipulate thread security contexts. This service provides setter and getter routines to access attributes of the server `Security_context` class, which includes attributes such as login user and host, authenticated user and host, and client IP address.
- `thd_alloc`: A memory-allocation service.
- `thd_wait`: A service for plugins to report when they are going to sleep or stall.

For developers who wish to modify the server to add a new service, see [MySQL Internals: MySQL Services for Plugins](#).

The remainder of this section describes how a plugin uses server functionality that is available as a service. See also the source for the “daemon” example plugin, which uses the `my_snprintf` service. Within a MySQL source distribution, that plugin is located in the `plugin/daemon_example` directory.

To use a service or services from within a plugin, the plugin source file must include the `plugin.h` header file to access service-related information:

```
#include <mysql/plugin.h>
```

This does not represent any additional setup cost. A plugin must include that file anyway because it contains definitions and structures that every plugin needs.

To access a service, a plugin calls service functions like any other function. For example, to format a string into a buffer for printing, call the `my_snprintf()` function provided by the service of the same name:

```
char buffer[BUFFER_SIZE];

my_snprintf(buffer, sizeof(buffer), format_string, argument_to_format, ...);
```

To report an error that the server will write to its error log, first choose an error level. `mysql/service_my_plugin_log.h` defines these levels:

```
enum plugin_log_level
{
    MY_ERROR_LEVEL,
    MY_WARNING_LEVEL,
    MY_INFORMATION_LEVEL
};
```

Then invoke `my_plugin_log_message()`:

```
int my_plugin_log_message(MYSQL_PLUGIN *plugin, enum plugin_log_level level,
                          const char *format, ...);
```

For example:

```
my_plugin_log_message(plugin_ptr, MY_ERROR_LEVEL, "Cannot initialize plugin");
```

Some services *for* plugins may be provided *by* plugins and thus are available only if the service-providing plugin is loaded. Any MySQL component that uses such a service should check whether the service is available.

When you build your plugin, use the `-lmysqldservices` flag at link time to link in the `libmysqldservices` library. For example, for CMake, put this in the top-level `CMakeLists.txt` file:

```
FIND_LIBRARY(MYSQLSERVICES_LIB mysqldservices
PATHS "${MYSQL_SRCDIR}/libservices" NO_DEFAULT_PATH)
```

Put this in the `CMakeLists.txt` file in the directory containing the plugin source:

```
# the plugin needs the mysql services library for error logging
TARGET_LINK_LIBRARIES (your_plugin_library_name ${MYSQLSERVICES_LIB})
```

## 27.3.1 The Locking Service

Distributions of MySQL 5.7.8 or higher provide a locking interface that is available at two levels:

- As a C language interface, callable as a plugin service from server plugins or user-defined functions
- At the SQL level, as a set of user-defined functions that map onto calls to the service routines

For general information about plugin services, see [Section 27.3, “MySQL Services for Plugins”](#). For general information about user-defined functions, see [Section 27.4.2, “Adding a New User-Defined Function”](#).

The locking interface has these characteristics:

- Locks have three attributes: Lock namespace, lock name, and lock mode:
  - Locks are identified by the combination of namespace and lock name. The namespace enables different applications to use the same lock names without colliding by creating locks in separate namespaces. For example, if applications A and B use namespaces of `ns1` and `ns2`, respectively, each application can use lock names `lock1` and `lock2` without interfering with the other application.
  - A lock mode is either read or write. Read locks are shared: If a session has a read lock on a given lock identifier, other sessions can acquire a read lock on the same identifier. Write locks are exclusive: If a session has a write lock on a given lock identifier, other sessions cannot acquire a read or write lock on the same identifier.
- Namespace and lock names must be non-`NULL`, nonempty, and have a maximum length of 64 characters. A namespace or lock name specified as `NULL`, the empty string, or a string longer than 64 characters results in an `ER_LOCKING_SERVICE_WRONG_NAME` error.
- The locking interface treats namespace and lock names as binary strings, so comparisons are case sensitive.
- The locking interface provides functions to acquire locks and release locks. No special privilege is required to call these functions. Privilege checking is the responsibility of the calling application.
- Locks can be waited for if not immediately available. Lock acquisition calls take an integer timeout value that indicates how many seconds to wait to acquire locks before giving up. If the timeout is reached without successful lock acquisition, an `ER_LOCKING_SERVICE_TIMEOUT` error occurs. If the timeout is 0, there is no waiting and the call produces an error if locks cannot be acquired immediately.

- The locking interface detects deadlock between lock-acquisition calls in different sessions. In this case, the locking service chooses a caller and terminates its lock-acquisition request with an [ER\\_LOCKING\\_SERVICE\\_DEADLOCK](#) error. This error does not cause transactions to roll back. To choose a session in case of deadlock, the locking service prefers sessions that hold read locks over sessions that hold write locks.
- A session can acquire multiple locks with a single lock-acquisition call. For a given call, lock acquisition is atomic: The call succeeds if all locks are acquired. If acquisition of any lock fails, the call acquires no locks and fails, typically with an [ER\\_LOCKING\\_SERVICE\\_TIMEOUT](#) or [ER\\_LOCKING\\_SERVICE\\_DEADLOCK](#) error.
- A session can acquire multiple locks for the same lock identifier (namespace and lock name combination). These lock instances can be read locks, write locks, or a mix of both.
- Locks acquired within a session are released explicitly by calling a release-locks function, or implicitly when the session terminates (either normally or abnormally). Locks are not released when transactions commit or roll back.
- Within a session, all locks for a given namespace when released are released together.

The interface provided by the locking service is distinct from that provided by [GET\\_LOCK\(\)](#) and related SQL functions (see [Section 13.20, “Miscellaneous Functions”](#)). For example, [GET\\_LOCK\(\)](#) does not implement namespaces and provides only exclusive locks, not distinct read and write locks.

### 27.3.1.1 The Locking Service C Interface

This section describes how to use the locking service C language interface. To use the UDF interface instead, see [Section 27.3.1.2, “The Locking Service UDF Interface”](#). For general characteristics of the locking service interface, see [Section 27.3.1, “The Locking Service”](#). For general information about plugin services, see [Section 27.3, “MySQL Services for Plugins”](#).

Source files that use the locking service should include this header file:

```
#include <mysql/service_locking.h>
```

To acquire one or more locks, call this function:

```
int mysql_acquire_locking_service_locks(MYSQL_THD opaque_thd,
                                       const char* lock_namespace,
                                       const char**lock_names,
                                       size_t lock_num,
                                       enum enum_locking_service_lock_type lock_type,
                                       unsigned long lock_timeout);
```

The arguments have these meanings:

- [opaque\\_thd](#): A thread handle. If specified as [NULL](#), the handle for the current thread is used.
- [lock\\_namespace](#): A null-terminated string that indicates the lock namespace.
- [lock\\_names](#): An array of null-terminated strings that provides the names of the locks to acquire.
- [lock\\_num](#): The number of names in the [lock\\_names](#) array.
- [lock\\_type](#): The lock mode, either [LOCKING\\_SERVICE\\_READ](#) or [LOCKING\\_SERVICE\\_WRITE](#) to acquire read locks or write locks, respectively.
- [lock\\_timeout](#): An integer number of seconds to wait to acquire the locks before giving up.

To release locks acquired for a given namespace, call this function:

```
int mysql_release_locking_service_locks(MYSQL_THD opaque_thd,
                                       const char* lock_namespace);
```

The arguments have these meanings:

- `opaque_thd`: A thread handle. If specified as `NULL`, the handle for the current thread is used.
- `lock_namespace`: A null-terminated string that indicates the lock namespace.

Locks acquired or waited for by the locking service can be monitored at the SQL level using the Performance Schema. For details, see [Locking Service Monitoring](#).

### 27.3.1.2 The Locking Service UDF Interface

This section describes how to use the locking service user-defined function (UDF) interface. To use the C language interface instead, see [Section 27.3.1.1, “The Locking Service C Interface”](#). For general characteristics of the locking service interface, see [Section 27.3.1, “The Locking Service”](#). For general information about user-defined functions, see [Section 27.4.2, “Adding a New User-Defined Function”](#).

#### Installing or Uninstalling the UDF Locking Interface

The locking service routines described in [Section 27.3.1.1, “The Locking Service C Interface”](#) need not be installed because they are built into the server. The same is not true of the user-defined functions (UDFs) that map onto calls to the service routines: The UDFs must be installed before use. This section describes how to do that. For general information about UDF installation, see [Section 27.4.2.5, “UDF Compiling and Installing”](#).

The locking service UDFs are implemented in a plugin library file located in the directory named by the `plugin_dir` system variable. The file base name is `locking_service`. The file name suffix differs per platform (for example, `.so` for Unix and Unix-like systems, `.dll` for Windows).

To install the locking service UDFs, use the `CREATE FUNCTION` statement (adjust the `.so` suffix for your platform as necessary):

```
CREATE FUNCTION service_get_read_locks RETURNS INT SONAME 'locking_service.so';
CREATE FUNCTION service_get_write_locks RETURNS INT SONAME 'locking_service.so';
CREATE FUNCTION service_release_locks RETURNS INT SONAME 'locking_service.so';
```

If the UDFs are used on a master replication server, install them on all slave servers as well to avoid replication problems.

Once installed, the UDFs remain installed until uninstalled. To remove them, use the `DROP FUNCTION` statement:

```
DROP FUNCTION service_get_read_locks;
DROP FUNCTION service_get_write_locks;
DROP FUNCTION service_release_locks;
```

#### Using the UDF Locking Interface

Before using the locking service UDFs, install them according to the instructions provided at [Installing or Uninstalling the UDF Locking Interface](#).

To acquire one or more read locks, call this function:

```
mysql> SELECT service_get_read_locks('mynamespace', 'rlock1', 'rlock2', 10);
+-----+
| service_get_read_locks('mynamespace', 'rlock1', 'rlock2', 10) |
+-----+
|                                                                    1 |
+-----+
```

For the example just shown, the function acquires locks with lock identifiers `(mynamespace, rlock1)` and `(mynamespace, rlock2)`.

```
mysql> SELECT service_get_write_locks('mynamespace', 'wlock1', 'wlock2', 10);
```

| service_get_write_locks('mynamespace', 'wlock1', 'wlock2', 10) |
|--|
| 1  |

To release all locks for a namespace, use this function:

```
mysql> SELECT service_release_locks('mysamespace');
+-----+
| service_release_locks('mysamespace') |
+-----+
| 1 |
+-----+
```

```
mysql> SELECT service_get_read_locks('mysnamespace', '', 10);
ERROR 3131 (42000): Incorrect locking service lock name ''.
```

```
SELECT service_get_write_locks('ns', 'lock1', 'lock1', 'lock1', 0);
SELECT service_get_read_locks('ns', 'lock1', 'lock1', 'lock1', 0);
```

Because the session holds at least one write lock on `(ns, lock1)`, no other session can acquire a lock for it, either read or write. If the session held only read locks for the identifier, other sessions could acquire read locks for it, but not write locks.

```
SELECT service_get_write_locks('ns', 'lock1', 'lock2', 0) FROM t1 WHERE ... ;
```

3995

```
INSERT INTO ... SELECT service_get_write_locks('ns', t1.col_name, 0) FROM t1;
```

These types of statements may have certain adverse effects. For example, if the statement fails part way through and rolls back, locks acquired up to the point of failure will still exist. If the intent is for there to be a correspondence between rows inserted and locks acquired, that intent will not be satisfied. Also, if it is important that locks are granted in a certain order, be aware that result set order may differ depending on which execution plan the optimizer chooses. For these reasons, it may be best to limit applications to a single lock-acquisition call per statement.

## Locking Service Monitoring

The locking service is implemented using the MySQL Server metadata locks framework, so you monitor locking service locks acquired or waited for by examining the Performance Schema `metadata_locks` table.

First, enable the metadata lock instrument:

```
mysql> UPDATE performance_schema.setup_instruments SET ENABLED = 'YES'
-> WHERE NAME = 'wait/lock/metadata/sql/mdl';
```

Then acquire some locks and check the contents of the `metadata_locks` table:

```
mysql> SELECT service_get_write_locks('mynamespace', 'lock1', 0);
+-----+
| service_get_write_locks('mynamespace', 'lock1', 0) |
+-----+
| 1 |
+-----+
mysql> SELECT service_get_read_locks('mynamespace', 'lock2', 0);
+-----+
| service_get_read_locks('mynamespace', 'lock2', 0) |
+-----+
| 1 |
+-----+
mysql> SELECT OBJECT_TYPE, OBJECT_SCHEMA, OBJECT_NAME, LOCK_TYPE, LOCK_STATUS
-> FROM performance_schema.metadata_locks
-> WHERE OBJECT_TYPE = 'LOCKING SERVICE'\G
***** 1. row *****
OBJECT_TYPE: LOCKING SERVICE
OBJECT_SCHEMA: mynamespace
OBJECT_NAME: lock1
LOCK_TYPE: EXCLUSIVE
LOCK_STATUS: GRANTED
***** 2. row *****
OBJECT_TYPE: LOCKING SERVICE
OBJECT_SCHEMA: mynamespace
OBJECT_NAME: lock2
LOCK_TYPE: SHARED
LOCK_STATUS: GRANTED
```

Locking service locks have an `OBJECT_TYPE` value of `LOCKING SERVICE`. This is distinct from, for example, locks acquired with the `GET_LOCK()` function, which have an `OBJECT_TYPE` of `USER LEVEL LOCK`.

The lock namespace, name, and mode appear in the `OBJECT_SCHEMA`, `OBJECT_NAME`, and `LOCK_TYPE` columns. Read and write locks have `LOCK_TYPE` values of `SHARED` and `EXCLUSIVE`, respectively.

The `LOCK_STATUS` value is `GRANTED` for an acquired lock, `PENDING` for a lock that is being waited for. You will see `PENDING` if one session holds a write lock and another session is attempting to acquire a lock having the same identifier.

## Locking Service UDF Interface Reference

The SQL interface to the locking service implements the user-defined functions described in this section. For usage examples, see [Using the UDF Locking Interface](#).

The functions share these characteristics:

- The return value is nonzero for success. Otherwise, an error occurs.
- Namespace and lock names must be non-`NULL`, nonempty, and have a maximum length of 64 characters.
- Timeout values must be integers indicating how many seconds to wait to acquire locks before giving up with an error. If the timeout is 0, there is no waiting and the function produces an error if locks cannot be acquired immediately.

These locking service UDFs are available:

- `service_get_read_locks(namespace, lock_name[, lock_name] ..., timeout)`

Acquires one or more read (shared) locks in the given namespace using the given lock names, timing out with an error if the locks are not acquired within the given timeout value.

- `service_get_write_locks(namespace, lock_name[, lock_name] ..., timeout)`

Acquires one or more write (exclusive) locks in the given namespace using the given lock names, timing out with an error if the locks are not acquired within the given timeout value.

- `service_release_locks(namespace)`

For the given namespace, releases all locks that were acquired within the current session using `service_get_read_locks()` and `service_get_write_locks()`.

It is not an error for there to be no locks in the namespace.

## 27.3.2 The Keyring Service

MySQL Server supports a keyring service that enables internal server components and plugins to securely store sensitive information for later retrieval. This section describes how to use the keyring service functions to store, retrieve, and remove keys in the MySQL keyring keystore. An SQL interface to the keyring service functions is also available as a set of user-defined functions (UDFs); see [Section 7.5.4.5, “General-Purpose Keyring Key-Management Functions”](#). For general keyring information, see [Section 7.5.4, “The MySQL Keyring”](#).

The keyring service uses whatever underlying keyring plugin is enabled, if any. If no keyring plugin is enabled, keyring service calls fail.

A “record” in the keystore consists of data (the key itself) and a unique identifier through which the key is accessed. The identifier has two parts:

- `key_id`: The key ID or name. `key_id` values that begin with `mysql_` are reserved by MySQL Server.
- `user_id`: The session effective user ID. If there is no user context, this value can be `NULL`. The value need not actually be a “user”; for example, `InnoDB` uses tablespace IDs to manage keys for tablespaces.

Functions that implement the keyring UDF interface pass the value of `CURRENT_USER()` as the `user_id` value to keyring service functions.

The keyring service functions have these characteristics in common:

- Each function returns 0 for success, 1 for failure.

- The `key_id` and `user_id` arguments form a unique combination indicating which key in the keyring to use.
- The `key_type` argument provides additional information about the key, such as its encryption method or intended use.
- Keyring service functions treat key IDs, user names, types, and values as binary strings, so comparisons are case sensitive. For example, IDs of `MyKey` and `mykey` refer to different keys.

These keyring service functions are available:

- `my_key_fetch()`

Deobfuscates and retrieves a key from the keyring, along with its type. The function allocates the memory for the buffers used to store the returned key and key type. The caller should zero or obfuscate the memory when it is no longer needed, then free it.

Syntax:

```
my_bool my_key_fetch(const char *key_id, const char **key_type,
                    const char* user_id, void **key, size_t *key_len)
```

Arguments:

- `key_id`, `user_id`: Null-terminated strings that as a pair form a unique identifier indicating which key to fetch.
- `key_type`: The address of a buffer pointer. The function stores into it a pointer to a null-terminated string that provides additional information about the key (stored when the key was added).
- `key`: The address of a buffer pointer. The function stores into it a pointer to the buffer containing the fetched key data.
- `key_len`: The address of a variable into which the function stores the size in bytes of the `*key` buffer.

Return values:

Returns 0 for success, 1 for failure.

- `my_key_generate()`

Generates a new random key of a given type and length and stores it in the keyring. The key has a length of `key_len` and is associated with the identifier formed from `key_id` and `user_id`. The type and length values must be consistent with the values supported by the underlying keyring plugin. See [Section 7.5.4.4, “Supported Keyring Types”](#).

Syntax:

```
my_bool my_key_generate(const char *key_id, const char *key_type,
                       const char *user_id, size_t key_len)
```

Arguments:

- `key_id`, `user_id`: Null-terminated strings that as a pair form a unique identifier for the key to be generated.
- `key_type`: A null-terminated string that provides additional information about the key.
- `key_len`: The size in bytes of the key to be generated.

Return values:

Returns 0 for success, 1 for failure.

- `my_key_remove()`

Removes a key from the keyring.

Syntax:

```
my_bool my_key_remove(const char *key_id, const char* user_id)
```

Arguments:

- `key_id`, `user_id`: Null-terminated strings that as a pair form a unique identifier for the key to be removed.

Return values:

Returns 0 for success, 1 for failure.

- `my_key_store()`

Obfuscates and stores a key in the keyring.

Syntax:

```
my_bool my_key_store(const char *key_id, const char *key_type,  
                    const char* user_id, void *key, size_t key_len)
```

Arguments:

- `key_id`, `user_id`: Null-terminated strings that as a pair form a unique identifier for the key to be stored.
- `key_type`: A null-terminated string that provides additional information about the key.
- `key`: The buffer containing the key data to be stored.
- `key_len`: The size in bytes of the `key` buffer.

Return values:

Returns 0 for success, 1 for failure.

## 27.4 Adding New Functions to MySQL

There are three ways to add new functions to MySQL:

- You can add functions through the user-defined function (UDF) interface. User-defined functions are compiled as library files and then added to and removed from the server dynamically using the `CREATE FUNCTION` and `DROP FUNCTION` statements. See [Section 14.7.3.1, “CREATE FUNCTION Syntax for User-Defined Functions”](#).
- You can add functions as native (built-in) MySQL functions. Native functions are compiled into the `mysqld` server and become available on a permanent basis.
- Another way to add functions is by creating stored functions. These are written using SQL statements rather than by compiling object code. The syntax for writing stored functions is not covered here. See [Section 22.2, “Using Stored Routines \(Procedures and Functions\)”](#).

Each method of creating compiled functions has advantages and disadvantages:

- If you write user-defined functions, you must install object files in addition to the server itself. If you compile your function into the server, you need not do that.
- Native functions require you to modify a source distribution. UDFs do not. You can add UDFs to a binary MySQL distribution. No access to MySQL source is necessary.
- If you upgrade your MySQL distribution, you can continue to use your previously installed UDFs, unless you upgrade to a newer version for which the UDF interface changes. For native functions, you must repeat your modifications each time you upgrade.

Whichever method you use to add new functions, they can be invoked in SQL statements just like native functions such as `ABS()` or `SOUNDEX()`.

See [Section 10.2.4, “Function Name Parsing and Resolution”](#), for the rules describing how the server interprets references to different kinds of functions.

The following sections describe features of the UDF interface, provide instructions for writing UDFs, discuss security precautions that MySQL takes to prevent UDF misuse, and describe how to add native MySQL functions.

For example source code that illustrates how to write UDFs, take a look at the `sql/udf_example.cc` file that is provided in MySQL source distributions.

## 27.4.1 Features of the User-Defined Function Interface

The MySQL interface for user-defined functions provides the following features and capabilities:

- Functions can return string, integer, or real values and can accept arguments of those same types.
- You can define simple functions that operate on a single row at a time, or aggregate functions that operate on groups of rows.
- Information is provided to functions that enables them to check the number, types, and names of the arguments passed to them.
- You can tell MySQL to coerce arguments to a given type before passing them to a function.
- You can indicate that a function returns `NULL` or that an error occurred.

## 27.4.2 Adding a New User-Defined Function

For the UDF mechanism to work, functions must be written in C or C++ and your operating system must support dynamic loading. MySQL source distributions include a file `sql/udf_example.cc` that defines five UDF functions. Consult this file to see how UDF calling conventions work. The `include/mysql_com.h` header file defines UDF-related symbols and data structures, although you need not include this header file directly; it is included by `mysql.h`.

A UDF contains code that becomes part of the running server, so when you write a UDF, you are bound by any and all constraints that apply to writing server code. For example, you may have problems if you attempt to use functions from the `libstdc++` library. These constraints may change in future versions of the server, so it is possible that server upgrades will require revisions to UDFs that were originally written for older servers. For information about these constraints, see [Section 2.9.4, “MySQL Source-Configuration Options”](#), and [Section 2.9.5, “Dealing with Problems Compiling MySQL”](#).

To be able to use UDFs, you must link `mysqld` dynamically. If you want to use a UDF that needs to access symbols from `mysqld` (for example, the `metaphone` function in `sql/udf_example.cc` uses `default_charset_info`), you must link the program with `-rdynamic` (see `man dlopen`).

For each function that you want to use in SQL statements, you should define corresponding C (or C++) functions. In the following discussion, the name “xxx” is used for an example function name. To

distinguish between SQL and C/C++ usage, `XXX()` (uppercase) indicates an SQL function call, and `xxx()` (lowercase) indicates a C/C++ function call.

#### Note

When using C++ you can encapsulate your C functions within:

```
extern "C" { ... }
```

This ensures that your C++ function names remain readable in the completed UDF.

The following list describes the C/C++ functions that you write to implement the interface for a function named `XXX()`. The main function, `xxx()`, is required. In addition, a UDF requires at least one of the other functions described here, for reasons discussed in [Section 27.4.2.6, “UDF Security Precautions”](#).

- `xxx()`

The main function. This is where the function result is computed. The correspondence between the SQL function data type and the return type of your C/C++ function is shown here.

| SQL Type             | C/C++ Type             |
|----------------------|------------------------|
| <code>STRING</code>  | <code>char *</code>    |
| <code>INTEGER</code> | <code>long long</code> |
| <code>REAL</code>    | <code>double</code>    |

It is also possible to declare a `DECIMAL` function, but currently the value is returned as a string, so you should write the UDF as though it were a `STRING` function. `ROW` functions are not implemented.

- `xxx_init()`

The initialization function for `xxx()`. If present, it can be used for the following purposes:

- To check the number of arguments to `xxx()`.
- To verify that the arguments are of a required type or, alternatively, to tell MySQL to coerce arguments to the required types when the main function is called.
- To allocate any memory required by the main function.
- To specify the maximum length of the result.
- To specify (for `REAL` functions) the maximum number of decimal places in the result.
- To specify whether the result can be `NULL`.

- `xxx_deinit()`

The deinitialization function for `xxx()`. If present, it should deallocate any memory allocated by the initialization function.

When an SQL statement invokes `xxx()`, MySQL calls the initialization function `xxx_init()` to let it perform any required setup, such as argument checking or memory allocation. If `xxx_init()` returns an error, MySQL aborts the SQL statement with an error message and does not call the main or deinitialization functions. Otherwise, MySQL calls the main function `xxx()` once for each row. After all rows have been processed, MySQL calls the deinitialization function `xxx_deinit()` so that it can perform any required cleanup.

For aggregate functions that work like `SUM()`, you must also provide the following functions:

- `xxx_clear()`

Reset the current aggregate value but do not insert the argument as the initial aggregate value for a new group.

- `xxx_add()`

Add the argument to the current aggregate value.

MySQL handles aggregate UDFs as follows:

1. Call `xxx_init()` to let the aggregate function allocate any memory it needs for storing results.
2. Sort the table according to the `GROUP BY` expression.
3. Call `xxx_clear()` for the first row in each new group.
4. Call `xxx_add()` for each row that belongs in the same group.
5. Call `xxx()` to get the result for the aggregate when the group changes or after the last row has been processed.
6. Repeat steps 3 to 5 until all rows has been processed
7. Call `xxx_deinit()` to let the UDF free any memory it has allocated.

All functions must be thread-safe. This includes not just the main function, but the initialization and deinitialization functions as well, and also the additional functions required by aggregate functions. A consequence of this requirement is that you are not permitted to allocate any global or static variables that change! If you need memory, you should allocate it in `xxx_init()` and free it in `xxx_deinit()`.

### 27.4.2.1 UDF Calling Sequences for Simple Functions

This section describes the different functions that you need to define when you create a simple UDF. [Section 27.4.2, “Adding a New User-Defined Function”](#), describes the order in which MySQL calls these functions.

The main `xxx()` function should be declared as shown in this section. Note that the return type and parameters differ, depending on whether you declare the SQL function `xxx()` to return `STRING`, `INTEGER`, or `REAL` in the `CREATE FUNCTION` statement:

For `STRING` functions:

```
char *xxx(UDF_INIT *initid, UDF_ARGS *args,
          char *result, unsigned long *length,
          char *is_null, char *error);
```

For `INTEGER` functions:

```
long long xxx(UDF_INIT *initid, UDF_ARGS *args,
              char *is_null, char *error);
```

For `REAL` functions:

```
double xxx(UDF_INIT *initid, UDF_ARGS *args,
           char *is_null, char *error);
```

`DECIMAL` functions return string values and should be declared the same way as `STRING` functions. `ROW` functions are not implemented.

The initialization and deinitialization functions are declared like this:

```
my_bool xxx_init(UDF_INIT *initid, UDF_ARGS *args, char *message);

void xxx_deinit(UDF_INIT *initid);
```

The `initid` parameter is passed to all three functions. It points to a `UDF_INIT` structure that is used to communicate information between functions. The `UDF_INIT` structure members follow. The initialization function should fill in any members that it wishes to change. (To use the default for a member, leave it unchanged.)

- `my_bool maybe_null`

`xxx_init()` should set `maybe_null` to 1 if `xxx()` can return `NULL`. The default value is 1 if any of the arguments are declared `maybe_null`.

- `unsigned int decimals`

The number of decimal digits to the right of the decimal point. The default value is the maximum number of decimal digits in the arguments passed to the main function. For example, if the function is passed 1.34, 1.345, and 1.3, the default would be 3, because 1.345 has 3 decimal digits.

For arguments that have no fixed number of decimals, the `decimals` value is set to 31, which is 1 more than the maximum number of decimals permitted for the `DECIMAL`, `FLOAT`, and `DOUBLE` data types. This value is available as the constant `NOT_FIXED_DEC` in the `mysql_com.h` header file.

A `decimals` value of 31 is used for arguments in cases such as a `FLOAT` or `DOUBLE` column declared without an explicit number of decimals (for example, `FLOAT` rather than `FLOAT(10,3)`) and for floating-point constants such as `1345E-3`. It is also used for string and other nonnumber arguments that might be converted within the function to numeric form.

The value to which the `decimals` member is initialized is only a default. It can be changed within the function to reflect the actual calculation performed. The default is determined such that the largest number of decimals of the arguments is used. If the number of decimals is `NOT_FIXED_DEC` for even one of the arguments, that is the value used for `decimals`.

- `unsigned int max_length`

The maximum length of the result. The default `max_length` value differs depending on the result type of the function. For string functions, the default is the length of the longest argument. For integer functions, the default is 21 digits. For real functions, the default is 13 plus the number of decimal digits indicated by `initid->decimals`. (For numeric functions, the length includes any sign or decimal point characters.)

If you want to return a blob value, you can set `max_length` to 65KB or 16MB. This memory is not allocated, but the value is used to decide which data type to use if there is a need to temporarily store the data.

- `char *ptr`

A pointer that the function can use for its own purposes. For example, functions can use `initid->ptr` to communicate allocated memory among themselves. `xxx_init()` should allocate the memory and assign it to this pointer:

```
initid->ptr = allocated_memory;
```

In `xxx()` and `xxx_deinit()`, refer to `initid->ptr` to use or deallocate the memory.

- `my_bool const_item`

`xxx_init()` should set `const_item` to 1 if `xxx()` always returns the same value and to 0 otherwise.

### 27.4.2.2 UDF Calling Sequences for Aggregate Functions

This section describes the different functions that you need to define when you create an aggregate UDF. [Section 27.4.2, “Adding a New User-Defined Function”](#), describes the order in which MySQL calls these functions.

- `xxx_reset()`

This function is called when MySQL finds the first row in a new group. It should reset any internal summary variables and then use the given `UDF_ARGS` argument as the first value in your internal summary value for the group. Declare `xxx_reset()` as follows:

```
void xxx_reset(UDF_INIT *initid, UDF_ARGS *args,
               char *is_null, char *error);
```

`xxx_reset()` is not needed or used in MySQL 5.7, in which the UDF interface uses `xxx_clear()` instead. However, you can define both `xxx_reset()` and `xxx_clear()` if you want to have your UDF work with older versions of the server. (If you do include both functions, the `xxx_reset()` function in many cases can be implemented internally by calling `xxx_clear()` to reset all variables, and then calling `xxx_add()` to add the `UDF_ARGS` argument as the first value in the group.)

- `xxx_clear()`

This function is called when MySQL needs to reset the summary results. It is called at the beginning for each new group but can also be called to reset the values for a query where there were no matching rows. Declare `xxx_clear()` as follows:

```
void xxx_clear(UDF_INIT *initid, char *is_null, char *error);
```

`is_null` is set to point to `CHAR(0)` before calling `xxx_clear()`.

If something went wrong, you can store a value in the variable to which the `error` argument points. `error` points to a single-byte variable, not to a string buffer.

`xxx_clear()` is required by MySQL 5.7.

- `xxx_add()`

This function is called for all rows that belong to the same group. You should use it to add the value in the `UDF_ARGS` argument to your internal summary variable.

```
void xxx_add(UDF_INIT *initid, UDF_ARGS *args,
             char *is_null, char *error);
```

The `xxx()` function for an aggregate UDF should be declared the same way as for a nonaggregate UDF. See [Section 27.4.2.1, “UDF Calling Sequences for Simple Functions”](#).

For an aggregate UDF, MySQL calls the `xxx()` function after all rows in the group have been processed. You should normally never access its `UDF_ARGS` argument here but instead return a value based on your internal summary variables.

Return value handling in `xxx()` should be done the same way as for a nonaggregate UDF. See [Section 27.4.2.4, “UDF Return Values and Error Handling”](#).

The `xxx_reset()` and `xxx_add()` functions handle their `UDF_ARGS` argument the same way as functions for nonaggregate UDFs. See [Section 27.4.2.3, “UDF Argument Processing”](#).

The pointer arguments to `is_null` and `error` are the same for all calls to `xxx_reset()`, `xxx_clear()`, `xxx_add()` and `xxx()`. You can use this to remember that you got an error or whether the `xxx()` function should return `NULL`. You should not store a string into `*error`! `error` points to a single-byte variable, not to a string buffer.

`*is_null` is reset for each group (before calling `xxx_clear()`). `*error` is never reset.

If `*is_null` or `*error` are set when `xxx()` returns, MySQL returns `NULL` as the result for the group function.

### 27.4.2.3 UDF Argument Processing

The `args` parameter points to a `UDF_ARGS` structure that has the members listed here:

- `unsigned int arg_count`

The number of arguments. Check this value in the initialization function if you require your function to be called with a particular number of arguments. For example:

```
if (args->arg_count != 2)
{
    strcpy(message, "XXX() requires two arguments");
    return 1;
}
```

For other `UDF_ARGS` member values that are arrays, array references are zero-based. That is, refer to array members using index values from 0 to `args->arg_count - 1`.

- `enum Item_result *arg_type`

A pointer to an array containing the types for each argument. The possible type values are `STRING_RESULT`, `INT_RESULT`, `REAL_RESULT`, and `DECIMAL_RESULT`.

To make sure that arguments are of a given type and return an error if they are not, check the `arg_type` array in the initialization function. For example:

```
if (args->arg_type[0] != STRING_RESULT ||
    args->arg_type[1] != INT_RESULT)
{
    strcpy(message, "XXX() requires a string and an integer");
    return 1;
}
```

Arguments of type `DECIMAL_RESULT` are passed as strings, so you should handle them the same way as `STRING_RESULT` values.

As an alternative to requiring your function's arguments to be of particular types, you can use the initialization function to set the `arg_type` elements to the types you want. This causes MySQL to coerce arguments to those types for each call to `xxx()`. For example, to specify that the first two arguments should be coerced to string and integer, respectively, do this in `xxx_init()`:

```
args->arg_type[0] = STRING_RESULT;
args->arg_type[1] = INT_RESULT;
```

Exact-value decimal arguments such as `1.3` or `DECIMAL` column values are passed with a type of `DECIMAL_RESULT`. However, the values are passed as strings. If you want to receive a number, use the initialization function to specify that the argument should be coerced to a `REAL_RESULT` value:

```
args->arg_type[2] = REAL_RESULT;
```

- `char **args`

`args->args` communicates information to the initialization function about the general nature of the arguments passed to your function. For a constant argument `i`, `args->args[i]` points to the argument value. (See later for instructions on how to access the value properly.) For a nonconstant argument, `args->args[i]` is `0`. A constant argument is an expression that uses only constants,

such as `3` or `4*7-2` or `SIN(3.14)`. A nonconstant argument is an expression that refers to values that may change from row to row, such as column names or functions that are called with nonconstant arguments.

For each invocation of the main function, `args->args` contains the actual arguments that are passed for the row currently being processed.

If argument `i` represents `NULL`, `args->args[i]` is a null pointer (0). If the argument is not `NULL`, functions can refer to it as follows:

- An argument of type `STRING_RESULT` is given as a string pointer plus a length, to enable handling of binary data or data of arbitrary length. The string contents are available as `args->args[i]` and the string length is `args->lengths[i]`. Do not assume that the string is null-terminated.
- For an argument of type `INT_RESULT`, you must cast `args->args[i]` to a `long long` value:

```
long long int_val;
int_val = *((long long*) args->args[i]);
```

- For an argument of type `REAL_RESULT`, you must cast `args->args[i]` to a `double` value:

```
double real_val;
real_val = *((double*) args->args[i]);
```

- For an argument of type `DECIMAL_RESULT`, the value is passed as a string and should be handled like a `STRING_RESULT` value.
- `ROW_RESULT` arguments are not implemented.
- `unsigned long *lengths`

For the initialization function, the `lengths` array indicates the maximum string length for each argument. You should not change these. For each invocation of the main function, `lengths` contains the actual lengths of any string arguments that are passed for the row currently being processed. For arguments of types `INT_RESULT` or `REAL_RESULT`, `lengths` still contains the maximum length of the argument (as for the initialization function).

- `char *maybe_null`

For the initialization function, the `maybe_null` array indicates for each argument whether the argument value might be null (0 if no, 1 if yes).

- `char **attributes`

`args->attributes` communicates information about the names of the UDF arguments. For argument `i`, the attribute name is available as a string in `args->attributes[i]` and the attribute length is `args->attribute_lengths[i]`. Do not assume that the string is null-terminated.

By default, the name of a UDF argument is the text of the expression used to specify the argument. For UDFs, an argument may also have an optional `[AS] alias_name` clause, in which case the argument name is `alias_name`. The `attributes` value for each argument thus depends on whether an alias was given.

Suppose that a UDF `my_udf()` is invoked as follows:

```
SELECT my_udf(expr1, expr2 AS alias1, expr3 alias2);
```

In this case, the `attributes` and `attribute_lengths` arrays will have these values:

```
args->attributes[0] = "expr1"
```

```
args->attribute_lengths[0] = 5

args->attributes[1] = "alias1"
args->attribute_lengths[1] = 6

args->attributes[2] = "alias2"
args->attribute_lengths[2] = 6
```

- `unsigned long *attribute_lengths`

The `attribute_lengths` array indicates the length of each argument name.

#### 27.4.2.4 UDF Return Values and Error Handling

The initialization function should return `0` if no error occurred and `1` otherwise. If an error occurs, `xxx_init()` should store a null-terminated error message in the `message` parameter. The message is returned to the client. The message buffer is `MYSQL_ERRMSG_SIZE` characters long, but you should try to keep the message to less than 80 characters so that it fits the width of a standard terminal screen.

The return value of the main function `xxx()` is the function value, for `long` `long` and `double` functions. A string function should return a pointer to the result and set `*length` to the length (in bytes) of the return value. For example:

```
memcpy(result, "result string", 13);
*length = 13;
```

MySQL passes a buffer to the `xxx()` function using the `result` parameter. This buffer is sufficiently long to hold 255 characters, which can be multibyte characters. The `xxx()` function can store the result in this buffer if it fits, in which case the return value should be a pointer to the buffer. If the function stores the result in a different buffer, it should return a pointer to that buffer.

If your string function does not use the supplied buffer (for example, if it needs to return a string longer than 255 characters), you must allocate the space for your own buffer with `malloc()` in your `xxx_init()` function or your `xxx()` function and free it in your `xxx_deinit()` function. You can store the allocated memory in the `ptr` slot in the `UDF_INIT` structure for reuse by future `xxx()` calls. See [Section 27.4.2.1, “UDF Calling Sequences for Simple Functions”](#).

To indicate a return value of `NULL` in the main function, set `*is_null` to `1`:

```
*is_null = 1;
```

To indicate an error return in the main function, set `*error` to `1`:

```
*error = 1;
```

If `xxx()` sets `*error` to `1` for any row, the function value is `NULL` for the current row and for any subsequent rows processed by the statement in which `xxx()` was invoked. (`xxx()` is not even called for subsequent rows.)

#### 27.4.2.5 UDF Compiling and Installing

Files implementing UDFs must be compiled and installed on the host where the server runs. This process is described below for the example UDF file `sql/udf_example.cc` that is included in MySQL source distributions.

If a UDF will be referred to in statements that will be replicated to slave servers, you must ensure that every slave also has the function available. Otherwise, replication will fail on the slaves when they attempt to invoke the function.

The immediately following instructions are for Unix. Instructions for Windows are given later in this section.

The `udf_example.cc` file contains the following functions:

- `metaphon()` returns a metaphon string of the string argument. This is something like a soundex string, but it is more tuned for English.
- `myfunc_double()` returns the sum of the ASCII values of the characters in its arguments, divided by the sum of the length of its arguments.
- `myfunc_int()` returns the sum of the length of its arguments.
- `sequence([const int])` returns a sequence starting from the given number or 1 if no number has been given.
- `lookup()` returns the IP address for a host name.
- `reverse_lookup()` returns the host name for an IP address. The function may be called either with a single string argument of the form '`xxx.xxx.xxx.xxx`' or with four numbers.
- `avgcost()` returns an average cost. This is an aggregate function.

A dynamically loadable file should be compiled as a sharable library file, using a command something like this:

```
shell> gcc -shared -o udf_example.so udf_example.cc
```

If you are using `gcc` with `CMake` (which is how MySQL is configured), you should be able to create `udf_example.so` with a simpler command:

```
shell> make udf_example
```

After you compile a shared object containing UDFs, you must install it and tell MySQL about it. Compiling a shared object from `udf_example.cc` using `gcc` directly produces a file named `udf_example.so`. Copy the shared object to the server's plugin directory and name it `udf_example.so`. This directory is given by the value of the `plugin_dir` system variable.

On some systems, the `ldconfig` program that configures the dynamic linker does not recognize a shared object unless its name begins with `lib`. In this case you should rename a file such as `udf_example.so` to `libudf_example.so`.

On Windows, you can compile user-defined functions by using the following procedure:

1. Obtain a MySQL source distribution. See [Section 2.1.2, "How to Get MySQL"](#).
2. Obtain the `CMake` build utility, if necessary, from <http://www.cmake.org>. (Version 2.6 or later is required).
3. In the source tree, look in the `sql` directory. There are files named `udf_example.def` and `udf_example.cc` there. Copy both files from this directory to your working directory.
4. Create a `CMake` makefile (`CMakeLists.txt`) with these contents:

```
PROJECT(udf_example)

# Path for MySQL include directory
INCLUDE_DIRECTORIES("c:/mysql/include")

ADD_DEFINITIONS("-DHAVE_DLOPEN")
ADD_LIBRARY(udf_example MODULE udf_example.cc udf_example.def)
TARGET_LINK_LIBRARIES(udf_example wsock32)
```

5. Create the VC project and solution files:

```
cmake -G "<Generator>"
```

Invoking `cmake --help` shows you a list of valid Generators.

#### 6. Create `udf_example.dll`:

```
devenv udf_example.sln /build Release
```

After the shared library file has been installed, notify `mysqld` about the new functions with the following statements. If library files have a suffix different from `.so` on your system, substitute the correct suffix throughout (for example, `.dll` on Windows).

```
mysql> CREATE FUNCTION metaphon RETURNS STRING SONAME 'udf_example.so';
mysql> CREATE FUNCTION myfunc_double RETURNS REAL SONAME 'udf_example.so';
mysql> CREATE FUNCTION myfunc_int RETURNS INTEGER SONAME 'udf_example.so';
mysql> CREATE FUNCTION sequence RETURNS INTEGER SONAME 'udf_example.so';
mysql> CREATE FUNCTION lookup RETURNS STRING SONAME 'udf_example.so';
mysql> CREATE FUNCTION reverse_lookup
-> RETURNS STRING SONAME 'udf_example.so';
mysql> CREATE AGGREGATE FUNCTION avgcost
-> RETURNS REAL SONAME 'udf_example.so';
```

Once installed, a function remains installed until it is uninstalled.

To delete functions, use `DROP FUNCTION`:

```
mysql> DROP FUNCTION metaphon;
mysql> DROP FUNCTION myfunc_double;
mysql> DROP FUNCTION myfunc_int;
mysql> DROP FUNCTION sequence;
mysql> DROP FUNCTION lookup;
mysql> DROP FUNCTION reverse_lookup;
mysql> DROP FUNCTION avgcost;
```

The `CREATE FUNCTION` and `DROP FUNCTION` statements update the `func` system table in the `mysql` database. The function's name, type and shared library name are saved in the table. You must have the `INSERT` or `DELETE` privilege for the `mysql` database to create or drop functions, respectively.

You should not use `CREATE FUNCTION` to add a function that has previously been created. If you need to reinstall a function, you should remove it with `DROP FUNCTION` and then reinstall it with `CREATE FUNCTION`. You would need to do this, for example, if you recompile a new version of your function, so that `mysqld` gets the new version. Otherwise, the server continues to use the old version.

An active function is one that has been loaded with `CREATE FUNCTION` and not removed with `DROP FUNCTION`. All active functions are reloaded each time the server starts, unless you start `mysqld` with the `--skip-grant-tables` option. In this case, UDF initialization is skipped and UDFs are unavailable.

### 27.4.2.6 UDF Security Precautions

MySQL takes several measures to prevent misuse of user-defined functions.

UDF library files cannot be placed in arbitrary directories. They must be located in the server's plugin directory. This directory is given by the value of the `plugin_dir` system variable.

To use `CREATE FUNCTION` or `DROP FUNCTION`, you must have the `INSERT` or `DELETE` privilege, respectively, for the `mysql` database. This is necessary because those statements add and delete rows from the `mysql.func` table.

UDFs should have at least one symbol defined in addition to the `xxx` symbol that corresponds to the main `xxx()` function. These auxiliary symbols correspond to the `xxx_init()`, `xxx_deinit()`, `xxx_reset()`, `xxx_clear()`, and `xxx_add()` functions. `mysqld` also supports an `--allow-suspicious-udfs` option that controls whether UDFs that have only an `xxx` symbol can be loaded.

By default, the option is off, to prevent attempts at loading functions from shared library files other than those containing legitimate UDFs. If you have older UDFs that contain only the `xxx` symbol and that cannot be recompiled to include an auxiliary symbol, it may be necessary to specify the `--allow-suspicious-udfs` option. Otherwise, you should avoid enabling this capability.

### 27.4.3 Adding a New Native Function

To add a new native MySQL function, use the procedure described here, which requires that you use a source distribution. You cannot add native functions to a binary distribution because it is necessary to modify MySQL source code and compile MySQL from the modified source. If you migrate to another version of MySQL (for example, when a new version is released), you must repeat the procedure with the new version.

If the new native function will be referred to in statements that will be replicated to slave servers, you must ensure that every slave server also has the function available. Otherwise, replication will fail on the slaves when they attempt to invoke the function.

To add a new native function, follow these steps to modify source files in the `sql` directory:

1. Create a subclass for the function in `item_create.cc`:
  - If the function takes a fixed number of arguments, create a subclass of `Create_func_arg0`, `Create_func_arg1`, `Create_func_arg2`, or `Create_func_arg3`, respectively, depending on whether the function takes zero, one, two, or three arguments. For examples, see the `Create_func_uuid`, `Create_func_abs`, `Create_func_pow`, and `Create_func_lpad` classes.
  - If the function takes a variable number of arguments, create a subclass of `Create_native_func`. For an example, see `Create_func_concat`.
2. To provide a name by which the function can be referred to in SQL statements, register the name in `item_create.cc` by adding a line to this array:

```
static Native_func_registry func_array[]
```

You can register several names for the same function. For example, see the lines for `"LCASE"` and `"LOWER"`, which are aliases for `Create_func_lcase`.

3. In `item_func.h`, declare a class inheriting from `Item_num_func` or `Item_str_func`, depending on whether your function returns a number or a string.
4. In `item_func.cc`, add one of the following declarations, depending on whether you are defining a numeric or string function:

```
double    Item_func_newname::val()
longlong Item_func_newname::val_int()
String    *Item_func_newname::Str(String *str)
```

If you inherit your object from any of the standard items (like `Item_num_func`), you probably only have to define one of these functions and let the parent object take care of the other functions. For example, the `Item_str_func` class defines a `val()` function that executes `atof()` on the value returned by `::str()`.

5. If the function is nondeterministic, include the following statement in the item constructor to indicate that function results should not be cached:

```
current_thd->lex->safe_to_cache_query=0;
```

A function is nondeterministic if, given fixed values for its arguments, it can return different results for different invocations.

6. You should probably also define the following object function:

```
void Item_func_newname::fix_length_and_dec()
```

This function should at least calculate `max_length` based on the given arguments. `max_length` is the maximum number of characters the function may return. This function should also set `maybe_null = 0` if the main function cannot return a `NULL` value. The function can check whether any of the function arguments can return `NULL` by checking the arguments' `maybe_null` variable. Look at `Item_func_mod::fix_length_and_dec` for a typical example of how to do this.

All functions must be thread-safe. In other words, do not use any global or static variables in the functions without protecting them with mutexes.

If you want to return `NULL` from `::val()`, `::val_int()`, or `::str()`, you should set `null_value` to 1 and return 0.

For `::str()` object functions, there are additional considerations to be aware of:

- The `String *str` argument provides a string buffer that may be used to hold the result. (For more information about the `String` type, take a look at the `sql_string.h` file.)
- The `::str()` function should return the string that holds the result, or `(char*) 0` if the result is `NULL`.
- All current string functions try to avoid allocating any memory unless absolutely necessary!

## 27.5 Debugging and Porting MySQL

This section helps you port MySQL to other operating systems. Do check the list of currently supported operating systems first. See <http://www.mysql.com/support/supportedplatforms/database.html>. If you have created a new port of MySQL, please let us know so that we can list it here and on our Web site (<http://www.mysql.com/>), recommending it to other users.

### Note

If you create a new port of MySQL, you are free to copy and distribute it under the GPL license, but it does not make you a copyright holder of MySQL.

A working POSIX thread library is needed for the server.

To build MySQL from source, your system must satisfy the tool requirements listed at [Section 2.9](#), “Installing MySQL from Source”.

### Important

If you are trying to build MySQL 5.7 with `icc` on the IA64 platform, and need support for MySQL Cluster, you should first ensure that you are using `icc` version 9.1.043 or later. (For details, see Bug #21875.)

If you run into problems with a new port, you may have to do some debugging of MySQL! See [Section 27.5.1](#), “Debugging a MySQL Server”.

### Note

Before you start debugging `mysqld`, first get the test program `mysys/thr_lock` to work. This ensures that your thread installation has even a remote chance to work!

### 27.5.1 Debugging a MySQL Server

If you are using some functionality that is very new in MySQL, you can try to run `mysqld` with the `--skip-new` (which disables all new, potentially unsafe functionality). See [Section B.5.3.3, “What to Do If MySQL Keeps Crashing”](#).

If `mysqld` does not want to start, verify that you have no `my.cnf` files that interfere with your setup! You can check your `my.cnf` arguments with `mysqld --print-defaults` and avoid using them by starting with `mysqld --no-defaults ....`

If `mysqld` starts to eat up CPU or memory or if it “hangs,” you can use `mysqladmin processlist status` to find out if someone is executing a query that takes a long time. It may be a good idea to run `mysqladmin -i10 processlist status` in some window if you are experiencing performance problems or problems when new clients cannot connect.

The command `mysqladmin debug` dumps some information about locks in use, used memory and query usage to the MySQL log file. This may help solve some problems. This command also provides some useful information even if you have not compiled MySQL for debugging!

If the problem is that some tables are getting slower and slower you should try to optimize the table with `OPTIMIZE TABLE` or `myisamchk`. See [Chapter 6, MySQL Server Administration](#). You should also check the slow queries with `EXPLAIN`.

You should also read the OS-specific section in this manual for problems that may be unique to your environment. See [Section 2.1, “General Installation Guidance”](#).

### 27.5.1.1 Compiling MySQL for Debugging

If you have some very specific problem, you can always try to debug MySQL. To do this you must configure MySQL with the `-DWITH_DEBUG=1` option. You can check whether MySQL was compiled with debugging by doing: `mysqld --help`. If the `--debug` flag is listed with the options then you have debugging enabled. `mysqladmin ver` also lists the `mysqld` version as `mysql ... --debug` in this case.

If `mysqld` stops crashing when you configure it with the `-DWITH_DEBUG=1` CMake option, you probably have found a compiler bug or a timing bug within MySQL. In this case, you can try to add `-g` using the `CMAKE_C_FLAGS` and `CMAKE_CXX_FLAGS` CMake options and not use `-DWITH_DEBUG=1`. If `mysqld` dies, you can at least attach to it with `gdb` or use `gdb` on the core file to find out what happened.

When you configure MySQL for debugging you automatically enable a lot of extra safety check functions that monitor the health of `mysqld`. If they find something “unexpected,” an entry is written to `stderr`, which `mysqld_safe` directs to the error log! This also means that if you are having some unexpected problems with MySQL and are using a source distribution, the first thing you should do is to configure MySQL for debugging! (The second thing is to send mail to a MySQL mailing list and ask for help. See [Section 1.6.1, “MySQL Mailing Lists”](#). If you believe that you have found a bug, please use the instructions at [Section 1.7, “How to Report Bugs or Problems”](#)).

### 27.5.1.2 Creating Trace Files

If the `mysqld` server does not start or it crashes easily, you can try to create a trace file to find the problem.

To do this, you must have a `mysqld` that has been compiled with debugging support. You can check this by executing `mysqld -V`. If the version number ends with `-debug`, it is compiled with support for trace files. (On Windows, the debugging server is named `mysqld-debug` rather than `mysqld`.)

Start the `mysqld` server with a trace log in `/tmp/mysqld.trace` on Unix or `\mysqld.trace` on Windows:

```
shell> mysqld --debug
```

On Windows, you should also use the `--standalone` flag to not start `mysqld` as a service. In a console window, use this command:

```
C:\> mysqld-debug --debug --standalone
```

After this, you can use the `mysql.exe` command-line tool in a second console window to reproduce the problem. You can stop the `mysqld` server with `mysqladmin shutdown`.

The trace file can become **very large**! To generate a smaller trace file, you can use debugging options something like this:

```
mysqld --debug=d,info,error,query,general,where:0,/tmp/mysqld.trace
```

This only prints information with the most interesting tags to the trace file.

If you make a bug report about this, please only send the lines from the trace file to the appropriate mailing list where something seems to go wrong! If you cannot locate the wrong place, you can open a bug report and upload the trace file to the report, so that a MySQL developer can take a look at it. For instructions, see [Section 1.7, “How to Report Bugs or Problems”](#).

The trace file is made with the **DEBUG** package by Fred Fish. See [Section 27.5.3, “The DEBUG Package”](#).

### 27.5.1.3 Using WER with PDB to create a Windows crashdump

Program Database files (extension `pdb`) are included in the **ZIP Archive Debug Binaries & Test Suite** distribution of MySQL. These files provide information for debugging your MySQL installation in the event of a problem. This is a separate download from the standard MSI or Zip file.

#### Note

As of MySQL 5.7.6, the PDB files are available in a separate file labeled "ZIP Archive Debug Binaries & Test Suite".

The PDB file contains more detailed information about `mysqld` and other tools that enables more detailed trace and dump files to be created. You can use these with `WinDbg` or Visual Studio to debug `mysqld`.

#### Note

The older *Dr. Watson* debugging tool was removed in Microsoft Vista, with `WinDbg` being a common alternative.

For more information on PDB files, see [Microsoft Knowledge Base Article 121366](#). For more information on the debugging options available, see [Debugging Tools for Windows](#).

To use `WinDbg`, either install the full Windows Driver Kit (WDK) or install the standalone version.

#### Important

The `.exe` and `.pdb` files must be an exact match (both version number and MySQL server edition) or `WinDBG` will complain while attempting to load the symbols.

1. To generate a minidump `mysqld.dmp`, enable the `core-file` option under the `[mysqld]` section in `my.ini`. Restart the MySQL server after making these changes.
2. Create a directory to store the generated files, such as `c:\symbols`
3. Determine the path to your `windbg.exe` executable using the Find GUI or from the command line, for example: `dir /s /b windbg.exe` -- a common default is `C:\Program Files\Debugging Tools for Windows (x64)\windbg.exe`

4. Launch `windbg.exe` giving it the paths to `mysqld-debug.exe`, `mysqld.pdb`, `mysqld.dmp`, and the source code. Alternatively, pass in each path from the WinDbg GUI. For example:

```
windbg.exe -i "C:\mysql-5.7.18-winx64\bin\" ^
-z "C:\mysql-5.7.18-winx64\data\mysqld.dmp" ^
-srcpath "E:\ade\mysql_archives\5.7\5.7.18\mysql-5.7.18" ^
-y "C:\mysql-5.7.18-winx64\bin;SRV*c:\symbols*http://msdl.microsoft.com/download/symbols" ^
-v -n -c "!analyze -vvvvv"
```

#### Note

The ^ character and newline are removed by the Windows command line processor, so be sure the spaces remain intact.

### 27.5.1.4 Debugging mysqld under gdb

On most systems you can also start `mysqld` from `gdb` to get more information if `mysqld` crashes.

With some older `gdb` versions on Linux you must use `run --one-thread` if you want to be able to debug `mysqld` threads. In this case, you can only have one thread active at a time. It is best to upgrade to `gdb` 5.1 because thread debugging works much better with this version!

NPTL threads (the new thread library on Linux) may cause problems while running `mysqld` under `gdb`. Some symptoms are:

- `mysqld` hangs during startup (before it writes `ready for connections`).
- `mysqld` crashes during a `pthread_mutex_lock()` or `pthread_mutex_unlock()` call.

In this case, you should set the following environment variable in the shell before starting `gdb`:

```
LD_ASSUME_KERNEL=2.4.1
export LD_ASSUME_KERNEL
```

When running `mysqld` under `gdb`, you should disable the stack trace with `--skip-stack-trace` to be able to catch segfaults within `gdb`.

Use the `--gdb` option to `mysqld` to install an interrupt handler for `SIGINT` (needed to stop `mysqld` with `^C` to set breakpoints) and disable stack tracing and core file handling.

It is very hard to debug MySQL under `gdb` if you do a lot of new connections the whole time as `gdb` does not free the memory for old threads. You can avoid this problem by starting `mysqld` with `thread_cache_size` set to a value equal to `max_connections + 1`. In most cases just using `--thread_cache_size=5` helps a lot!

If you want to get a core dump on Linux if `mysqld` dies with a `SIGSEGV` signal, you can start `mysqld` with the `--core-file` option. This core file can be used to make a backtrace that may help you find out why `mysqld` died:

```
shell> gdb mysqld core
gdb> backtrace full
gdb> quit
```

See [Section B.5.3.3, "What to Do If MySQL Keeps Crashing"](#).

If you are using `gdb` 4.17.x or above on Linux, you should install a `.gdb` file, with the following information, in your current directory:

```
set print sevenbit off
handle SIGUSR1 nostop noprint
handle SIGUSR2 nostop noprint
handle SIGWAITING nostop noprint
handle SIGLWP nostop noprint
handle SIGPIPE nostop
handle SIGALRM nostop
handle SIGHUP nostop
handle SIGTERM nostop noprint
```

If you have problems debugging threads with `gdb`, you should download `gdb 5.x` and try this instead. The new `gdb` version has very improved thread handling!

Here is an example how to debug `mysqld`:

```
shell> gdb /usr/local/libexec/mysqld
gdb> run
...
backtrace full # Do this when mysqld crashes
```

Include the preceding output in a bug report, which you can file using the instructions in [Section 1.7, “How to Report Bugs or Problems”](#).

If `mysqld` hangs, you can try to use some system tools like `strace` or `/usr/proc/bin/pstack` to examine where `mysqld` has hung.

```
strace /tmp/log libexec/mysqld
```

If you are using the Perl `DBI` interface, you can turn on debugging information by using the `trace` method or by setting the `DBI_TRACE` environment variable.

### 27.5.1.5 Using a Stack Trace

On some operating systems, the error log contains a stack trace if `mysqld` dies unexpectedly. You can use this to find out where (and maybe why) `mysqld` died. See [Section 6.4.2, “The Error Log”](#). To get a stack trace, you must not compile `mysqld` with the `-fomit-frame-pointer` option to `gcc`. See [Section 27.5.1.1, “Compiling MySQL for Debugging”](#).

A stack trace in the error log looks something like this:

```
mysqld got signal 11;
Attempting backtrace. You can use the following information
to find out where mysqld died. If you see no messages after
this, something went terribly wrong...

stack_bottom = 0x41fd0110 thread_stack 0x40000
mysqld(my_print_stacktrace+0x32)[0x9da402]
mysqld(handle_segfault+0x28a)[0x6648e9]
/lib/libpthread.so.0[0x7f1a5af000f0]
/lib/libc.so.6(strcmp+0x2)[0x7f1a5a10f0f2]
mysqld(_Z21check_change_passwordP3THDPKcS2_Pcj+0x7c)[0x7412cb]
mysqld(_ZN16set_var_password5checkEP3THD+0xd0)[0x688354]
mysqld(_Z17sql_set_variablesP3THDP4ListI12set_var_baseE+0x68)[0x688494]
mysqld(_Z21mysql_execute_commandP3THD+0x41a0)[0x67a170]
mysqld(_Z11mysql_parseP3THDPKcjPS2_+0x282)[0x67f0ad]
mysqld(_Z16dispatch_command19enum_server_commandP3THDPcj+0xbb7)[0x67fdf8]
mysqld(_Z10do_commandP3THD+0x24d)[0x6811b6]
mysqld(handle_one_connection+0x11c)[0x66e05e]
```

If resolution of function names for the trace fails, the trace contains less information:

```
mysqld got signal 11;
```

```
Attempting backtrace. You can use the following information
to find out where mysqld died. If you see no messages after
this, something went terribly wrong...
```

```
stack_bottom = 0x41fd0110 thread_stack 0x40000
[0x9da402]
[0x6648e9]
[0x7f1a5af000f0]
[0x7f1a5a10f0f2]
[0x7412cb]
[0x688354]
[0x688494]
[0x67a170]
[0x67f0ad]
[0x67fdf8]
[0x6811b6]
[0x66e05e]
```

In the latter case, you can use the `resolve_stack_dump` utility to determine where `mysqld` died by using the following procedure:

1. Copy the numbers from the stack trace to a file, for example `mysqld.stack`. The numbers should not include the surrounding square brackets:

```
0x9da402
0x6648e9
0x7f1a5af000f0
0x7f1a5a10f0f2
0x7412cb
0x688354
0x688494
0x67a170
0x67f0ad
0x67fdf8
0x6811b6
0x66e05e
```

2. Make a symbol file for the `mysqld` server:

```
shell> nm -n libexec/mysqld > /tmp/mysqld.sym
```

If `mysqld` is not linked statically, use the following command instead:

```
shell> nm -D -n libexec/mysqld > /tmp/mysqld.sym
```

If you want to decode C++ symbols, use the `--demangle`, if available, to `nm`. If your version of `nm` does not have this option, you will need to use the `c++filt` command after the stack dump has been produced to demangle the C++ names.

3. Execute the following command:

```
shell> resolve_stack_dump -s /tmp/mysqld.sym -n mysqld.stack
```

If you were not able to include demangled C++ names in your symbol file, process the `resolve_stack_dump` output using `c++filt`:

```
shell> resolve_stack_dump -s /tmp/mysqld.sym -n mysqld.stack | c++filt
```

This prints out where `mysqld` died. If that does not help you find out why `mysqld` died, you should create a bug report and include the output from the preceding command with the bug report.

However, in most cases it does not help us to have just a stack trace to find the reason for the problem. To be able to locate the bug or provide a workaround, in most cases we need to know the

statement that killed `mysqld` and preferably a test case so that we can repeat the problem! See [Section 1.7, “How to Report Bugs or Problems”](#).

Newer versions of `glibc` stack trace functions also print the address as relative to the object. On `glibc`-based systems (Linux), the trace for a crash within a plugin looks something like:

```
plugin/auth/auth_test_plugin.so(+0x9a6)[0x7ff4d11c29a6]
```

To translate the relative address (`+0x9a6`) into a file name and line number, use this command:

```
shell> addr2line -fie auth_test_plugin.so 0x9a6
auth_test_plugin
mysql-trunk/plugin/auth/test_plugin.c:65
```

The `addr2line` utility is part of the `binutils` package on Linux.

On Solaris, the procedure is similar. The Solaris `printstack()` already prints relative addresses:

```
plugin/auth/auth_test_plugin.so:0x1510
```

To translate, use this command:

```
shell> gaddr2line -fie auth_test_plugin.so 0x1510
mysql-trunk/plugin/auth/test_plugin.c:88
```

Windows already prints the address, function name and line:

```
000007FEF07E10A4 auth_test_plugin.dll!auth_test_plugin()[test_plugin.c:72]
```

### 27.5.1.6 Using Server Logs to Find Causes of Errors in `mysqld`

Note that before starting `mysqld` with the general query log enabled, you should check all your tables with `myisamchk`. See [Chapter 6, MySQL Server Administration](#).

If `mysqld` dies or hangs, you should start `mysqld` with the general query log enabled. See [Section 6.4.3, “The General Query Log”](#). When `mysqld` dies again, you can examine the end of the log file for the query that killed `mysqld`.

If you use the default general query log file, the log is stored in the database directory as `host_name.log`. In most cases it is the last query in the log file that killed `mysqld`, but if possible you should verify this by restarting `mysqld` and executing the found query from the `mysql` command-line tools. If this works, you should also test all complicated queries that did not complete.

You can also try the command `EXPLAIN` on all `SELECT` statements that takes a long time to ensure that `mysqld` is using indexes properly. See [Section 14.8.2, “EXPLAIN Syntax”](#).

You can find the queries that take a long time to execute by starting `mysqld` with the slow query log enabled. See [Section 6.4.5, “The Slow Query Log”](#).

If you find the text `mysqld restarted` in the error log file (normally named `hostname.err`) you probably have found a query that causes `mysqld` to fail. If this happens, you should check all your tables with `myisamchk` (see [Chapter 6, MySQL Server Administration](#)), and test the queries in the MySQL log files to see whether one fails. If you find such a query, try first upgrading to the newest MySQL version. If this does not help and you cannot find anything in the `mysql` mail archive, you should report the bug to a MySQL mailing list. The mailing lists are described at <http://lists.mysql.com/>, which also has links to online list archives.

If you have started `mysqld` with `--myisam-recover-options`, MySQL automatically checks and tries to repair `MyISAM` tables if they are marked as 'not closed properly' or 'crashed'. If this happens, MySQL writes an entry in the `hostname.err` file 'Warning: Checking table ...' which is

followed by `Warning: Repairing table` if the table needs to be repaired. If you get a lot of these errors, without `mysqld` having died unexpectedly just before, then something is wrong and needs to be investigated further. See [Section 6.1.4, “Server Command Options”](#).

When the server detects `MyISAM` table corruption, it writes additional information to the error log, such as the name and line number of the source file, and the list of threads accessing the table. Example: `Got an error from thread_id=1, mi_dynrec.c:368`. This is useful information to include in bug reports.

It is not a good sign if `mysqld` did die unexpectedly, but in this case, you should not investigate the `Checking table...` messages, but instead try to find out why `mysqld` died.

### 27.5.1.7 Making a Test Case If You Experience Table Corruption

The following procedure applies to `MyISAM` tables. For information about steps to take when encountering `InnoDB` table corruption, see [Section 1.7, “How to Report Bugs or Problems”](#).

If you encounter corrupted `MyISAM` tables or if `mysqld` always fails after some update statements, you can test whether the issue is reproducible by doing the following:

1. Stop the MySQL daemon with `mysqladmin shutdown`.
2. Make a backup of the tables to guard against the very unlikely case that the repair does something bad.
3. Check all tables with `myisamchk -s database/*.MYI`. Repair any corrupted tables with `myisamchk -r database/table.MYI`.
4. Make a second backup of the tables.
5. Remove (or move away) any old log files from the MySQL data directory if you need more space.
6. Start `mysqld` with the binary log enabled. If you want to find a statement that crashes `mysqld`, you should start the server with the general query log enabled as well. See [Section 6.4.3, “The General Query Log”](#), and [Section 6.4.4, “The Binary Log”](#).
7. When you have gotten a crashed table, stop the `mysqld` server.
8. Restore the backup.
9. Restart the `mysqld` server *without* the binary log enabled.
10. Re-execute the statements with `mysqlbinlog binary-log-file | mysql`. The binary log is saved in the MySQL database directory with the name `hostname-bin.NNNNNN`.
11. If the tables are corrupted again or you can get `mysqld` to die with the above command, you have found a reproducible bug. FTP the tables and the binary log to our bugs database using the instructions given in [Section 1.7, “How to Report Bugs or Problems”](#). If you are a support customer, you can use the MySQL Customer Support Center (<http://www.mysql.com/support/>) to alert the MySQL team about the problem and have it fixed as soon as possible.

## 27.5.2 Debugging a MySQL Client

To be able to debug a MySQL client with the integrated debug package, you should configure MySQL with `-DWITH_DEBUG=1`. See [Section 2.9.4, “MySQL Source-Configuration Options”](#).

Before running a client, you should set the `MYSQL_DEBUG` environment variable:

```
shell> MYSQL_DEBUG=d:t:O,/tmp/client.trace
shell> export MYSQL_DEBUG
```

This causes clients to generate a trace file in `/tmp/client.trace`.

If you have problems with your own client code, you should attempt to connect to the server and run your query using a client that is known to work. Do this by running `mysql` in debugging mode (assuming that you have compiled MySQL with debugging on):

```
shell> mysql --debug=d:t:o,/tmp/client.trace
```

This provides useful information in case you mail a bug report. See [Section 1.7, “How to Report Bugs or Problems”](#).

If your client crashes at some 'legal' looking code, you should check that your `mysql.h` include file matches your MySQL library file. A very common mistake is to use an old `mysql.h` file from an old MySQL installation with new MySQL library.

### 27.5.3 The DBUG Package

The MySQL server and most MySQL clients are compiled with the DBUG package originally created by Fred Fish. When you have configured MySQL for debugging, this package makes it possible to get a trace file of what the program is doing. See [Section 27.5.1.2, “Creating Trace Files”](#).

This section summarizes the argument values that you can specify in debug options on the command line for MySQL programs that have been built with debugging support. For more information about programming with the DBUG package, see the DBUG manual in the `debug` directory of MySQL source distributions. It's best to use a recent distribution to get the most updated DBUG manual.

The DBUG package can be used by invoking a program with the `--debug[=debug_options]` or `-#[debug_options]` option. If you specify the `--debug` or `-#` option without a `debug_options` value, most MySQL programs use a default value. The server default is `d:t:i:o,/tmp/mysqld.trace` on Unix and `d:t:i:o,\mysqld.trace` on Windows. The effect of this default is:

- `d`: Enable output for all debug macros
- `t`: Trace function calls and exits
- `i`: Add PID to output lines
- `o,/tmp/mysqld.trace, O,\mysqld.trace`: Set the debug output file.

Most client programs use a default `debug_options` value of `d:t:o,/tmp/program_name.trace`, regardless of platform.

Here are some example debug control strings as they might be specified on a shell command line:

```
--debug=d:t
--debug=d:f,main,subr1:F:L:t,20
--debug=d,input,output,files:n
--debug=d:t:i:o,\mysqld.trace
```

For `mysqld`, it is also possible to change DBUG settings at runtime by setting the `debug` system variable. This variable has global and session values:

```
mysql> SET GLOBAL debug = 'debug_options';
mysql> SET SESSION debug = 'debug_options';
```

Changes at runtime require the `SUPER` privilege, even for the session value.

The `debug_options` value is a sequence of colon-separated fields:

```
field_1:field_2:...:field_N
```

Each field within the value consists of a mandatory flag character, optionally preceded by a `+` or `-` character, and optionally followed by a comma-delimited list of modifiers:

```
[+|-]flag[,modifier,modifier,...,modifier]
```

The following table describes the permitted flag characters. Unrecognized flag characters are silently ignored.

| Flag           | Description  |
|----------------|--|
| <code>d</code> | Enable output from <code>DEBUG_XXX</code> macros for the current state. May be followed by a list of keywords, which enables output only for the <code>DEBUG</code> macros with that keyword. An empty list of keywords enables output for all macros.<br><br>In MySQL, common debug macro keywords to enable are <code>enter</code> , <code>exit</code> , <code>error</code> , <code>warning</code> , <code>info</code> , and <code>loop</code> . |
| <code>D</code> | Delay after each debugger output line. The argument is the delay, in tenths of seconds, subject to machine capabilities. For example, <code>D,20</code> specifies a delay of two seconds.  |
| <code>f</code> | Limit debugging, tracing, and profiling to the list of named functions. An empty list enables all functions. The appropriate <code>d</code> or <code>t</code> flags must still be given; this flag only limits their actions if they are enabled.  |
| <code>F</code> | Identify the source file name for each line of debug or trace output.  |
| <code>i</code> | Identify the process with the PID or thread ID for each line of debug or trace output.   |
| <code>L</code> | Identify the source file line number for each line of debug or trace output.   |
| <code>n</code> | Print the current function nesting depth for each line of debug or trace output.   |
| <code>N</code> | Number each line of debug output.  |
| <code>o</code> | Redirect the debugger output stream to the specified file. The default output is <code>stderr</code> .   |
| <code>O</code> | Like <code>o</code> , but the file is really flushed between each write. When needed, the file is closed and reopened between each write.  |
| <code>p</code> | Limit debugger actions to specified processes. A process must be identified with the <code>DEBUG_PROCESS</code> macro and match one in the list for debugger actions to occur.   |
| <code>P</code> | Print the current process name for each line of debug or trace output.   |
| <code>r</code> | When pushing a new state, do not inherit the previous state's function nesting level. Useful when the output is to start at the left margin.   |
| <code>S</code> | Do function <code>_sanity(_file_,_line_)</code> at each debugged function until <code>_sanity()</code> returns something that differs from 0.  |
| <code>t</code> | Enable function call/exit trace lines. May be followed by a list (containing only one modifier) giving a numeric maximum trace level, beyond which no output occurs for either debugging or tracing macros. The default is a compile time option.  |

The leading `+` or `-` character and trailing list of modifiers are used for flag characters such as `d` or `f` that can enable a debug operation for all applicable modifiers or just some of them:

- With no leading `+` or `-`, the flag value is set to exactly the modifier list as given.
- With a leading `+` or `-`, the modifiers in the list are added to or subtracted from the current modifier list.

The following examples show how this works for the `d` flag. An empty `d` list enabled output for all debug macros. A nonempty list enables output only for the macro keywords in the list.

These statements set the `d` value to the modifier list as given:

```
mysql> SET debug = 'd';
mysql> SELECT @@debug;
+-----+
| @@debug |
+-----+
```

```

| d      |
+-----+
mysql> SET debug = 'd,error,warning';
mysql> SELECT @@debug;
+-----+
| @@debug      |
+-----+
| d,error,warning |
+-----+

```

A leading + or - adds to or subtracts from the current `d` value:

```

mysql> SET debug = '+d,loop';
mysql> SELECT @@debug;
+-----+
| @@debug      |
+-----+
| d,error,warning,loop |
+-----+
mysql> SET debug = '-d,error,loop';
mysql> SELECT @@debug;
+-----+
| @@debug      |
+-----+
| d,warning     |
+-----+

```

Adding to “all macros enabled” results in no change:

```

mysql> SET debug = 'd';
mysql> SELECT @@debug;
+-----+
| @@debug      |
+-----+
| d            |
+-----+
mysql> SET debug = '+d,loop';
mysql> SELECT @@debug;
+-----+
| @@debug      |
+-----+
| d            |
+-----+

```

Disabling all enabled macros disables the `d` flag entirely:

```

mysql> SET debug = 'd,error,loop';
mysql> SELECT @@debug;
+-----+
| @@debug      |
+-----+
| d,error,loop  |
+-----+
mysql> SET debug = '-d,error,loop';
mysql> SELECT @@debug;
+-----+
| @@debug      |
+-----+
|              |
+-----+

```

#### Note

Prior to MySQL 5.7.2, the + and - modifiers were not always handled correctly and could leave a flag value in an incorrect state. Verify your `debug`-setting sequence in advance or set it without using + or -.

---

## Chapter 28 MySQL Enterprise Edition

### Table of Contents

|  |      |

| 28.4 MySQL Enterprise Encryption Overview .....  | 4025 |
| 28.5 MySQL Enterprise Audit Overview .....       | 4025 |
| 28.6 MySQL Enterprise Firewall Overview .....    | 4025 |
| 28.7 MySQL Enterprise Thread Pool Overview ..... | 4026 |

MySQL Enterprise Edition is a commercial product. Like MySQL Community Edition, MySQL Enterprise Edition includes MySQL Server, a fully integrated transaction-safe, ACID-compliant database with full commit, rollback, crash-recovery, and row-level locking capabilities. In addition, MySQL Enterprise Edition includes the following components designed to provide monitoring and online backup, as well as improved security and scalability:

The following sections briefly discuss each of these components and indicate where to find more detailed information. To learn more about commercial products, see <http://www.mysql.com/products/>.

- [MySQL Enterprise Monitor](#)
- [MySQL Enterprise Backup](#)
- [MySQL Enterprise Security](#)
- [MySQL Enterprise Encryption](#)
- [MySQL Enterprise Audit](#)
- [MySQL Enterprise Firewall](#)
- [MySQL Enterprise Thread Pool](#)

### 28.1 MySQL Enterprise Monitor Overview

MySQL Enterprise Monitor is an enterprise monitoring system for MySQL that keeps an eye on your MySQL servers, notifies you of potential issues and problems, and advises you how to fix the issues. MySQL Enterprise Monitor can monitor all kinds of configurations, from a single MySQL server that is important to your business, all the way up to a huge farm of MySQL servers powering a busy web site.

The following discussion briefly summarizes the basic components that make up the MySQL Enterprise Monitor product. For more information, see the MySQL Enterprise Monitor manual, available at <http://dev.mysql.com/doc/mysql-monitor/en/>.

MySQL Enterprise Monitor components can be installed in various configurations depending on your database and network topology, to give you the best combination of reliable and responsive monitoring data, with minimal overhead on the database server machines. A typical MySQL Enterprise Monitor installation consists of:

- One or more MySQL servers to monitor. MySQL Enterprise Monitor can monitor both Community and Enterprise MySQL server releases.
- A MySQL Enterprise Monitor Agent for each monitored host.
- A single MySQL Enterprise Service Manager, which collates information from the agents and provides the user interface to the collected data.

MySQL Enterprise Monitor is designed to monitor one or more MySQL servers. The monitoring information is collected by using an agent, *MySQL Enterprise Monitor Agent*. The agent communicates with the hosts and MySQL servers that it monitors, collecting variables, status and health information, and sending this information to the MySQL Enterprise Service Manager.

The information collected by the agent about each MySQL server and host you are monitoring is sent to the *MySQL Enterprise Service Manager*. This server collates all of the information from the agents. As it collates the information sent by the agents, the MySQL Enterprise Service Manager continually tests the collected data, comparing the status of the server to reasonable values. When thresholds are reached, the server can trigger an event (including an alarm and notification) to highlight a potential issue, such as low memory, high CPU usage, or more complex conditions such as insufficient buffer sizes and status information. We call each test, with its associated threshold value, a *rule*.

These rules, and the alarms and notifications, are each known as a *MySQL Enterprise Advisors*. Advisors form a critical part of the MySQL Enterprise Service Manager, as they provide warning information and troubleshooting advice about potential problems.

The MySQL Enterprise Service Manager includes a web server, and you interact with it through any web browser. This interface, the MySQL Enterprise Monitor User Interface, displays all of the information collected by the agents, and lets you view all of your servers and their current status as a group or individually. You control and configure all aspects of the service using the MySQL Enterprise Monitor User Interface.

The information supplied by the MySQL Enterprise Monitor Agent processes also includes statistical and query information, which you can view in the form of graphs. For example, you can view aspects such as server load, query numbers, or index usage information as a graph over time. The graph lets you pinpoint problems or potential issues on your server, and can help diagnose the impact from database or external problems (such as external system or network failure) by examining the data from a specific time interval.

The MySQL Enterprise Monitor Agent can also be configured to collect detailed information about the queries executed on your server, including the row counts and performance times for executing each query. You can correlate the detailed query data with the graphical information to identify which queries were executing when you experienced a particularly high load, index or other issue. The query data is supported by a system called Query Analyzer, and the data can be presented in different ways depending on your needs.

## 28.2 MySQL Enterprise Backup Overview

MySQL Enterprise Backup performs hot backup operations for MySQL databases. The product is architected for efficient and reliable backups of tables created by the InnoDB storage engine. For completeness, it can also back up tables from MyISAM and other storage engines.

The following discussion briefly summarizes MySQL Enterprise Backup. For more information, see the MySQL Enterprise Backup manual, available at <http://dev.mysql.com/doc/mysql-enterprise-backup/en/>.

Hot backups are performed while the database is running and applications are reading and writing to it. This type of backup does not block normal database operations, and it captures even changes that occur while the backup is happening. For these reasons, hot backups are desirable when your database “grows up” -- when the data is large enough that the backup takes significant time, and when your data is important enough to your business that you must capture every last change, without taking your application, web site, or web service offline.

MySQL Enterprise Backup does a hot backup of all tables that use the InnoDB storage engine. For tables using MyISAM or other non-InnoDB storage engines, it does a “warm” backup, where the database continues to run, but those tables cannot be modified while being backed up. For efficient backup operations, you can designate InnoDB as the default storage engine for new tables, or convert existing tables to use the InnoDB storage engine.

## 28.3 MySQL Enterprise Security Overview

MySQL Enterprise Edition provides plugins that implement authentication using external services:

- MySQL Enterprise Edition includes an authentication plugin that enables MySQL Server to use PAM (Pluggable Authentication Modules) to authenticate MySQL users. PAM enables a system to use a standard interface to access various kinds of authentication methods, such as Unix passwords or an LDAP directory. For more information, see [Section 7.5.1.5, “The PAM Authentication Plugin”](#).
- MySQL Enterprise Edition includes an authentication plugin that performs external authentication on Windows, enabling MySQL Server to use native Windows services to authenticate client connections. Users who have logged in to Windows can connect from MySQL client programs to the server based on the information in their environment without specifying an additional password. For more information, see [Section 7.5.1.6, “The Windows Native Authentication Plugin”](#).
- MySQL Enterprise Edition includes a keyring plugin that uses Oracle Key Vault for keyring backend storage. For more information, see [Section 7.5.4, “The MySQL Keyring”](#).

For other related Enterprise security features, see [Section 28.4, “MySQL Enterprise Encryption Overview”](#).

## 28.4 MySQL Enterprise Encryption Overview

MySQL Enterprise Edition includes a set of encryption functions based on the OpenSSL library that expose OpenSSL capabilities at the SQL level. These functions enable Enterprise applications to perform the following operations:

- Implement added data protection using public-key asymmetric cryptography
- Create public and private keys and digital signatures
- Perform asymmetric encryption and decryption
- Use cryptographic hashing for digital signing and data verification and validation

For more information, see [Section 13.18, “MySQL Enterprise Encryption Functions”](#).

For other related Enterprise security features, see [Section 28.3, “MySQL Enterprise Security Overview”](#).

## 28.5 MySQL Enterprise Audit Overview

MySQL Enterprise Edition includes MySQL Enterprise Audit, implemented using a server plugin. MySQL Enterprise Audit uses the open MySQL Audit API to enable standard, policy-based monitoring and logging of connection and query activity executed on specific MySQL servers. Designed to meet the Oracle audit specification, MySQL Enterprise Audit provides an out of box, easy to use auditing and compliance solution for applications that are governed by both internal and external regulatory guidelines.

When installed, the audit plugin enables MySQL Server to produce a log file containing an audit record of server activity. The log contents include when clients connect and disconnect, and what actions they perform while connected, such as which databases and tables they access.

For more information, see [Section 7.5.5, “MySQL Enterprise Audit”](#).

## 28.6 MySQL Enterprise Firewall Overview

MySQL Enterprise Edition includes MySQL Enterprise Firewall, an application-level firewall that enables database administrators to permit or deny SQL statement execution based on matching against whitelists of accepted statement patterns. This helps harden MySQL Server against attacks such as SQL injection or attempts to exploit applications by using them outside of their legitimate query workload characteristics.

Each MySQL account registered with the firewall has its own statement whitelist, enabling protection to be tailored per account. For a given account, the firewall can operate in recording or protecting mode, for training in the accepted statement patterns or protection against unacceptable statements.

For more information, see [Section 7.5.6, “MySQL Enterprise Firewall”](#).

## 28.7 MySQL Enterprise Thread Pool Overview

MySQL Enterprise Edition includes MySQL Enterprise Thread Pool, implemented using a server plugin. The default thread-handling model in MySQL Server executes statements using one thread per client connection. As more clients connect to the server and execute statements, overall performance degrades. In MySQL Enterprise Edition, a thread pool plugin provides an alternative thread-handling model designed to reduce overhead and improve performance. The plugin implements a thread pool that increases server performance by efficiently managing statement execution threads for large numbers of client connections.

For more information, see [Section 6.5.4, “MySQL Enterprise Thread Pool”](#).

---

## Chapter 29 MySQL Workbench

MySQL Workbench provides a graphical tool for working with MySQL servers and databases. MySQL Workbench fully supports MySQL versions 5.1 and above.

The following discussion briefly describes MySQL Workbench capabilities. For more information, see the MySQL Workbench manual, available at <http://dev.mysql.com/doc/workbench/en/>.

MySQL Workbench provides five main areas of functionality:

- **SQL Development:** Enables you to create and manage connections to database servers. As well as enabling you to configure connection parameters, MySQL Workbench provides the capability to execute SQL queries on the database connections using the built-in SQL Editor. This functionality replaces that previously provided by the Query Browser standalone application.
- **Data Modeling:** Enables you to create models of your database schema graphically, reverse and forward engineer between a schema and a live database, and edit all aspects of your database using the comprehensive Table Editor. The Table Editor provides easy-to-use facilities for editing Tables, Columns, Indexes, Triggers, Partitioning, Options, Inserts and Privileges, Routines and Views.
- **Server Administration:** Enables you to create and administer server instances.
- **Data Migration:** Allows you to migrate from Microsoft SQL Server, Sybase ASE, SQLite, SQL Anywhere, PostgreSQL, and other RDBMS tables, objects and data to MySQL. Migration also supports migrating from earlier versions of MySQL to the latest releases.
- **MySQL Enterprise Support:** Support for Enterprise products such as MySQL Enterprise Backup and MySQL Audit.

MySQL Workbench is available in two editions, the Community Edition and the Commercial Edition. The Community Edition is available free of charge. The Commercial Edition provides additional Enterprise features, such as database documentation generation, at low cost.

---

## A.1 MySQL 5.7 FAQ: General

|  |      |
|--|------|
| A.1.1 Which version of MySQL is production-ready (GA)? .....                                 | 4029 |
| A.1.2 What is the state of development (non-GA) versions? .....                              | 4029 |
| A.1.3 Can MySQL 5.7 do subqueries? .....   | 4030 |
| A.1.4 Can MySQL 5.7 perform multiple-table inserts, updates, and deletes? .....              | 4030 |
| A.1.5 Does MySQL 5.7 have a Query Cache? Does it work on Server, Instance or Database? ..... | 4030 |
| A.1.6 Does MySQL 5.7 have Sequences? .....   | 4030 |
| A.1.7 Does MySQL 5.7 have a <code>NOW( )</code> function with fractions of seconds? .....    | 4030 |
| A.1.8 Does MySQL 5.7 work with multi-core processors? .....                                  | 4030 |
| A.1.9 Why do I see multiple processes for <code>mysqld</code> ? .....                        | 4030 |
| A.1.10 Can MySQL 5.7 perform ACID transactions? .....  | 4030 |

### A.1.1. Which version of MySQL is production-ready (GA)?

MySQL 5.7 and MySQL 5.6 are supported for production use.

MySQL 5.7 achieved General Availability (GA) status with MySQL 5.7.9, which was released for production use on 21 October 2015.

MySQL 5.6 achieved General Availability (GA) status with MySQL 5.6.10, which was released for production use on 5 February 2013.

MySQL 5.5 achieved General Availability (GA) status with MySQL 5.5.8, which was released for production use on 3 December 2010. The MySQL 5.5 series is no longer current, but still supported in production.

MySQL 5.1 achieved General Availability (GA) status with MySQL 5.1.30, which was released for production use on 14 November 2008. Active development for MySQL 5.1 has ended.

MySQL 5.0 achieved General Availability (GA) status with MySQL 5.0.15, which was released for production use on 19 October 2005. Active development for MySQL 5.0 has ended.

### A.1.2. What is the state of development (non-GA) versions?

MySQL follows a milestone release model that introduces pre-production-quality features and stabilizes them to release quality (see <http://dev.mysql.com/doc/mysql-development-cycle/en/index.html>). This process then repeats, so releases cycle between pre-production and release quality status. Please check the change logs to identify the status of a given release.

MySQL 5.4 was a development series. Work on this series has ceased.

A successor to MySQL 5.7 is being actively developed using the milestone release methodology described above.

**A.1.3. Can MySQL 5.7 do subqueries?**

Yes. See [Section 14.2.10, “Subquery Syntax”](#).

**A.1.4. Can MySQL 5.7 perform multiple-table inserts, updates, and deletes?**

Yes. For the syntax required to perform multiple-table updates, see [Section 14.2.11, “UPDATE Syntax”](#); for that required to perform multiple-table deletes, see [Section 14.2.2, “DELETE Syntax”](#).

A multiple-table insert can be accomplished using a trigger whose `FOR EACH ROW` clause contains multiple `INSERT` statements within a `BEGIN ... END` block. See [Section 22.3, “Using Triggers”](#).

**A.1.5. Does MySQL 5.7 have a Query Cache? Does it work on Server, Instance or Database?**

Yes. The query cache operates on the server level, caching complete result sets matched with the original query string. If an exactly identical query is made (which often happens, particularly in web applications), no parsing or execution is necessary; the result is sent directly from the cache. Various tuning options are available. See [Section 9.10.3, “The MySQL Query Cache”](#).

**A.1.6. Does MySQL 5.7 have Sequences?**

No. However, MySQL has an `AUTO_INCREMENT` system, which in MySQL 5.7 can also handle inserts in a multi-master replication setup. With the `auto_increment_increment` and `auto_increment_offset` system variables, you can set each server to generate auto-increment values that don't conflict with other servers. The `auto_increment_increment` value should be greater than the number of servers, and each server should have a unique offset.

**A.1.7. Does MySQL 5.7 have a `NOW( )` function with fractions of seconds?**

Yes, see [Section 12.3.6, “Fractional Seconds in Time Values”](#).

**A.1.8. Does MySQL 5.7 work with multi-core processors?**

Yes. MySQL is fully multi-threaded, and will make use of multiple CPUs, provided that the operating system supports them.

**A.1.9. Why do I see multiple processes for `mysqld`?**

When using LinuxThreads, you should see a minimum of three `mysqld` processes running. These are in fact threads. There is one thread for the LinuxThreads manager, one thread to handle connections, and one thread to handle alarms and signals.

**A.1.10 Can MySQL 5.7 perform ACID transactions?**

Yes. All current MySQL versions support transactions. The `InnoDB` storage engine offers full ACID transactions with row-level locking, multi-versioning, nonlocking repeatable reads, and all four SQL standard isolation levels.

The `NDB` storage engine supports the `READ COMMITTED` transaction isolation level only.

## A.2 MySQL 5.7 FAQ: Storage Engines

|  |      |
|--|------|
| A.2.1 Where can I obtain complete documentation for MySQL storage engines? .....   | 4031 |
| A.2.2 Are there any new storage engines in MySQL 5.7? .....  | 4031 |
| A.2.3 Have any storage engines been removed in MySQL 5.7? .....  | 4031 |
| A.2.4 Can I prevent the use of a particular storage engine? .....  | 4031 |
| A.2.5 Is there an advantage to using the <a href="#">InnoDB</a> storage engine exclusively, as opposed to a combination of <a href="#">InnoDB</a> and non- <a href="#">InnoDB</a> storage engines? ..... | 4031 |
| A.2.6 What are the unique benefits of the <a href="#">ARCHIVE</a> storage engine? .....  | 4031 |

### A.2.1. Where can I obtain complete documentation for MySQL storage engines?

See [Chapter 16, \*Alternative Storage Engines\*](#). That chapter contains information about all MySQL storage engines except for the [InnoDB](#) storage engine and the [NDB](#) storage engine (used for MySQL Cluster). [InnoDB](#) is covered in [Chapter 15, \*The InnoDB Storage Engine\*](#). [NDB](#) is covered in [Chapter 20, \*MySQL NDB Cluster 7.5\*](#).

### A.2.2. Are there any new storage engines in MySQL 5.7?

No. [InnoDB](#) is the default storage engine for new tables. See [Section 15.1, “Introduction to InnoDB”](#) for details.

### A.2.3. Have any storage engines been removed in MySQL 5.7?

No.

### A.2.4. Can I prevent the use of a particular storage engine?

Yes. The [disabled\\_storage\\_engines](#) configuration option defines which storage engines cannot be used to create tables or tablespaces. By default, [disabled\\_storage\\_engines](#) is empty (no engines disabled), but it can be set to a comma-separated list of one or more engines.

### A.2.5. Is there an advantage to using the [InnoDB](#) storage engine exclusively, as opposed to a combination of [InnoDB](#) and non-[InnoDB](#) storage engines?

Yes. Using [InnoDB](#) tables exclusively can simplify backup and recovery operations. MySQL Enterprise Backup does a [hot backup](#) of all tables that use the [InnoDB](#) storage engine. For tables using [MyISAM](#) or other non-[InnoDB](#) storage engines, it does a “warm” backup, where the database continues to run, but those tables cannot be modified while being backed up. See [Section 28.2, “MySQL Enterprise Backup Overview”](#).

### A.2.6. What are the unique benefits of the [ARCHIVE](#) storage engine?

The [ARCHIVE](#) storage engine stores large amounts of data without indexes; it has a small footprint, and performs selects using table scans. See [Section 16.5, “The ARCHIVE Storage Engine”](#), for details.

## A.3 MySQL 5.7 FAQ: Server SQL Mode

|  |      |
|--|------|
| A.3.1 What are server SQL modes? .....                                       | 4031 |
| A.3.2 How many server SQL modes are there? .....                             | 4032 |
| A.3.3 How do you determine the server SQL mode? .....                        | 4032 |
| A.3.4 Is the mode dependent on the database or connection? .....             | 4032 |
| A.3.5 Can the rules for strict mode be extended? .....                       | 4032 |
| A.3.6 Does strict mode impact performance? .....                             | 4032 |
| A.3.7 What is the default server SQL mode when MySQL 5.7 is installed? ..... | 4032 |

### A.3.1. What are server SQL modes?

Server SQL modes define what SQL syntax MySQL should support and what kind of data validation checks it should perform. This makes it easier to use MySQL in different environments

and to use MySQL together with other database servers. The MySQL Server apply these modes individually to different clients. For more information, see [Section 6.1.8, “Server SQL Modes”](#).

**A.3.2.** How many server SQL modes are there?

Each mode can be independently switched on and off. See [Section 6.1.8, “Server SQL Modes”](#), for a complete list of available modes.

**A.3.3.** How do you determine the server SQL mode?

You can set the default SQL mode (for `mysqld` startup) with the `--sql-mode` option. Using the statement `SET [GLOBAL|SESSION] sql_mode='modes'`, you can change the settings from within a connection, either locally to the connection, or to take effect globally. You can retrieve the current mode by issuing a `SELECT @@sql_mode` statement.

**A.3.4.** Is the mode dependent on the database or connection?

A mode is not linked to a particular database. Modes can be set locally to the session (connection), or globally for the server. you can change these settings using `SET [GLOBAL|SESSION] sql_mode='modes'`.

**A.3.5.** Can the rules for strict mode be extended?

When we refer to *strict mode*, we mean a mode where at least one of the modes `TRADITIONAL`, `STRICT_TRANS_TABLES`, or `STRICT_ALL_TABLES` is enabled. Options can be combined, so you can add restrictions to a mode. See [Section 6.1.8, “Server SQL Modes”](#), for more information.

**A.3.6.** Does strict mode impact performance?

The intensive validation of input data that some settings requires more time than if the validation is not done. While the performance impact is not that great, if you do not require such validation (perhaps your application already handles all of this), then MySQL gives you the option of leaving strict mode disabled. However, if you do require it, strict mode can provide such validation.

**A.3.7.** What is the default server SQL mode when MySQL 5.7 is installed?

The default SQL mode in MySQL 5.7 includes these modes: `ONLY_FULL_GROUP_BY`, `STRICT_TRANS_TABLES`, `NO_ZERO_IN_DATE`, `NO_ZERO_DATE`, `ERROR_FOR_DIVISION_BY_ZERO`, `NO_AUTO_CREATE_USER`, and `NO_ENGINE_SUBSTITUTION`.

The `ONLY_FULL_GROUP_BY` and `STRICT_TRANS_TABLES` modes were added in MySQL 5.7.5. The `NO_AUTO_CREATE_USER` mode was added in MySQL 5.7.7. The `ERROR_FOR_DIVISION_BY_ZERO`, `NO_ZERO_DATE`, and `NO_ZERO_IN_DATE` modes were added in MySQL 5.7.8. For information about all available modes and default MySQL behavior, see [Section 6.1.8, “Server SQL Modes”](#).

## A.4 MySQL 5.7 FAQ: Stored Procedures and Functions

|  |      |
|--|------|
| A.4.1 Does MySQL 5.7 support stored procedures and functions? .....                                | 4033 |
| A.4.2 Where can I find documentation for MySQL stored procedures and stored functions? .....       | 4033 |
| A.4.3 Is there a discussion forum for MySQL stored procedures? .....                               | 4033 |

| A.4.25 Are there special security requirements for using stored procedures and functions together with replication? .....                               | 4035 |
| A.4.26 What limitations exist for replicating stored procedure and function actions? .....  | 4035 |
| A.4.27 Do the preceding limitations affect the ability of MySQL to do point-in-time recovery? .....   | 4036 |
| A.4.28 What is being done to correct the aforementioned limitations? .....  | 4036 |

**A.4.1. Does MySQL 5.7 support stored procedures and functions?**

Yes. MySQL 5.7 supports two types of stored routines, stored procedures and stored functions.

**A.4.2. Where can I find documentation for MySQL stored procedures and stored functions?**

See [Section 22.2, “Using Stored Routines \(Procedures and Functions\)”](#).

**A.4.3. Is there a discussion forum for MySQL stored procedures?**

Yes. See <http://forums.mysql.com/list.php?98>.

**A.4.4. Where can I find the ANSI SQL 2003 specification for stored procedures?**

Unfortunately, the official specifications are not freely available (ANSI makes them available for purchase). However, there are books, such as *SQL-99 Complete, Really* by Peter Gultzan and Trudy Pelzer, that provide a comprehensive overview of the standard, including coverage of stored procedures.

**A.4.5. How do you manage stored routines?**

It is always good practice to use a clear naming scheme for your stored routines. You can manage stored procedures with `CREATE [FUNCTION|PROCEDURE]`, `ALTER [FUNCTION|PROCEDURE]`, `DROP [FUNCTION|PROCEDURE]`, and `SHOW CREATE [FUNCTION|PROCEDURE]`. You can obtain information about existing stored procedures using the `ROUTINES` table in the `INFORMATION_SCHEMA` database (see [Section 23.20, “The INFORMATION\\_SCHEMA ROUTINES Table”](#)).

**A.4.6. Is there a way to view all stored procedures and stored functions in a given database?**

Yes. For a database named `dbname`, use this query on the `INFORMATION_SCHEMA.ROUTINES` table:

```
SELECT ROUTINE_TYPE, ROUTINE_NAME
FROM INFORMATION_SCHEMA.ROUTINES
WHERE ROUTINE_SCHEMA='dbname' ;
```

For more information, see [Section 23.20, “The INFORMATION\\_SCHEMA ROUTINES Table”](#).

The body of a stored routine can be viewed using `SHOW CREATE FUNCTION` (for a stored function) or `SHOW CREATE PROCEDURE` (for a stored procedure). See [Section 14.7.5.9, “SHOW CREATE PROCEDURE Syntax”](#), for more information.

**A.4.7.** Where are stored procedures stored?

In the `proc` table of the `mysql` system database. However, you should not access the tables in the system database directly. Instead, query the `INFORMATION_SCHEMA ROUTINES` and `PARAMETERS` tables. See [Section 23.20, “The INFORMATION\\_SCHEMA ROUTINES Table”](#), and [Section 23.14, “The INFORMATION\\_SCHEMA PARAMETERS Table”](#).

You can also use `SHOW CREATE FUNCTION` to obtain information about stored functions, and `SHOW CREATE PROCEDURE` to obtain information about stored procedures. See [Section 14.7.5.9, “SHOW CREATE PROCEDURE Syntax”](#).

**A.4.8.** Is it possible to group stored procedures or stored functions into packages?

No. This is not supported in MySQL 5.7.

**A.4.9.** Can a stored procedure call another stored procedure?

Yes.

**A.4.10** Can a stored procedure call a trigger?

A stored procedure can execute an SQL statement, such as an `UPDATE`, that causes a trigger to activate.

**A.4.11** Can a stored procedure access tables?

Yes. A stored procedure can access one or more tables as required.

**A.4.12** Do stored procedures have a statement for raising application errors?

Yes. MySQL 5.7 implements the SQL standard `SIGNAL` and `RESIGNAL` statements. See [Section 14.6.7, “Condition Handling”](#).

**A.4.13** Do stored procedures provide exception handling?

MySQL implements `HANDLER` definitions according to the SQL standard. See [Section 14.6.7.2, “DECLARE ... HANDLER Syntax”](#), for details.

**A.4.14** Can MySQL 5.7 stored routines return result sets?

*Stored procedures* can, but *stored functions* cannot. If you perform an ordinary `SELECT` inside a stored procedure, the result set is returned directly to the client. You need to use the MySQL 4.1 (or higher) client/server protocol for this to work. This means that, for example, in PHP, you need to use the `mysqli` extension rather than the old `mysql` extension.

**A.4.15** Is `WITH RECOMPILE` supported for stored procedures?

Not in MySQL 5.7.

**A.4.16** Is there a MySQL equivalent to using `mod_plsql` as a gateway on Apache to talk directly to a stored procedure in the database?

There is no equivalent in MySQL 5.7.

**A.4.17** Can I pass an array as input to a stored procedure?

Not in MySQL 5.7.

**A.4.18** Can I pass a cursor as an `IN` parameter to a stored procedure?

In MySQL 5.7, cursors are available inside stored procedures only.

**A.4.19** Can I return a cursor as an `OUT` parameter from a stored procedure?

In MySQL 5.7, cursors are available inside stored procedures only. However, if you do not open a cursor on a `SELECT`, the result will be sent directly to the client. You can also `SELECT INTO` variables. See [Section 14.2.9, “SELECT Syntax”](#).

**A.4.20** Can I print out a variable's value within a stored routine for debugging purposes?

Yes, you can do this in a *stored procedure*, but not in a stored function. If you perform an ordinary `SELECT` inside a stored procedure, the result set is returned directly to the client. You will need to use the MySQL 4.1 (or above) client/server protocol for this to work. This means that, for example, in PHP, you need to use the `mysqli` extension rather than the old `mysql` extension.

**A.4.21** Can I commit or roll back transactions inside a stored procedure?

Yes. However, you cannot perform transactional operations within a stored function.

**A.4.22** Do MySQL 5.7 stored procedures and functions work with replication?

Yes, standard actions carried out in stored procedures and functions are replicated from a master MySQL server to a slave server. There are a few limitations that are described in detail in [Section 22.7, “Binary Logging of Stored Programs”](#).

**A.4.23** Are stored procedures and functions created on a master server replicated to a slave?

Yes, creation of stored procedures and functions carried out through normal DDL statements on a master server are replicated to a slave, so the objects will exist on both servers. `ALTER` and `DROP` statements for stored procedures and functions are also replicated.

**A.4.24** How are actions that take place inside stored procedures and functions replicated?

MySQL records each DML event that occurs in a stored procedure and replicates those individual actions to a slave server. The actual calls made to execute stored procedures are not replicated.

Stored functions that change data are logged as function invocations, not as the DML events that occur inside each function.

**A.4.25** Are there special security requirements for using stored procedures and functions together with replication?

Yes. Because a slave server has authority to execute any statement read from a master's binary log, special security constraints exist for using stored functions with replication. If replication or binary logging in general (for the purpose of point-in-time recovery) is active, then MySQL DBAs have two security options open to them:

1. Any user wishing to create stored functions must be granted the `SUPER` privilege.
2. Alternatively, a DBA can set the `log_bin_trust_function_creators` system variable to 1, which enables anyone with the standard `CREATE ROUTINE` privilege to create stored functions.

**A.4.26** What limitations exist for replicating stored procedure and function actions?

Nondeterministic (random) or time-based actions embedded in stored procedures may not replicate properly. By their very nature, randomly produced results are not predictable and cannot be exactly reproduced, and therefore, random actions replicated to a slave will not mirror those performed on a master. Declaring stored functions to be `DETERMINISTIC` or setting the `log_bin_trust_function_creators` system variable to 0 will not allow random-valued operations to be invoked.

In addition, time-based actions cannot be reproduced on a slave because the timing of such actions in a stored procedure is not reproducible through the binary log used for replication. It records only DML events and does not factor in timing constraints.

Finally, nontransactional tables for which errors occur during large DML actions (such as bulk inserts) may experience replication issues in that a master may be partially updated from DML activity, but no updates are done to the slave because of the errors that occurred. A workaround is for a function's DML actions to be carried out with the `IGNORE` keyword so that updates on the master that cause errors are ignored and updates that do not cause errors are replicated to the slave.

**A.4.27** Do the preceding limitations affect the ability of MySQL to do point-in-time recovery?

The same limitations that affect replication do affect point-in-time recovery.

**A.4.28** What is being done to correct the aforementioned limitations?

You can choose either statement-based replication or row-based replication. The original replication implementation is based on statement-based binary logging. Row-based binary logging resolves the limitations mentioned earlier.

*Mixed* replication is also available (by starting the server with `--binlog-format=mixed`). This hybrid, “smart” form of replication “knows” whether statement-level replication can safely be used, or row-level replication is required.

For additional information, see [Section 18.2.1, “Replication Formats”](#).

## A.5 MySQL 5.7 FAQ: Triggers

|  |      |
|--|------|
| A.5.1 Where can I find the documentation for MySQL 5.7 triggers? .....                       | 4036 |
| A.5.2 Is there a discussion forum for MySQL Triggers? .....                                  | 4036 |
| A.5.3 Does MySQL 5.7 have statement-level or row-level triggers? .....                       | 4036 |
| A.5.4 Are there any default triggers? .....  | 4036 |
| A.5.5 How are triggers managed in MySQL? .....   | 4036 |
| A.5.6 Is there a way to view all triggers in a given database? .....                         | 4037 |
| A.5.7 Where are triggers stored? .....   | 4037 |
| A.5.8 Can a trigger call a stored procedure? .....   | 4037 |
| A.5.9 Can triggers access tables? .....  | 4037 |
| A.5.10 Can a table have multiple triggers with the same trigger event and action time? ..... | 4037 |
| A.5.11 Can triggers call an external application through a UDF? .....                        | 4037 |
| A.5.12 Is it possible for a trigger to update tables on a remote server? .....               | 4037 |
| A.5.13 Do triggers work with replication? .....  | 4037 |
| A.5.14 How are actions carried out through triggers on a master replicated to a slave? ..... | 4038 |

**A.5.1.** Where can I find the documentation for MySQL 5.7 triggers?

See [Section 22.3, “Using Triggers”](#).

**A.5.2.** Is there a discussion forum for MySQL Triggers?

Yes. It is available at <http://forums.mysql.com/list.php?99>.

**A.5.3.** Does MySQL 5.7 have statement-level or row-level triggers?

In MySQL 5.7, all triggers are `FOR EACH ROW`; that is, the trigger is activated for each row that is inserted, updated, or deleted. MySQL 5.7 does not support triggers using `FOR EACH STATEMENT`.

**A.5.4.** Are there any default triggers?

Not explicitly. MySQL does have specific special behavior for some `TIMESTAMP` columns, as well as for columns which are defined using `AUTO_INCREMENT`.

**A.5.5.** How are triggers managed in MySQL?

In MySQL 5.7, triggers can be created using the `CREATE TRIGGER` statement, and dropped using `DROP TRIGGER`. See [Section 14.1.20, “CREATE TRIGGER Syntax”](#), and [Section 14.1.31, “DROP TRIGGER Syntax”](#), for more about these statements.

Information about triggers can be obtained by querying the `INFORMATION_SCHEMA.TRIGGERS` table. See [Section 23.28, “The INFORMATION\\_SCHEMA TRIGGERS Table”](#).

**A.5.6.** Is there a way to view all triggers in a given database?

Yes. You can obtain a listing of all triggers defined on database `dbname` using a query on the `INFORMATION_SCHEMA.TRIGGERS` table such as the one shown here:

```
SELECT TRIGGER_NAME, EVENT_MANIPULATION, EVENT_OBJECT_TABLE, ACTION_STATEMENT
FROM INFORMATION_SCHEMA.TRIGGERS
WHERE TRIGGER_SCHEMA= 'dbname' ;
```

For more information about this table, see [Section 23.28, “The INFORMATION\\_SCHEMA TRIGGERS Table”](#).

You can also use the `SHOW TRIGGERS` statement, which is specific to MySQL. See [Section 14.7.5.38, “SHOW TRIGGERS Syntax”](#).

**A.5.7.** Where are triggers stored?

Triggers are stored in `.TRG` files, with one such file one per table.

**A.5.8.** Can a trigger call a stored procedure?

Yes.

**A.5.9.** Can triggers access tables?

A trigger can access both old and new data in its own table. A trigger can also affect other tables, but it is not permitted to modify a table that is already being used (for reading or writing) by the statement that invoked the function or trigger.

**A.5.10** Can a table have multiple triggers with the same trigger event and action time?

As of MySQL 5.7.2, it is possible to define multiple triggers for a given table that have the same trigger event and action time. For example, you can have two `BEFORE UPDATE` triggers for a table. By default, triggers that have the same trigger event and action time activate in the order they were created. To affect trigger order, specify a clause after `FOR EACH ROW` that indicates `FOLLOWS` or `PRECEDES` and the name of an existing trigger that also has the same trigger event and action time. With `FOLLOWS`, the new trigger activates after the existing trigger. With `PRECEDES`, the new trigger activates before the existing trigger.

**A.5.11** Can triggers call an external application through a UDF?

Yes. For example, a trigger could invoke the `sys_exec( )` UDF.

**A.5.12** Is it possible for a trigger to update tables on a remote server?

Yes. A table on a remote server could be updated using the `FEDERATED` storage engine. (See [Section 16.8, “The FEDERATED Storage Engine”](#)).

**A.5.13** Do triggers work with replication?

Yes. However, the way in which they work depends whether you are using MySQL's “classic” statement-based replication available in all versions of MySQL, or the row-based replication format introduced in MySQL 5.1.

When using statement-based replication, triggers on the slave are executed by statements that are executed on the master (and replicated to the slave).

When using row-based replication, triggers are not executed on the slave due to statements that were run on the master and then replicated to the slave. Instead, when using row-based replication, the changes caused by executing the trigger on the master are applied on the slave.

For more information, see [Section 18.4.1.35, “Replication and Triggers”](#).

#### **A.5.14**How are actions carried out through triggers on a master replicated to a slave?

Again, this depends on whether you are using statement-based or row-based replication.

**Statement-based replication.** First, the triggers that exist on a master must be re-created on the slave server. Once this is done, the replication flow works as any other standard DML statement that participates in replication. For example, consider a table `EMP` that has an `AFTER` insert trigger, which exists on a master MySQL server. The same `EMP` table and `AFTER` insert trigger exist on the slave server as well. The replication flow would be:

1. An `INSERT` statement is made to `EMP`.
2. The `AFTER` trigger on `EMP` activates.
3. The `INSERT` statement is written to the binary log.
4. The replication slave picks up the `INSERT` statement to `EMP` and executes it.
5. The `AFTER` trigger on `EMP` that exists on the slave activates.

**Row-based replication.** When you use row-based replication, the changes caused by executing the trigger on the master are applied on the slave. However, the triggers themselves are not actually executed on the slave under row-based replication. This is because, if both the master and the slave applied the changes from the master and, in addition, the trigger causing these changes were applied on the slave, the changes would in effect be applied twice on the slave, leading to different data on the master and the slave.

In most cases, the outcome is the same for both row-based and statement-based replication. However, if you use different triggers on the master and slave, you cannot use row-based replication. (This is because the row-based format replicates the changes made by triggers executing on the master to the slaves, rather than the statements that caused the triggers to execute, and the corresponding triggers on the slave are not executed.) Instead, any statements causing such triggers to be executed must be replicated using statement-based replication.

For more information, see [Section 18.4.1.35, “Replication and Triggers”](#).

## **A.6 MySQL 5.7 FAQ: Views**

|  |      |
|--|------|
| A.6.1 Where can I find documentation covering MySQL Views? .....                 | 4038 |
| A.6.2 Is there a discussion forum for MySQL Views? .....                         | 4038 |
| A.6.3 What happens to a view if an underlying table is dropped or renamed? ..... | 4038 |
| A.6.4 Does MySQL 5.7 have table snapshots? .....                                 | 4039 |
| A.6.5 Does MySQL 5.7 have materialized views? .....                              | 4039 |
| A.6.6 Can you insert into views that are based on joins? .....                   | 4039 |

#### **A.6.1.** Where can I find documentation covering MySQL Views?

See [Section 22.5, “Using Views”](#).

#### **A.6.2.** Is there a discussion forum for MySQL Views?

Yes. See <http://forums.mysql.com/list.php?100>

#### **A.6.3.** What happens to a view if an underlying table is dropped or renamed?

After a view has been created, it is possible to drop or alter a table or view to which the definition refers. To check a view definition for problems of this kind, use the [CHECK TABLE](#) statement. (See [Section 14.7.2.2](#), “[CHECK TABLE Syntax](#)”.)

**A.6.4.** Does MySQL 5.7 have table snapshots?

No.

**A.6.5.** Does MySQL 5.7 have materialized views?

No.

**A.6.6.** Can you insert into views that are based on joins?

It is possible, provided that your [INSERT](#) statement has a column list that makes it clear there is only one table involved.

You *cannot* insert into multiple tables with a single insert on a view.

## A.7 MySQL 5.7 FAQ: INFORMATION\_SCHEMA

|  |      |
|--|------|
| A.7.1 Where can I find documentation for the MySQL <a href="#">INFORMATION_SCHEMA</a> database? .....                | 4039 |
| A.7.2 Is there a discussion forum for <a href="#">INFORMATION_SCHEMA</a> ? .....                                     | 4039 |
| A.7.3 Where can I find the ANSI SQL 2003 specification for <a href="#">INFORMATION_SCHEMA</a> ? .....                | 4039 |
| A.7.4 What is the difference between the Oracle Data Dictionary and MySQL <a href="#">INFORMATION_SCHEMA</a> ? ..... | 4039 |
| A.7.5 Can I add to or otherwise modify the tables found in the <a href="#">INFORMATION_SCHEMA</a> database? .....    | 4039 |

**A.7.1.** Where can I find documentation for the MySQL [INFORMATION\\_SCHEMA](#) database?

See [Chapter 23](#), [INFORMATION\\_SCHEMA Tables](#)

**A.7.2.** Is there a discussion forum for [INFORMATION\\_SCHEMA](#)?

See <http://forums.mysql.com/list.php?101>.

**A.7.3.** Where can I find the ANSI SQL 2003 specification for [INFORMATION\\_SCHEMA](#)?

Unfortunately, the official specifications are not freely available. (ANSI makes them available for purchase.) However, there are books available, such as *SQL-99 Complete, Really* by Peter Gultzan and Trudy Pelzer, that provide a comprehensive overview of the standard, including [INFORMATION\\_SCHEMA](#).

**A.7.4.** What is the difference between the Oracle Data Dictionary and MySQL [INFORMATION\\_SCHEMA](#)?

Both Oracle and MySQL provide metadata in tables. However, Oracle and MySQL use different table names and column names. The MySQL implementation is more similar to those found in DB2 and SQL Server, which also support [INFORMATION\\_SCHEMA](#) as defined in the SQL standard.

**A.7.5.** Can I add to or otherwise modify the tables found in the [INFORMATION\\_SCHEMA](#) database?

No. Since applications may rely on a certain standard structure, this should not be modified. For this reason, *we cannot support bugs or other issues which result from modifying [INFORMATION\\_SCHEMA](#) tables or data.*

## A.8 MySQL 5.7 FAQ: Migration

|  |      |
|--|------|
| A.8.1 Where can I find information on how to migrate from MySQL 5.6 to MySQL 5.7? .....              | 4040 |
| A.8.2 How has storage engine (table type) support changed in MySQL 5.7 from previous versions? ..... | 4040 |

**A.8.1.** Where can I find information on how to migrate from MySQL 5.6 to MySQL 5.7?

For detailed upgrade information, see [Section 2.11.1, “Upgrading MySQL”](#). Do not skip a major version when upgrading, but rather complete the process in steps, upgrading from one major version to the next in each step. This may seem more complicated, but it will save you time and trouble. If you encounter problems during the upgrade, their origin will be easier to identify, either by you or, if you have a MySQL Enterprise subscription, by MySQL support.

**A.8.2.** How has storage engine (table type) support changed in MySQL 5.7 from previous versions?

Storage engine support has changed as follows:

- Support for [ISAM](#) tables was removed in MySQL 5.0 and you should now use the [MyISAM](#) storage engine in place of [ISAM](#). To convert a table [tblname](#) from [ISAM](#) to [MyISAM](#), simply issue a statement such as this one:

```
ALTER TABLE tblname ENGINE=MYISAM;
```

- Internal [RAID](#) for [MyISAM](#) tables was also removed in MySQL 5.0. This was formerly used to allow large tables in file systems that did not support file sizes greater than 2GB. All modern file systems allow for larger tables; in addition, there are now other solutions such as [MERGE](#) tables and views.
- The [VARCHAR](#) column type now retains trailing spaces in all storage engines.
- [MEMORY](#) tables (formerly known as [HEAP](#) tables) can also contain [VARCHAR](#) columns.

## A.9 MySQL 5.7 FAQ: Security

A.9.1 Where can I find documentation that addresses security issues for MySQL? ..... 4040

A.9.2 Does MySQL 5.7 have native support for SSL? ..... 4040

A.9.3 Is SSL support built into MySQL binaries, or must I recompile the binary myself to enable it? 4041

A.9.4 Does MySQL 5.7 have built-in authentication against LDAP directories? ..... 4041

A.9.5 Does MySQL 5.7 include support for Roles Based Access Control (RBAC)? ..... 4041

**A.9.1.** Where can I find documentation that addresses security issues for MySQL?

The best place to start is [Chapter 7, Security](#).

Other portions of the MySQL Documentation which you may find useful with regard to specific security concerns include the following:

- [Section 7.1.1, “Security Guidelines”](#).
- [Section 7.1.3, “Making MySQL Secure Against Attackers”](#).
- [Section B.5.3.2, “How to Reset the Root Password”](#).
- [Section 7.1.5, “How to Run MySQL as a Normal User”](#).
- [Section 27.4.2.6, “UDF Security Precautions”](#).
- [Section 7.1.4, “Security-Related mysqld Options and Variables”](#).
- [Section 7.1.6, “Security Issues with LOAD DATA LOCAL”](#).
- [Section 2.10, “Postinstallation Setup and Testing”](#).
- [Section 7.4, “Using Secure Connections”](#).

**A.9.2.** Does MySQL 5.7 have native support for SSL?

Most 5.7 binaries have support for SSL connections between the client and server. See [Section 7.4, “Using Secure Connections”](#).

You can also tunnel a connection using SSH, if (for example) the client application does not support SSL connections. For an example, see [Section 7.4.7, “Connecting to MySQL Remotely from Windows with SSH”](#).

**A.9.3.** Is SSL support built into MySQL binaries, or must I recompile the binary myself to enable it?

Most 5.7 binaries have SSL enabled for client/server connections that are secured, authenticated, or both. See [Section 7.4, “Using Secure Connections”](#).

**A.9.4.** Does MySQL 5.7 have built-in authentication against LDAP directories?

The Enterprise edition includes a [PAM Authentication Plugin](#) that supports authentication against an LDAP directory.

**A.9.5.** Does MySQL 5.7 include support for Roles Based Access Control (RBAC)?

Not at this time.

## A.10 MySQL 5.7 FAQ: MySQL Cluster

In the following section, we answer questions that are frequently asked about MySQL Cluster and the [NDB](#) storage engine.

|   |      |
|---|------|
| A.10.1 Which versions of the MySQL software support NDB Cluster? Do I have to compile from source? .....  | 4042 |

**A.10.1** Which versions of the MySQL software support NDB Cluster? Do I have to compile from source?

NDB Cluster is not supported in standard MySQL Server 5.7 releases. Instead, MySQL NDB Cluster is provided as a separate product. Currently, the following NDB Cluster release series are available for production use:

- **NDB Cluster 7.2.** This series is a previous General Availability (GA) version of NDB Cluster, still available for production, although we recommend that new deployments use the latest NDB Cluster 7.5 release. The most recent NDB Cluster 7.2 release can be obtained from <http://dev.mysql.com/downloads/cluster/>.
- **NDB Cluster 7.3.** This series is a General Availability (GA) version of NDB Cluster, still available for production, although we recommend that new deployments use the latest NDB Cluster 7.5 release. The most recent NDB Cluster 7.3 release can be obtained from <http://dev.mysql.com/downloads/cluster/>.
- **NDB Cluster 7.4.** This series is the latest Generally Available (GA) version of NDB Cluster, based on version 7.4 of the [NDB](#) storage engine and MySQL Server 5.6, and still available for production, although we recommend that new deployments use the latest NDB Cluster 7.5 release. The most recent NDB Cluster 7.4 release can be obtained from <http://dev.mysql.com/downloads/cluster/>.
- **NDB Cluster 7.5.** This series is the most recent General Availability (GA) version of NDB Cluster, based on version 7.5 of the [NDB](#) storage engine and MySQL Server 5.7. NDB Cluster 7.5 is available for production use; new deployments intended for production should use the latest GA release in this series, which is currently NDB Cluster 7.5.5. The latest NDB Cluster 7.5 releases can be obtained from <http://dev.mysql.com/downloads/cluster/>.

You should use NDB Cluster 7.5 for any new deployments; if you are using an older version of NDB Cluster, you should upgrade to this version soon as possible. For an overview of improvements made in NDB Cluster 7.5, see [Section 20.1.4, “What is New in MySQL NDB Cluster 7.5”](#). For an overview of improvements made in NDB Cluster 7.4, see [What is New in NDB Cluster 7.4](#); for information about improvements made in NDB Cluster 7.3, see [What is New in NDB Cluster 7.3](#). For information about improvements made in NDB Cluster 7.2, see [What is New in NDB Cluster in NDB Cluster 7.2](#).

You can determine whether your MySQL Server has [NDB](#) support using one of the statements `SHOW VARIABLES LIKE 'have_%%'`, `SHOW ENGINES`, or `SHOW PLUGINS`.

**A.10.2** What do “NDB” and “NDBCLUSTER” mean?

“NDB” stands for “**N**etwork **D**atabase”. [NDB](#) and [NDBCLUSTER](#) are both names for the storage engine that enables clustering support with MySQL. [NDB](#) is preferred, but either name is correct.

**A.10.3** Do I need any special networking to run NDB Cluster? How do computers in a cluster communicate?

NDB Cluster is intended to be used in a high-bandwidth environment, with computers connecting using TCP/IP. Its performance depends directly upon the connection speed between the cluster's computers. The minimum connectivity requirements for NDB Cluster include a typical 100-megabit Ethernet network or the equivalent. We recommend you use gigabit Ethernet whenever available.

**A.10.4** How many computers do I need to run an NDB Cluster, and why?

A minimum of three computers is required to run a viable cluster. However, the minimum *recommended* number of computers in an NDB Cluster is four: one each to run the management and SQL nodes, and two computers to serve as data nodes. The purpose of the two data nodes is to provide redundancy; the management node must run on a separate machine to guarantee continued arbitration services in the event that one of the data nodes fails.

To provide increased throughput and high availability, you should use multiple SQL nodes (MySQL Servers connected to the cluster). It is also possible (although not strictly necessary) to run multiple management servers.

**A.10.5** What do the different computers do in an NDB Cluster?

An NDB Cluster has both a physical and logical organization, with computers being the physical elements. The logical or functional elements of a cluster are referred to as *nodes*, and a computer housing a cluster node is sometimes referred to as a *cluster host*. There are three types of nodes, each corresponding to a specific role within the cluster. These are:

- **Management node.** This node provides management services for the cluster as a whole, including startup, shutdown, backups, and configuration data for the other nodes. The management node server is implemented as the application `ndb_mgmd`; the management client used to control NDB Cluster is `ndb_mgm`. See [Section 20.4.4, “ndb\\_mgmd — The NDB Cluster Management Server Daemon”](#), and [Section 20.4.5, “ndb\\_mgm — The NDB Cluster Management Client”](#), for information about these programs.
- **Data node.** This type of node stores and replicates data. Data node functionality is handled by instances of the NDB data node process `ndbd`. For more information, see [Section 20.4.1, “ndbd — The NDB Cluster Data Node Daemon”](#).
- **SQL node.** This is simply an instance of MySQL Server (`mysqld`) that is built with support for the `NDBCLUSTER` storage engine and started with the `--ndb-cluster` option to enable the engine and the `--ndb-connectstring` option to enable it to connect to an NDB Cluster management server. For more about these options, see [MySQL Server Options for NDB Cluster](#).

**Note**

An *API node* is any application that makes direct use of Cluster data nodes for data storage and retrieval. An SQL node can thus be considered a type of API node that uses a MySQL Server to provide an SQL interface to the Cluster. You can write such applications (that do not depend on a MySQL Server) using the NDB API, which supplies a direct, object-oriented transaction and scanning interface to NDB Cluster data; see [NDB Cluster API Overview: The NDB API](#), for more information.

**A.10.6** When I run the `SHOW` command in the NDB Cluster management client, I see a line of output that looks like this:

```
id=2      @10.100.10.32  (Version: 5.6.34-ndb-7.3.16 Nodegroup: 0, *)
```

What does the \* mean? How is this node different from the others?

The simplest answer is, “It’s not something you can control, and it’s nothing that you need to worry about in any case, unless you’re a software engineer writing or analyzing the NDB Cluster source code”.

If you don’t find that answer satisfactory, here’s a longer and more technical version:

A number of mechanisms in NDB Cluster require distributed coordination among the data nodes. These distributed algorithms and protocols include global checkpointing, DDL (schema) changes, and node restart handling. To make this coordination simpler, the data nodes “elect” one of their number to act as leader. (This node was once referred to as a “master”, but this terminology was dropped to avoid confusion with master server in MySQL Replication.) There is no user-facing mechanism for influencing this selection, which is completely automatic; the fact that it *is* automatic is a key part of NDB Cluster’s internal architecture.

When a node acts as the “leader” for any of these mechanisms, it is usually the point of coordination for the activity, and the other nodes act as “followers”, carrying out their parts of the activity as directed by the leader. If the node acting as leader fails, then the remaining nodes elect a new leader. Tasks in progress that were being coordinated by the old leader may either fail or be continued by the new leader, depending on the actual mechanism involved.

It is possible for some of these different mechanisms and protocols to have different leader nodes, but in general the same leader is chosen for all of them. The node indicated as the leader in the output of `SHOW` in the management client is known internally as the `DICT` manager (see [The DBDICT Block](#), in the *NDB Cluster API Developer Guide*, for more information), responsible for coordinating DDL and metadata activity.

NDB Cluster is designed in such a way that the choice of leader has no discernible effect outside the cluster itself. For example, the current leader does not have significantly higher CPU or resource usage than the other data nodes, and failure of the leader should not have a significantly different impact on the cluster than the failure of any other data node.

#### **A.10.7**With which operating systems can I use NDB Cluster?

NDB Cluster is supported on most Unix-like operating systems. NDB Cluster is also supported in production settings on Microsoft Windows operating systems.

For more detailed information concerning the level of support which is offered for NDB Cluster on various operating system versions, operating system distributions, and hardware platforms, please refer to <http://www.mysql.com/support/supportedplatforms/cluster.html>.

#### **A.10.8**What are the hardware requirements for running NDB Cluster?

NDB Cluster should run on any platform for which `NDB`-enabled binaries are available. For data nodes and API nodes, faster CPUs and more memory are likely to improve performance, and 64-bit CPUs are likely to be more effective than 32-bit processors. There must be sufficient memory on machines used for data nodes to hold each node’s share of the database (see *How much RAM do I Need?* for more information). For a computer which is used only for running the NDB Cluster management server, the requirements are minimal; a common desktop PC (or the equivalent) is generally sufficient for this task. Nodes can communicate through the standard TCP/IP network and hardware. They can also use the high-speed SCI protocol; however, special networking hardware and software are required to use SCI (see [Section 20.3.4, “Using High-Speed Interconnects with NDB Cluster”](#)).

#### **A.10.9**How much RAM do I need to use NDB Cluster? Is it possible to use disk memory at all?

Formerly NDB Cluster was in-memory only. MySQL 5.1 and later also provide the ability to store NDB Cluster on disk. (Note that we have no plans to backport this capability to previous releases.) See [Section 20.5.13, “NDB Cluster Disk Data Tables”](#), for more information.

For in-memory [NDB](#) tables, you can use the following formula for obtaining a rough estimate of how much RAM is needed for each data node in the cluster:

```
(SizeofDatabase × NumberOfReplicas × 1.1 ) / NumberOfDataNodes
```

To calculate the memory requirements more exactly requires determining, for each table in the cluster database, the storage space required per row (see [Section 12.8, “Data Type Storage Requirements”](#), for details), and multiplying this by the number of rows. You must also remember to account for any column indexes as follows:

- Each primary key or hash index created for an [NDBCLUSTER](#) table requires 21–25 bytes per record. These indexes use [IndexMemory](#).
- Each ordered index requires 10 bytes storage per record, using [DataMemory](#).
- Creating a primary key or unique index also creates an ordered index, unless this index is created with [USING HASH](#). In other words:
  - A primary key or unique index on a Cluster table normally takes up 31 to 35 bytes per record.
  - However, if the primary key or unique index is created with [USING HASH](#), then it requires only 21 to 25 bytes per record.

Creating NDB Cluster tables with [USING HASH](#) for all primary keys and unique indexes will generally cause table updates to run more quickly—in some cases by as much as 20 to 30 percent faster than updates on tables where [USING HASH](#) was not used in creating primary and unique keys. This is due to the fact that less memory is required (because no ordered indexes are created), and that less CPU must be utilized (because fewer indexes must be read and possibly updated). However, it also means that queries that could otherwise use range scans must be satisfied by other means, which can result in slower selects.

When calculating Cluster memory requirements, you may find useful the [ndb\\_size.pl](#) utility which is available in recent MySQL 5.7 releases. This Perl script connects to a current (non-Cluster) MySQL database and creates a report on how much space that database would require if it used the [NDBCLUSTER](#) storage engine. For more information, see [Section 20.4.25, “ndb\\_size.pl — NDBCLUSTER Size Requirement Estimator”](#).

It is especially important to keep in mind that *every NDB Cluster table must have a primary key*. The [NDB](#) storage engine creates a primary key automatically if none is defined; this primary key is created without [USING HASH](#).

You can determine how much memory is being used for storage of NDB Cluster data and indexes at any given time using the [REPORT MEMORYUSAGE](#) command in the [ndb\\_mgm](#) client; see [Section 20.5.2, “Commands in the NDB Cluster Management Client”](#), for more information. In addition, warnings are written to the cluster log when 80% of available [DataMemory](#) or [IndexMemory](#) is in use, and again when usage reaches 85%, 90%, and so on.

#### **A.10.10** What file systems can I use with NDB Cluster? What about network file systems or network shares?

Generally, any file system that is native to the host operating system should work well with NDB Cluster. If you find that a given file system works particularly well (or not so especially well) with NDB Cluster, we invite you to discuss your findings in the [NDB Cluster Forums](#).

For Windows, we recommend that you use [NTFS](#) file systems for NDB Cluster, just as we do for standard MySQL. We do not test NDB Cluster with [FAT](#) or [VFAT](#) file systems. Because of this, we do not recommend their use with MySQL or NDB Cluster.

NDB Cluster is implemented as a shared-nothing solution; the idea behind this is that the failure of a single piece of hardware should not cause the failure of multiple cluster nodes, or possibly even the failure of the cluster as a whole. For this reason, the use of network shares or network file systems is not supported for NDB Cluster. This also applies to shared storage devices such as SANs.

**A.10.11** Can I run NDB Cluster nodes inside virtual machines (such as those created by VMWare, Parallels, or Xen)?

NDB Cluster is supported for use in virtual machines beginning with NDB Cluster 7.2. We currently support and test using [Oracle VM](#).

Some NDB Cluster users have successfully deployed NDB Cluster using other virtualization products; in such cases, Oracle can provide NDB Cluster support, but issues specific to the virtual environment must be referred to that product's vendor.

**A.10.12** I am trying to populate an NDB Cluster database. The loading process terminates prematurely and I get an error message like this one:

```
ERROR 1114: The table 'my_cluster_table' is full
```

Why is this happening?

The cause is very likely to be that your setup does not provide sufficient RAM for all table data and all indexes, *including the primary key required by the NDB storage engine and automatically created in the event that the table definition does not include the definition of a primary key.*

It is also worth noting that all data nodes should have the same amount of RAM, since no data node in a cluster can use more memory than the least amount available to any individual data node. For example, if there are four computers hosting Cluster data nodes, and three of these have 3GB of RAM available to store Cluster data while the remaining data node has only 1GB RAM, then each data node can devote at most 1GB to NDB Cluster data and indexes.

In some cases it is possible to get `Table is full` errors in MySQL client applications even when `ndb_mgm -e "ALL REPORT MEMORYUSAGE"` shows significant free `DataMemory`. You can force NDB to create extra partitions for NDB Cluster tables and thus have more memory available for hash indexes by using the `MAX_ROWS` option for `CREATE TABLE`. In general, setting `MAX_ROWS` to twice the number of rows that you expect to store in the table should be sufficient.

For similar reasons, you can also sometimes encounter problems with data node restarts on nodes that are heavily loaded with data. In NDB Cluster 7.1 and later, the addition of the `MinFreePct` parameter helps with this issue by reserving a portion (5% by default) of `DataMemory` and `IndexMemory` for use in restarts. This reserved memory is not available for storing NDB tables or data.

**A.10.13** NDB Cluster uses TCP/IP. Does this mean that I can run it over the Internet, with one or more nodes in remote locations?

It is very unlikely that a cluster would perform reliably under such conditions, as NDB Cluster was designed and implemented with the assumption that it would be run under conditions guaranteeing dedicated high-speed connectivity such as that found in a LAN setting using 100 Mbps or gigabit Ethernet—preferably the latter. We neither test nor warrant its performance using anything slower than this.

Also, it is extremely important to keep in mind that communications between the nodes in an NDB Cluster are not secure; they are neither encrypted nor safeguarded by any other protective mechanism. The most secure configuration for a cluster is in a private network behind a firewall, with no direct access to any Cluster data or management nodes from outside. (For SQL nodes,

you should take the same precautions as you would with any other instance of the MySQL server.) For more information, see [Section 20.5.12, “NDB Cluster Security Issues”](#).

**A.10.14** Do I have to learn a new programming or query language to use NDB Cluster?

No. Although some specialized commands are used to manage and configure the cluster itself, only standard (My)SQL statements are required for the following operations:

- Creating, altering, and dropping tables
- Inserting, updating, and deleting table data
- Creating, changing, and dropping primary and unique indexes

Some specialized configuration parameters and files are required to set up an NDB Cluster—see [Section 20.3.3, “NDB Cluster Configuration Files”](#), for information about these.

A few simple commands are used in the NDB Cluster management client ([ndb\\_mgm](#)) for tasks such as starting and stopping cluster nodes. See [Section 20.5.2, “Commands in the NDB Cluster Management Client”](#).

**A.10.15** What programming languages and APIs are supported by NDB Cluster?

NDB Cluster supports the same programming APIs and languages as the standard MySQL Server, including ODBC, .Net, the MySQL C API, and numerous drivers for popular scripting languages such as PHP, Perl, and Python. NDB Cluster applications written using these APIs behave similarly to other MySQL applications; they transmit SQL statements to a MySQL Server (in the case of NDB Cluster, an SQL node), and receive responses containing rows of data. For more information about these APIs, see [Chapter 26, Connectors and APIs](#).

NDB Cluster also supports application programming using the NDB API, which provides a low-level C++ interface to NDB Cluster data without needing to go through a MySQL Server. See [The NDB API](#). In addition, many [NDBCLUSTER](#) management functions are exposed by the C-language MGM API; see [The MGM API](#), for more information.

NDB Cluster (NDB 7.1 and later) also supports Java application programming using ClusterJ, which supports a domain object model of data using sessions and transactions. See [Java and NDB Cluster](#), for more information.

NDB Cluster (NDB 7.2 and later) also supports [memcached](#), allowing developers to access data stored in NDB Cluster using the [memcached](#) interface; for more information, see [ndbmemcache —Memcache API for NDB Cluster](#).

NDB Cluster 7.3 adds adapters supporting NoSQL applications written against [Node.js](#), with NDB Cluster as the data store. See [MySQL NoSQL Connector for JavaScript](#), for more information.

**A.10.16** Does NDB Cluster include any management tools?

NDB Cluster includes a command line client for performing basic management functions. See [Section 20.4.5, “ndb\\_mgm — The NDB Cluster Management Client”](#), and [Section 20.5.2, “Commands in the NDB Cluster Management Client”](#).

NDB Cluster 7.0 and later is also supported by MySQL Cluster Manager, a separate product providing an advanced command line interface that can automate many NDB Cluster management tasks such as rolling restarts and configuration changes. For more information about MySQL Cluster Manager, see [MySQL™ Cluster Manager 1.4.1 User Manual](#).

NDB Cluster 7.3 introduces a graphical, browser-based Auto-Installer for setting up and deploying NDB Cluster, as part of the NDB Cluster software distribution. For more information, see [Section 20.2.1, “The NDB Cluster Auto-Installer”](#).

**A.10.17** How do I find out what an error or warning message means when using NDB Cluster?

There are two ways in which this can be done:

- From within the `mysql` client, use `SHOW ERRORS` or `SHOW WARNINGS` immediately upon being notified of the error or warning condition.
- From a system shell prompt, use `pererror --ndb error_code`.

**A.10.18** Is NDB Cluster transaction-safe? What isolation levels are supported?

Yes. For tables created with the `NDB` storage engine, transactions are supported. Currently, NDB Cluster supports only the `READ COMMITTED` transaction isolation level.

**A.10.19** What storage engines are supported by NDB Cluster?

Clustering with MySQL is supported only by the `NDB` storage engine. That is, in order for a table to be shared between nodes in an NDB Cluster, the table must be created using `ENGINE=NDB` (or the equivalent option `ENGINE=NDBCLUSTER`).

It is possible to create tables using other storage engines (such as `InnoDB` or `MyISAM`) on a MySQL server being used with an NDB Cluster, but since these tables do not use `NDB`, they do not participate in clustering; each such table is strictly local to the individual MySQL server instance on which it is created.

**A.10.20** In the event of a catastrophic failure—for example, the whole city loses power *and* my UPS fails—would I lose all my data?

All committed transactions are logged. Therefore, although it is possible that some data could be lost in the event of a catastrophe, this should be quite limited. Data loss can be further reduced by minimizing the number of operations per transaction. (It is not a good idea to perform large numbers of operations per transaction in any case.)

**A.10.21** Is it possible to use `FULLTEXT` indexes with NDB Cluster?

`FULLTEXT` indexing is currently supported only by the `InnoDB` and `MyISAM` storage engines. See [Section 13.9, “Full-Text Search Functions”](#), for more information.

**A.10.22** Can I run multiple nodes on a single computer?

It is possible but not always advisable. One of the chief reasons to run a cluster is to provide redundancy. To obtain the full benefits of this redundancy, each node should reside on a separate machine. If you place multiple nodes on a single machine and that machine fails, you lose all of those nodes. For this reason, if you do run multiple data nodes on a single machine, it is *extremely* important that they be set up in such a way that the failure of this machine does not cause the loss of all the data nodes in a given node group.

Given that NDB Cluster can be run on commodity hardware loaded with a low-cost (or even no-cost) operating system, the expense of an extra machine or two is well worth it to safeguard mission-critical data. It is also worth noting that the requirements for a cluster host running a management node are minimal. This task can be accomplished with a 300 MHz Pentium or equivalent CPU and sufficient RAM for the operating system, plus a small amount of overhead for the `ndb_mgmd` and `ndb_mgm` processes.

It is acceptable to run multiple cluster data nodes on a single host that has multiple CPUs, cores, or both. NDB Cluster 7.0 and later also provide a multi-threaded version of the data node binary intended for use on such systems. For more information, see [Section 20.4.3, “ndbmt — The NDB Cluster Data Node Daemon \(Multi-Threaded\)”](#).

It is also possible in some cases to run data nodes and SQL nodes concurrently on the same machine; how well such an arrangement performs is dependent on a number of factors such

as number of cores and CPUs as well as the amount of disk and memory available to the data node and SQL node processes, and you must take these factors into account when planning such a configuration.

**A.10.23**Can I add data nodes to an NDB Cluster without restarting it?

It is possible to add new data nodes to a running NDB Cluster without taking the cluster offline. For more information, see [Section 20.5.14, “Adding NDB Cluster Data Nodes Online”](#).

For other types of NDB Cluster nodes, a rolling restart is all that is required (see [Section 20.5.5, “Performing a Rolling Restart of an NDB Cluster”](#)).

**A.10.24**Are there any limitations that I should be aware of when using NDB Cluster?

Limitations on [NDB](#) tables in MySQL NDB Cluster 7.3 and later include the following:

- Temporary tables are not supported; a `CREATE TEMPORARY TABLE` statement using `ENGINE=NDB` or `ENGINE=NDBCLUSTER` fails with an error.
- The only types of user-defined partitioning supported for `NDBCLUSTER` tables are `KEY` and `LINEAR KEY`. Trying to create an `NDB` table using any other partitioning type fails with an error.
- `FULLTEXT` indexes are not supported.
- Index prefixes are not supported. Only complete columns may be indexed.
- Spatial indexes are not supported (although spatial columns can be used). See [Section 12.5, “Extensions for Spatial Data”](#).
- Support for partial transactions and partial rollbacks is comparable to that of other transactional storage engines such as `InnoDB` that can roll back individual statements.
- The maximum number of attributes allowed per table is 512. Attribute names cannot be any longer than 31 characters. For each table, the maximum combined length of the table and database names is 122 characters.
- The maximum size for a table row is 14 kilobytes, not counting `BLOB` values.

There is no set limit for the number of rows per `NDB` table. Limits on table size depend on a number of factors, in particular on the amount of RAM available to each data node.

For a complete listing of limitations in NDB Cluster, see [Section 20.1.6, “Known Limitations of NDB Cluster”](#). See also [Previous NDB Cluster Issues Resolved in NDB Cluster 7.3](#).

**A.10.25**Does NDB Cluster support foreign keys?

NDB Cluster 7.3 and later provide support for foreign key constraints, comparable to that found in the `InnoDB` storage engine; see [Section 1.8.3.2, “FOREIGN KEY Constraints”](#), for more detailed information, as well as [Section 14.1.18.5, “Using FOREIGN KEY Constraints”](#). Applications requiring foreign key support should use NDB Cluster 7.3, NDB Cluster 7.4, or later.

**A.10.26**How do I import an existing MySQL database into an NDB Cluster?

You can import databases into NDB Cluster much as you would with any other version of MySQL. Other than the limitations mentioned elsewhere in this FAQ, the only other special requirement is that any tables to be included in the cluster must use the `NDB` storage engine. This means that the tables must be created with `ENGINE=NDB` or `ENGINE=NDBCLUSTER`.

It is also possible to convert existing tables that use other storage engines to `NDBCLUSTER` using one or more `ALTER TABLE` statement. However, the definition of the table must be compatible with the `NDBCLUSTER` storage engine prior to making the conversion. In MySQL

5.7, an additional workaround is also required; see [Section 20.1.6, “Known Limitations of NDB Cluster”](#), for details.

**A.10.27**How do NDB Cluster nodes communicate with one another?

Cluster nodes can communicate through any of three different transport mechanisms: TCP/IP, SHM (shared memory), and SCI (Scalable Coherent Interface). Where available, SHM is used by default between nodes residing on the same cluster host; however, this is considered experimental. SCI is a high-speed (1 gigabit per second and higher), high-availability protocol used in building scalable multi-processor systems; it requires special hardware and drivers. See [Section 20.3.4, “Using High-Speed Interconnects with NDB Cluster”](#), for more about using SCI as a transport mechanism for NDB Cluster.

**A.10.28**What is an *arbitrator*?

If one or more data nodes in a cluster fail, it is possible that not all cluster data nodes will be able to “see” one another. In fact, it is possible that two sets of data nodes might become isolated from one another in a network partitioning, also known as a “split-brain” scenario. This type of situation is undesirable because each set of data nodes tries to behave as though it is the entire cluster. An arbitrator is required to decide between the competing sets of data nodes.

When all data nodes in at least one node group are alive, network partitioning is not an issue, because no single subset of the cluster can form a functional cluster on its own. The real problem arises when no single node group has all its nodes alive, in which case network partitioning (the “split-brain” scenario) becomes possible. Then an arbitrator is required. All cluster nodes recognize the same node as the arbitrator, which is normally the management server; however, it is possible to configure any of the MySQL Servers in the cluster to act as the arbitrator instead. The arbitrator accepts the first set of cluster nodes to contact it, and tells the remaining set to shut down. Arbitrator selection is controlled by the `ArbitrationRank` configuration parameter for MySQL Server and management server nodes. In NDB 7.0.7 and later, you can also use the `ArbitrationRank` configuration parameter to control the arbitrator selection process. For more information about these parameters, see [Section 20.3.3.5, “Defining an NDB Cluster Management Server”](#).

The role of arbitrator does not in and of itself impose any heavy demands upon the host so designated, and thus the arbitrator host does not need to be particularly fast or to have extra memory especially for this purpose.

**A.10.29**What data types are supported by NDB Cluster?

NDB Cluster supports all of the usual MySQL data types, including those associated with MySQL’s spatial extensions; however, the NDB storage engine does not support spatial indexes. (Spatial indexes are supported only by `MyISAM`; see [Section 12.5, “Extensions for Spatial Data”](#), for more information.) In addition, there are some differences with regard to indexes when used with NDB tables.

**Note**

NDB Cluster Disk Data tables (that is, tables created with `TABLESPACE ... STORAGE DISK ENGINE=NDB` or `TABLESPACE ... STORAGE DISK ENGINE=NDBCLUSTER`) have only fixed-width rows. This means that (for example) each Disk Data table record containing a `VARCHAR(255)` column requires space for 255 characters (as required for the character set and collation being used for the table), regardless of the actual number of characters stored therein.

See [Section 20.1.6, “Known Limitations of NDB Cluster”](#), for more information about these issues.

**A.10.30**How do I start and stop NDB Cluster?

It is necessary to start each node in the cluster separately, in the following order:

1. Start the management node, using the `ndb_mgmd` command.

You must include the `-f` or `--config-file` option to tell the management node where its configuration file can be found.

2. Start each data node with the `ndbd` command.

Each data node must be started with the `-c` or `--ndb-connectstring` option so that the data node knows how to connect to the management server.

3. Start each MySQL Server (SQL node) using your preferred startup script, such as `mysqld_safe`.

Each MySQL Server must be started with the `--ndbcluster` and `--ndb-connectstring` options. These options cause `mysqld` to enable `NDBCLUSTER` storage engine support and how to connect to the management server.

Each of these commands must be run from a system shell on the machine housing the affected node. (You do not have to be physically present at the machine—a remote login shell can be used for this purpose.) You can verify that the cluster is running by starting the `NDB` management client `ndb_mgm` on the machine housing the management node and issuing the `SHOW` or `ALL STATUS` command.

To shut down a running cluster, issue the command `SHUTDOWN` in the management client. Alternatively, you may enter the following command in a system shell:

```
shell> ndb_mgm -e "SHUTDOWN"
```

(The quotation marks in this example are optional, since there are no spaces in the command string following the `-e` option; in addition, the `SHUTDOWN` command, like other management client commands, is not case-sensitive.)

Either of these commands causes the `ndb_mgm`, `ndb_mgm`, and any `ndbd` processes to terminate gracefully. MySQL servers running as SQL nodes can be stopped using `mysqladmin shutdown`.

For more information, see [Section 20.5.2, “Commands in the NDB Cluster Management Client”](#), and [Section 20.2.7, “Safe Shutdown and Restart of NDB Cluster”](#).

#### **A.10.3** What happens to NDB Cluster data when the NDB Cluster is shut down?

The data that was held in memory by the cluster's data nodes is written to disk, and is reloaded into memory the next time that the cluster is started.

#### **A.10.3** Is it a good idea to have more than one management node for an NDB Cluster?

It can be helpful as a fail-safe. Only one management node controls the cluster at any given time, but it is possible to configure one management node as primary, and one or more additional management nodes to take over in the event that the primary management node fails.

See [Section 20.3.3, “NDB Cluster Configuration Files”](#), for information on how to configure NDB Cluster management nodes.

#### **A.10.3** Can I mix different kinds of hardware and operating systems in one NDB Cluster?

Yes, as long as all machines and operating systems have the same “endianness” (all big-endian or all little-endian).

It is also possible to use software from different NDB Cluster releases on different nodes. However, we support this only as part of a rolling upgrade procedure (see [Section 20.5.5, “Performing a Rolling Restart of an NDB Cluster”](#)).

**A.10.34** Can I run two data nodes on a single host? Two SQL nodes?

Yes, it is possible to do this. In the case of multiple data nodes, it is advisable (but not required) for each node to use a different data directory. If you want to run multiple SQL nodes on one machine, each instance of `mysqld` must use a different TCP/IP port.

Running data nodes and SQL nodes together on the same host is possible, but you should be aware that the `ndbd` (or `ndbmtd`) and `mysqld` processes may compete for memory.

**A.10.35** Can I use host names with NDB Cluster?

Yes, it is possible to use DNS and DHCP for cluster hosts. However, if your application requires “five nines” availability, you should use fixed (numeric) IP addresses, since making communication between Cluster hosts dependent on services such as DNS and DHCP introduces additional potential points of failure.

**A.10.36** Does NDB Cluster support IPv6?

IPv6 is supported for connections between SQL nodes (MySQL servers), but connections between all other types of NDB Cluster nodes must use IPv4.

In practical terms, this means that you can use IPv6 for replication between NDB Clusters, but connections between nodes in the same NDB Cluster must use IPv4. For more information, see [Section 20.6.3, “Known Issues in NDB Cluster Replication”](#).

**A.10.37** How do I handle MySQL users in an NDB Cluster having multiple MySQL servers?

MySQL user accounts and privileges are normally not automatically propagated between different MySQL servers accessing the same NDB Cluster. MySQL NDB Cluster 7.2 and later provides support for distributed privileges. While privilege distribution is not enabled automatically, you can activate it by following a procedure provided in the MySQL NDB Cluster documentation. See [Section 20.5.15, “Distributed MySQL Privileges for NDB Cluster”](#), for more information.

**A.10.38** How do I continue to send queries in the event that one of the SQL nodes fails?

MySQL NDB Cluster does not provide any sort of automatic failover between SQL nodes. Your application must be prepared to handle the loss of SQL nodes and to fail over between them.

**A.10.39** How do I back up and restore an NDB Cluster?

You can use the NDB Cluster native backup and restore functionality in the NDB management client and the `ndb_restore` program. See [Section 20.5.3, “Online Backup of NDB Cluster”](#), and [Section 20.4.20, “ndb\\_restore — Restore an NDB Cluster Backup”](#).

You can also use the traditional functionality provided for this purpose in `mysqldump` and the MySQL server. See [Section 5.5.4, “mysqldump — A Database Backup Program”](#), for more information.

**A.10.40** What is an “angel process”?

This process monitors and, if necessary, attempts to restart the data node process. If you check the list of active processes on your system after starting `ndbd`, you can see that there are actually 2 processes running by that name, as shown here (we omit the output from `ndb_mgmd` and `ndbd` for brevity):

```
shell> ./ndb_mgmd
```

```

shell> ps aux | grep ndb
me      23002  0.0  0.0 122948  3104 ?        Ssl  14:14   0:00 ./ndb_mgmd
me      23025  0.0  0.0   5284    820 pts/2    S+   14:14   0:00 grep ndb

shell> ./ndbd -c 127.0.0.1 --initial

shell> ps aux | grep ndb
me      23002  0.0  0.0 123080  3356 ?        Ssl  14:14   0:00 ./ndb_mgmd
me      23096  0.0  0.0  35876  2036 ?        Ss   14:14   0:00 ./ndbd -c 127.0.0.1 --initial
me      23097  1.0  2.4 524116 91096 ?        Sl   14:14   0:00 ./ndbd -c 127.0.0.1 --initial
me      23168  0.0  0.0   5284    812 pts/2    R+   14:15   0:00 grep ndb

```

The `ndbd` process showing 0 memory and CPU usage is the angel process. It actually does use a very small amount of each, of course. It simply checks to see if the main `ndbd` process (the primary data node process that actually handles the data) is running. If permitted to do so (for example, if the `StopOnError` configuration parameter is set to false—see [Section 20.3.2.1, “NDB Cluster Data Node Configuration Parameters”](#)), the angel process tries to restart the primary data node process.

## A.11 MySQL 5.7 FAQ: MySQL Chinese, Japanese, and Korean Character Sets

This set of Frequently Asked Questions derives from the experience of MySQL's Support and Development groups in handling many inquiries about CJK (Chinese-Japanese-Korean) issues.

- A.11.1 What CJK character sets are available in MySQL? ..... 4053
- A.11.2 I have inserted CJK characters into my table. Why does `SELECT` display them as “?” characters? ..... 4055
- A.11.3 What problems should I be aware of when working with the Big5 Chinese character set? .. 4056
- A.11.4 Why do Japanese character set conversions fail? ..... 4056
- A.11.5 What should I do if I want to convert SJIS 81CA to cp932? ..... 4057
- A.11.6 How does MySQL represent the Yen (¥) sign? ..... 4057
- A.11.7 Of what issues should I be aware when working with Korean character sets in MySQL? .... 4058
- A.11.8 Why do I get `Incorrect string value` error messages? ..... 4058
- A.11.9 Why does my GUI front end or browser display CJK characters incorrectly in my application using Access, PHP, or another API? ..... 4058
- A.11.10 I've upgraded to MySQL 5.7. How can I revert to behavior like that in MySQL 4.0 with regard to character sets? ..... 4059
- A.11.11 Why do some `LIKE` and `FULLTEXT` searches with CJK characters fail? ..... 4060
- A.11.12 How do I know whether character `x` is available in all character sets? ..... 4061
- A.11.13 Why do CJK strings sort incorrectly in Unicode? (I) ..... 4062
- A.11.14 Why do CJK strings sort incorrectly in Unicode? (II) ..... 4063
- A.11.15 Why are my supplementary characters rejected by MySQL? ..... 4064
- A.11.16 Should “CJK” be “CJKV”? ..... 4064
- A.11.17 Does MySQL permit CJK characters to be used in database and table names? ..... 4064
- A.11.18 Where can I find translations of the MySQL Manual into Chinese, Japanese, and Korean? ..... 4064
- A.11.19 Where can I get help with CJK and related issues in MySQL? ..... 4064

### A.11.1 What CJK character sets are available in MySQL?

The list of CJK character sets may vary depending on your MySQL version. For example, the `gb18030` character set is not supported prior to MySQL 5.7.4. However, since the name of the applicable language appears in the `DESCRIPTION` column for every entry in the `INFORMATION_SCHEMA.CHARACTER_SETS` table, you can obtain a current list of all the non-Unicode CJK character sets using this query:

```

mysql> SELECT CHARACTER_SET_NAME, DESCRIPTION
FROM INFORMATION_SCHEMA.CHARACTER_SETS
WHERE DESCRIPTION LIKE '%Chin%'
OR DESCRIPTION LIKE '%Japanese%'

```

```

OR DESCRIPTION LIKE '%Korean%'
ORDER BY CHARACTER_SET_NAME;

```

| CHARACTER_SET_NAME | DESCRIPTION                     |
|--------------------|---------------------------------|
| big5               | Big5 Traditional Chinese        |
| cp932              | SJIS for Windows Japanese       |
| ucjps              | UJIS for Windows Japanese       |
| euckr              | EUC-KR Korean                   |
| gb18030            | China National Standard GB18030 |
| gb2312             | GB2312 Simplified Chinese       |
| gbk                | GBK Simplified Chinese          |
| sjis               | Shift-JIS Japanese              |
| ujis               | EUC-JP Japanese                 |

(For more information, see [Section 23.1, “The INFORMATION\\_SCHEMA CHARACTER\\_SETS Table”](#).)

MySQL supports three variants of the *GB* (*Guojia Biaozhun*, or *National Standard*, or *Simplified Chinese*) character sets which are official in the People's Republic of China: `gb2312`, `gbk`, and (as of MySQL 5.7.4) `gb18030`.

Sometimes people try to insert `gbk` characters into `gb2312`, and it works most of the time because `gbk` is a superset of `gb2312`. But eventually they try to insert a rarer Chinese character and it does not work. (For an example, see Bug #16072).

Here, we try to clarify exactly what characters are legitimate in `gb2312` or `gbk`, with reference to the official documents. Please check these references before reporting `gb2312` or `gbk` bugs:

- The MySQL `gbk` character set is in reality “Microsoft code page 936”. This differs from the official `gbk` for characters `A1A4` (middle dot), `A1AA` (em dash), `A6E0–A6F5`, and `A8BB–A8C0`.
- For a listing of `gbk`/Unicode mappings, see <http://www.unicode.org/Public/MAPPINGS/VENDORS/MICSFT/WINDOWS/CP936.TXT>.

It is also possible to store CJK characters in Unicode character sets, although the available collations may not sort characters quite as you expect:

- The `utf8` and `ucs2` character sets support the characters from Unicode Basic Multilingual Plane (BMP). These characters have code point values between `U+0000` and `U+FFFF`.
- The `utf8mb4`, `utf16`, `utf16le`, and `utf32` character sets support BMP characters, as well as supplementary characters that lie outside the BMP. Supplementary characters have code point values between `U+10000` and `U+10FFFF`.

The collation used for a Unicode character set determines the ability to sort (that is, distinguish) characters in the set:

- Collations based on Unicode Collation Algorithm (UCA) 4.0.0 distinguish only BMP characters.
- Collations based on UCA 5.2.0 or 9.0.0 distinguish BMP and supplementary characters.
- Non-UCA collations may not distinguish all Unicode characters. For example, the `utf8mb4` default collation is `utf8mb4_general_ci`, which distinguishes only BMP characters.

Moreover, distinguishing characters is not the same as ordering them per the conventions of a given CJK language. Currently, MySQL has only one CJK-specific UCA collation, `gb18030_unicode_520_ci` (which requires use of the non-Unicode `gb18030` character set).

For information about Unicode collations and their differentiating properties, including collation properties for supplementary characters, see [Section 11.1.10.1, “Unicode Character Sets”](#).

**A.11.2** I have inserted CJK characters into my table. Why does `SELECT` display them as “?” characters?

This problem is usually due to a setting in MySQL that does not match the settings for the application program or the operating system. Here are some common steps for correcting these types of issues:

- *Be certain of what MySQL version you are using.*

Use the statement `SELECT VERSION();` to determine this.

- *Make sure that the database is actually using the desired character set.*

People often think that the client character set is always the same as either the server character set or the character set used for display purposes. However, both of these are false assumptions. You can make sure by checking the result of `SHOW CREATE TABLE tablename` or, better yet, by using this statement:

```
SELECT character_set_name, collation_name
FROM information_schema.columns
WHERE table_schema = your_database_name
      AND table_name = your_table_name
      AND column_name = your_column_name;
```

- *Determine the hexadecimal value of the character or characters that are not being displayed correctly.*

You can obtain this information for a column `column_name` in the table `table_name` using the following query:

```
SELECT HEX(column_name)
FROM table_name;
```

`3F` is the encoding for the `?` character; this means that `?` is the character actually stored in the column. This most often happens because of a problem converting a particular character from your client character set to the target character set.

- *Make sure that a round trip is possible. When you select `literal` (or `_introducer hexadecimal-value`), do you obtain `literal` as a result?*

For example, the Japanese Katakana character *Pe* (ペ) exists in all CJK character sets, and has the code point value (hexadecimal coding) `0x30da`. To test a round trip for this character, use this query:

```
SELECT 'ペ' AS `ペ`;          /* or SELECT _ucs2 0x30da; */
```

If the result is not also ペ, the round trip failed.

For bug reports regarding such failures, we might ask you to follow up with `SELECT HEX('ペ');`. Then we can determine whether the client encoding is correct.

- *Make sure that the problem is not with the browser or other application, rather than with MySQL.*

Use the `mysql` client program to accomplish this task. If `mysql` displays characters correctly but your application does not, your problem is probably due to system settings.

To determine your settings, use the `SHOW VARIABLES` statement, whose output should resemble what is shown here:

```
mysql> SHOW VARIABLES LIKE 'char%';
```

| Variable_name            | Value                                 |
|--------------------------|---------------------------------------|
| character_set_client     | utf8                                  |
| character_set_connection | utf8                                  |
| character_set_database   | latin1                                |
| character_set_filesystem | binary                                |
| character_set_results    | utf8                                  |
| character_set_server     | latin1                                |
| character_set_system     | utf8                                  |
| character_sets_dir       | /usr/local/mysql/share/mysqlCharsets/ |

These are typical character-set settings for an international-oriented client (notice the use of `utf8` Unicode) connected to a server in the West (`latin1` is a West Europe character set).

Although Unicode (usually the `utf8` variant on Unix, and the `ucs2` variant on Windows) is preferable to Latin, it is often not what your operating system utilities support best. Many Windows users find that a Microsoft character set, such as `cp932` for Japanese Windows, is suitable.

If you cannot control the server settings, and you have no idea what setting your underlying computer uses, try changing to a common character set for the country that you're in (`euckr` = Korea; `gb18030`, `gb2312` or `gbk` = People's Republic of China; `big5` = Taiwan; `sjis`, `ujis`, `cp932`, or `eucjpms` = Japan; `ucs2` or `utf8` = anywhere). Usually it is necessary to change only the client and connection and results settings. The `SET NAMES` statement changes all three at once. For example:

```
SET NAMES 'big5';
```

Once the setting is correct, you can make it permanent by editing `my.cnf` or `my.ini`. For example you might add lines looking like these:

```
[mysqld]
character-set-server=big5
[client]
default-character-set=big5
```

It is also possible that there are issues with the API configuration setting being used in your application; see *Why does my GUI front end or browser not display CJK characters correctly...?* for more information.

#### A.11.3 What problems should I be aware of when working with the Big5 Chinese character set?

MySQL supports the Big5 character set which is common in Hong Kong and Taiwan (Republic of China). The MySQL `big5` character set is in reality Microsoft code page 950, which is very similar to the original `big5` character set.

A feature request for adding `HKSCS` extensions has been filed. People who need this extension may find the suggested patch for Bug #13577 to be of interest.

#### A.11.4 Why do Japanese character set conversions fail?

MySQL supports the `sjis`, `ujis`, `cp932`, and `eucjpms` character sets, as well as Unicode. A common need is to convert between character sets. For example, there might be a Unix server (typically with `sjis` or `ujis`) and a Windows client (typically with `cp932`).

In the following conversion table, the `ucs2` column represents the source, and the `sjis`, `cp932`, `ujis`, and `eucjpms` columns represent the destinations; that is, the last 4 columns provide the hexadecimal result when we use `CONVERT(ucs2)` or we assign a `ucs2` column containing the value to an `sjis`, `cp932`, `ujis`, or `eucjpms` column.

| Character Name         | ucs2 | sjis | cp932 | ujis   | eucjpms |
|------------------------|------|------|-------|--------|---------|
| BROKEN BAR             | 00A6 | 3F   | 3F    | 8FA2C3 | 3F      |

| MINUS SIGN             | 2212 | 817C | 3F    | A1DD   | 3F      |
| FULLWIDTH HYPHEN-MINUS | FF0D | 3F   | 817C  | 3F     | A1DD    |
| CENT SIGN              | 00A2 | 8191 | 3F    | A1F1   | 3F      |
| FULLWIDTH CENT SIGN    | FFE0 | 3F   | 8191  | 3F     | A1F1    |
| POUND SIGN             | 00A3 | 8192 | 3F    | A1F2   | 3F      |
| FULLWIDTH POUND SIGN   | FFE1 | 3F   | 8192  | 3F     | A1F2    |
| NOT SIGN               | 00AC | 81CA | 3F    | A2CC   | 3F      |
| FULLWIDTH NOT SIGN     | FFE2 | 3F   | 81CA  | 3F     | A2CC    |

Now consider the following portion of the table.

|                    | ucs2 | sjis | cp932 |
|--------------------|------|------|-------|
| NOT SIGN           | 00AC | 81CA | 3F    |
| FULLWIDTH NOT SIGN | FFE2 | 3F   | 81CA  |

This means that MySQL converts the `NOT SIGN` (Unicode `U+00AC`) to `sjis` code point `0x81CA` and to `cp932` code point `3F`. (`3F` is the question mark (“?”). This is what is always used when the conversion cannot be performed.)

#### A.11.5 What should I do if I want to convert SJIS `81CA` to `cp932`?

Our answer is: “?”. There are disadvantages to this, and many people would prefer a “loose” conversion, so that `81CA (NOT SIGN)` in `sjis` becomes `81CA (FULLWIDTH NOT SIGN)` in `cp932`.

#### A.11.6 How does MySQL represent the Yen (¥) sign?

A problem arises because some versions of Japanese character sets (both `sjis` and `euc`) treat `5C` as a *reverse solidus* (`\`, also known as a backslash), whereas others treat it as a yen sign (¥).

MySQL follows only one version of the JIS (Japanese Industrial Standards) standard description. In MySQL, `5C` is always the *reverse solidus* (`\`).

**A.11.7**Of what issues should I be aware when working with Korean character sets in MySQL?

In theory, while there have been several versions of the `euckr` (*Extended Unix Code Korea*) character set, only one problem has been noted. We use the “ASCII” variant of EUC-KR, in which the code point `0x5c` is REVERSE SOLIDUS, that is `\`, instead of the “KS-Roman” variant of EUC-KR, in which the code point `0x5c` is WON SIGN (₩). This means that you cannot convert Unicode `U+20A9` to `euckr`:

```
mysql> SELECT
        CONVERT('₩' USING euckr) AS euckr,
        HEX(CONVERT('₩' USING euckr)) AS hexeuckr;
+-----+-----+
| euckr | hexeuckr |
+-----+-----+
| ?     | 3F       |
+-----+-----+
```

**A.11.8**Why do I get `Incorrect string value` error messages?

To see the problem, create a table with one Unicode (`ucs2`) column and one Chinese (`gb2312`) column.

```
mysql> CREATE TABLE ch
        (ucs2 CHAR(3) CHARACTER SET ucs2,
         gb2312 CHAR(3) CHARACTER SET gb2312);
```

In nonstrict SQL mode, try to place the rare character 𪛗 in both columns.

```
mysql> SET sql_mode = '';
mysql> INSERT INTO ch VALUES ('A𪛗B','A𪛗B');
Query OK, 1 row affected, 1 warning (0.00 sec)
```

The `INSERT` produces a warning. Use the following statement to see what it is:

```
mysql> SHOW WARNINGS\G
***** 1. row *****
Level: Warning
Code: 1366
Message: Incorrect string value: '\xE6\xB1\x8CB' for column 'gb2312' at row 1
```

So it is a warning about the `gb2312` column only.

```
mysql> SELECT ucs2,HEX(ucs2),gb2312,HEX(gb2312) FROM ch;
+-----+-----+-----+-----+
| ucs2 | HEX(ucs2) | gb2312 | HEX(gb2312) |
+-----+-----+-----+-----+
| A𪛗B | 00416C4C0042 | A?B    | 413F42       |
+-----+-----+-----+-----+
```

Several things need explanation here:

1. The 𪛗 character is not in the `gb2312` character set, as described earlier.
2. If you are using an old version of MySQL, you may see a different message.
3. A warning occurs rather than an error because MySQL is not set to use strict SQL mode. In nonstrict mode, MySQL tries to do what it can, to get the best fit, rather than give up. With strict SQL mode, the `Incorrect string value` message occurs as an error rather than a warning, and the `INSERT` fails.

**A.11.9**Why does my GUI front end or browser display CJK characters incorrectly in my application using Access, PHP, or another API?

Obtain a direct connection to the server using the `mysql` client, and try the same query there. If `mysql` responds correctly, the trouble may be that your application interface requires initialization. Use `mysql` to tell you what character set or sets it uses with the statement `SHOW VARIABLES LIKE 'char%';`. If you are using Access, you are most likely connecting with Connector/ODBC. In this case, you should check [Configuring Connector/ODBC](#). If, for example, you use `big5`, you would enter `SET NAMES 'big5'`. (In this case, no `;` character is required.) If you are using ASP, you might need to add `SET NAMES` in the code. Here is an example that has worked in the past:

```
<%
Session.CodePage=0
Dim strConnection
Dim Conn
strConnection="driver={MySQL ODBC 3.51 Driver};server=server;uid=username;" \
    & "pwd=password;database=database;stmt=SET NAMES 'big5';"
Set Conn = Server.CreateObject("ADODB.Connection")
Conn.Open strConnection
%>
```

In much the same way, if you are using any character set other than `latin1` with Connector/Net, you must specify the character set in the connection string. See [Connecting to MySQL Using Connector/Net](#), for more information.

If you are using PHP, try this:

```
<?php
$link = new mysqli($host, $usr, $pwd, $db);

if( mysqli_connect_errno() )
{
    printf("Connect failed: %s\n", mysqli_connect_error());
    exit();
}

$link->query("SET NAMES 'utf8'");
?>
```

In this case, we used `SET NAMES` to change `character_set_client`, `character_set_connection`, and `character_set_results`.

Another issue often encountered in PHP applications has to do with assumptions made by the browser. Sometimes adding or changing a `<meta>` tag suffices to correct the problem: for example, to insure that the user agent interprets page content as UTF-8, include `<meta http-equiv="Content-Type" content="text/html; charset=utf-8">` in the `<head>` section of the HTML page.

If you are using Connector/J, see [Using Character Sets and Unicode](#).

**A.11.10** I've upgraded to MySQL 5.7. How can I revert to behavior like that in MySQL 4.0 with regard to character sets?

In MySQL Version 4.0, there was a single “global” character set for both server and client, and the decision as to which character to use was made by the server administrator. This changed starting with MySQL Version 4.1. What happens now is a “handshake”, as described in [Section 11.1.4, “Connection Character Sets and Collations”](#):

When a client connects, it sends to the server the name of the character set that it wants to use. The server uses the name to set the `character_set_client`, `character_set_results`, and `character_set_connection` system variables. In effect, the server performs a `SET NAMES` operation using the character set name.

The effect of this is that you cannot control the client character set by starting `mysqld` with `--character-set-server=utf8`. However, some Asian customers prefer the MySQL 4.0 behavior. To make it possible to retain this behavior, we added a `mysqld` switch, `--character-set-client-handshake`, which can be turned off with `--skip-character-set-client-handshake`. If you start `mysqld` with `--skip-character-set-client-handshake`, then, when a client connects, it sends to the server the name of the character set that it wants to use. However, *the server ignores this request from the client*.

By way of example, suppose that your favorite server character set is `latin1` (unlikely in a CJK area, but this is the default value). Suppose further that the client uses `utf8` because this is what the client's operating system supports. Now, start the server with `latin1` as its default character set:

```
mysqld --character-set-server=latin1
```

And then start the client with the default character set `utf8`:

```
mysql --default-character-set=utf8
```

The resulting settings can be seen by viewing the output of `SHOW VARIABLES`:

```
mysql> SHOW VARIABLES LIKE 'char%';
```

| Variable_name            | Value                                  |
|--------------------------|--|
| character_set_client     | utf8                                   |
| character_set_connection | utf8                                   |
| character_set_database   | latin1                                 |
| character_set_filesystem | binary                                 |
| character_set_results    | utf8                                   |
| character_set_server     | latin1                                 |
| character_set_system     | utf8                                   |
| character_sets_dir       | /usr/local/mysql/share/mysql/charsets/ |

Now stop the client, and stop the server using `mysqladmin`. Then start the server again, but this time tell it to skip the handshake like so:

```
mysqld --character-set-server=utf8 --skip-character-set-client-handshake
```

Start the client with `utf8` once again as the default character set, then display the resulting settings:

```
mysql> SHOW VARIABLES LIKE 'char%';
```

| Variable_name            | Value                                  |
|--------------------------|--|
| character_set_client     | latin1                                 |
| character_set_connection | latin1                                 |
| character_set_database   | latin1                                 |
| character_set_filesystem | binary                                 |
| character_set_results    | latin1                                 |
| character_set_server     | latin1                                 |
| character_set_system     | utf8                                   |
| character_sets_dir       | /usr/local/mysql/share/mysql/charsets/ |

As you can see by comparing the differing results from `SHOW VARIABLES`, the server ignores the client's initial settings if the `--skip-character-set-client-handshake` option is used.

#### A.11.1 Why do some `LIKE` and `FULLTEXT` searches with CJK characters fail?

For `LIKE` searches, there is a very simple problem with binary string column types such as `BINARY` and `BLOB`: we must know where characters end. With multibyte character sets, different characters might have different octet lengths. For example, in `utf8`, `A` requires one byte but `へ` requires three bytes, as shown here:

```
+-----+-----+
| OCTET_LENGTH(_utf8 'A') | OCTET_LENGTH(_utf8 'へ') |
+-----+-----+
|                1 |                3 |
+-----+-----+
```

If we do not know where the first character in a string ends, we do not know where the second character begins, in which case even very simple searches such as `LIKE '_A%'` fail. The solution is to use a nonbinary string column type defined to have the proper CJK character set. For example: `mycol TEXT CHARACTER SET sjis`. Alternatively, convert to a CJK character set before comparing.

This is one reason why MySQL cannot permit encodings of nonexistent characters. If it is not strict about rejecting bad input, it has no way of knowing where characters end.

For `FULLTEXT` searches, we must know where words begin and end. With Western languages, this is rarely a problem because most (if not all) of these use an easy-to-identify word boundary: the space character. However, this is not usually the case with Asian writing. We could use arbitrary halfway measures, like assuming that all Han characters represent words, or (for Japanese) depending on changes from Katakana to Hiragana due to grammatical endings. However, the only sure solution requires a comprehensive word list, which means that we would have to include a dictionary in the server for each Asian language supported. This is simply not feasible.

#### A.11.12 How do I know whether character `x` is available in all character sets?

The majority of simplified Chinese and basic nonhalfwidth Japanese Kana characters appear in all CJK character sets. The following stored procedure accepts a `UCS-2` Unicode character, converts it to other character sets, and displays the results in hexadecimal.

```
DELIMITER //

CREATE PROCEDURE p_convert(ucs2_char CHAR(1) CHARACTER SET ucs2)
BEGIN

CREATE TABLE tj
(ucs2 CHAR(1) character set ucs2,
 utf8 CHAR(1) character set utf8,
 big5 CHAR(1) character set big5,
 cp932 CHAR(1) character set cp932,
 eucjpms CHAR(1) character set eucjpms,
 euckr CHAR(1) character set euckr,
 gb2312 CHAR(1) character set gb2312,
 gbk CHAR(1) character set gbk,
 sjis CHAR(1) character set sjis,
 ujis CHAR(1) character set ujis);

INSERT INTO tj (ucs2) VALUES (ucs2_char);

UPDATE tj SET utf8=ucs2,
             big5=ucs2,
             cp932=ucs2,
             eucjpms=ucs2,
             euckr=ucs2,
             gb2312=ucs2,
             gbk=ucs2,
             sjis=ucs2,
             ujis=ucs2;

/* If there are conversion problems, UPDATE produces warnings. */
```

```

SELECT hex(ucs2) AS ucs2,
       hex(utf8) AS utf8,
       hex(big5) AS big5,
       hex(cp932) AS cp932,
       hex(eucjpms) AS eucjpms,
       hex(euckr) AS euckr,
       hex(gb2312) AS gb2312,
       hex(gbk) AS gbk,
       hex(sjis) AS sjis,
       hex(ujis) AS ujis
FROM tj;

DROP TABLE tj;

END//

DELIMITER ;

```

The input can be any single `ucs2` character, or it can be the code value (hexadecimal representation) of that character. For example, from Unicode's list of `ucs2` encodings and names (<http://www.unicode.org/Public/UNIDATA/UnicodeData.txt>), we know that the Katakana character *Pe* appears in all CJK character sets, and that its code value is `X'30DA'`. If we use this value as the argument to `p_convert()`, the result is as shown here:

```

mysql> CALL p_convert(X'30DA');
+-----+-----+-----+-----+-----+-----+-----+-----+-----+-----+
| ucs2 | utf8  | big5  | cp932 | eucjpms | euckr | gb2312 | gbk   | sjis   | ujis   |
+-----+-----+-----+-----+-----+-----+-----+-----+-----+-----+
| 30DA | E3839A | C772  | 8379  | A5DA    | ABDA  | A5DA    | A5DA  | 8379   | A5DA   |
+-----+-----+-----+-----+-----+-----+-----+-----+-----+-----+

```

Since none of the column values is `3F` (that is, the question mark character, `?`), we know that every conversion worked.

#### A.11.13 Why do CJK strings sort incorrectly in Unicode? (I)

Sometimes people observe that the result of a `utf8_unicode_ci` or `ucs2_unicode_ci` search, or of an `ORDER BY` sort is not what they think a native would expect. Although we never rule out the possibility that there is a bug, we have found in the past that many people do not correctly read the standard table of weights for the Unicode Collation Algorithm. MySQL uses the tables found under <http://www.unicode.org/Public/UCA/>:

- UCA 4.0.0 table: <http://www.unicode.org/Public/UCA/4.0.0/allkeys-4.0.0.txt>

This includes `xxx_unicode_ci` collations with no version number in the collation name.

- UCA 5.2.0 table: <http://www.unicode.org/Public/UCA/5.2.0/allkeys.txt>

This includes collations with `_520_` in the collation name.

- UCA 9.0.0 table: <http://www.unicode.org/Public/UCA/9.0.0/allkeys.txt>

This includes collations with `_0900_` in the collation name.

To handle newer UCA versions, we create new collations. We are very wary about changing ordering of existing collations because that affects indexes, which can bring about situations such as that reported in Bug #16526, illustrated as follows:

```

mysql> CREATE TABLE tj (s1 CHAR(1) CHARACTER SET utf8 COLLATE utf8_unicode_ci);
Query OK, 0 rows affected (0.05 sec)

mysql> INSERT INTO tj VALUES ('が'),('か');
Query OK, 2 rows affected (0.00 sec)

```

```
Records: 2  Duplicates: 0  Warnings: 0

mysql> SELECT * FROM tj WHERE s1 = 'か';
+-----+
| s1    |
+-----+
| か    |
|      |
+-----+
```

The character in the first result row is not the one that we searched for. Why did MySQL retrieve it? First we look for the Unicode code point value, which is possible by reading the hexadecimal number for the `ucs2` version of the characters:

```
mysql> SELECT s1, HEX(CONVERT(s1 USING ucs2)) FROM tj;
+-----+-----+
| s1    | HEX(CONVERT(s1 USING ucs2)) |
+-----+-----+
| か    | 304C                        |
|      |                             |
|      |                             |
+-----+-----+
```

Now we search for `304B` and `304C` in the `4.0.0 allkeys` table, and find these lines:

```
304B ; [.1E57.0020.000E.304B] # HIRAGANA LETTER KA
304C ; [.1E57.0020.000E.304B][.0000.0140.0002.3099] # HIRAGANA LETTER GA; QQCM
```

The official Unicode names (following the “#” mark) tell us the Japanese syllabary (Hiragana), the informal classification (letter, digit, or punctuation mark), and the Western identifier (`KA` or `GA`, which happen to be voiced and unvoiced components of the same letter pair). More importantly, the *primary weight* (the first hexadecimal number inside the square brackets) is `1E57` on both lines. For comparisons in both searching and sorting, MySQL pays attention to the primary weight only, ignoring all the other numbers. This means that we are sorting `か` and `カ` correctly according to the Unicode specification. If we wanted to distinguish them, we'd have to use a non-UCA (Unicode Collation Algorithm) collation (`utf8_bin` or `utf8_general_ci`), or to compare the `HEX()` values, or use `ORDER BY CONVERT(s1 USING sjis)`. Being correct “according to Unicode” is not enough, of course: the person who submitted the bug was equally correct. To solve this, we need another collation for Japanese according to the JIS X 4061 standard, in which voiced/unvoiced letter pairs like `KA/GA` are distinguishable for ordering purposes.

#### A.11.14 Why do CJK strings sort incorrectly in Unicode? (II)

If you are using Unicode (`ucs2` or `utf8`), and you know what the Unicode sort order is (see [Section A.11, “MySQL 5.7 FAQ: MySQL Chinese, Japanese, and Korean Character Sets”](#)), but MySQL still seems to sort your table incorrectly, first verify the character set in the table definition:

```
mysql> SHOW CREATE TABLE t\G
***** 1. row *****
Table: t
Create Table: CREATE TABLE `t` (
`s1` char(1) CHARACTER SET ucs2 DEFAULT NULL
) ENGINE=MyISAM DEFAULT CHARSET=latin1
```

Since the character set for the column `s1` appears to be correct (`ucs2`), check what information the `INFORMATION_SCHEMA.COLUMNS` table can provide about this column:

```
mysql> SELECT COLUMN_NAME, CHARACTER_SET_NAME, COLLATION_NAME
FROM INFORMATION_SCHEMA.COLUMNS
WHERE COLUMN_NAME = 's1'
AND TABLE_NAME = 't';
```

| COLUMN_NAME | CHARACTER_SET_NAME | COLLATION_NAME  |
|-------------|--------------------|-----------------|
| s1          | ucs2               | ucs2_general_ci |

(See [Section 23.4](#), “The `INFORMATION_SCHEMA.COLUMNS` Table”, for more information.)

You can see that the collation is `ucs2_general_ci` instead of `ucs2_unicode_ci`. The reason why this is so can be found using `SHOW CHARACTER SET`, as shown here:

```
mysql> SHOW CHARSET LIKE 'ucs2%';
```

| Charset | Description   | Default collation | Maxlen |
|---------|---------------|-------------------|--------|
| ucs2    | UCS-2 Unicode | ucs2_general_ci   | 2      |

For `ucs2` and `utf8`, the default collation is “general”. To specify a Unicode UCA collation, use `COLLATE ucs2_unicode_ci`, as shown in the preceding item.

#### A.11.15 Why are my supplementary characters rejected by MySQL?

Supplementary characters lie outside the Unicode *Basic Multilingual Plane / Plane 0*. BMP characters have code point values between `U+0000` and `U+FFFF`. Supplementary characters have code point values between `U+10000` and `U+10FFFF`.

To store supplementary characters, you must use a character set that permits them:

- The `utf8` and `ucs2` character sets support BMP characters only.

The `utf8` character set permits only `UTF-8` characters that take up to three bytes. This has led to reports such as that found in Bug #12600, which we rejected as “not a bug”. With `utf8`, MySQL must truncate an input string when it encounters bytes that it does not understand. Otherwise, it is unknown how long the bad multibyte character is.

One possible workaround is to use `ucs2` instead of `utf8`, in which case the “bad” characters are changed to question marks. However, no truncation takes place. You can also change the data type to `BLOB` or `BINARY`, which perform no validity checking.

- The `utf8mb4`, `utf16`, `utf16le`, and `utf32` character sets support BMP characters, as well as supplementary characters outside the BMP.

#### A.11.16 Should “CJK” be “CJKV”?

No. The term “CJKV” (*Chinese Japanese Korean Vietnamese*) refers to Vietnamese character sets which contain Han (originally Chinese) characters. MySQL supports the modern Vietnamese script with Western characters, but does not support the old Vietnamese script using Han characters.

As of MySQL 5.6, there are Vietnamese collations for Unicode character sets, as described in [Section 11.1.10.1](#), “Unicode Character Sets”.

#### A.11.17 Does MySQL permit CJK characters to be used in database and table names?

Yes.

#### A.11.18 Where can I find translations of the MySQL Manual into Chinese, Japanese, and Korean?

The Japanese translation of the MySQL 5.6 manual can be downloaded from <http://dev.mysql.com/doc/>.

#### A.11.19 Where can I get help with CJK and related issues in MySQL?

The following resources are available:

- A listing of MySQL user groups can be found at <https://wikis.oracle.com/display/mysql/List+of+MySQL+User+Groups>.
- View feature requests relating to character set issues at <http://tinyurl.com/y6xcuf>.
- Visit the MySQL [Character Sets, Collation, Unicode Forum](http://forums.mysql.com/). <http://forums.mysql.com/> also provides foreign-language forums.

## A.12 MySQL 5.7 FAQ: Connectors & APIs

For common questions, issues, and answers relating to the MySQL Connectors and other APIs, see the following areas of the Manual:

- [Section 26.8.15, “Common Questions and Problems When Using the C API”](#)
- [Common Problems with MySQL and PHP](#)
- [Connector/ODBC Notes and Tips](#)
- [Connector/Net Programming](#)
- [MySQL Connector/J 5.1 Developer Guide](#)

## A.13 MySQL 5.7 FAQ: Replication

In the following section, we provide answers to questions that are most frequently asked about MySQL Replication.

|  |      |
|--|------|
| A.13.1 Must the slave be connected to the master all the time? .....   | 4065 |
| A.13.2 Must I enable networking on my master and slave to enable replication? .....  | 4066 |
| A.13.3 How do I know how late a slave is compared to the master? In other words, how do I know the date of the last statement replicated by the slave? ..... | 4066 |
| A.13.4 How do I force the master to block updates until the slave catches up? .....  | 4066 |
| A.13.5 What issues should I be aware of when setting up two-way replication? .....   | 4066 |
| A.13.6 How can I use replication to improve performance of my system? .....  | 4067 |
| A.13.7 What should I do to prepare client code in my own applications to use performance-enhancing replication? .....  | 4067 |
| A.13.8 When and how much can MySQL replication improve the performance of my system? .....   | 4067 |
| A.13.9 How can I use replication to provide redundancy or high availability? .....   | 4068 |
| A.13.10 How do I tell whether a master server is using statement-based or row-based binary logging format? .....   | 4068 |
| A.13.11 How do I tell a slave to use row-based replication? .....  | 4068 |
| A.13.12 How do I prevent <a href="#">GRANT</a> and <a href="#">REVOKE</a> statements from replicating to slave machines? ....                                | 4068 |
| A.13.13 Does replication work on mixed operating systems (for example, the master runs on Linux while slaves run on OS X and Windows)? .....                 | 4068 |
| A.13.14 Does replication work on mixed hardware architectures (for example, the master runs on a 64-bit machine while slaves run on 32-bit machines)? .....  | 4069 |

### A.13.1 Must the slave be connected to the master all the time?

No, it does not. The slave can go down or stay disconnected for hours or even days, and then reconnect and catch up on updates. For example, you can set up a master/slave relationship over a dial-up link where the link is up only sporadically and for short periods of time. The implication of this is that, at any given time, the slave is not guaranteed to be in synchrony with the master unless you take some special measures.

To ensure that catchup can occur for a slave that has been disconnected, you must not remove binary log files from the master that contain information that has not yet been replicated to the

slaves. Asynchronous replication can work only if the slave is able to continue reading the binary log from the point where it last read events.

**A.13.2** Must I enable networking on my master and slave to enable replication?

Yes, networking must be enabled on the master and slave. If networking is not enabled, the slave cannot connect to the master and transfer the binary log. Check that the `skip-networking` option has not been enabled in the configuration file for either server.

**A.13.3** How do I know how late a slave is compared to the master? In other words, how do I know the date of the last statement replicated by the slave?

Check the `Seconds_Behind_Master` column in the output from `SHOW SLAVE STATUS`. See [Section 18.1.7.1, “Checking Replication Status”](#).

When the slave SQL thread executes an event read from the master, it modifies its own time to the event timestamp. (This is why `TIMESTAMP` is well replicated.) In the `Time` column in the output of `SHOW PROCESSLIST`, the number of seconds displayed for the slave SQL thread is the number of seconds between the timestamp of the last replicated event and the real time of the slave machine. You can use this to determine the date of the last replicated event. Note that if your slave has been disconnected from the master for one hour, and then reconnects, you may immediately see large `Time` values such as 3600 for the slave SQL thread in `SHOW PROCESSLIST`. This is because the slave is executing statements that are one hour old. See [Section 18.2.2, “Replication Implementation Details”](#).

**A.13.4** How do I force the master to block updates until the slave catches up?

Use the following procedure:

1. On the master, execute these statements:

```
mysql> FLUSH TABLES WITH READ LOCK;
mysql> SHOW MASTER STATUS;
```

Record the replication coordinates (the current binary log file name and position) from the output of the `SHOW` statement.

2. On the slave, issue the following statement, where the arguments to the `MASTER_POS_WAIT()` function are the replication coordinate values obtained in the previous step:

```
mysql> SELECT MASTER_POS_WAIT('log_name', log_pos);
```

The `SELECT` statement blocks until the slave reaches the specified log file and position. At that point, the slave is in synchrony with the master and the statement returns.

3. On the master, issue the following statement to enable the master to begin processing updates again:

```
mysql> UNLOCK TABLES;
```

**A.13.5** What issues should I be aware of when setting up two-way replication?

MySQL replication currently does not support any locking protocol between master and slave to guarantee the atomicity of a distributed (cross-server) update. In other words, it is possible for client A to make an update to co-master 1, and in the meantime, before it propagates to co-master 2, client B could make an update to co-master 2 that makes the update of client A work differently than it did on co-master 1. Thus, when the update of client A makes it to co-master 2, it produces tables that are different from what you have on co-master 1, even after all the updates from co-master 2 have also propagated. This means that you should not chain two

servers together in a two-way replication relationship unless you are sure that your updates can safely happen in any order, or unless you take care of mis-ordered updates somehow in the client code.

You should also realize that two-way replication actually does not improve performance very much (if at all) as far as updates are concerned. Each server must do the same number of updates, just as you would have a single server do. The only difference is that there is a little less lock contention because the updates originating on another server are serialized in one slave thread. Even this benefit might be offset by network delays.

**A.13.6**How can I use replication to improve performance of my system?

Set up one server as the master and direct all writes to it. Then configure as many slaves as you have the budget and rackspace for, and distribute the reads among the master and the slaves. You can also start the slaves with the `--skip-innodb`, `--low-priority-updates`, and `--delay-key-write=ALL` options to get speed improvements on the slave end. In this case, the slave uses nontransactional `MyISAM` tables instead of `InnoDB` tables to get more speed by eliminating transactional overhead.

**A.13.7**What should I do to prepare client code in my own applications to use performance-enhancing replication?

See the guide to using replication as a scale-out solution, [Section 18.3.4, “Using Replication for Scale-Out”](#).

**A.13.8**When and how much can MySQL replication improve the performance of my system?

MySQL replication is most beneficial for a system that processes frequent reads and infrequent writes. In theory, by using a single-master/multiple-slave setup, you can scale the system by adding more slaves until you either run out of network bandwidth, or your update load grows to the point that the master cannot handle it.

To determine how many slaves you can use before the added benefits begin to level out, and how much you can improve performance of your site, you must know your query patterns, and determine empirically by benchmarking the relationship between the throughput for reads and writes on a typical master and a typical slave. The example here shows a rather simplified calculation of what you can get with replication for a hypothetical system. Let `reads` and `writes` denote the number of reads and writes per second, respectively.

Let's say that system load consists of 10% writes and 90% reads, and we have determined by benchmarking that `reads` is `1200 - 2 * writes`. In other words, the system can do 1,200 reads per second with no writes, the average write is twice as slow as the average read, and the relationship is linear. Suppose that the master and each slave have the same capacity, and that we have one master and `N` slaves. Then we have for each server (master or slave):

$$\text{reads} = 1200 - 2 * \text{writes}$$

$$\text{reads} = 9 * \text{writes} / (N + 1) \text{ (reads are split, but writes replicated to all slaves)}$$

$$9 * \text{writes} / (N + 1) + 2 * \text{writes} = 1200$$

$$\text{writes} = 1200 / (2 + 9/(N + 1))$$

The last equation indicates the maximum number of writes for `N` slaves, given a maximum possible read rate of 1,200 per second and a ratio of nine reads per write.

This analysis yields the following conclusions:

- If `N` = 0 (which means we have no replication), our system can handle about  $1200/11 = 109$  writes per second.

- If  $N = 1$ , we get up to 184 writes per second.
- If  $N = 8$ , we get up to 400 writes per second.
- If  $N = 17$ , we get up to 480 writes per second.
- Eventually, as  $N$  approaches infinity (and our budget negative infinity), we can get very close to 600 writes per second, increasing system throughput about 5.5 times. However, with only eight servers, we increase it nearly four times.

These computations assume infinite network bandwidth and neglect several other factors that could be significant on your system. In many cases, you may not be able to perform a computation similar to the one just shown that accurately predicts what will happen on your system if you add  $N$  replication slaves. However, answering the following questions should help you decide whether and by how much replication will improve the performance of your system:

- What is the read/write ratio on your system?
- How much more write load can one server handle if you reduce the reads?
- For how many slaves do you have bandwidth available on your network?

#### **A.13.9**How can I use replication to provide redundancy or high availability?

How you implement redundancy is entirely dependent on your application and circumstances. High-availability solutions (with automatic failover) require active monitoring and either custom scripts or third party tools to provide the failover support from the original MySQL server to the slave.

To handle the process manually, you should be able to switch from a failed master to a pre-configured slave by altering your application to talk to the new server or by adjusting the DNS for the MySQL server from the failed server to the new server.

For more information and some example solutions, see [Section 18.3.7, “Switching Masters During Failover”](#).

#### **A.13.10**How do I tell whether a master server is using statement-based or row-based binary logging format?

Check the value of the `binlog_format` system variable:

```
mysql> SHOW VARIABLES LIKE 'binlog_format';
```

The value shown will be one of `STATEMENT`, `ROW`, or `MIXED`. For `MIXED` mode, statement-based logging is used by default but replication switches automatically to row-based logging under certain conditions, such as unsafe statements. For information about when this may occur, see [Section 6.4.4.3, “Mixed Binary Logging Format”](#).

#### **A.13.11**How do I tell a slave to use row-based replication?

Slaves automatically know which format to use.

#### **A.13.12**How do I prevent `GRANT` and `REVOKE` statements from replicating to slave machines?

Start the server with the `--replicate-wild-ignore-table=mysql.%` option to ignore replication for tables in the `mysql` database.

#### **A.13.13**Does replication work on mixed operating systems (for example, the master runs on Linux while slaves run on OS X and Windows)?

Yes.

**A.13.14** Does replication work on mixed hardware architectures (for example, the master runs on a 64-bit machine while slaves run on 32-bit machines)?

Yes.

## A.14 MySQL 5.7 FAQ: MySQL Enterprise Thread Pool

|   |      |
|---|------|
| A.14.1 What is the Thread Pool and what problem does it solve? .....  | 4069 |
| A.14.2 How does the Thread Pool limit and manage concurrent sessions and transactions for optimal performance and throughput? ..... | 4069 |
| A.14.3 How is the Thread Pool different from the client side Connection Pool? .....   | 4069 |
| A.14.4 When should I use the Thread Pool? .....   | 4069 |
| A.14.5 Are there recommended Thread Pool configurations? .....  | 4070 |

**A.14.1** What is the Thread Pool and what problem does it solve?

The MySQL Thread Pool is a MySQL server plugin that extends the default connection-handling capabilities of the MySQL server to limit the number of concurrently executing statements/queries and transactions to ensure that each has sufficient CPU and memory resources to fulfill its task. Commercial distributions of MySQL 5.7 include the Thread Pool plugin.

The default thread-handling model in MySQL Server executes statements using one thread per client connection. As more clients connect to the server and execute statements, overall performance degrades. The Thread Pool plugin provides an alternative thread-handling model designed to reduce overhead and improve performance. The Thread Pool plugin increases server performance by efficiently managing statement execution threads for large numbers of client connections, especially on modern multi-CPU/Core systems.

For more information, see [Section 6.5.4, “MySQL Enterprise Thread Pool”](#).

**A.14.2** How does the Thread Pool limit and manage concurrent sessions and transactions for optimal performance and throughput?

The Thread Pool uses a “divide and conquer” approach to limiting and balancing concurrency. Unlike the default connection handling of the MySQL Server, the Thread Pool separates connections and threads, so there is no fixed relationship between connections and the threads that execute statements received from those connections. The Thread Pool then manages client connections within configurable thread groups, where they are prioritized and queued based on the nature of the work they were submitted to accomplish.

For more information, see [Section 6.5.4.3, “Thread Pool Operation”](#).

**A.14.3** How is the Thread Pool different from the client side Connection Pool?

The MySQL Connection Pool operates on the client side to ensure that a MySQL client does not constantly connect to and disconnect from the MySQL server. It is designed to cache idle connections in the MySQL client for use by other users as they are needed. This minimizes the overhead and expense of establishing and tearing down connections as queries are submitted to the MySQL server. The MySQL Connection Pool has no visibility as to the query handling capabilities or load of the backend MySQL server. By contrast, the Thread Pool operates on the MySQL server side and is designed to manage the execution of inbound concurrent connections and queries as they are received from the client connections accessing the backend MySQL database. Because of the separation of duties, the MySQL Connection Pool and Thread Pool are orthogonal and can be used independent of each other.

MySQL Connection Pooling via the MySQL Connectors is covered in [Chapter 26, Connectors and APIs](#).

**A.14.4** When should I use the Thread Pool?

There are a few rules of thumb to consider for optimal Thread Pool use cases:

The MySQL `Threads_running` variable keeps track of the number of concurrent statements currently executing in the MySQL Server. If this variable consistently exceeds a region where the server won't operate optimally (usually going beyond 40 for InnoDB workloads), the Thread Pool will be beneficial, especially in extreme parallel overload situations.

If you are using the `innodb_thread_concurrency` to limit the number of concurrently executing statements, you will find the Thread Pool solves the same problem, only better, by assigning connections to thread groups, then queuing executions based on transactional content, user defined designations, and so forth.

Lastly, if your workload comprises mainly short queries, the Thread Pool will be beneficial.

To learn more, see [Section 6.5.4.4, "Thread Pool Tuning"](#).

#### **A.14.5** Are there recommended Thread Pool configurations?

The Thread Pool has a number of user case driven configuration parameters that affect its performance. To learn about these and tips on tuning, see [Section 6.5.4.4, "Thread Pool Tuning"](#).

## **A.15 MySQL 5.7 FAQ: InnoDB Change Buffer**

|  |      |
|--|------|
| A.15.1 What types of operations modify secondary indexes and result in change buffering? ..... | 4070 |
| A.15.2 What is the benefit of the <code>InnoDB</code> change buffer? .....                     | 4070 |
| A.15.3 Does the change buffer support other types of indexes? .....                            | 4070 |
| A.15.4 How much space does <code>InnoDB</code> use for the change buffer? .....                | 4070 |
| A.15.5 How do I determine the current size of the change buffer? .....                         | 4071 |
| A.15.6 When does change buffer merging occur? .....  | 4071 |
| A.15.7 When is the change buffer flushed? .....  | 4071 |
| A.15.8 When should the change buffer be used? .....  | 4071 |
| A.15.9 When should the change buffer not be used? .....  | 4071 |
| A.15.10 Where can I find additional information about the change buffer? .....                 | 4072 |

#### **A.15.1** What types of operations modify secondary indexes and result in change buffering?

`INSERT`, `UPDATE`, and `DELETE` operations can modify secondary indexes. If an affected index page is not in the buffer pool, the changes can be buffered in the change buffer.

#### **A.15.2** What is the benefit of the `InnoDB` change buffer?

Buffering secondary index changes when secondary index pages are not in the buffer pool avoids expensive random access I/O operations that would be required to immediately read in affected index pages from disk. Buffered changes can be applied later, in batches, as pages are read into the buffer pool by other read operations.

#### **A.15.3** Does the change buffer support other types of indexes?

No. The change buffer only supports secondary indexes. Clustered indexes, full-text indexes, and spatial indexes are not supported. Full-text indexes have their own caching mechanism.

#### **A.15.4** How much space does `InnoDB` use for the change buffer?

Prior to the introduction of the `innodb_change_buffer_max_size` configuration option in MySQL 5.6, the maximum size of the on-disk change buffer in the system tablespace was 1/3 of the `InnoDB` buffer pool size.

In MySQL 5.6 and later, the `innodb_change_buffer_max_size` configuration option defines the maximum size of the change buffer as a percentage of the total buffer pool size. By default, `innodb_change_buffer_max_size` is set to 25. The maximum setting is 50.

[InnoDB](#) does not buffer an operation if it would cause the on-disk change buffer to exceed the defined limit.

Change buffer pages are not required to persist in the buffer pool and may be evicted by LRU operations.

#### A.15.5 How do I determine the current size of the change buffer?

The current size of the change buffer is reported by `SHOW ENGINE INNODB STATUS \G`, under the `INSERT BUFFER AND ADAPTIVE HASH INDEX` heading. For example:

```
-----  
INSERT BUFFER AND ADAPTIVE HASH INDEX  
-----  
Ibuf: size 1, free list len 0, seg size 2, 0 merges
```

Relevant data points include:

- `size`: The number of pages used within the change buffer. Change buffer size is equal to `seg size - (1 + free list len)`. The `1 +` value represents the change buffer header page.
- `seg size`: The size of the change buffer, in pages.

For information about monitoring change buffer status, see [Section 15.4.2, “Change Buffer”](#).

#### A.15.6 When does change buffer merging occur?

- When a page is read into the buffer pool, buffered changes are merged upon completion of the read, before the page is made available.
- Change buffer merging is performed as a background task. The `innodb_io_capacity` parameter sets an upper limit on the I/O activity performed by [InnoDB](#) background tasks such as merging data from the change buffer.
- A change buffer merge is performed during crash recovery. Changes are applied from the change buffer (in the system tablespace) to leaf pages of secondary indexes as index pages are read into the buffer pool.
- The change buffer is fully durable and will survive a system crash. Upon restart, change buffer merge operations resume as part of normal operations.
- A full merge of the change buffer can be forced as part of a slow server shutdown using `--innodb-fast-shutdown=0`.

#### A.15.7 When is the change buffer flushed?

Updated pages are flushed by the same flushing mechanism that flushes the other pages that occupy the buffer pool.

#### A.15.8 When should the change buffer be used?

The change buffer is a feature designed to reduce random I/O to secondary indexes as indexes grow larger and no longer fit in the [InnoDB](#) buffer pool. Generally, the change buffer should be used when the entire data set does not fit into the buffer pool, when there is substantial DML activity that modifies secondary index pages, or when there are lots of secondary indexes that are regularly changed by DML activity.

#### A.15.9 When should the change buffer not be used?

You might consider disabling the change buffer if the entire data set fits within the [InnoDB](#) buffer pool, if you have relatively few secondary indexes, or if you are using solid-state storage, where

random reads are about as fast as sequential reads. Before making configuration changes, it is recommended that you run tests using a representative workload to determine if disabling the change buffer provides any benefit.

**A.15.10**Where can I find additional information about the change buffer?

The following sections and blog post provide additional information about the [InnoDB](#) change buffer:

- [Section 15.4.2, “Change Buffer”](#)
- [Section 15.6.5, “Configuring InnoDB Change Buffering”](#)
- [MySQL 5.5: InnoDB Change Buffering](#)

## A.16 MySQL 5.7 FAQ: InnoDB Tablespace Encryption

|  |      |
|--|------|
| A.16.1 Is data decrypted for users who are authorized to see it? .....   | 4072 |
| A.16.2 What is the overhead associated with <a href="#">InnoDB</a> tablespace encryption? .....  | 4072 |

| A.16.5 Can indexed columns be encrypted? .....   | 4073 |
| A.16.6 What data types and data lengths does <a href="#">InnoDB</a> tablespace encryption support? .....   | 4073 |
| A.16.7 Does data remain encrypted on the network? .....  | 4073 |
| A.16.8 Does database memory contain clear-text or encrypted data? .....  | 4073 |
| A.16.9 How do I know which data to encrypt? .....  | 4073 |
| A.16.10 How is <a href="#">InnoDB</a> tablespace encryption different from encryption functions MySQL already provides? .....                                | 4073 |
| A.16.11 Does the transportable tablespaces feature work with <a href="#">InnoDB</a> tablespace encryption? ...   | 4073 |
| A.16.12 Does compression work with <a href="#">InnoDB</a> tablespace encryption? .....   | 4073 |
| A.16.13 Can I use <a href="#">mysqldump</a> or <a href="#">mysqlpump</a> with encrypted tables? .....  | 4073 |
| A.16.14 How do I change (rotate, re-key) the master encryption key? .....  | 4073 |
| A.16.15 How do I migrate data from a clear-text <a href="#">InnoDB</a> tablespace to an encrypted <a href="#">InnoDB</a> tablespace? .....                   | 4074 |
| A.16.16 Can the <a href="#">InnoDB</a> tablespace encryption feature store the master encryption key in an external device using the PKSC11 interface? ..... | 4074 |

**A.16.1**Is data decrypted for users who are authorized to see it?

Yes. [InnoDB](#) tablespace encryption is designed to provide customers with the ability to transparently apply encryption within the database without impacting existing applications. Returning data in encrypted format would break most existing applications. [InnoDB](#) tablespace encryption provides the benefit of encryption without the overhead associated with traditional database encryption solutions, which would typically require expensive and substantial changes to applications, database triggers, and views.

**A.16.2**What is the overhead associated with [InnoDB](#) tablespace encryption?

There is no additional storage overhead. According to internal benchmarks, performance overhead amounts to a single digit percentage difference.

**A.16.3**What are the encryption algorithms used with [InnoDB](#) tablespace encryption?

[InnoDB](#) tablespace encryption supports the Advanced Encryption Standard (AES256) block-based encryption algorithm. It uses Electronic Codebook (ECB) block encryption mode for tablespace key encryption and Cipher Block Chaining (CBC) block encryption mode for data encryption.

**A.16.4**Is it possible to use 3rd party encryption algorithms in place of the one provided by the [InnoDB](#) tablespace encryption feature?

No, it is not possible to use other encryption algorithms. The provided encryption algorithm is broadly accepted.

**A.16.5** Can indexed columns be encrypted?

[InnoDB](#) tablespace encryption supports all indexes transparently.

**A.16.6** What data types and data lengths does [InnoDB](#) tablespace encryption support?

[InnoDB](#) tablespace encryption supports all supported data types. There is no data length limitation.

**A.16.7** Does data remain encrypted on the network?

Data encrypted by the [InnoDB](#) tablespace encryption feature is decrypted when it is read from the tablespace file. Thus, if the data is on the network, it is in clear-text form. However, data on the network can be encrypted using MySQL network encryption, which encrypts data traveling to and from a database using SSL/TLS.

**A.16.8** Does database memory contain clear-text or encrypted data?

With [InnoDB](#) tablespace encryption, in-memory data is decrypted, which provides 100% transparency.

**A.16.9** How do I know which data to encrypt?

Compliance with the PCI-DSS standard requires that credit card numbers (Primary Account Number, or 'PAN') be stored in encrypted form. Breach Notification Laws (for example, CA SB 1386, CA AB 1950, and similar laws in 43+ more US states) require encryption of first name, last name, driver license number, and other PII data. In early 2008, CA AB 1298 added medical and health insurance information to PII data. Additionally, industry specific privacy and security standards may require encryption of certain assets. For example, assets such as pharmaceutical research results, oil field exploration results, financial contracts, or personal data of law enforcement informants may require encryption. In the health care industry, the privacy of patient data, health records and X-ray images is of the highest importance.

**A.16.10** How is [InnoDB](#) tablespace encryption different from encryption functions MySQL already provides?

There are symmetric and asymmetric encryption APIs in MySQL that can be used to manually encrypt data within the database. However, the application must manage encryption keys and perform required encryption and decryption operations by calling API functions. [InnoDB](#) tablespace encryption requires no application changes, is transparent to end users, and provides automated, built-in key management.

**A.16.11** Does the transportable tablespaces feature work with [InnoDB](#) tablespace encryption?

Yes. For more information, see [Exporting Encrypted Tables](#).

**A.16.12** Does compression work with [InnoDB](#) tablespace encryption?

Customers using [InnoDB](#) tablespace encryption receive the full benefit of compression because compression is applied before data blocks are encrypted.

**A.16.13** Can I use [mysqlpump](#) or [mysqldump](#) with encrypted tables?

Yes. Because these utilities create logical backups, the data dumped from encrypted tables is not encrypted.

**A.16.14** How do I change (rotate, re-key) the master encryption key?

[InnoDB](#) tablespace encryption uses a two tier key mechanism. When tablespace encryption is used, individual tablespace keys are stored in the header of the underlying tablespace data

file. Tablespace keys are encrypted using the master encryption key. The master encryption key is generated when tablespace encryption is enabled, and is stored outside the database. The master encryption key is rotated using the `ALTER INSTANCE ROTATE INNODB MASTER KEY` statement, which generates a new master encryption key, stores the key, and rotates the key into use.

**A.16.15** How do I migrate data from a clear-text [InnoDB](#) tablespace to an encrypted [InnoDB](#) tablespace?

Transferring data from one tablespace to another is not required. To encrypt data in an [InnoDB](#) tablespace, run `ALTER TABLE tbl_name ENCRYPTION='Y'`. [InnoDB](#) tablespace encryption is only supported with [file-per-table](#) tablespaces.

**A.16.16** Can the [InnoDB](#) tablespace encryption feature store the master encryption key in an external device using the PKSC11 interface?

Not at this time. Currently, the KMIP v1.2 protocol is supported with the [keyring\\_okv](#) plugin, which is available with MySQL Enterprise Edition.

## A.17 MySQL 5.7 FAQ: Virtualization Support

A.17.1 Is MySQL supported on virtualized environments such as Oracle VM, VMWare, Docker, Microsoft Hyper-V, or others? ..... 4074

**A.17.1** Is MySQL supported on virtualized environments such as Oracle VM, VMWare, Docker, Microsoft Hyper-V, or others?

MySQL is supported on virtualized environments, but is certified only for [Oracle VM](#). Contact Oracle Support for more information.

Be aware of potential problems when using virtualization software. The usual ones are related to performance, performance degradations, slowness, or unpredictability of disk, I/O, network, and memory.

---

## Appendix B Errors, Error Codes, and Common Problems

### Table of Contents

|  |      |

| B.5.6 Table Definition-Related Issues .....            | 4194 |
| B.5.7 Known Issues in MySQL .....                      | 4195 |

This appendix lists common problems and errors that may occur and potential resolutions, in addition to listing the errors that may appear when you call MySQL from any host language. The first section covers problems and resolutions. Detailed information on errors is provided: One list displays server error messages. Another list displays client program messages.

### B.1 Sources of Error Information

There are several sources of error information in MySQL:

- Each SQL statement executed results in an error code, an SQLSTATE value, and an error message, as described in [Section B.2, “Types of Error Values”](#). These errors are returned from the server side; see [Section B.3, “Server Error Codes and Messages”](#).
- Errors can occur on the client side, usually involving problems communicating with the server; see [Section B.4, “Client Error Codes and Messages”](#).
- SQL statement warning and error information is available through the `SHOW WARNINGS` and `SHOW ERRORS` statements. The `warning_count` system variable indicates the number of errors, warnings, and notes. The `error_count` system variable indicates the number of errors. Its value excludes warnings and notes.
- The `GET DIAGNOSTICS` statement may be used to inspect the diagnostic information in the diagnostics area. See [Section 14.6.7.3, “GET DIAGNOSTICS Syntax”](#).
- `SHOW SLAVE STATUS` statement output includes information about replication errors occurring on the slave side.
- `SHOW ENGINE INNODB STATUS` statement output includes information about the most recent foreign key error if a `CREATE TABLE` statement for an `InnoDB` table fails.
- The `pererror` program provides information from the command line about error numbers. See [Section 5.8.2, “pererror — Explain Error Codes”](#).

Descriptions of server and client errors are provided later in this Appendix. For information about errors related to `InnoDB`, see [Section 15.21.4, “InnoDB Error Handling”](#).

### B.2 Types of Error Values

When an error occurs in MySQL, the server returns two types of error values:

- A MySQL-specific error code. This value is numeric. It is not portable to other database systems.

- An SQLSTATE value. The value is a five-character string (for example, '42S02'). The values are taken from ANSI SQL and ODBC and are more standardized.

A message string that provides a textual description of the error is also available.

When an error occurs, the MySQL error code, SQLSTATE value, and message string are available using C API functions:

- MySQL error code: Call `mysql_errno()`
- SQLSTATE value: Call `mysql_sqlstate()`
- Error message: Call `mysql_error()`

For prepared statements, the corresponding error functions are `mysql_stmt_errno()`, `mysql_stmt_sqlstate()`, and `mysql_stmt_error()`. All error functions are described in [Section 26.8, “MySQL C API”](#).

The number of errors, warnings, and notes for the previous statement can be obtained by calling `mysql_warning_count()`. See [Section 26.8.7.78, “mysql\\_warning\\_count\(\)”](#).

The first two characters of an SQLSTATE value indicate the error class:

- Class = '00' indicates success.
- Class = '01' indicates a warning.
- Class = '02' indicates “not found.” This is relevant within the context of cursors and is used to control what happens when a cursor reaches the end of a data set. This condition also occurs for `SELECT ... INTO var_list` statements that retrieve no rows.
- Class > '02' indicates an exception.

## B.3 Server Error Codes and Messages

MySQL programs have access to several types of error information when the server returns an error. For example, the `mysql` client program displays errors using the following format:

```
shell> SELECT * FROM no_such_table;
ERROR 1146 (42S02): Table 'test.no_such_table' doesn't exist
```

The message displayed contains three types of information:

- A numeric error code (1146). This number is MySQL-specific and is not portable to other database systems.
- A five-character SQLSTATE value ('42S02'). The values are taken from ANSI SQL and ODBC and are more standardized. Not all MySQL error numbers have corresponding SQLSTATE values. In these cases, 'HY000' (general error) is used.
- A message string that provides a textual description of the error.

For error checking, use error codes, not error messages. Error messages do not change often, but it is possible. Also if the database administrator changes the language setting, that affects the language of error messages.

Error codes are stable across GA releases of a given MySQL series. Before a series reaches GA status, new codes may still be under development and subject to change.

Server error information comes from the following source files. For details about the way that error information is defined, see the [MySQL Internals Manual](#).

- Error message information is listed in the [share/errmsg-utf8.txt](#) file. %d and %s represent numbers and strings, respectively, that are substituted into the Message values when they are displayed.
- The Error values listed in [share/errmsg-utf8.txt](#) are used to generate the definitions in the [include/mysqld\\_error.h](#) and [include/mysqld\\_ename.h](#) MySQL source files.
- The SQLSTATE values listed in [share/errmsg-utf8.txt](#) are used to generate the definitions in the [include/sql\\_state.h](#) MySQL source file.

Because updates are frequent, it is possible that those files will contain additional error information not listed here.

- Error: 1000 SQLSTATE: HY000 (ER\_HASHCHK)

Message: hashchk

Unused.

- Error: 1001 SQLSTATE: HY000 (ER\_NISAMCHK)

Message: isamchk

Unused.

- Error: 1002 SQLSTATE: HY000 (ER\_NO)

Message: NO

Used in the construction of other messages.

- Error: 1003 SQLSTATE: HY000 (ER\_YES)

Message: YES

Used in the construction of other messages.

Extended [EXPLAIN](#) format generates Note messages. [ER\\_YES](#) is used in the [Code](#) column for these messages in subsequent [SHOW WARNINGS](#) output.

- Error: 1004 SQLSTATE: HY000 (ER\_CANT\_CREATE\_FILE)

Message: Can't create file '%s' (errno: %d - %s)

Occurs for failure to create or copy a file needed for some operation.

Possible causes: Permissions problem for source file; destination file already exists but is not writeable.

- Error: 1005 SQLSTATE: HY000 (ER\_CANT\_CREATE\_TABLE)

Message: Can't create table '%s' (errno: %d)

[InnoDB](#) reports this error when a table cannot be created. If the error message refers to error 150, table creation failed because a [foreign key constraint](#) was not correctly formed. If the error message refers to error -1, table creation probably failed because the table includes a column name that matched the name of an internal [InnoDB](#) table.

- Error: 1006 SQLSTATE: HY000 (ER\_CANT\_CREATE\_DB)

Message: Can't create database '%s' (errno: %d)

- Error: 1007 SQLSTATE: HY000 (ER\_DB\_CREATE\_EXISTS)

Message: Can't create database '%s'; database exists

An attempt to create a database failed because the database already exists.

Drop the database first if you really want to replace an existing database, or add an `IF NOT EXISTS` clause to the `CREATE DATABASE` statement if to retain an existing database without having the statement produce an error.

- Error: 1008 SQLSTATE: HY000 (ER\_DB\_DROP\_EXISTS)

Message: Can't drop database '%s'; database doesn't exist

- Error: 1009 SQLSTATE: HY000 (ER\_DB\_DROP\_DELETE)

Message: Error dropping database (can't delete '%s', errno: %d)

- Error: 1010 SQLSTATE: HY000 (ER\_DB\_DROP\_RMDIR)

Message: Error dropping database (can't rmdir '%s', errno: %d)

- Error: 1011 SQLSTATE: HY000 (ER\_CANT\_DELETE\_FILE)

Message: Error on delete of '%s' (errno: %d - %s)

- Error: 1012 SQLSTATE: HY000 (ER\_CANT\_FIND\_SYSTEM\_REC)

Message: Can't read record in system table

Returned by InnoDB for attempts to access InnoDB INFORMATION\_SCHEMA tables when InnoDB is unavailable.

- Error: 1013 SQLSTATE: HY000 (ER\_CANT\_GET\_STAT)

Message: Can't get status of '%s' (errno: %d - %s)

- Error: 1014 SQLSTATE: HY000 (ER\_CANT\_GET\_WD)

Message: Can't get working directory (errno: %d - %s)

- Error: 1015 SQLSTATE: HY000 (ER\_CANT\_LOCK)

Message: Can't lock file (errno: %d - %s)

- Error: 1016 SQLSTATE: HY000 (ER\_CANT\_OPEN\_FILE)

Message: Can't open file: '%s' (errno: %d - %s)

InnoDB reports this error when the table from the InnoDB data files cannot be found, even though the `.frm` file for the table exists. See [Section 15.21.3, “Troubleshooting InnoDB Data Dictionary Operations”](#).

- Error: 1017 SQLSTATE: HY000 (ER\_FILE\_NOT\_FOUND)

Message: Can't find file: '%s' (errno: %d - %s)

- Error: 1018 SQLSTATE: HY000 (ER\_CANT\_READ\_DIR)

Message: Can't read dir of '%s' (errno: %d - %s)

- Error: 1019 SQLSTATE: HY000 (ER\_CANT\_SET\_WD)

Message: Can't change dir to '%s' (errno: %d - %s)

- Error: 1020 SQLSTATE: HY000 (ER\_CHECKREAD)

Message: Record has changed since last read in table '%s'

- Error: 1021 SQLSTATE: HY000 (ER\_DISK\_FULL)

Message: Disk full (%s); waiting for someone to free some space... (errno: %d - %s)

- Error: 1022 SQLSTATE: 23000 (ER\_DUP\_KEY)

Message: Can't write; duplicate key in table '%s'

- Error: 1023 SQLSTATE: HY000 (ER\_ERROR\_ON\_CLOSE)

Message: Error on close of '%s' (errno: %d - %s)

- Error: 1024 SQLSTATE: HY000 (ER\_ERROR\_ON\_READ)

Message: Error reading file '%s' (errno: %d - %s)

- Error: 1025 SQLSTATE: HY000 (ER\_ERROR\_ON\_RENAME)

Message: Error on rename of '%s' to '%s' (errno: %d - %s)

- Error: 1026 SQLSTATE: HY000 (ER\_ERROR\_ON\_WRITE)

Message: Error writing file '%s' (errno: %d - %s)

- Error: 1027 SQLSTATE: HY000 (ER\_FILE\_USED)

Message: '%s' is locked against change

- Error: 1028 SQLSTATE: HY000 (ER\_FILSORT\_ABORT)

Message: Sort aborted

- Error: 1029 SQLSTATE: HY000 (ER\_FORM\_NOT\_FOUND)

Message: View '%s' doesn't exist for '%s'

- Error: 1030 SQLSTATE: HY000 (ER\_GET\_ERRNO)

Message: Got error %d from storage engine

Check the %d value to see what the OS error means. For example, 28 indicates that you have run out of disk space.

- Error: 1031 SQLSTATE: HY000 (ER\_ILLEGAL\_HA)

Message: Table storage engine for '%s' doesn't have this option

- Error: 1032 SQLSTATE: HY000 (ER\_KEY\_NOT\_FOUND)

Message: Can't find record in '%s'

- Error: 1033 SQLSTATE: HY000 (ER\_NOT\_FORM\_FILE)

Message: Incorrect information in file: '%s'

- Error: 1034 SQLSTATE: HY000 (ER\_NOT\_KEYFILE)

Message: Incorrect key file for table '%s'; try to repair it

- Error: 1035 SQLSTATE: HY000 (ER\_OLD\_KEYFILE)

Message: Old key file for table '%s'; repair it!

- Error: 1036 SQLSTATE: HY000 (ER\_OPEN\_AS\_READONLY)  
Message: Table '%s' is read only
- Error: 1037 SQLSTATE: HY001 (ER\_OUTOFMEMORY)  
Message: Out of memory; restart server and try again (needed %d bytes)
- Error: 1038 SQLSTATE: HY001 (ER\_OUT\_OF\_SORTMEMORY)  
Message: Out of sort memory, consider increasing server sort buffer size
- Error: 1039 SQLSTATE: HY000 (ER\_UNEXPECTED\_EOF)  
Message: Unexpected EOF found when reading file '%s' (errno: %d - %s)
- Error: 1040 SQLSTATE: 08004 (ER\_CON\_COUNT\_ERROR)  
Message: Too many connections
- Error: 1041 SQLSTATE: HY000 (ER\_OUT\_OF\_RESOURCES)  
Message: Out of memory; check if mysqld or some other process uses all available memory; if not, you may have to use 'ulimit' to allow mysqld to use more memory or you can add more swap space
- Error: 1042 SQLSTATE: 08S01 (ER\_BAD\_HOST\_ERROR)  
Message: Can't get hostname for your address
- Error: 1043 SQLSTATE: 08S01 (ER\_HANDSHAKE\_ERROR)  
Message: Bad handshake
- Error: 1044 SQLSTATE: 42000 (ER\_DBACCESS\_DENIED\_ERROR)  
Message: Access denied for user '%s'@'%s' to database '%s'
- Error: 1045 SQLSTATE: 28000 (ER\_ACCESS\_DENIED\_ERROR)  
Message: Access denied for user '%s'@'%s' (using password: %s)
- Error: 1046 SQLSTATE: 3D000 (ER\_NO\_DB\_ERROR)  
Message: No database selected
- Error: 1047 SQLSTATE: 08S01 (ER\_UNKNOWN\_COM\_ERROR)  
Message: Unknown command
- Error: 1048 SQLSTATE: 23000 (ER\_BAD\_NULL\_ERROR)  
Message: Column '%s' cannot be null
- Error: 1049 SQLSTATE: 42000 (ER\_BAD\_DB\_ERROR)  
Message: Unknown database '%s'
- Error: 1050 SQLSTATE: 42S01 (ER\_TABLE\_EXISTS\_ERROR)  
Message: Table '%s' already exists
- Error: 1051 SQLSTATE: 42S02 (ER\_BAD\_TABLE\_ERROR)  
Message: Unknown table '%s'
- Error: 1052 SQLSTATE: 23000 (ER\_NON\_UNIQ\_ERROR)

Message: Column '%s' in %s is ambiguous

```
%s = column name
%s = location of column (for example, "field list")
```

Likely cause: A column appears in a query without appropriate qualification, such as in a select list or ON clause.

Examples:

```
mysql> SELECT i FROM t INNER JOIN t AS t2;
ERROR 1052 (23000): Column 'i' in field list is ambiguous

mysql> SELECT * FROM t LEFT JOIN t AS t2 ON i = i;
ERROR 1052 (23000): Column 'i' in on clause is ambiguous
```

Resolution:

- Qualify the column with the appropriate table name:

```
mysql> SELECT t2.i FROM t INNER JOIN t AS t2;
```

- Modify the query to avoid the need for qualification:

```
mysql> SELECT * FROM t LEFT JOIN t AS t2 USING (i);
```

- Error: [1053](#) SQLSTATE: [08S01](#) ([ER\\_SERVER\\_SHUTDOWN](#))

Message: Server shutdown in progress

- Error: [1054](#) SQLSTATE: [42S22](#) ([ER\\_BAD\\_FIELD\\_ERROR](#))

Message: Unknown column '%s' in '%s'

- Error: [1055](#) SQLSTATE: [42000](#) ([ER\\_WRONG\\_FIELD\\_WITH\\_GROUP](#))

Message: '%s' isn't in GROUP BY

- Error: [1056](#) SQLSTATE: [42000](#) ([ER\\_WRONG\\_GROUP\\_FIELD](#))

Message: Can't group on '%s'

- Error: [1057](#) SQLSTATE: [42000](#) ([ER\\_WRONG\\_SUM\\_SELECT](#))

Message: Statement has sum functions and columns in same statement

- Error: [1058](#) SQLSTATE: [21S01](#) ([ER\\_WRONG\\_VALUE\\_COUNT](#))

Message: Column count doesn't match value count

- Error: [1059](#) SQLSTATE: [42000](#) ([ER\\_TOO\\_LONG\\_IDENT](#))

Message: Identifier name '%s' is too long

- Error: [1060](#) SQLSTATE: [42S21](#) ([ER\\_DUP\\_FIELDNAME](#))

Message: Duplicate column name '%s'

- Error: [1061](#) SQLSTATE: [42000](#) ([ER\\_DUP\\_KEYNAME](#))

Message: Duplicate key name '%s'

- Error: 1062 SQLSTATE: 23000 ([ER\\_DUP\\_ENTRY](#))  
Message: Duplicate entry '%s' for key %d  
The message returned with this error uses the format string for [ER\\_DUP\\_ENTRY\\_WITH\\_KEY\\_NAME](#).
- Error: 1063 SQLSTATE: 42000 ([ER\\_WRONG\\_FIELD\\_SPEC](#))  
Message: Incorrect column specifier for column '%s'
- Error: 1064 SQLSTATE: 42000 ([ER\\_PARSE\\_ERROR](#))  
Message: %s near '%s' at line %d
- Error: 1065 SQLSTATE: 42000 ([ER\\_EMPTY\\_QUERY](#))  
Message: Query was empty
- Error: 1066 SQLSTATE: 42000 ([ER\\_NONUNIQ\\_TABLE](#))  
Message: Not unique table/alias: '%s'
- Error: 1067 SQLSTATE: 42000 ([ER\\_INVALID\\_DEFAULT](#))  
Message: Invalid default value for '%s'
- Error: 1068 SQLSTATE: 42000 ([ER\\_MULTIPLE\\_PRI\\_KEY](#))  
Message: Multiple primary key defined
- Error: 1069 SQLSTATE: 42000 ([ER\\_TOO\\_MANY\\_KEYS](#))  
Message: Too many keys specified; max %d keys allowed
- Error: 1070 SQLSTATE: 42000 ([ER\\_TOO\\_MANY\\_KEY\\_PARTS](#))  
Message: Too many key parts specified; max %d parts allowed
- Error: 1071 SQLSTATE: 42000 ([ER\\_TOO\\_LONG\\_KEY](#))  
Message: Specified key was too long; max key length is %d bytes
- Error: 1072 SQLSTATE: 42000 ([ER\\_KEY\\_COLUMN\\_DOES\\_NOT\\_EXISTS](#))  
Message: Key column '%s' doesn't exist in table
- Error: 1073 SQLSTATE: 42000 ([ER\\_BLOB\\_USED\\_AS\\_KEY](#))  
Message: BLOB column '%s' can't be used in key specification with the used table type
- Error: 1074 SQLSTATE: 42000 ([ER\\_TOO\\_BIG\\_FIELDLENGTH](#))  
Message: Column length too big for column '%s' (max = %lu); use BLOB or TEXT instead
- Error: 1075 SQLSTATE: 42000 ([ER\\_WRONG\\_AUTO\\_KEY](#))  
Message: Incorrect table definition; there can be only one auto column and it must be defined as a key
- Error: 1076 SQLSTATE: HY000 ([ER\\_READY](#))  
Message: %s: ready for connections. Version: '%s' socket: '%s' port: %d
- Error: 1077 SQLSTATE: HY000 ([ER\\_NORMAL\\_SHUTDOWN](#))

Message: %s: Normal shutdown

- Error: 1078 SQLSTATE: HY000 (ER\_GOT\_SIGNAL)

Message: %s: Got signal %d. Aborting!

- Error: 1079 SQLSTATE: HY000 (ER\_SHUTDOWN\_COMPLETE)

Message: %s: Shutdown complete

- Error: 1080 SQLSTATE: 08S01 (ER\_FORCING\_CLOSE)

Message: %s: Forcing close of thread %ld user: '%s'

- Error: 1081 SQLSTATE: 08S01 (ER\_IPSOCK\_ERROR)

Message: Can't create IP socket

- Error: 1082 SQLSTATE: 42S12 (ER\_NO\_SUCH\_INDEX)

Message: Table '%s' has no index like the one used in CREATE INDEX; recreate the table

- Error: 1083 SQLSTATE: 42000 (ER\_WRONG\_FIELD\_TERMINATORS)

Message: Field separator argument is not what is expected; check the manual

- Error: 1084 SQLSTATE: 42000 (ER\_BLOBS\_AND\_NO\_TERMINATED)

Message: You can't use fixed rowlength with BLOBs; please use 'fields terminated by'

- Error: 1085 SQLSTATE: HY000 (ER\_TEXTFILE\_NOT\_READABLE)

Message: The file '%s' must be in the database directory or be readable by all

- Error: 1086 SQLSTATE: HY000 (ER\_FILE\_EXISTS\_ERROR)

Message: File '%s' already exists

- Error: 1087 SQLSTATE: HY000 (ER\_LOAD\_INFO)

Message: Records: %ld Deleted: %ld Skipped: %ld Warnings: %ld

- Error: 1088 SQLSTATE: HY000 (ER\_ALTER\_INFO)

Message: Records: %ld Duplicates: %ld

- Error: 1089 SQLSTATE: HY000 (ER\_WRONG\_SUB\_KEY)

Message: Incorrect prefix key; the used key part isn't a string, the used length is longer than the key part, or the storage engine doesn't support unique prefix keys

- Error: 1090 SQLSTATE: 42000 (ER\_CANT\_REMOVE\_ALL\_FIELDS)

Message: You can't delete all columns with ALTER TABLE; use DROP TABLE instead

- Error: 1091 SQLSTATE: 42000 (ER\_CANT\_DROP\_FIELD\_OR\_KEY)

Message: Can't DROP '%s'; check that column/key exists

- Error: 1092 SQLSTATE: HY000 (ER\_INSERT\_INFO)

Message: Records: %ld Duplicates: %ld Warnings: %ld

- Error: 1093 SQLSTATE: HY000 (ER\_UPDATE\_TABLE\_USED)

Message: You can't specify target table '%s' for update in FROM clause

This error occurs for attempts to select from and modify the same table within a single statement. If the select attempt occurs within a derived table, you can avoid this error by setting the [derived\\_merge](#) flag of the [optimizer\\_switch](#) system variable to force the subquery to be materialized into a temporary table, which effectively causes it to be a different table from the one modified. See [Optimizing Derived Tables and View References](#).

- Error: [1094](#) SQLSTATE: [HY000](#) ([ER\\_NO\\_SUCH\\_THREAD](#))

Message: Unknown thread id: %lu

Message: Host '%s' is blocked because of many connection errors; unblock with 'mysqladmin flush-hosts'

- Error: 1130 SQLSTATE: HY000 (ER\_HOST\_NOT\_PRIVILEGED)

Message: Host '%s' is not allowed to connect to this MySQL server

- Error: 1131 SQLSTATE: 42000 (ER\_PASSWORD\_ANONYMOUS\_USER)

Message: You are using MySQL as an anonymous user and anonymous users are not allowed to change passwords

- Error: 1132 SQLSTATE: 42000 (ER\_PASSWORD\_NOT\_ALLOWED)

Message: You must have privileges to update tables in the mysql database to be able to change passwords for others

- Error: 1133 SQLSTATE: 42000 (ER\_PASSWORD\_NO\_MATCH)

Message: Can't find any matching row in the user table

- Error: 1134 SQLSTATE: HY000 (ER\_UPDATE\_INFO)

Message: Rows matched: %ld Changed: %ld Warnings: %ld

- Error: 1135 SQLSTATE: HY000 (ER\_CANT\_CREATE\_THREAD)

Message: Can't create a new thread (errno %d); if you are not out of available memory, you can consult the manual for a possible OS-dependent bug

- Error: 1136 SQLSTATE: 21S01 (ER\_WRONG\_VALUE\_COUNT\_ON\_ROW)

Message: Column count doesn't match value count at row %ld

- Error: 1137 SQLSTATE: HY000 (ER\_CANT\_REOPEN\_TABLE)

Message: Can't reopen table: '%s'

- Error: 1138 SQLSTATE: 22004 (ER\_INVALID\_USE\_OF\_NULL)

Message: Invalid use of NULL value

- Error: 1139 SQLSTATE: 42000 (ER\_REGEX\_ERROR)

Message: Got error '%s' from regexp

- Error: 1140 SQLSTATE: 42000 (ER\_MIX\_OF\_GROUP\_FUNC\_AND\_FIELDS)

Message: Mixing of GROUP columns (MIN(),MAX(),COUNT(),...) with no GROUP columns is illegal if there is no GROUP BY clause

- Error: 1141 SQLSTATE: 42000 (ER\_NONEXISTING\_GRANT)

Message: There is no such grant defined for user '%s' on host '%s'

- Error: 1142 SQLSTATE: 42000 (ER\_TABLEACCESS\_DENIED\_ERROR)

Message: %s command denied to user '%s'@'%s' for table '%s'

- Error: 1143 SQLSTATE: 42000 (ER\_COLUMNACCESS\_DENIED\_ERROR)

Message: %s command denied to user '%s'@'%s' for column '%s' in table '%s'

- Error: 1144 SQLSTATE: 42000 (ER\_ILLEGAL\_GRANT\_FOR\_TABLE)

Message: Illegal GRANT/REVOKE command; please consult the manual to see which privileges can be used

- Error: 1145 SQLSTATE: 42000 (ER\_GRANT\_WRONG\_HOST\_OR\_USER)

Message: The host or user argument to GRANT is too long

- Error: 1146 SQLSTATE: 42S02 (ER\_NO\_SUCH\_TABLE)

Message: Table '%s.%s' doesn't exist

- Error: 1147 SQLSTATE: 42000 (ER\_NONEXISTING\_TABLE\_GRANT)

Message: There is no such grant defined for user '%s' on host '%s' on table '%s'

- Error: 1148 SQLSTATE: 42000 (ER\_NOT\_ALLOWED\_COMMAND)

Message: The used command is not allowed with this MySQL version

- Error: 1149 SQLSTATE: 42000 (ER\_SYNTAX\_ERROR)

Message: You have an error in your SQL syntax; check the manual that corresponds to your MySQL server version for the right syntax to use

- Error: 1150 SQLSTATE: HY000 (ER\_UNUSED1)

Message: Delayed insert thread couldn't get requested lock for table %s

- Error: 1151 SQLSTATE: HY000 (ER\_UNUSED2)

Message: Too many delayed threads in use

- Error: 1152 SQLSTATE: 08S01 (ER\_ABORTING\_CONNECTION)

Message: Aborted connection %ld to db: '%s' user: '%s' (%s)

- Error: 1153 SQLSTATE: 08S01 (ER\_NET\_PACKET\_TOO\_LARGE)  
Message: Got a packet bigger than 'max\_allowed\_packet' bytes
- Error: 1154 SQLSTATE: 08S01 (ER\_NET\_READ\_ERROR\_FROM\_PIPE)  
Message: Got a read error from the connection pipe
- Error: 1155 SQLSTATE: 08S01 (ER\_NET\_FCNTL\_ERROR)  
Message: Got an error from fcntl()
- Error: 1156 SQLSTATE: 08S01 (ER\_NET\_PACKETS\_OUT\_OF\_ORDER)  
Message: Got packets out of order
- Error: 1157 SQLSTATE: 08S01 (ER\_NET\_UNCOMPRESS\_ERROR)  
Message: Couldn't uncompress communication packet
- Error: 1158 SQLSTATE: 08S01 (ER\_NET\_READ\_ERROR)  
Message: Got an error reading communication packets
- Error: 1159 SQLSTATE: 08S01 (ER\_NET\_READ\_INTERRUPTED)  
Message: Got timeout reading communication packets
- Error: 1160 SQLSTATE: 08S01 (ER\_NET\_ERROR\_ON\_WRITE)  
Message: Got an error writing communication packets
- Error: 1161 SQLSTATE: 08S01 (ER\_NET\_WRITE\_INTERRUPTED)  
Message: Got timeout writing communication packets
- Error: 1162 SQLSTATE: 42000 (ER\_TOO\_LONG\_STRING)  
Message: Result string is longer than 'max\_allowed\_packet' bytes
- Error: 1163 SQLSTATE: 42000 (ER\_TABLE\_CANT\_HANDLE\_BLOB)  
Message: The used table type doesn't support BLOB/TEXT columns
- Error: 1164 SQLSTATE: 42000 (ER\_TABLE\_CANT\_HANDLE\_AUTO\_INCREMENT)  
Message: The used table type doesn't support AUTO\_INCREMENT columns
- Error: 1165 SQLSTATE: HY000 (ER\_UNUSED3)  
Message: INSERT DELAYED can't be used with table '%s' because it is locked with LOCK TABLES
- Error: 1166 SQLSTATE: 42000 (ER\_WRONG\_COLUMN\_NAME)  
Message: Incorrect column name '%s'
- Error: 1167 SQLSTATE: 42000 (ER\_WRONG\_KEY\_COLUMN)  
Message: The used storage engine can't index column '%s'
- Error: 1168 SQLSTATE: HY000 (ER\_WRONG\_MRG\_TABLE)  
Message: Unable to open underlying table which is differently defined or of non-MyISAM type or doesn't exist

- Error: 1169 SQLSTATE: 23000 (ER\_DUP\_UNIQUE)  
Message: Can't write, because of unique constraint, to table '%s'
- Error: 1170 SQLSTATE: 42000 (ER\_BLOB\_KEY\_WITHOUT\_LENGTH)  
Message: BLOB/TEXT column '%s' used in key specification without a key length
- Error: 1171 SQLSTATE: 42000 (ER\_PRIMARY\_CANT\_HAVE\_NULL)  
Message: All parts of a PRIMARY KEY must be NOT NULL; if you need NULL in a key, use UNIQUE instead
- Error: 1172 SQLSTATE: 42000 (ER\_TOO\_MANY\_ROWS)  
Message: Result consisted of more than one row
- Error: 1173 SQLSTATE: 42000 (ER\_REQUIRES\_PRIMARY\_KEY)  
Message: This table type requires a primary key
- Error: 1174 SQLSTATE: HY000 (ER\_NO\_RAID\_COMPILED)  
Message: This version of MySQL is not compiled with RAID support
- Error: 1175 SQLSTATE: HY000 (ER\_UPDATE\_WITHOUT\_KEY\_IN\_SAFE\_MODE)  
Message: You are using safe update mode and you tried to update a table without a WHERE that uses a KEY column
- Error: 1176 SQLSTATE: 42000 (ER\_KEY\_DOES\_NOT\_EXISTS)  
Message: Key '%s' doesn't exist in table '%s'
- Error: 1177 SQLSTATE: 42000 (ER\_CHECK\_NO\_SUCH\_TABLE)  
Message: Can't open table
- Error: 1178 SQLSTATE: 42000 (ER\_CHECK\_NOT\_IMPLEMENTED)  
Message: The storage engine for the table doesn't support %s
- Error: 1179 SQLSTATE: 25000 (ER\_CANT\_DO\_THIS\_DURING\_AN\_TRANSACTION)  
Message: You are not allowed to execute this command in a transaction
- Error: 1180 SQLSTATE: HY000 (ER\_ERROR\_DURING\_COMMIT)  
Message: Got error %d during COMMIT
- Error: 1181 SQLSTATE: HY000 (ER\_ERROR\_DURING\_ROLLBACK)  
Message: Got error %d during ROLLBACK
- Error: 1182 SQLSTATE: HY000 (ER\_ERROR\_DURING\_FLUSH\_LOGS)  
Message: Got error %d during FLUSH\_LOGS
- Error: 1183 SQLSTATE: HY000 (ER\_ERROR\_DURING\_CHECKPOINT)  
Message: Got error %d during CHECKPOINT
- Error: 1184 SQLSTATE: 08S01 (ER\_NEW\_ABORTING\_CONNECTION)  
Message: Aborted connection %u to db: '%s' user: '%s' host: '%s' (%s)

- Error: 1185 SQLSTATE: HY000 (ER\_DUMP\_NOT\_IMPLEMENTED)  
Message: The storage engine for the table does not support binary table dump
- Error: 1186 SQLSTATE: HY000 (ER\_FLUSH\_MASTER\_BINLOG\_CLOSED)  
Message: Binlog closed, cannot RESET MASTER
- Error: 1187 SQLSTATE: HY000 (ER\_INDEX\_REBUILD)  
Message: Failed rebuilding the index of dumped table '%s'
- Error: 1188 SQLSTATE: HY000 (ER\_MASTER)  
Message: Error from master: '%s'
- Error: 1189 SQLSTATE: 08S01 (ER\_MASTER\_NET\_READ)  
Message: Net error reading from master
- Error: 1190 SQLSTATE: 08S01 (ER\_MASTER\_NET\_WRITE)  
Message: Net error writing to master
- Error: 1191 SQLSTATE: HY000 (ER\_FT\_MATCHING\_KEY\_NOT\_FOUND)  
Message: Can't find FULLTEXT index matching the column list
- Error: 1192 SQLSTATE: HY000 (ER\_LOCK\_OR\_ACTIVE\_TRANSACTION)  
Message: Can't execute the given command because you have active locked tables or an active transaction
- Error: 1193 SQLSTATE: HY000 (ER\_UNKNOWN\_SYSTEM\_VARIABLE)  
Message: Unknown system variable '%s'
- Error: 1194 SQLSTATE: HY000 (ER\_CRASHED\_ON\_USAGE)  
Message: Table '%s' is marked as crashed and should be repaired
- Error: 1195 SQLSTATE: HY000 (ER\_CRASHED\_ON\_REPAIR)  
Message: Table '%s' is marked as crashed and last (automatic?) repair failed
- Error: 1196 SQLSTATE: HY000 (ER\_WARNING\_NOT\_COMPLETE\_ROLLBACK)  
Message: Some non-transactional changed tables couldn't be rolled back
- Error: 1197 SQLSTATE: HY000 (ER\_TRANS\_CACHE\_FULL)  
Message: Multi-statement transaction required more than 'max\_binlog\_cache\_size' bytes of storage; increase this mysqld variable and try again
- Error: 1198 SQLSTATE: HY000 (ER\_SLAVE\_MUST\_STOP)  
Message: This operation cannot be performed with a running slave; run STOP SLAVE first
- Error: 1199 SQLSTATE: HY000 (ER\_SLAVE\_NOT\_RUNNING)  
Message: This operation requires a running slave; configure slave and do START SLAVE
- Error: 1200 SQLSTATE: HY000 (ER\_BAD\_SLAVE)  
Message: The server is not configured as slave; fix in config file or with CHANGE MASTER TO

- Error: 1201 SQLSTATE: HY000 (ER\_MASTER\_INFO)  
 Message: Could not initialize master info structure; more error messages can be found in the MySQL error log
- Error: 1202 SQLSTATE: HY000 (ER\_SLAVE\_THREAD)  
 Message: Could not create slave thread; check system resources
- Error: 1203 SQLSTATE: 42000 (ER\_TOO\_MANY\_USER\_CONNECTIONS)  
 Message: User %s already has more than 'max\_user\_connections' active connections
- Error: 1204 SQLSTATE: HY000 (ER\_SET\_CONSTANTS\_ONLY)  
 Message: You may only use constant expressions with SET
- Error: 1205 SQLSTATE: HY000 (ER\_LOCK\_WAIT\_TIMEOUT)  
 Message: Lock wait timeout exceeded; try restarting transaction  
  
 InnoDB reports this error when lock wait timeout expires. The statement that waited too long was **rolled back** (not the entire **transaction**). You can increase the value of the `innodb_lock_wait_timeout` configuration option if SQL statements should wait longer for other transactions to complete, or decrease it if too many long-running transactions are causing **locking** problems and reducing **concurrency** on a busy system.
- Error: 1206 SQLSTATE: HY000 (ER\_LOCK\_TABLE\_FULL)  
 Message: The total number of locks exceeds the lock table size  
  
 InnoDB reports this error when the total number of locks exceeds the amount of memory devoted to managing locks. To avoid this error, increase the value of `innodb_buffer_pool_size`. Within an individual application, a workaround may be to break a large operation into smaller pieces. For example, if the error occurs for a large **INSERT**, perform several smaller **INSERT** operations.
- Error: 1207 SQLSTATE: 25000 (ER\_READ\_ONLY\_TRANSACTION)  
 Message: Update locks cannot be acquired during a READ UNCOMMITTED transaction
- Error: 1208 SQLSTATE: HY000 (ER\_DROP\_DB\_WITH\_READ\_LOCK)  
 Message: DROP DATABASE not allowed while thread is holding global read lock
- Error: 1209 SQLSTATE: HY000 (ER\_CREATE\_DB\_WITH\_READ\_LOCK)  
 Message: CREATE DATABASE not allowed while thread is holding global read lock
- Error: 1210 SQLSTATE: HY000 (ER\_WRONG\_ARGUMENTS)  
 Message: Incorrect arguments to %s
- Error: 1211 SQLSTATE: 42000 (ER\_NO\_PERMISSION\_TO\_CREATE\_USER)  
 Message: '%s'@'%s' is not allowed to create new users
- Error: 1212 SQLSTATE: HY000 (ER\_UNION\_TABLES\_IN\_DIFFERENT\_DIR)  
 Message: Incorrect table definition; all MERGE tables must be in the same database
- Error: 1213 SQLSTATE: 40001 (ER\_LOCK\_DEADLOCK)  
 Message: Deadlock found when trying to get lock; try restarting transaction

InnoDB reports this error when a [transaction](#) encounters a [deadlock](#) and is automatically [rolled back](#) so that your application can take corrective action. To recover from this error, run all the operations in this transaction again. A deadlock occurs when requests for locks arrive in inconsistent order between transactions. The transaction that was rolled back released all its locks, and the other transaction can now get all the locks it requested. Thus, when you re-run the transaction that was rolled back, it might have to wait for other transactions to complete, but typically the deadlock does not recur. If you encounter frequent deadlocks, make the sequence of locking operations ([LOCK TABLES](#), [SELECT ... FOR UPDATE](#), and so on) consistent between the different transactions or applications that experience the issue. See [Section 15.5.5, “Deadlocks in InnoDB”](#) for details.

- Error: [1214](#) SQLSTATE: [HY000](#) ([ER\\_TABLE\\_CANT\\_HANDLE\\_FT](#))

Message: The used table type doesn't support FULLTEXT indexes

- Error: [1215](#) SQLSTATE: [HY000](#) ([ER\\_CANNOT\\_ADD\\_FOREIGN](#))

Message: Cannot add foreign key constraint

- Error: [1216](#) SQLSTATE: [23000](#) ([ER\\_NO\\_REFERENCED\\_ROW](#))

Message: Cannot add or update a child row: a foreign key constraint fails

InnoDB reports this error when you try to add a row but there is no parent row, and a [foreign key constraint](#) fails. Add the parent row first.

- Error: [1217](#) SQLSTATE: [23000](#) ([ER\\_ROW\\_IS\\_REFERENCED](#))

Message: Cannot delete or update a parent row: a foreign key constraint fails

InnoDB reports this error when you try to delete a parent row that has children, and a [foreign key constraint](#) fails. Delete the children first.

- Error: [1218](#) SQLSTATE: [08S01](#) ([ER\\_CONNECT\\_TO\\_MASTER](#))

Message: Error connecting to master: %s

- Error: [1219](#) SQLSTATE: [HY000](#) ([ER\\_QUERY\\_ON\\_MASTER](#))

Message: Error running query on master: %s

- Error: [1220](#) SQLSTATE: [HY000](#) ([ER\\_ERROR\\_WHEN\\_EXECUTING\\_COMMAND](#))

Message: Error when executing command %s: %s

- Error: [1221](#) SQLSTATE: [HY000](#) ([ER\\_WRONG\\_USAGE](#))

Message: Incorrect usage of %s and %s

- Error: [1222](#) SQLSTATE: [21000](#) ([ER\\_WRONG\\_NUMBER\\_OF\\_COLUMNS\\_IN\\_SELECT](#))

Message: The used SELECT statements have a different number of columns

- Error: [1223](#) SQLSTATE: [HY000](#) ([ER\\_CANT\\_UPDATE\\_WITH\\_READLOCK](#))

Message: Can't execute the query because you have a conflicting read lock

- Error: [1224](#) SQLSTATE: [HY000](#) ([ER\\_MIXING\\_NOT\\_ALLOWED](#))

Message: Mixing of transactional and non-transactional tables is disabled

- Error: [1225](#) SQLSTATE: [HY000](#) ([ER\\_DUP\\_ARGUMENT](#))

Message: Option '%s' used twice in statement

- Error: 1226 SQLSTATE: 42000 (ER\_USER\_LIMIT\_REACHED)  
Message: User '%s' has exceeded the '%s' resource (current value: %ld)
- Error: 1227 SQLSTATE: 42000 (ER\_SPECIFIC\_ACCESS\_DENIED\_ERROR)  
Message: Access denied; you need (at least one of) the %s privilege(s) for this operation
- Error: 1228 SQLSTATE: HY000 (ER\_LOCAL\_VARIABLE)  
Message: Variable '%s' is a SESSION variable and can't be used with SET GLOBAL
- Error: 1229 SQLSTATE: HY000 (ER\_GLOBAL\_VARIABLE)  
Message: Variable '%s' is a GLOBAL variable and should be set with SET GLOBAL
- Error: 1230 SQLSTATE: 42000 (ER\_NO\_DEFAULT)  
Message: Variable '%s' doesn't have a default value
- Error: 1231 SQLSTATE: 42000 (ER\_WRONG\_VALUE\_FOR\_VAR)  
Message: Variable '%s' can't be set to the value of '%s'
- Error: 1232 SQLSTATE: 42000 (ER\_WRONG\_TYPE\_FOR\_VAR)  
Message: Incorrect argument type to variable '%s'
- Error: 1233 SQLSTATE: HY000 (ER\_VAR\_CANT\_BE\_READ)  
Message: Variable '%s' can only be set, not read
- Error: 1234 SQLSTATE: 42000 (ER\_CANT\_USE\_OPTION\_HERE)  
Message: Incorrect usage/placement of '%s'
- Error: 1235 SQLSTATE: 42000 (ER\_NOT\_SUPPORTED\_YET)  
Message: This version of MySQL doesn't yet support '%s'
- Error: 1236 SQLSTATE: HY000 (ER\_MASTER\_FATAL\_ERROR\_READING\_BINLOG)  
Message: Got fatal error %d from master when reading data from binary log: '%s'
- Error: 1237 SQLSTATE: HY000 (ER\_SLAVE\_IGNORED\_TABLE)  
Message: Slave SQL thread ignored the query because of replicate-\*table rules
- Error: 1238 SQLSTATE: HY000 (ER\_INCORRECT\_GLOBAL\_LOCAL\_VAR)  
Message: Variable '%s' is a %s variable
- Error: 1239 SQLSTATE: 42000 (ER\_WRONG\_FK\_DEF)  
Message: Incorrect foreign key definition for '%s': %s
- Error: 1240 SQLSTATE: HY000 (ER\_KEY\_REF\_DO\_NOT\_MATCH\_TABLE\_REF)  
Message: Key reference and table reference don't match
- Error: 1241 SQLSTATE: 21000 (ER\_OPERAND\_COLUMNS)  
Message: Operand should contain %d column(s)
- Error: 1242 SQLSTATE: 21000 (ER\_SUBQUERY\_NO\_1\_ROW)

Message: Subquery returns more than 1 row

- Error: 1243 SQLSTATE: HY000 (ER\_UNKNOWN\_STMT\_HANDLER)

Message: Unknown prepared statement handler (%.\*s) given to %s

- Error: 1244 SQLSTATE: HY000 (ER\_CORRUPT\_HELP\_DB)

Message: Help database is corrupt or does not exist

- Error: 1245 SQLSTATE: HY000 (ER\_CYCLIC\_REFERENCE)

Message: Cyclic reference on subqueries

- Error: 1246 SQLSTATE: HY000 (ER\_AUTO\_CONVERT)

Message: Converting column '%s' from %s to %s

- Error: 1247 SQLSTATE: 42S22 (ER\_ILLEGAL\_REFERENCE)

Message: Reference '%s' not supported (%s)

- Error: 1248 SQLSTATE: 42000 (ER\_DERIVED\_MUST\_HAVE\_ALIAS)

Message: Every derived table must have its own alias

- Error: 1249 SQLSTATE: 01000 (ER\_SELECT\_REDUCE)

Message: Select %u was reduced during optimization

- Error: 1250 SQLSTATE: 42000 (ER\_TABLENAME\_NOT\_ALLOWED\_HERE)

Message: Table '%s' from one of the SELECTs cannot be used in %s

- Error: 1251 SQLSTATE: 08004 (ER\_NOT\_SUPPORTED\_AUTH\_MODE)

Message: Client does not support authentication protocol requested by server; consider upgrading MySQL client

- Error: 1252 SQLSTATE: 42000 (ER\_SPATIAL\_CANT\_HAVE\_NULL)

Message: All parts of a SPATIAL index must be NOT NULL

- Error: 1253 SQLSTATE: 42000 (ER\_COLLATION\_CHARSET\_MISMATCH)

Message: COLLATION '%s' is not valid for CHARACTER SET '%s'

- Error: 1254 SQLSTATE: HY000 (ER\_SLAVE\_WAS\_RUNNING)

Message: Slave is already running

- Error: 1255 SQLSTATE: HY000 (ER\_SLAVE\_WAS\_NOT\_RUNNING)

Message: Slave already has been stopped

- Error: 1256 SQLSTATE: HY000 (ER\_TOO\_BIG\_FOR\_UNCOMPRESS)

Message: Uncompressed data size too large; the maximum size is %d (probably, length of uncompressed data was corrupted)

- Error: 1257 SQLSTATE: HY000 (ER\_ZLIB\_Z\_MEM\_ERROR)

Message: ZLIB: Not enough memory

- Error: 1258 SQLSTATE: HY000 (ER\_ZLIB\_Z\_BUF\_ERROR)  
 Message: ZLIB: Not enough room in the output buffer (probably, length of uncompressed data was corrupted)
- Error: 1259 SQLSTATE: HY000 (ER\_ZLIB\_Z\_DATA\_ERROR)  
 Message: ZLIB: Input data corrupted
- Error: 1260 SQLSTATE: HY000 (ER\_CUT\_VALUE\_GROUP\_CONCAT)  
 Message: Row %u was cut by GROUP\_CONCAT()
- Error: 1261 SQLSTATE: 01000 (ER\_WARN\_TOO\_FEW\_RECORDS)  
 Message: Row %ld doesn't contain data for all columns
- Error: 1262 SQLSTATE: 01000 (ER\_WARN\_TOO\_MANY\_RECORDS)  
 Message: Row %ld was truncated; it contained more data than there were input columns
- Error: 1263 SQLSTATE: 22004 (ER\_WARN\_NULL\_TO\_NOTNULL)  
 Message: Column set to default value; NULL supplied to NOT NULL column '%s' at row %ld
- Error: 1264 SQLSTATE: 22003 (ER\_WARN\_DATA\_OUT\_OF\_RANGE)  
 Message: Out of range value for column '%s' at row %ld
- Error: 1265 SQLSTATE: 01000 (WARN\_DATA\_TRUNCATED)  
 Message: Data truncated for column '%s' at row %ld
- Error: 1266 SQLSTATE: HY000 (ER\_WARN\_USING\_OTHER\_HANDLER)  
 Message: Using storage engine %s for table '%s'
- Error: 1267 SQLSTATE: HY000 (ER\_CANT\_AGGREGATE\_2COLLATIONS)  
 Message: Illegal mix of collations (%s,%s) and (%s,%s) for operation '%s'
- Error: 1268 SQLSTATE: HY000 (ER\_DROP\_USER)  
 Message: Cannot drop one or more of the requested users
- Error: 1269 SQLSTATE: HY000 (ER\_REVOKE\_GRANTS)  
 Message: Can't revoke all privileges for one or more of the requested users
- Error: 1270 SQLSTATE: HY000 (ER\_CANT\_AGGREGATE\_3COLLATIONS)  
 Message: Illegal mix of collations (%s,%s), (%s,%s), (%s,%s) for operation '%s'
- Error: 1271 SQLSTATE: HY000 (ER\_CANT\_AGGREGATE\_NCOLLATIONS)  
 Message: Illegal mix of collations for operation '%s'
- Error: 1272 SQLSTATE: HY000 (ER\_VARIABLE\_IS\_NOT\_STRUCT)  
 Message: Variable '%s' is not a variable component (can't be used as XXXX.variable\_name)
- Error: 1273 SQLSTATE: HY000 (ER\_UNKNOWN\_COLLATION)  
 Message: Unknown collation: '%s'

- Error: 1274 SQLSTATE: HY000 (ER\_SLAVE\_IGNORED\_SSL\_PARAMS)

Message: SSL parameters in CHANGE MASTER are ignored because this MySQL slave was compiled without SSL support; they can be used later if MySQL slave with SSL is started

- Error: 1275 SQLSTATE: HY000 (ER\_SERVER\_IS\_IN\_SECURE\_AUTH\_MODE)

Message: Server is running in --secure-auth mode, but '%s'@'%s' has a password in the old format; please change the password to the new format

- Error: 1276 SQLSTATE: HY000 (ER\_WARN\_FIELD\_RESOLVED)

Message: Field or reference '%s%s%s%s%s' of SELECT #%d was resolved in SELECT #%d

- Error: 1277 SQLSTATE: HY000 (ER\_BAD\_SLAVE\_UNTIL\_COND)

Message: Incorrect parameter or combination of parameters for START SLAVE UNTIL

- Error: 1278 SQLSTATE: HY000 (ER\_MISSING\_SKIP\_SLAVE)

Message: It is recommended to use --skip-slave-start when doing step-by-step replication with START SLAVE UNTIL; otherwise, you will get problems if you get an unexpected slave's mysqld restart

- Error: 1279 SQLSTATE: HY000 (ER\_UNTIL\_COND\_IGNORED)

Message: SQL thread is not to be started so UNTIL options are ignored

- Error: 1280 SQLSTATE: 42000 (ER\_WRONG\_NAME\_FOR\_INDEX)

Message: Incorrect index name '%s'

- Error: 1281 SQLSTATE: 42000 (ER\_WRONG\_NAME\_FOR\_CATALOG)

Message: Incorrect catalog name '%s'

- Error: 1282 SQLSTATE: HY000 (ER\_WARN\_QC\_RESIZE)

Message: Query cache failed to set size %lu; new query cache size is %lu

- Error: 1283 SQLSTATE: HY000 (ER\_BAD\_FT\_COLUMN)

Message: Column '%s' cannot be part of FULLTEXT index

- Error: 1284 SQLSTATE: HY000 (ER\_UNKNOWN\_KEY\_CACHE)

Message: Unknown key cache '%s'

- Error: 1285 SQLSTATE: HY000 (ER\_WARN\_HOSTNAME\_WONT\_WORK)

Message: MySQL is started in --skip-name-resolve mode; you must restart it without this switch for this grant to work

- Error: 1286 SQLSTATE: 42000 (ER\_UNKNOWN\_STORAGE\_ENGINE)

Message: Unknown storage engine '%s'

- Error: 1287 SQLSTATE: HY000 (ER\_WARN\_DEPRECATED\_SYNTAX)

Message: '%s' is deprecated and will be removed in a future release. Please use %s instead

- Error: 1288 SQLSTATE: HY000 (ER\_NON\_UPDATABLE\_TABLE)

Message: The target table %s of the %s is not updatable

- Error: 1289 SQLSTATE: HY000 (ER\_FEATURE\_DISABLED)  
Message: The '%s' feature is disabled; you need MySQL built with '%s' to have it working
- Error: 1290 SQLSTATE: HY000 (ER\_OPTION\_PREVENTS\_STATEMENT)  
Message: The MySQL server is running with the %s option so it cannot execute this statement
- Error: 1291 SQLSTATE: HY000 (ER\_DUPLICATED\_VALUE\_IN\_TYPE)  
Message: Column '%s' has duplicated value '%s' in %s
- Error: 1292 SQLSTATE: 22007 (ER\_TRUNCATED\_WRONG\_VALUE)  
Message: Truncated incorrect %s value: '%s'
- Error: 1293 SQLSTATE: HY000 (ER\_TOO\_MUCH\_AUTO\_TIMESTAMP\_COLS)  
Message: Incorrect table definition; there can be only one TIMESTAMP column with CURRENT\_TIMESTAMP in DEFAULT or ON UPDATE clause
- Error: 1294 SQLSTATE: HY000 (ER\_INVALID\_ON\_UPDATE)  
Message: Invalid ON UPDATE clause for '%s' column
- Error: 1295 SQLSTATE: HY000 (ER\_UNSUPPORTED\_PS)  
Message: This command is not supported in the prepared statement protocol yet
- Error: 1296 SQLSTATE: HY000 (ER\_GET\_ERRMSG)

- Error: 1360 SQLSTATE: HY000 (ER\_TRG\_DOES\_NOT\_EXIST)  
Message: Trigger does not exist
- Error: 1361 SQLSTATE: HY000 (ER\_TRG\_ON\_VIEW\_OR\_TEMP\_TABLE)  
Message: Trigger's '%s' is view or temporary table
- Error: 1362 SQLSTATE: HY000 (ER\_TRG\_CANT\_CHANGE\_ROW)  
Message: Updating of %s row is not allowed in %strigger
- Error: 1363 SQLSTATE: HY000 (ER\_TRG\_NO\_SUCH\_ROW\_IN\_TRG)  
Message: There is no %s row in %s trigger
- Error: 1364 SQLSTATE: HY000 (ER\_NO\_DEFAULT\_FOR\_FIELD)  
Message: Field '%s' doesn't have a default value
- Error: 1365 SQLSTATE: 22012 (ER\_DIVISION\_BY\_ZERO)  
Message: Division by 0
- Error: 1366 SQLSTATE: HY000 (ER\_TRUNCATED\_WRONG\_VALUE\_FOR\_FIELD)  
Message: Incorrect %s value: '%s' for column '%s' at row %ld
- Error: 1367 SQLSTATE: 22007 (ER\_ILLEGAL\_VALUE\_FOR\_TYPE)

Message: Illegal %s '%s' value found during parsing

- Error: 1368 SQLSTATE: HY000 (ER\_VIEW\_NONUPD\_CHECK)

Message: CHECK OPTION on non-updatable view '%s.%s'

- Error: 1369 SQLSTATE: HY000 (ER\_VIEW\_CHECK\_FAILED)

Message: CHECK OPTION failed '%s.%s'

- Error: 1370 SQLSTATE: 42000 (ER\_PROCAccess\_DENIED\_ERROR)

Message: %s command denied to user '%s'@'%s' for routine '%s'

- Error: 1371 SQLSTATE: HY000 (ER\_RELAY\_LOG\_FAIL)

Message: Failed purging old relay logs: %s

- Error: 1372 SQLSTATE: HY000 (ER\_PASSWD\_LENGTH)

Message: Password hash should be a %d-digit hexadecimal number

- Error: 1373 SQLSTATE: HY000 (ER\_UNKNOWN\_TARGET\_BINLOG)

Message: Target log not found in binlog index

- Error: 1374 SQLSTATE: HY000 (ER\_IO\_ERR\_LOG\_INDEX\_READ)

Message: I/O error reading log index file

- Error: 1375 SQLSTATE: HY000 (ER\_BINLOG\_PURGE\_PROHIBITED)

Message: Server configuration does not permit binlog purge

- Error: 1376 SQLSTATE: HY000 (ER\_FSEEK\_FAIL)

Message: Failed on fseek()

- Error: 1377 SQLSTATE: HY000 (ER\_BINLOG\_PURGE\_FATAL\_ERR)

Message: Fatal error during log purge

- Error: 1378 SQLSTATE: HY000 (ER\_LOG\_IN\_USE)

Message: A purgeable log is in use, will not purge

- Error: 1379 SQLSTATE: HY000 (ER\_LOG\_PURGE\_UNKNOWN\_ERR)

Message: Unknown error during log purge

- Error: 1380 SQLSTATE: HY000 (ER\_RELAY\_LOG\_INIT)

Message: Failed initializing relay log position: %s

- Error: 1381 SQLSTATE: HY000 (ER\_NO\_BINARY\_LOGGING)

Message: You are not using binary logging

- Error: 1382 SQLSTATE: HY000 (ER\_RESERVED\_SYNTAX)

Message: The '%s' syntax is reserved for purposes internal to the MySQL server

- Error: 1383 SQLSTATE: HY000 (ER\_WSAS\_FAILED)

Message: WSASStartup Failed

- Error: 1384 SQLSTATE: HY000 (ER\_DIFF\_GROUPS\_PROC)  
Message: Can't handle procedures with different groups yet
- Error: 1385 SQLSTATE: HY000 (ER\_NO\_GROUP\_FOR\_PROC)  
Message: Select must have a group with this procedure
- Error: 1386 SQLSTATE: HY000 (ER\_ORDER\_WITH\_PROC)  
Message: Can't use ORDER clause with this procedure
- Error: 1387 SQLSTATE: HY000 (ER\_LOGGING\_PROHIBIT\_CHANGING\_OF)  
Message: Binary logging and replication forbid changing the global server %s
- Error: 1388 SQLSTATE: HY000 (ER\_NO\_FILE\_MAPPING)  
Message: Can't map file: %s, errno: %d
- Error: 1389 SQLSTATE: HY000 (ER\_WRONG\_MAGIC)  
Message: Wrong magic in %s
- Error: 1390 SQLSTATE: HY000 (ER\_PS\_MANY\_PARAM)  
Message: Prepared statement contains too many placeholders
- Error: 1391 SQLSTATE: HY000 (ER\_KEY\_PART\_0)  
Message: Key part '%s' length cannot be 0
- Error: 1392 SQLSTATE: HY000 (ER\_VIEW\_CHECKSUM)  
Message: View text checksum failed
- Error: 1393 SQLSTATE: HY000 (ER\_VIEW\_MULTIUPDATE)  
Message: Can not modify more than one base table through a join view '%s.%s'
- Error: 1394 SQLSTATE: HY000 (ER\_VIEW\_NO\_INSERT\_FIELD\_LIST)  
Message: Can not insert into join view '%s.%s' without fields list
- Error: 1395 SQLSTATE: HY000 (ER\_VIEW\_DELETE\_MERGE\_VIEW)  
Message: Can not delete from join view '%s.%s'
- Error: 1396 SQLSTATE: HY000 (ER\_CANNOT\_USER)  
Message: Operation %s failed for %s
- Error: 1397 SQLSTATE: XAE04 (ER\_XAER\_NOTA)  
Message: XAER\_NOTA: Unknown XID
- Error: 1398 SQLSTATE: XAE05 (ER\_XAER\_INVAL)  
Message: XAER\_INVAL: Invalid arguments (or unsupported command)
- Error: 1399 SQLSTATE: XAE07 (ER\_XAER\_RMFAIL)  
Message: XAER\_RMFAIL: The command cannot be executed when global transaction is in the %s state
- Error: 1400 SQLSTATE: XAE09 (ER\_XAER\_OUTSIDE)

Message: XAER\_OUTSIDE: Some work is done outside global transaction

- Error: 1401 SQLSTATE: XAE03 (ER\_XAER\_RMERR)

Message: XAER\_RMERR: Fatal error occurred in the transaction branch - check your data for consistency

- Error: 1402 SQLSTATE: XA100 (ER\_XA\_RBROLLBACK)

Message: XA\_RBROLLBACK: Transaction branch was rolled back

- Error: 1403 SQLSTATE: 42000 (ER\_NONEXISTING\_PROC\_GRANT)

Message: There is no such grant defined for user '%s' on host '%s' on routine '%s'

- Error: 1404 SQLSTATE: HY000 (ER\_PROC\_AUTO\_GRANT\_FAIL)

Message: Failed to grant EXECUTE and ALTER ROUTINE privileges

- Error: 1405 SQLSTATE: HY000 (ER\_PROC\_AUTO\_REVOKE\_FAIL)

Message: Failed to revoke all privileges to dropped routine

- Error: 1406 SQLSTATE: 22001 (ER\_DATA\_TOO\_LONG)

Message: Data too long for column '%s' at row %ld

- Error: 1407 SQLSTATE: 42000 (ER\_SP\_BAD\_SQLSTATE)

Message: Bad SQLSTATE: '%s'

- Error: 1408 SQLSTATE: HY000 (ER\_STARTUP)

Message: %s: ready for connections. Version: '%s' socket: '%s' port: %d %s

- Error: 1409 SQLSTATE: HY000 (ER\_LOAD\_FROM\_FIXED\_SIZE\_ROWS\_TO\_VAR)

Message: Can't load value from file with fixed size rows to variable

- Error: 1410 SQLSTATE: 42000 (ER\_CANT\_CREATE\_USER\_WITH\_GRANT)

Message: You are not allowed to create a user with GRANT

- Error: 1411 SQLSTATE: HY000 (ER\_WRONG\_VALUE\_FOR\_TYPE)

Message: Incorrect %s value: '%s' for function %s

- Error: 1412 SQLSTATE: HY000 (ER\_TABLE\_DEF\_CHANGED)

Message: Table definition has changed, please retry transaction

- Error: 1413 SQLSTATE: 42000 (ER\_SP\_DUP\_HANDLER)

Message: Duplicate handler declared in the same block

- Error: 1414 SQLSTATE: 42000 (ER\_SP\_NOT\_VAR\_ARG)

Message: OUT or INOUT argument %d for routine %s is not a variable or NEW pseudo-variable in BEFORE trigger

- Error: 1415 SQLSTATE: 0A000 (ER\_SP\_NO\_RETSET)

Message: Not allowed to return a result set from a %s

- Error: 1416 SQLSTATE: 22003 (ER\_CANT\_CREATE\_GEOMETRY\_OBJECT)

Message: Cannot get geometry object from data you send to the GEOMETRY field

- Error: 1417 SQLSTATE: HY000 (ER\_FAILED\_ROUTINE\_BREAK\_BINLOG)

Message: A routine failed and has neither NO SQL nor READS SQL DATA in its declaration and binary logging is enabled; if non-transactional tables were updated, the binary log will miss their changes

- Error: 1418 SQLSTATE: HY000 (ER\_BINLOG\_UNSAFE\_ROUTINE)

Message: This function has none of DETERMINISTIC, NO SQL, or READS SQL DATA in its declaration and binary logging is enabled (you \*might\* want to use the less safe log\_bin\_trust\_function\_creators variable)

- Error: 1419 SQLSTATE: HY000 (ER\_BINLOG\_CREATE\_ROUTINE\_NEED\_SUPER)

Message: You do not have the SUPER privilege and binary logging is enabled (you \*might\* want to use the less safe log\_bin\_trust\_function\_creators variable)

- Error: 1420 SQLSTATE: HY000 (ER\_EXEC\_STMT\_WITH\_OPEN\_CURSOR)

Message: You can't execute a prepared statement which has an open cursor associated with it. Reset the statement to re-execute it.

- Error: 1421 SQLSTATE: HY000 (ER\_STMT\_HAS\_NO\_OPEN\_CURSOR)

Message: The statement (%lu) has no open cursor.

- Error: 1422 SQLSTATE: HY000 (ER\_COMMIT\_NOT\_ALLOWED\_IN\_SF\_OR\_TRG)

Message: Explicit or implicit commit is not allowed in stored function or trigger.

- Error: 1423 SQLSTATE: HY000 (ER\_NO\_DEFAULT\_FOR\_VIEW\_FIELD)

Message: Field of view '%s.%s' underlying table doesn't have a default value

- Error: 1424 SQLSTATE: HY000 (ER\_SP\_NO\_RECURSION)

Message: Recursive stored functions and triggers are not allowed.

- Error: 1425 SQLSTATE: 42000 (ER\_TOO\_BIG\_SCALE)

Message: Too big scale %d specified for column '%s'. Maximum is %lu.

- Error: 1426 SQLSTATE: 42000 (ER\_TOO\_BIG\_PRECISION)

Message: Too-big precision %d specified for '%s'. Maximum is %lu.

- Error: 1427 SQLSTATE: 42000 (ER\_M\_BIGGER\_THAN\_D)

Message: For float(M,D), double(M,D) or decimal(M,D), M must be >= D (column '%s').

- Error: 1428 SQLSTATE: HY000 (ER\_WRONG\_LOCK\_OF\_SYSTEM\_TABLE)

Message: You can't combine write-locking of system tables with other tables or lock types

- Error: 1429 SQLSTATE: HY000 (ER\_CONNECT\_TO\_FOREIGN\_DATA\_SOURCE)

Message: Unable to connect to foreign data source: %s

- Error: 1430 SQLSTATE: HY000 (ER\_QUERY\_ON\_FOREIGN\_DATA\_SOURCE)

Message: There was a problem processing the query on the foreign data source. Data source error: %s

- Error: 1431 SQLSTATE: HY000 (ER\_FOREIGN\_DATA\_SOURCE\_DOESNT\_EXIST)  
Message: The foreign data source you are trying to reference does not exist. Data source error: %s
- Error: 1432 SQLSTATE: HY000 (ER\_FOREIGN\_DATA\_STRING\_INVALID\_CANT\_CREATE)  
Message: Can't create federated table. The data source connection string '%s' is not in the correct format
- Error: 1433 SQLSTATE: HY000 (ER\_FOREIGN\_DATA\_STRING\_INVALID)  
Message: The data source connection string '%s' is not in the correct format
- Error: 1434 SQLSTATE: HY000 (ER\_CANT\_CREATE\_FEDERATED\_TABLE)  
Message: Can't create federated table. Foreign data src error: %s
- Error: 1435 SQLSTATE: HY000 (ER\_TRG\_IN\_WRONG\_SCHEMA)  
Message: Trigger in wrong schema
- Error: 1436 SQLSTATE: HY000 (ER\_STACK\_OVERRUN\_NEED\_MORE)  
Message: Thread stack overrun: %ld bytes used of a %ld byte stack, and %ld bytes needed. Use 'mysqld --thread\_stack=#' to specify a bigger stack.
- Error: 1437 SQLSTATE: 42000 (ER\_TOO\_LONG\_BODY)  
Message: Routine body for '%s' is too long
- Error: 1438 SQLSTATE: HY000 (ER\_WARN\_CANT\_DROP\_DEFAULT\_KEYCACHE)  
Message: Cannot drop default keycache
- Error: 1439 SQLSTATE: 42000 (ER\_TOO\_BIG\_DISPLAYWIDTH)  
Message: Display width out of range for column '%s' (max = %lu)
- Error: 1440 SQLSTATE: XAE08 (ER\_XAER\_DUPID)  
Message: XAER\_DUPID: The XID already exists
- Error: 1441 SQLSTATE: 22008 (ER\_DATETIME\_FUNCTION\_OVERFLOW)  
Message: Datetime function: %s field overflow
- Error: 1442 SQLSTATE: HY000 (ER\_CANT\_UPDATE\_USED\_TABLE\_IN\_SF\_OR\_TRG)  
Message: Can't update table '%s' in stored function/trigger because it is already used by statement which invoked this stored function/trigger.
- Error: 1443 SQLSTATE: HY000 (ER\_VIEW\_PREVENT\_UPDATE)  
Message: The definition of table '%s' prevents operation %s on table '%s'.
- Error: 1444 SQLSTATE: HY000 (ER\_PS\_NO\_RECURSION)  
Message: The prepared statement contains a stored routine call that refers to that same statement. It's not allowed to execute a prepared statement in such a recursive manner
- Error: 1445 SQLSTATE: HY000 (ER\_SP\_CANT\_SET\_AUTOCOMMIT)  
Message: Not allowed to set autocommit from a stored function or trigger

- Error: 1446 SQLSTATE: HY000 (ER\_MALFORMED\_DEFINER)  
Message: Definer is not fully qualified
- Error: 1447 SQLSTATE: HY000 (ER\_VIEW\_FRM\_NO\_USER)  
Message: View '%s'.'%s' has no definer information (old table format). Current user is used as definer. Please recreate the view!
- Error: 1448 SQLSTATE: HY000 (ER\_VIEW\_OTHER\_USER)  
Message: You need the SUPER privilege for creation view with '%s'@'%s' definer
- Error: 1449 SQLSTATE: HY000 (ER\_NO\_SUCH\_USER)  
Message: The user specified as a definer ('%s'@'%s') does not exist
- Error: 1450 SQLSTATE: HY000 (ER\_FORBID\_SCHEMA\_CHANGE)  
Message: Changing schema from '%s' to '%s' is not allowed.
- Error: 1451 SQLSTATE: 23000 (ER\_ROW\_IS\_REFERENCED\_2)  
Message: Cannot delete or update a parent row: a foreign key constraint fails (%s)
- Error: 1452 SQLSTATE: 23000 (ER\_NO\_REFERENCED\_ROW\_2)  
Message: Cannot add or update a child row: a foreign key constraint fails (%s)
- Error: 1453 SQLSTATE: 42000 (ER\_SP\_BAD\_VAR\_SHADOW)  
Message: Variable '%s' must be quoted with `...`, or renamed
- Error: 1454 SQLSTATE: HY000 (ER\_TRG\_NO\_DEFINER)  
Message: No definer attribute for trigger '%s'.'%s'. The trigger will be activated under the authorization of the invoker, which may have insufficient privileges. Please recreate the trigger.
- Error: 1455 SQLSTATE: HY000 (ER\_OLD\_FILE\_FORMAT)  
Message: '%s' has an old format, you should re-create the '%s' object(s)
- Error: 1456 SQLSTATE: HY000 (ER\_SP\_RECURSION\_LIMIT)  
Message: Recursive limit %d (as set by the max\_sp\_recursion\_depth variable) was exceeded for routine %s
- Error: 1457 SQLSTATE: HY000 (ER\_SP\_PROC\_TABLE\_CORRUPT)  
Message: Failed to load routine %s. The table mysql.proc is missing, corrupt, or contains bad data (internal code %d)
- Error: 1458 SQLSTATE: 42000 (ER\_SP\_WRONG\_NAME)  
Message: Incorrect routine name '%s'
- Error: 1459 SQLSTATE: HY000 (ER\_TABLE\_NEEDS\_UPGRADE)  
Message: Table upgrade required. Please do "REPAIR TABLE '%s'" or dump/reload to fix it!
- Error: 1460 SQLSTATE: 42000 (ER\_SP\_NO\_AGGREGATE)  
Message: AGGREGATE is not supported for stored functions
- Error: 1461 SQLSTATE: 42000 (ER\_MAX\_PREPARED\_STMT\_COUNT\_REACHED)

Message: Can't create more than max\_prepared\_stmt\_count statements (current value: %lu)

- Error: 1462 SQLSTATE: HY000 (ER\_VIEW\_RECURSIVE)

Message: `%s`.`%s` contains view recursion

- Error: 1463 SQLSTATE: 42000 (ER\_NON\_GROUPING\_FIELD\_USED)

Message: Non-grouping field '%s' is used in %s clause

- Error: 1464 SQLSTATE: HY000 (ER\_TABLE\_CANT\_HANDLE\_SPKEYS)

Message: The used table type doesn't support SPATIAL indexes

- Error: 1465 SQLSTATE: HY000 (ER\_NO\_TRIGGERS\_ON\_SYSTEM\_SCHEMA)

Message: Triggers can not be created on system tables

- Error: 1466 SQLSTATE: HY000 (ER\_REMOVED\_SPACES)

Message: Leading spaces are removed from name '%s'

- Error: 1467 SQLSTATE: HY000 (ER\_AUTOINC\_READ\_FAILED)

Message: Failed to read auto-increment value from storage engine

- Error: 1468 SQLSTATE: HY000 (ER\_USERNAME)

Message: user name

- Error: 1469 SQLSTATE: HY000 (ER\_HOSTNAME)

Message: host name

- Error: 1470 SQLSTATE: HY000 (ER\_WRONG\_STRING\_LENGTH)

Message: String '%s' is too long for %s (should be no longer than %d)

- Error: 1471 SQLSTATE: HY000 (ER\_NON\_INSERTABLE\_TABLE)

Message: The target table %s of the %s is not insertable-into

- Error: 1472 SQLSTATE: HY000 (ER\_ADMIN\_WRONG\_MRG\_TABLE)

Message: Table '%s' is differently defined or of non-MyISAM type or doesn't exist

- Error: 1473 SQLSTATE: HY000 (ER\_TOO\_HIGH\_LEVEL\_OF\_NESTING\_FOR\_SELECT)

Message: Too high level of nesting for select

- Error: 1474 SQLSTATE: HY000 (ER\_NAME\_BECOMES\_EMPTY)

Message: Name '%s' has become "

- Error: 1475 SQLSTATE: HY000 (ER\_AMBIGUOUS\_FIELD\_TERM)

Message: First character of the FIELDS TERMINATED string is ambiguous; please use non-optional and non-empty FIELDS ENCLOSED BY

- Error: 1476 SQLSTATE: HY000 (ER\_FOREIGN\_SERVER\_EXISTS)

Message: The foreign server, %s, you are trying to create already exists.

- Error: 1477 SQLSTATE: HY000 (ER\_FOREIGN\_SERVER\_DOESNT\_EXIST)

Message: The foreign server name you are trying to reference does not exist. Data source error: %s

- Error: 1478 SQLSTATE: HY000 (ER\_ILLEGAL\_HA\_CREATE\_OPTION)

Message: Table storage engine '%s' does not support the create option '%s'

- Error: 1479 SQLSTATE: HY000 (ER\_PARTITION\_REQUIRES\_VALUES\_ERROR)

Message: Syntax error: %s PARTITIONING requires definition of VALUES %s for each partition

- Error: 1480 SQLSTATE: HY000 (ER\_PARTITION\_WRONG\_VALUES\_ERROR)

Message: Only %s PARTITIONING can use VALUES %s in partition definition

- Error: 1481 SQLSTATE: HY000 (ER\_PARTITION\_MAXVALUE\_ERROR)

Message: MAXVALUE can only be used in last partition definition

- Error: 1482 SQLSTATE: HY000 (ER\_PARTITION\_SUBPARTITION\_ERROR)

Message: Subpartitions can only be hash partitions and by key

- Error: 1483 SQLSTATE: HY000 (ER\_PARTITION\_SUBPART\_MIX\_ERROR)

Message: Must define subpartitions on all partitions if on one partition

- Error: 1484 SQLSTATE: HY000 (ER\_PARTITION\_WRONG\_NO\_PART\_ERROR)

Message: Wrong number of partitions defined, mismatch with previous setting

- Error: 1485 SQLSTATE: HY000 (ER\_PARTITION\_WRONG\_NO\_SUBPART\_ERROR)

Message: Wrong number of subpartitions defined, mismatch with previous setting

- Error: 1486 SQLSTATE: HY000 (ER\_WRONG\_EXPR\_IN\_PARTITION\_FUNC\_ERROR)

Message: Constant, random or timezone-dependent expressions in (sub)partitioning function are not allowed

- Error: 1487 SQLSTATE: HY000 (ER\_NO\_CONST\_EXPR\_IN\_RANGE\_OR\_LIST\_ERROR)

Message: Expression in RANGE/LIST VALUES must be constant

- Error: 1488 SQLSTATE: HY000 (ER\_FIELD\_NOT\_FOUND\_PART\_ERROR)

Message: Field in list of fields for partition function not found in table

- Error: 1489 SQLSTATE: HY000 (ER\_LIST\_OF\_FIELDS\_ONLY\_IN\_HASH\_ERROR)

Message: List of fields is only allowed in KEY partitions

- Error: 1490 SQLSTATE: HY000 (ER\_INCONSISTENT\_PARTITION\_INFO\_ERROR)

Message: The partition info in the frm file is not consistent with what can be written into the frm file

- Error: 1491 SQLSTATE: HY000 (ER\_PARTITION\_FUNC\_NOT\_ALLOWED\_ERROR)

Message: The %s function returns the wrong type

- Error: 1492 SQLSTATE: HY000 (ER\_PARTITIONS\_MUST\_BE\_DEFINED\_ERROR)

Message: For %s partitions each partition must be defined

- Error: 1493 SQLSTATE: HY000 (ER\_RANGE\_NOT\_INCREASING\_ERROR)

Message: VALUES LESS THAN value must be strictly increasing for each partition
